Preface

The history of Sony Semiconductor began in 1954, with the first commercial introduction of the transistor in Japan. Since then, Sony has applied this leading edge, innovative technology in the development of the Semiconductors, currently used in most of its consumer and professional electronic products.

This Computer Audio/Video semiconductor data book has been compiled with the aim of providing the circuit designer with a reference guide describing Sony's presently available line, together with application information for each category of Computer Audio/Video Semiconductors.

© 1992 Sony Corporation of America.

Sony is a trademark of Sony.

The contents of this book although accurate and complete at the time of publication, are subject to incorporate improvements on the products. Circuits shown are typical examples illustrating the operation of the devices. They are not meant to convey any patents or other rights. Sony cannot assume responsibility for any problems arising out of the use of these circuits.

3. IC Nomenclature

1) Nomenclature of IC product name
Currently, both the conventional and new nomenclature systems are mixed in naming IC products.

a) Conventional nomenclature system
[Example] C X 2 0 0 1 1 A

- Improvement mark
  "A" is affixed when specifications are partially improved.
- Product number
  Identifies individual product.
- Category number
  Indicates the product category in one or two digits.
  Bipolar IC: 0, 1, 8, 10, 20, 22
  MOS IC: 5, 7, 23, 79
- Sony IC mark

b) New nomenclature
[Example] C X A 1 0 0 1 A P

- Package mark
  P: Plastic Dual In-line Package
  D: Ceramic Dual In-line Package
  M: Small Outline L-Leaded Package
  L: Single In-line Package
  Q: Quad Flat L-Leaded Package
  S: Shrink Dual In-line Package
  N: Very Small Outline Package (SSOP)
  R: Very Small Quad Flat Package

- Improvement mark
  "A" is affixed when specifications are improved.
- Product number
  Identifies the individual product.
- Product category mark
  A: Bipolar IC
  B: Bipolar digital IC
  D: MOS logic IC
  K: Memory, Mask ROM
  P, Q: Microcomputer, Microprocessor
  L: CCD signal processor
- Sony IC mark
2) Hybrids nomenclature

(1) Conventional nomenclature system

[Example] BX - □□□□ - □

- Improvement mark
- Product's number identifies individual product.
- Hybrid IC mark

(2) New nomenclature

[Example] SBX - □□□□ - □

- Classification
- Product's number identifies individual product.
- Hybrid IC mark

Hybrids have carried SBX or BX prefix up to January 1987. i.e. BX-1452, Those developed after the above due all stand by SBX. i.e. SBX1435/SBX1475.
4. Precautions for IC Application

1) Absolute maximum ratings

The maximum ratings for semiconductor devices are normally specified by "absolute maximum ratings". The values shown in the maximum ratings table must never be exceeded even for a moment.

If the maximum rating is ever exceeded, device deterioration or damage will occur immediately. Then, even if the affected device can operate, the life will be considerably shortened.

IC maximum ratings

The following maximum ratings are used for ICs.

(1) Maximum power supply voltage $V_{cc}$ ($V_{DD}$)

The maximum voltage that can be applied between the power supply pin and ground pin.

This power supply voltage rating is directly related to the dielectric voltage of transistors in the internal circuit. The transistors may be destroyed if this voltage is exceeded.

(2) Allowable power dissipation $P_{o}$

The maximum power consumption allowed in IC.

Usage beyond the Allowable power dissipation will cause ultimate destruction through the IC's heat generation.

(3) Operating ambient temperature $T_{opr}$

The temperature range within which IC can operate satisfactorily.

Even if this temperature range is exceeded and some deterioration in operating characteristics is noted, the IC is not always damaged.

For some ICs, the electrical characteristics at $T_a=25^\circ C$ are not guaranteed even in this temperature range.

(4) Storage temperature $T_{stg}$

The temperature range for storing the IC which is not operating.

This temperature is restricted by the package material, and the intrinsic properties of the semiconductor.

(5) Other values

The input voltage $V_{in}$, output voltage $V_{out}$, input current $I_{in}$, output current $I_{out}$ and other values may be specified in some IC's.

---

A general example on the relation with Absolute Maxium Ratings.

<td></td>
</tr>
</tbody>
</table>

Po-Ta curve

Ambient temperature (°C)

Main points on Circuit design.

In the circuit design the absolute maximum ratings must not be exceeded, and it must be designed only after considering the worst situations among the following:

- Fluctuation in source voltage
- Scattering in the electrical characteristics of electrical parts (transistors, resistors, capacitors, etc.)
- Power dissipation in circuit adjustment
- Ambient temperature
- Fluctuation in input signal
- Abnormal pulses

If this allowable power dissipation is exceeded, electrical and thermal damage may result.

This value varies with amount of IC integration in package types.
2) Protection against electrostatic breakdown

There have been problems concerning electrostatic destruction of electronic devices since the 2nd World War. Those are closely related to the advancement made in the field of semiconductor devices; this is, with the development of semiconductor technology, new problems in electrostatic destruction have arisen. This situation, perhaps, can be understood by recalling the case of MOS FET.

Today, electrostatic destruction is again drawing people's attention as we are entering the era of LSI and VLSI. Here are our suggestions for preventing such destruction in the device fabrication process.

Factors causing electrostatic generation in manufacture process

A number of dielectric materials are used in manufacture process. Friction of these materials with the substrate can generate static electricity which may destroy the semiconductor device.

Factors that can cause electrostatic destruction in the manufacture process are shown below:

Causes of electrostatic destruction of semiconductor parts in manufacture process

Output
Handling precautions for the prevention of electrostatic destruction

Explained below are procedures that must be taken in fabrication to prevent the electrostatic destruction of semiconductor devices.

The following basic rules must be obeyed.
(1) Equalize potentials of terminals when transporting or storing.
(2) Equalize the potentials of the electric device, work bench, and operator's body that may come in contact with the semiconductor device.
(3) Prepare an environment that does not generate static electricity.
One method is keeping relative humidity in the work room to about 50%.

Operator

(1) Clothes
Do not use nylon, rubber and other materials which easily generate static electricity. For clothes, use cotton, or antistatic-treated materials. Wear gloves during operation.

(2) Grounding of operator's body
The operator should connect the specified wrist strap to his arm. If the wrist strap is not available, then the operator should touch the grounding point with his hand, before handling and semiconductor device.

Example of grounding band

When using a copper wire for grounding, connect a 1MΩ resistance in series near the hand for safety.

(3) Handling of semiconductor device
Do not touch the lead. Touch the body of the semiconductor device when holding. Limit the number of handling times to a minimum. Do not take the device out of the magazine or package box unless it is absolutely necessary.

Equipment and tools

(1) Grounding of equipment and tools
Ground the equipments and tools that are to be used. Check insulation beforehand to prevent leakage.

[Check point]
- measuring instrument
- conveyer
- electric deburr brush
- carrier
- solder dipping tank
- lead cutter
- shelves and racks
(2) **Grounding of work table**

Ground the work table as illustrated. Do not put anything which can easily generate static electricity, such as foam styrol, on the work table.

![grounding of work table](image)

(3) **Semiconductor device case**

Use a conductive case, or an antistatic plastic case (lined with conductive sheet).

![plastic case for semiconductor devices](image)

(4) **Insertion of semiconductor device**

Insert the semiconductor device during the mounting process or on the belt conveyer. The insertion should be done on a conductive sheet.

(5) **Other points of caution**

Take note of the kind of brush material used for removing lead chips. Use metal or antistatic-treated plastic brushes.

---

**Transporting, storing and packaging methods**

(1) **Magazine**

Use conductive, or antistatic-treated plastic IC magazines.

Plastic magazines used for shipping ICs are antistatic-treated, and they can be used for storing ICs.

![conductive magazine](image)

(2) **Bag**

Use a conductive bag to store ICs. If the use of vinyl bag is unavoidable, be sure to wrap the IC with aluminum foil.

![conductive bag](image)
(3) Handling of delivery box
The delivery box used for carrying substrates must be made of conductive plastic. Do not use a vinyl chloride or acrylic delivery box, otherwise static electricity will be generated.

(4) Treatment after vehicle transport
After truck transport, place the magazine, package box or delivery box on the grounded rack, work table for discharging.

(5) Handling of mounted substrates
Wear cotton gloves when handling. As far as possible, avoid touching soldered faces. When handling mounted substrates individually, be sure to use a conductive bag. Do not use a polyethylene bag.

Soldering operation
(1) Soldering iron
Use a soldering iron with a grounded metal part or a soldering iron with an insulation resistance greater than 10MΩ (DC 500V) after five minutes from energizing.

(2) Operation
After inserting the semiconductor device into the substrate, solder it as quickly as possible. Do not carry the substrate with the inserted semiconductor device by car.

(3) Correction
When correcting parts (semiconductor device and CR parts) after solder-dipping, be sure to wear cotton gloves. Also, connect the grounding band to the arm, or touch the grounding point before operation.

(4) Manual soldering
Solder with wrist strap connected to the hand, or by touching the grounding point from time to during operation.

(5) Removing semiconductor device
Do not use the Solder-Pult when removing the semiconductor device. Use a Solder-wick or equivalent.

(6) Soldering work table
Use a grounded work table for soldering. Do not solder on foam styrol, vinyl, or melamine resin.
3) Mounting method
Soldering and solderability
(1) Solderability by JIS

JIS specifies solderability of an IC terminal (lead) in “JIS-C7022 Test Procedure A-2”. An abstract of this standard follows:

- Rosin flux must be used, and the terminal must be dipped in it for 5-10 seconds.
- H63A or equivalent solder must be used, and the terminal must be dipped in the solder which been heated to 230°C±5°C for 5±1 seconds.
- Using a microscope, measure the area (%) deposited with solder. JIS specifies that more than 95% of the total area should be coated with solder.

(2) Area for soldering warranty

Soldering is warranted for a specific portion of the terminal. The warranted portion is shown in the following figure.

The tie-bar cut portion also serves as a dam to prevent the sealing resin flowing out during device fabrication; it is cut off at the end of the process. Since the terminal is exposed at the cut-off end, the area for soldering is restricted. The portion near the resin is often covered with burrs when sealing with resin; it is not in the soldering warranty area.

Resistence to soldering heat
(1) Specification of JIS

JIS specifies the method for testing the resistance to soldering heat. This method is used for guaranteeing the IC resistance against thermal stresses by soldering. An abstract of this standard is as follows:

- Dip the device terminal only once for 10±1 seconds in a solder bath of 260°C±5°C, or for 3±0.5 seconds in a solder bath of 350°C±10°C, for a distance of up to 1 to 1.5 mm from the main body.

For the solder flow system temperature should be 260°C±5°C. To solder by soldering iron temperature should be 350°C±10°C.

- Leave the device for more than two hours after dipping, then measure the device characteristics.
- Normally, the warranty is limited to 10 seconds at 260°C±5°C. The distance between the device main body and solder bath is 1.6 mm.
(2) Resistance to soldering heat when mounting infrared reflow.
When surface mount Devices (SOP, QFP etc) are dipped directly into a solder pot.
The device moisture resistance may deteriorate and thermal stress generate cracks in the pallet.
Carefully observe the mounting conditions.
Recommended temperature profile when mounting infrared reflows is shown in the figure below.

![Temperature profile diagram](image-url)
5. Quality Assurance and Reliability

The Concept to Quality Assurance

There are 2 fundamental principles guiding Sony Semiconductors.

1. Customer satisfaction
2. Top level performance

What comes first is the ability to respond convincingly to given requirements in terms of Quality, Delivery, Cost and Servicing. This involves all operations involved in the process. The second requisite is the quest for superior accomplishment. Here, talent is demanded to fulfill customer expectations, where quality is concerned, and pursue related activities.

To this effect an elaborate system of quality assurance is firmly established. From the early stages of research and development well into production, sales and servicing, orderly control is applied for the maintenance of high standards and further improvement. Systematization and automation are pushed ahead to provide a stable output of high quality production.

In this respect, the force in charge of implementing the program is nonetheless subject to constant polishing. Gifted people well aware of the problems inherent to their tasks are at the core of the excellence reflected on their yield.

With the aim of providing the most economical, the most useful and at the same time the most gratifying products where quality is the criterion, Sony keeps fueling a relentless urge for achievement.

Quality assurance criteria and reliability test criteria

1) Quality assurance in shipping

Establishing quality in the design and in fabrication is essential to keep the quality and reliability levels of the semiconductor devices at a high level. This is done by the “Zero-defect” (ZD) movement. Further sampling checks, in units of shipping lot, is done on products that have been “totally-inspected” at the final fabrication stage, thus ensuring no detective items. This sampling inspection is done in accordance with MIL-STD-105D.

2) Reliability

The reliability test is done, periodically, to confirm reliability level.

### Periodic Reliability Test

**Description**

The CXA1213AS is a Y/chroma/jungle signal processing IC of PAL, NTSC (4.43MHz, 3.58MHz) systems color TVs.

**Features**

- TV system is compatible with PAL, SECAM, and NTSC (4.43MHz, 3.58MHz) through combination with the CXA1214P.
- No adjustment of H,V oscillation frequency by count down system.
- Built-in 50/60Hz automatic discrimination circuit and compulsory mode applicable.
- Built-in 3.58/4.43MHz color sub carrier oscillation frequency automatic discrimination circuit and compulsory mode applicable.
- Input prohibition gate function according to frequency of input vertical synchronization. (Noise elimination ability)
- Black expansion function. (New dynamic picture)
- High speed blanking function which blanks interval of characters.

**Applications**

Color decoder for PAL/NTSC system

**Structure**

Bipolar silicon monolithic IC

**Details of measurement**

- Test each level $V_{BGH}, V_{BGH},$ and pulse width $t_{BG1}$ from GND of Pin 20 output.
- Test each level from GND of Pin 33 output wave and pulse width.
- Input SIG1 or SIG5 to Input C when $t_{BLK1}$ and $t_{BLK2}$ are tested.
- Test the time difference $t_{BGD}$ at this point.

**Pin 20 output waveform**

- Min: 2.7, Typ: 3.3, Max: 4.1 V
- Min: 2.9, Typ: 3.4, Max: 3.9 µs

**Pin 33 output waveform**

- Min: 1.8, Typ: 2.2, Max: 2.6 V
- Min: 10.8, Typ: 11.7, Max: 12.5 µs

- Min: 4.2, Typ: 4.8, Max: 5.4 V
- Min: 1.70, Typ: 1.76, Max: 1.80 ms
- Min: 1.40, Typ: 1.44, Max: 1.50 ms

*Raise the voltage of E5 from 5.6V subsequently and test offset voltage from 5.6V of E5 when HD pulse of Pin 27 stops.*

Operation Description

(1) Luminance signal system

(i) SHP circuit
The luminance signal that is input from Pin 46 is emphasized around 3.0 MHz of luminance signal by SHP circuit. Connect Pin 45 to VCC so that SHP circuit gets OFF when it is not necessary.

(ii) BLK MUTE circuit
Connecting Pin 41 to VCC replaces BLK section to black level and connection with auto white balance IC (CXA1024S) applicable.

(iii) Fast BLK circuit
Inputting the character signal etc. to CBLK pin makes the function that attenuates the character signal part of video signals available.

(iv) New Dynamic Picture circuit
The function to expand black operates in the signals under 50IRE of input signal. Connecting Pin 40 at around 10kΩ resistance makes the function cancelled.

(2) Chroma system

(i) ACC circuit
Detects the burst signal (that is demodulated by average level detection) by ACC DET and applies return to ACC amplifier according to the detection output to keep the demodulated burst level always stable.

(ii) APC circuit
The input chroma component from Pin 1 composes B-Y signal and R-Y signal by detecting to the external crystal at Pin 8 (3.58MHz) or Pin 10 (4.43MHz), which are output of VCO by APC circuit, after it is amplified via ACC and color amplifiers.

(iii) Matrix
Composes G-Y signal by mixing B-Y and R-Y signals. Then, outputs at R, G, and B original signal by these signals and the luminance signal Y.

(iv) ID correction
PAL system is sent after R-Y (V) component of the signal gets inverted every 1H. Due to this reason, the demodulation axis also needs to be inverted every 1H. The R-Y axis is inverted every 1H synchronizing with HP in this IC, however, the flip-flop corrects it if it is wrong according to R-Y burst detection output.

(v) SECAM system applicable (Combined with the CXA1214P)
The combination with the CXA1214P enables the SECAM signal demodulated. (See Application Circuit 2) Inputting the direct voltage of H level (over 2.5V) and R-Y and B-Y signals, which SECAM signal is demodulated to R CLP (Pin 35) and B CLP (Pin 34) via direct capacitor make the original signals R, G, and B output.
(3) Jungle system

The count down system is adopted by the $32f_{H}$ ceramic oscillator.
Due to these reasons, no adjustment of H and V free run frequency is realized and the number of pins and external parts get lesser.

The horizontal synchronization circuit adopts double loops. The input, VCO frequency and phase are combined and the HD pulse is generated in the first loop and the phase with FBP of deflection is combined in the second loop.

The burst gate pulse is generated synchronizing with the input horizontal sync, however this generates an artificial pulse at no signal with an artificial horizontal sync from the horizontal count down circuit.

The vertical synchronization circuit varies the width of input prohibition gate according to input frequency and shortens the section that vertical sync passes through to improve the elimination capacity of the noises going into vertical sync. (See Diagram of (i) Vertical Synchronization Prohibition Gate)

At the same time, the eliminated capacity of the noises are furthermore improved since the peak hold circuit is adopted at vertical sync separation circuit.

The auto discrimination circuit is built in when Switching 50 or 60Hz.

(i) Vertical synchronization prohibition gate

\[ \text{Diagram 1. Vertical pull-in range} \]

This is synchronized in state 1 to 4 by vertical sync wavelength. The vertical pull-in range is composed as Diagram 1. Through this, the noise is eliminated as providing the input prohibition gate severely not to discriminate the non-continuous noise pulse besides vertical sync (ex. VHS noise).
(ii) 50/60Hz Discrimination Operation

The count number is 64 µs by a count (=1/f) 

Diagram 2. 50/60Hz Discrimination Range

This IC automatically discriminates the discrimination of 50Hz and 60Hz from the input vertical sync. The 50Hz has priority when the power supply is on and discriminates as in Diagram 2 by vertical sync wavelength. The discrimination output pin is Pin 13, and outputs as 60Hz mode H and 50Hz mode L.

For example, this discriminates as 60Hz mode when the input signal is from 242.5 to 295.5 counts and 50Hz mode when the input signal is from 275.5 to 337.5 counts. And the hysteresis is provided between the count from 275.5 to 295.5. No discrimination occurs besides those so that the discrimination output of former state is held.

The mark , which is a discrimination error occurs due to like an error of vertical sync separation circuit in this IC, is a state that discriminates as either 50Hz or 60Hz.
Application circuits shown are typical examples illustrating the operation of the devices. Sony cannot assume responsibility for any problems arising out of the use of these circuits or for any infringement of third party patent and other rights due to same.

**Notes or Operation**

1. Recommend adjusting the free run frequency to 4.433619MHz and 3.579545MHz by using the trimmer capacitor.
2. The HUE characteristics 1 and 2 are tested at HUE pin voltage 8V and 2V. The HUE center is about 6.0V.
3. Adjust the detection axis of PAL mode B output to 0deg by controlling Pin 4 (PHASE).
4. Input the signal to Pin 33 in the emitter follower type when the high speed blanking function used.

SONY:

SECAM Color Decoder

Description
The CXA1214P is a color signal processing IC for SECAM color television system. The IC has an ID determination circuit as well as the video processing circuits required for processing of color signals.

Features
• Combined use of the CXA1214P and CXA1213S makes it possible to configure a system compatible with all three systems, PAL, SECAM and NTSC.
• Has a self-contained automatic ID determination circuit.

Applications
• Color television
• SECAM color decoder

Block Diagram

24pin DIP (Plastic)

Structure
Bipolar silicon monolithic IC

SONY reserves the right to change products and specifications without notice.

Pin Configuration

Operating Condition
- Supply voltage $V_{CC}$ 8.5 to 9.5 V

Absolute Maximum Ratings (Ta=25°C)
- Supply voltage $V_{CC1}, V_{CC2}$ 7 V
- Operating temperature $T_{opr}$ -20 to +75 °C
- Storage temperature $T_{stg}$ -55 to +125 °C
- Allowable power dissipation $P_D$ 1.3 W

- Input signal: 200mVP-p
- Duration: 28.5µsec
- Frequency: fm - 100K, fm + 100K

SG6:
- Input signal: FM wave 1
- Frequency: fm
- Center frequency: fm = f0
- Maximum frequency deviation: Δf = 100kHz
- Modulation frequency: P = 100kHz

Center frequency: fm = f0
Maximum frequency deviation: Δf = 100kHz
Modulation frequency: P = 100kHz
Operation

SECAM color signal is input from Pin 2 via the bell filter.
The signal is passed through the limiter from which it is directly routed to the permutator and is also output to Pin 24.
The signal output from Pin 24 passes through the 1H delay line and is re-input from Pin 21 and it is sent through the limiter to the permutator.

In response to a switching pulse from the determination system, the permutator sends either the signal directly input from the bell filter or the signal input via the 1H delay line to the R-Y or B-Y FM detector.

The color signals passed through the FM detectors are output through the respective de-emphasis circuits and color control circuits to Pins 10 (R-Y output) and 11 (B-Y output).

The determination system monitors the outputs from the FM detectors to check whether the permutator is correctly switching the signals, and provides controls to make sure that the permutator correctly switches the signals. When no SECAM signal is input, the forced killer is activated to block output of R-Y and B-Y signals. In addition, the output at Pin 14 is caused to be "Low".

Application Circuit
Adjustment procedure

Input SECAM color bar signal to Pin 2 via the bell filter. Adjust coil L1 so that the video section black level and BLK level will be in alignment in the output at Pin 10.

Similarly, adjust coil L2 so that the black level and BLK level will be in alignment in the output at Pin 11.

Example of characteristics

SONY®

CXA1218S/CXA1228S

NTSC/PAL Decoder

Description
CXA1218S and CXA1228S are decoder ICs used to convert composite video signals into color difference signals. They have signal outputs, such as composite sync, burst flag, subcarrier, and alternate signal outputs, necessary for image processing. CXA1228S operates in both NTSC and PAL modes.

Ratio is R-Y : B-Y = 1.4 : 1.0 for CXA1218S
R-Y : B-Y = 1 : 1.27 for CXA1228S

Features
- Single supply operation 5V
- Low power consumption (85 mW Typ.)
- Compatible with both NTSC and PAL modes
- Provides composite sync, burst flag, subcarrier, and line alternate signal output

Function
Synchronous separation, composite sync output, burst flag output, ACC, ACK, APC, demodulator, DL amplifier, PAL ID, HUE control.

Structure
Bipolar silicon monolithic IC

Absolute Maximum Ratings (Ta=25°C)
- Supply voltage $V_{CC}$ 10 V
- Operating temperature $T_{opr}$ -20 to +75 °C
- Storage temperature $T_{stg}$ -55 to +150 °C
- Allowable power dissipation $P_{o}$ 250 mW

Recommended Operating Condition
- Supply voltage $V_{CC}$ 5 ± 0.25 V

Application Circuit (NTSC mode)

![NTSC Circuit Diagram]

Application Circuit (PAL mode)

![PAL Circuit Diagram]
Applications

1. Input signals

Composite video signal input is separated into video signal (Y) and chroma signal (C) by band-pass filter, trap and delay line, Y is input to Pin 27 and C to Pin 24. While composite video signal is input at 1 Vp-p, the typical levels of the input signals are as shown in the table below.

<table>
<thead>
<tr>
<th>Composite video input (Synchronous negative polarity)</th>
<th>CXA1218S</th>
<th>CXA1228S</th>

</tr>
<tr>
<td>Chroma Burst input</td>
<td>0.143Vp-p</td>
<td>0.143Vp-p</td>
</tr>
</tbody>
</table>

2. Time pulse adjustment

BF (Burst Flag) pulse positional adjustment can be performed by changing the current to be taken out from Pin 5. Setting to (BF) at 5.6 µs by this adjustment results in that BF pulse width is set at approx. 2.4 µs and BLK (blanking) pulse width at 10 µs.

3. Monochrome (free-running)/color mode switching

If Pin 23 (CHROMA ADJ) is set to H (≥2.0 V), the color mode is established. Input chroma signal will be decoded and output in the form of color difference signal. If Pin 23 is set to L (≤0.8V), the monochrome (free-running) mode is established and the APC circuit is made to stop. As a result, VXO oscillates in the free-running mode.

4. NTSC/PAL mode switching

Setting Pin 20 (DL A BIAS) to H (≥2.0V), establishes the PAL mode, and setting the pin to L (≤0.8V).

5. Chroma output

Chroma signal subjected to ACC and blanking is output at Pin 21 (CHROMA OUT). Output amplitude is approx. 160mVp-p with typical input (75% color bar).

In the PAL mode, this output is to be input to 1 H DL. In the NTSC mode, connect Pin 21 to the power supply (Vcc).

6. DL (Delay Line) AMP

An amplifier for insertion of 1 H DL and matching loss compensation when in the PAL mode. Its gain is variable within 14 ± 4 dB to absorb DL dispersion.

Its input pin is Pin 19 (DL A IN); apply to this pin a bias voltage of the same potential as with Pin 20 (DL A BIAS). The signal having passed through 1 H DL is to be input to Pin 19 after adjusted at the delay adjusting transformer (DAT) so that the delay time is 1 H (64 µs).

In the NTSC mode, this amplifier is not used; set the levels of Pins 19 and 20 at L (≤0.8V).
7. VXO and APC
   Pin 9 (APC TC) a time constant pin for APC. In the monochrome (free-running) mode in which the
   APC circuit does not operate, the free-running frequency depends on the DC voltage across this pin.
   VXO can operate either for NTSC or PAL by changing the quartz oscillator and series capacity.

8. Adjustment procedure
   Input signal : 100% color bar

[NTSC mode]
   1) BF positional adjustment
      Adjust the resistance between Pin 5 and GND so that BF position to = 5.6 µs.
   2) Video amplifier level adjustment
      Adjust Y ADJ so that Y output white peak (100% white) is of 0.714 Vp-p.
   3) fo adjustment
      Establish the monochrome (free-running) mode, and adjust fo ADJ so that oscillation frequency
      (output subcarrier) frequency is fsc.
   4) Hue adjustment
      Establish the color mode, and adjust HUE ADJ so that output amplitudes A, B and C are all
      equal.
   5) Chroma level adjustment
      CXA1218S: Adjust C ADJ so that the maximum amplitude of output B-Y is 1.0 Vp-p.
      CXA1228S: Adjust C ADJ so that the maximum amplitude of output B-Y is 1.27 Vp-p.

[PAL mode]
   1) BF positional adjustment ........ Same as with NTSC mode.
   2) Video amplifier level adjustment .. Same as with NTSC mode.
   3) fo adjustment ................... Same as with NTSC mode.
   4) DL amplifier adjustment
      Establish the color mode, and adjust DLA ADJ so that the R output amplitude is the same for
      any adjacent two H intervals.
   5) Chroma level adjustment
      CXA1218S: Adjust C ADJ so that the maximum amplitude of output B-Y is 1.0 Vp-p.
      CXA1228S: Adjust C ADJ so that the maximum amplitude of output B-Y is 1.27 Vp-p.
Description of Operation

1. Sync separation system
   The sync separation system clamps the sync tip of the video signal having been input from Pin 27 to separate the sync signal from the input video signal. Sync pulses are then processed to form BF, H, and BLK pulses, which are supplied to subsequent circuits. Of these pulses, sync and BF pulses are output at Pins 2 and 3, respectively, after transformed to TTL level via buffer.

2. Luminance signal regeneration system
   Video signal input from Pin 27 has its pedestal clamped, and amplified by the Y amplifier.

3. ACC system
   The burst component of the chroma signal having been input from Pin 24 is detected at ACC DET. Feedback to ACC AMP occurs depending on the detected output so that the burst level is kept constant.

4. APC system
   After the signal level is brought to the fixed value at ACC AMP, the burst component alone goes into the APC circuit via the BURST GATE circuit. Meanwhile, a 0° carrier and a 90° carrier are formed from VXO output, and the 90° carrier goes into APC via the HUE circuit. At APC, phase comparison is carried out between the 90° carrier and the input burst, and feedback to VXO is performed so that the phase difference is 90°. The 0° and 90° carriers thus formed are supplied to B-Y DEM and R-Y DEM, respectively. Therefore, demodulation axis can be changed by rotating the phase of the 90° carrier at the HUE circuit.

5. Color signal regeneration system
   1) NTSC system
      The chroma signal amplified at ACC AMP is amplified again at CHROMA AMP, then demodulated at B-Y DEM and R-Y DEM, and output at Pins 16 and 17 in the form of color difference signal.

   2) PAL system
      Processing is the same as with the NTSC system up to CHROMA AMP. The chroma signal output at Pin 21 goes into DL AMP at Pin 19 via 1 H DL and DAT, and then input to the ADD/SUB circuit after level-controlled. At the ADD/SUB circuit, the signal is subjected to addition and subtraction with respect to the original signal. The signals obtained by addition and subtraction are input to B-Y DEM and R-Y DEM, and demodulated by the 0° carrier and the 90° carrier inverted every H. After that, the signal is output in the form of color difference signal as with the NTSC system.

6. PAL ID
   The PAL signal is transmitted with its R-Y component inverted every H. It is therefore necessary to inverse the demodulation axis every H. In this IC, the 90° carrier is inverted in synchronization with H BLK pulses, and checking for correspondence with the input burst is performed by synchronous detection. If an error is detected, feedback to FF (Flip Flop) is performed for correction.
Description
The CXA1385Q is a LCD TV IC that converts the composite video signals to RGB equivalents. It is ideally suited for use in a 2- to 4-inch LCD TV set. It incorporates all filters necessary for signal processing.

Features
- Built-in delay line (Y/C delay alignment)
- Built-in TRAP, BPF, and SHARPNESS functions
- Built-in APL circuit
- Few number of parts (approximately 50 parts)
- Low power consumption 135mV (Vcc=5V).

Absolute Maximum Ratings
- Supply voltage Vcc 14 V
- Operating temperature Topr -20 to +75 °C
- Storage temperature Tstg -65 to +150 °C
- Allowable power dissipation Po 500 mW

Operating Conditions
Supply voltage Vcc 4.75 to 5.25 V

Detailed Test Procedures

1. YAMP voltage gain

\[
G = 20 \log \left( \frac{V_{OUT}}{V_{IN}} \right) \text{ (dB)}
\]

2. Primary color output voltage

Adjustment Procedure (Input signal: 75% color-bar)
1. Adjust the HUE ADJ and C CONT controls so that B output amplitudes A, B, C, and D are equal.
* Change the C19 input capacitor polarity in accordance with the operating conditions.

Application circuits shown are typical examples illustrating the operation of the devices. Sony cannot assume responsibility for any problems arising out of the use of these circuits or for any infringement of third party patent and other right due to same.
Description of Operation

(1) Luminance Signal Regeneration System

i) Trap Filters
   Two LPFs and two trap filters are used to derive the luminance signal from the composite signal.

ii) Delay Line Filter
   Makes delay amount adjustment relative to the color signal.

iii) Sharpness Filter
   Accentuates the 1.5MHz region of the luminance signal passing through the delay line. The voltage applied to Pin 24 (SHP CTL) varies the 1.5MHz component over the range from -5 to +5dB (with reference to 300kHz). When 2.5V is applied to Pin 24 (SHP CTL), the 0dB level (with reference to 300kHz) results.

iv) APL Circuit
   The APL (average picture level) is used to control the YAMP gain. When the APL is low, the gain is increased. When the APL is high, on the other hand, the gain is decreased. The AGC turns ON when 2.5V is present at Pin 22 (APL CTL). If the AGC function is not needed, the AGC circuit is turned OFF by applying 0V to Pin 22.

(2) Color Signal Regeneration System

i) BPF
   Derives the chroma signal from the composite signal.

ii) ACC Circuit
   After the chroma signal is passed through the BPF, the burst signal is detected by the ACC DET. The feedback resulting from detection is then returned to the ACC AMP so as to maintain the burst level constant.

iii) APC Circuit
   After being adjusted to a fixed level by the ACC AMP, the signal passes through the burst gate circuit so that only the burst signal enters the APC circuit. Meanwhile, the VXO output is fed to the phase circuit, where the 0°, 90°, and 180° signals are generated. These signals then go into the hue circuit, and the resultant synthesized signal (90° carrier) enters the APC circuit. The phase of this signal is compared against that of the burst signal, and a feedback signal is transmitted to the VXO so that a phase difference of 90° occurs. The 0° and 90° carriers generated in this manner are supplied to the B–Y and R–Y DEM sections. Therefore, the DC voltage applied to Pin 2 (HUE ADJ) controls the synthesized wave phase to vary the demodulation axis.

iv) DEM Circuit
   After being adjusted to a fixed level by the ACC AMP, the chroma signal is amplified by the CHROMA AMP, demodulated by the B–Y DEM and R–Y DEM, fed to the Y/C MIX circuit together with the G–Y signal generated by the resistor matrix, and mixed with the luminance signal to generate the R, G, and B primary color outputs.

(3) Sync Separation System

After the composite video signal is entered via Pin 31 (COMP IN), the sync tip is clamped so that sync separation occurs. The resulting SYNC pulse is used to generate the BF (burst flag), BLK, and other timing pulses to be supplied to various circuits. The SYNC and BF pulses are converted to TTL level through buffer, and transferred out.
Adjustment Procedures

Input signal: 75% color-bar (NTSC)

1) \( f_o \) adjustment
Adjust the Pin 4 (APC TC) DC voltage so that the Pin 7 (SCOUT) oscillation frequency (subcarrier output) is within \( f_{sc} = 3.579545 \text{MHz} \pm 20 \text{Hz} \) in a no-signal state (free-run).

2) BF position adjustment
Adjust the resistance between Pin 19 and GND to set the BF (burst flag) position to (BF) to 5.6 \( \mu \text{s} \).

3) Input level adjustment
With Pin 22 (APL CTL) connected to the GND, adjust the input level so that the B output white peak (75% white) is 0.75Vp-p.

4) HUE ADJ and C CONT adjustments
Adjust the HUE ADJ and C CONT controls so that the amplitudes of all B output colors (A, B, C, and D below) are equal.
Application

1. The maximum input dynamic range is 0.56Vp-p. The details are given below.

<table>
<thead>
<tr>
<th>Signal Type</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Composite video</td>
<td>0.56Vp-p</td>
</tr>
<tr>
<td>Sync signal</td>
<td>0.16Vp-p</td>
</tr>
<tr>
<td>Luminance signal</td>
<td>0.40Vp-p (100% white)</td>
</tr>
<tr>
<td>Burst signal</td>
<td>0.16Vp-p</td>
</tr>
</tbody>
</table>

The value 0.56Vp-p is measured from the sync tip to the white peak. Note that the output may be clipped and distorted if the input signal is greater than 0.56Vp-p. However, this applies when the AGC is OFF (Pin 22 [APL CTL]=0V).

2. Filter F0 pin
The filter F0 sensitivities are as follows.

<table>
<thead>
<tr>
<th>Filter Type</th>
<th>Sensitivity</th>
</tr>
</thead>
<tbody>
<tr>
<td>BPF F0</td>
<td>-150kHz/+kΩ</td>
</tr>
<tr>
<td>TRAP F0</td>
<td>-140kHz/+kΩ</td>
</tr>
<tr>
<td>SHARP F0</td>
<td>-40kHz/+kΩ</td>
</tr>
<tr>
<td>DELAY F0</td>
<td>+4nS/+kΩ</td>
</tr>
</tbody>
</table>

3. To obtain a deeper trap, connect the LC (100 µH, 20 pF) in series between Pin 28 (TRAP OUT) and GND. The trap is then rendered about 3dB deeper.

4. Notes on operation

i) When making wiring connections, ensure that Pin 28 (TRAP OUT) is not affected by signal input or X'tal (crystal oscillator) oscillation frequency.

ii) The fo value of the X'tal varies with the floating capacity and other factors. Therefore, mount the X'tal as close as possible to the IC using a minimum of connecting wiring.

Package Outline

Unit: mm

32pin QFP (Plastic) 0.2g
Description

V7021 is a decoder IC used to convert composite video signals into analog RGB signals. It has signal outputs, such as composite sync, burst flag, sub-carrier, and alternate signal outputs, necessary for image processing. V7021 operates in both NTSC and PAL mode.

Features

- 5V single supply operation
- Low power consumption (about 85mW)
- Compatible with both NTSC and PAL modes.
- Provides composite sync, burst flag, sub-carrier, and line alternate signal outputs.

Function

Synchronous separation, Composite sync output, burst flag output, ACC, ACK, APC, demodulator, Y/C mixer, DL amplifier, PAL ID, HUE control

Structure

Bipolar silicon monolithic IC

Absolute Maximum Ratings

- Supply voltage \( V_{CC} \) 10 V
- Operating temperature \( T_{OPR} \) -20 to +75 °C
- Storage temperature \( T_{STG} \) -55 to +150 °C
- Allowable power dissipation \( P_D \) 1250 mW

Recommended Operating Conditions

- Supply voltage \( V_{CC} \) 5 ± 0.25 V
Block Diagram and Pin Configuration

\[ G_v = 20 \log \frac{V_{out}}{V_{in}} \text{ (dB)} \]

2. Original color output voltage

<table>
<thead>
<tr>
<th>Input waveform</th>
<th>VIDEO IN</th>
<th>CHROMA IN</th>
</tr>
</thead>
<tbody>
<tr>
<td>Output waveform</td>
<td>R OUT</td>
<td>G OUT</td>
</tr>
</tbody>
</table>

Adjustment

1. Adjust HUE ADJ so that output B is the same amplitude.
2. Adjust CHROMA ADJ so that output B is 1Vp-p.
Application Circuit
(NTSC mode)

(PAL mode)
Applications

1. Input signals

Composite video signal input is separated into video signal (Y) and chroma signal (C) by band-pass filter, trap and delay line. Y is input to pin 27 and C to pin 24. While composite video signal is input at 1Vp-p, the typical levels of the input signals are as shown in the table below.

<table>
<thead>
<tr>
<th>Composite video input (Synchronous negative polarity)</th>
<th>1.0Vp-p</th>
</tr>
</thead>
<tbody>
<tr>
<td>Video input</td>
<td></td>
</tr>
<tr>
<td>Luminance</td>
<td>0.256Vp-p</td>
</tr>
<tr>
<td>Sync</td>
<td>0.103Vp-p</td>
</tr>
<tr>
<td>Chroma input</td>
<td></td>
</tr>
<tr>
<td>Burst</td>
<td>0.143Vp-p</td>
</tr>
</tbody>
</table>

2. Time pulse adjustment

BF (Burst Flag) pulse positional adjustment can be performed by changing the current to be taken out from pin 5. Setting to (BF) at 5.6 µs by this adjustment results in that BF pulse width is set at approx. 2.4 µs and BLK (blanking) pulse width at 10 µs.

3. Monochrome (free-running) /color mode switching

If pin 23 (CHROMA ADJ) is set to H (≥ 2.0V), the color mode is established. Input chroma signal will be decoded and output in the form of color difference signal. If pin 23 is set to L (≤ 0.8V), the monochrome (free-running) mode is established and the APC circuit is made to stop. As a result, VXO oscillates in the free-running mode.

4. NTSC/PAL mode switching

Setting pin 20 (DL A BIAS) to H (≥ 2.0V), establishes the PAL mode, and setting the pin to L (≤ 0.8V).

5. Chroma output

Chroma signal subjected to ACC and blanking is output at pin 21 (CHROMA OUT). Output amplitude is approx. 160mVp-p with typical input (75% color bar).

In the PAL mode, this output is to be input to 1 H DL. In the NTSC mode, connect pin 21 to the power supply (Vcc).

6. DL (Delay Line) AMP

An amplifier for insertion of 1 H DL and matching loss compensation when in the PAL mode. Its gain is variable within 14 ± 4dB to absorb DL dispersion.

Its input pin is pin 19 (DL A IN); apply to this pin a bias voltage of the same potential as with pin 20 (DL A BIAS). The signal having passed through 1 H DL is to be input to pin 19 after adjusted at the delay adjusting transformer (DAT) so that the delay time is 1 H (64 µs).

In the NTSC mode, this amplifier is not used; set the levels of pins 19 and 20 at L (≤ 0.8V).
7. VXO, APC

Pin 9 (APC TC) is the APC time constant pin. When APC circuit is not active in PC mode, free run frequency is determined by means of the DC voltage of this pin to compensate the free run frequency temperature characteristics execute temperature compensation as in the example for application circuits. VXO can be used to handle NTSC and PAL by changing the crystal oscillator and the linear capacitance.

8. Order of adjustment

Input signal 100% Color bar

[NTSC mode]

1) BF (burst flag) position adjustment
   Adjusting the resistance between pin 5 and the ground, BF position is rendered to = 5.6 µs.
2) Adjustment of video amplifier level
   Adjust YADJ with RGB output, so that white peak (100% white) becomes 1.0Vp-p.
3) \( f_0 \) adjustment
   Adjustment \( f_0 \) ADJ, so that in PC mode oscillating frequency (subcarrier output) becomes fsc.
4) HUE adjustment
   Adjust HUE ADJ so that in SI mode, the amplitude be the same for the respective colors from B output amplitude.
5) Chroma level adjustment
   Adjust C ADJ so that the respective colors of B output amplitude, become 0.75Vp-p.

[PAL mode]

1) BF position adjustment
2) Adjustment of video amplifier level
3) \( f_0 \) adjustment.
4) DL amplifier adjustment.
   Adjust DLA ADJ so that in SI mode, the R output amplitude former and latter parts, in H section, be equal.
5) Chroma level adjustment
   Adjust C ADJ so that the respective colors from B output amplitude, become 0.75Vp-p.
Operation

1. Sync separation system
   The sync separation system clamps the sync tip of the video signal having been input from pin 27 to separate the sync signal from the input video signal. Sync pulses are then processed to form BF, H, and BLK pulses, which are supplied to subsequent circuits. Of these pulses, sync and BF pulses are output at pins 2 and 3, respectively, after transformed to TTL level via buffer.

2. Luminance signal regeneration system
   Video signal input from pin 27 has its pedestal clamped, and amplified by the Y amplifier.

3. ACC system
   The burst component of the chroma signal having been input from pin 24 is detected at ACC DET. Feedback to ACC AMP occurs depending on the detected output so that the burst level is kept constant.

4. APC system
   After the signal level is brought to the fixed value at ACC AMP, the burst component alone goes into the APC circuit via the BURST GATE circuit. Meanwhile, a 0° carrier and a 90° carrier are formed from VXO output, and the 90° carrier goes into APC via the HUE circuit. At APC, phase comparison is carried out between the 90° carrier and the input burst, and feedback to VXO is performed so that the phase difference is 90°. The 0° and 90° carriers thus formed are supplied to B-Y DEM and R-Y DEM, respectively. Therefore, demodulation axis can be changed by rotating the phase of the 90° carrier at the HUE circuit.

5. Color signal regeneration system
   1) NTSC system
      The chroma signal amplified at ACC AMP is amplified again at CHROMA AMP, then demodulated at B-Y DEM and R-Y DEM, and output at pins 16 and 17 in the form of color difference signal.

   2) PAL system
      Processing is the same as with the NTSC system up to CHROMA AMP. The chroma signal output at pin 21 goes into DL AMP at pin 19 via 1 H DL and DAT, and then input to the ADD/SUB circuit after level-controlled. At the ADD/SUB circuit, the signal is subjected to addition and subtraction with respect to the original signal. The signals obtained by addition and subtraction are input to B-Y DEM and R-Y DEM, and demodulated by the 0° carrier and the 90° carrier inverted every H. After that, the signal is output in the form of color difference signal as with the NTSC system.

6. PAL ID
   The PAL signal is transmitted with its R-Y component inverted every H. It is therefore necessary to inverse the demodulation axis every H. In this IC, the 90° carrier is inverted in synchronization with H BLK pulses, and checking for correspondence with the input burst is performed by synchronous detection. If an error is detected, feedback to FF (Flip Flop) is performed for correction.
Package Outline

Unit: mm

28pin SDIP (Plastic) 400mil 1.7g

Sony NAME SDIP-28P-01
EIAJ NAME SDIP028-P-0400-A
JEDEC CODE
RGB Encoder

Description
The CXA1145P/M encoder converts an analog RGB signal to a composite video signal. With its built-in circuit various pulses required for an encoder, composite video outputs are obtained just by inputting the composite sync and analog RGB signal.

Features
- Single power supply 5 V
- Low power consumption (110 mW)
- Compatible both with NTSC and PAL systems
- Built-in 75Ω driver (RGB output, composite video output, composite sync output)
- Built-in oscillator for subcarrier
- External input of subcarrier is also possible.
- Built-in audio buffer circuit

Functions
- MTX circuit
- R-Y, B-Y MOD circuit
- Y/C MIX circuit
- 75Ω driver for RGB, composite video and composite sync outputs
- PAL ALT circuit
- BF generator
- Half H killer circuit
- Subcarrier oscillator
- Audio buffer circuit

Structure
Bipolar silicon monolithic IC

Absolute Maximum Ratings (Ta = 25°C)
- Supply voltage Vcc 10 V
- Operating temperature Topr -20 to +75 °C
- Storage temperature Tstg -55 to +150 °C
- Allowable power dissipation Pb 1250 mW (CXA1145P) 780 mW (CXA1145M)

Recommended Operating Condition
- Supply voltage Vcc 5 ± 0.25 V

Fig. 7
Burst Signal
CXA1145P/M generates the burst signal in the timings below following an input composite sync.
Application Circuit (NTSC mode)

When a subcarrier is added externally, this section will be as follows:

![NTSC Circuit Diagram]

<How to adjust the oscillation level>
Regulating the trimmer capacitor, set XO out level between 400 to 1000 mVp-p.

* Metal film resistor ± 1%

BPF: Toko H287BSJS-3108HWD
DL: Matsushita ELB-5F020N

Application Circuit (PAL mode)

When a subcarrier is added externally, this section will be as follows:

![PAL Circuit Diagram]

<How to adjust the oscillation level>
Regulating the trimmer capacitor, set XO out level between 400 to 1000 mVp-p.

* Metal film resistor ± 1%

BPF: Toko H287BSJS-3108HWD
DL: Matsushita ELB-5F020N

<How to set to NTSC/PAL modes>
To set to NTSC/PAL modes, connect CXA1145P's pin 7 to 9 either Vee (supply pin) or GND. Connection to Vcc produces NTSC mode, and to GND PAL mode. This is executed by connecting the jumper line of the desired mode on the evaluation board.

Evaluation PC board pattern arrangement diagram

Parts arrangement diagram (parts side)

Pattern diagram (reverse side)
Note) For details refer to the test signals in the Electrical Characteristics Test Circuits.
Description
CXA1219P/M and CXA1229P/M are encoder ICs used to convert Y, R-Y, B-Y signals into composite video or RGB signals.

The composite sync can be separated from the incoming luminous of the signal, as well as the external sync.

With a ratio of R-Y : B-Y = 1.4 : 1 CXA1219P/M is ideally suited for still video floppy usage.
CXA1229P/M R-Y : B-Y = 1 : 1.27

Features
• Single power supply 5V
• Low power consumption (130 mW)
• Compatible with both NTSC and PAL mode
• Built-In 75 Ω driver (RGB output, composite video output, composite sync output)
• Built-in crystal oscillator for subcarrier
• External subcarrier input possible
• Audio buffer

Function
• Matrix circuit
• R-Y, B-Y modulator circuit
• Y/C mixer circuit
• 75 Ω driver for RGB, composite video and composite sync output.
• PAL alternate circuit
• Burst flag generator
• Half H killer circuit
• Oscillator for subcarrier
• Buffer amplifier circuit for audio's

Structure
Bipolar silicon monolithic IC

Absolute Maximum Ratings (Ta=25°C)
• Supply voltage Vcc 10 V
• Operating temperature Topr -20 to +75 °C
• Storage temperature Tstg -55 to +150 °C
• Allowable power dissipation Pd 1,250 mW (CXA1219P, CXA1229P)
• 780 mW (CXA1219M, CXA1229M)

Recommended Operating Condition (Ta=25°C)
• Supply voltage Vcc 5 ± 0.25 V

Application Circuit

NTSC mode (Evaluation board)

External supply to the subcarrier
To supply the subcarrier from the exterior connect as shown in Figure below.

* Metal film resistor ±1%
BPF  Toko H287BSJS-3108HWD
DL  Matsushita ELB-5F020N

Adjusting the frequency level
Adjusting the trimmer capacitor, set XOut level to 400 through 1000 mVp-p.

PAL mode (Evaluation board)

External supply to the subcarrier
To supply the subcarrier from the exterior connect as shown in Figure below.

* Metal film resistor ±1%
BPF  Toko H287BSJS-3108HWD
DL  Matsushita ELB-5F020N

Setting the NTSC/PAL mode
Setting the CXA1219P/M or CXA1229P/M to the NTSC or PAL mode is to be carried out by connecting pin 7 to the power supply pin (Vcc) or GND. Connecting pin 7 to Vcc sets the board to the NTSC mode, and connecting pin 7 to GND sets the board to the PAL mode. On the evaluation board, make connection by the jumper wire for the desired mode.

Notes on Use
When you connect C VIDEO OUT to TV and input characters from personal computer for example, you may notice rainbow-hued blurs along edges of characters displayed on the screen, or unevenness of color distribution. This phenomenon results from mixing of Y-signal's high-frequency components into chrominance components (cross-color interference), and does not represent a faulty operation of the board.
SONY V7040

NTSC/PAL Encoder

Description

The V7040 is an IC that can operate in both NTSC and PAL modes. It superimposes analog RGB signals and outputs them as such, or as composite video signals. Both types of output can drive the 75Ω load directly.

Features

• 5 V single supply operation
• Low power consumption (135 mW)
• Built-in 75Ω driver (RGB output, 2 systems of composite video output)
• Compatible with both NTSC and PAL modes
• Superimposition (MIX, half-tone functions)

Functions

• SW circuit for superimposition
• MTX circuit
• R-Y, B-Y MOD circuit
• 75Ω driver for RGB and composite video outputs

Structure

Bipolar silicon monolithic IC

Absolute Maximum Ratings

- Supply voltage \( V_{cc} \) 10 V
- Operating temperature \( T_{opr} \) -20 to +75 °C
- Storage temperature \( T_{sig} \) -55 to +150 °C
- Allowable power dissipation \( P_{o} \) 1250 mW

Recommended Operating Condition

- Supply voltage \( V_{cc} \) 5 ± 0.25 V

Application Circuit PAL
Application Notes

1. RGB signal input
   Input the RGB signal to pins 1 to 3 and 4 to 6 via a clamp capacitor. RGB signal is pedestal clamped by means of the burst flag signal input from pin 8. Input with a sufficiently low impedance.

2. SW mode
   RGB signal input from pins 1 to 3 and RGB signal input from pins 4 to 6 are switched into the specified Y mode at the SW circuit. This, by means of the YS, YMIX, YM signals input from pins 25 to 27. The SW mode is in accordance with the following table.
   1. PC mode
      RGB signal input from pins 1 to 3 is output via SW circuit.
   2. TV mode
      RGB signal input from pins 4 to 6 is output via SW circuit.
   3. MIX mode
      RGB signal input from pins 1 to 3 and RGB signal input from pins 4 to 6 are respectively lowered to a level of $-6\, \text{dB}$, mixed and output via SW circuit.
   4. Halftone mode
      RGB signal input from pins 4 to 6, lowers $-6\, \text{dB}$ level and is output. When superimposing, the background can be darkened and the letters made easier to read. For normal superimposing, ground pin 26 YMIX and pin 27 YM. Input superimpose signal to pin 25 YS.

$L \leq 0.8\, \text{V}$
$H \geq 2.0\, \text{V}$

3. NT/PAL/B & W mode
   By turning pin 7 (NT/PAL/B & W) to 4 V and over, NTSC mode is switched on. By turning it to 3 to 2 V, PAL mode is switched on. By turning it to 0.8 V or under, B & W mode is switched on. In NTSC mode, burst signal, with B-Y shaft at 0°, is output to 180° direction. In PAL mode, burst signal, in accordance with PAL ALT signal input from pin 9, is output to 135°, 225° direction. In B & W mode, chroma signal and burst signal are not output. As for V7020, to use in NTSC mode, pin 7 is left open or connected to Vcc.
4. BF signal
In accordance with burst flag signal input from pin 8, the burst signal from the composite video signal, is formed. Also, the clamping of RGB signal is executed in accordance with this burst flag signal.

5. PAL ALT signal
In accordance with PAL ALT signal input from pin 9, the R-Y shaft direction of the modulator from the chroma signal, is inverted. When pin 9 is at "H" (≥2.0V) it is set to normal direction. When it is at "L", it is set to the inverted direction.

6. Subcarrier input
Input the subcarrier through a 0.4 to 0.8 Vp-p sine wave, via pin 10 (SC IN). With the subcarrier input, too many harmonic waves may adversely affect the phase characteristics of the chroma modulator.

7. Vcc, GND
Connect with as low as possible an impedance, pin 12 and GND 1, pin 18 and GND 2. Pin 24 (Vcc 2) and pin 18 (GND 2) are the power supply of 75Ω driver (RGB OUT circuit, C.V.OUT circuit). As large currents flow in, execute decoupling with a sufficiently large capacitor.

8. BPF, DL
Eliminates harmonic waves contained in the chroma demodulator output, at the band-pass filter. Use a delay line matching the band-pass filter delay time.

9. RGBOUT, C.V.OUT
At pins 19 and 20 (V.OUT) a composite video signal of about 2 Vp-p is output. At pins 21 through 23 (RGB OUT), an RGB signal (superimposed or else) of about 1.4 Vp-p is output. For the composite sync signal used together with RGB signal, use the composite video signal of pins 19 and 20.
Both C.V.OUT of pins 19, 20 and RGB OUT of pins 21 through 23, can directly drive a load of 75Ω.

10. Composite sync signal
Through the composite sync signal input from pin 11, sync is added to Y signal. At "H" (≥2.0V) Y signal is activated while at "L" (≤0.8V) sync is activated.
Descriptions of Operation

1. Clamp circuit, SW circuit, SW CONT circuit
   RGB signal from PC is input to pins 1 through 3 via a clamp capacitor. In the same way, RGB signal from TV is input to pins 4 through 6. Input RGB signals are pedestal clamped together, by means of the clamp circuit operating in accordance with the burst flag signal. Clamped RGB signals are switched at the SW circuit, in accordance with the 4 modes, specified by YS, YMIX and YM signals, which are input from pins 25 through 27. RGB signals switched at SW circuit are sent to MTX, MOD and RGB OUT circuits.

2. MTX circuit, MOD circuit, SC phase shift circuit
   From RGB signal switched at SW circuit, Y signal is formed by means of MTX circuit. As for these Y and R signals, B signal goes to R-Y MOD circuit and B-Y MOD circuit. Also, this Y signal is sent to SYNC ADD circuit; composite sync signal input from pin 11 is added to it, and it is sent through pin 14 to delay line. SC shift phase circuit creates 0°, 90° subcarriers by phase shifting the subcarrier input from pin 10. 0° and 90° subcarriers are respectively sent to B-Y MOD circuit and R-Y MOD circuit. By means of R with Y signals and B with Y signals, they undergo quadrature double phase modulation to become chroma signals. Chroma signals are sent to BPF via pin 13.

3. YC MIX circuit
   Chroma signals from which harmonic waves have been eliminated at BPF, and Y signals that have passed through the delay line are sent to YC MIX circuit via pins 17 and 16. They are mixed, become composite video signals and sent to C.V.OUT circuit.

4. COMPOSITE VIDEO OUT circuit (C.V.OUT circuit)
   Composite video signals from YC MIX circuit, are amplified at C.V.OUT circuit into about 2 Vp-p video signals, and output through pins 19 and 20. C.V.OUT circuit, from each of pins 19 and 20 can directly drive a load of 75Ω.

5. RGB OUT circuit
   Signal RGB switched at SW circuit is amplified to about 1.4 Vp-p by RGB OUT circuit and output via pins 21 through 23. RGB OUT circuit can directly drive a load of 75Ω.

6. REG 2V
   The internal reference voltage is obtained through the band gap reference circuit. The reference voltage becomes the standard for the volume of each of the clamp electric potential, the burst and the sync.
Sync Discrimination for CRT Display

Description
CXA1365S is used for sync signal discrimination and waveform shaping in the CRT display. There are 3 types of Sync input signals for discrimination.
- V. separate sync signals
- Composite sync or H. separate sync signals
- Sync on video

Features
- Polarity and amplitude of input signals
<table>
<thead>
<tr>
<th>Polarity</th>

Applications
- CRT display monitor

Operating Conditions
- Supply voltage Vcc 8.5 to 9.5 V

Pin Configuration (Top View)

Block Diagram

Absolute Maximum Ratings (Ta=25 °C)
- Supply voltage Vcc 12 V
- Operating temperature Topr -20 to +75 °C
- Storage temperature Tstg -65 to +150 °C
- Allowable power dissipation PD 1.35 W

Cxd1030M

Sync. Signal Generator for Camera

Description

The Cxd1030M is a sync. signal generator for video cameras.

Features

• Adapts to NTSC or PAL by switching mode
• Low power consumption
  (Standard NTSC: 25 mW; PAL: 30 mW)
• Built-in phase comparator and inverter for active filter (separate power supply for the filter inverter)
• External sync.

Function

Sync. signal generator

Structure

Silicon gate CMOS IC

Application

Video • Camera

Absolute Maximum Ratings (Ta = 25°C)

- Supply voltage VDD Vss* -0.3 to 7.0 V
- Input voltage Vi Vss* -0.3 to VDD +0.3 V
- Output voltage Vo Vss* -0.3 to VDD +0.3 V
- Operating temperature Topr -20 to +75 °C
- Storage temperature Tstg -55 to +150 °C
  * Vss = 0V

Recommended Operating Conditions

- Supply voltage VDD 4.50 to 5.50 V
- Operating temperature Topr -20 to +75 °C

Description of Function

1. Generation of various sync. signals (See the Timing Chart.)
   Various sync. signals are generated from clocks.
   • Clock frequencies
     NTSC: 910 fH (14.31818 MHz)
     PAL : 908 fH (14.1875 MHz)
     4 fsc (17.734475 MHz)

2. PAL 4 fsc PLL
   Using 908 fH as the master clock, the 4 fsc is put in phase. Corresponding to an external filter (passive or active), the phase comparator polarity can be switched.

<table>
<thead>
<tr>

<td>EXT</td>
<td>NTSC EXT 4 fs/4</td>
</tr>
<tr>
<td>PAL</td>
<td>×</td>
<td>PAL 4 fs/4</td>
</tr>
</tbody>
</table>

Unused counters are stopped in any of the mode.
When SC is not required, any counters on SC are stopped and SC is not output by SCOF being set to L.

4. Initialization and Reset
   In the INT mode, the circuit is initialized with the fall of VINT. At this time, the H reset, V reset, and LALT reset are not accepted. In the EXT mode, VINT is not accepted but the H reset, V reset, and LALT reset are accepted.
   • Initialization (VINT)
     When EXT is L, the fall of VINT is detected and operation is started by the circuit being initialized at the VD fall position immediately prior to field I. (The initialization is completed within 100 ns after the fall is detected.)
• H reset (HR)
A reset is executed with the first fall but no reset will be done as long as the subsequent edges do not deviate by more than two clocks (0.98 µs).
The minimum reset pulse width is 0.98 µs.
HD is reset 2.94 to 3.43 µs in advance of HR input.

![HR and HD waveform diagram]

• V reset (VR)
VD is reset 3.5H in advance of VR input.
The minimum reset pulse width is 32 µs.

![VR and VD waveform diagram]

• LALT reset (LR)
LALT is reset in the same phase as the LR input.
The minimum reset pulse width is 32 µs.

![LR and LALT waveform diagram]

Description

CXD1225M are used for the digital selection of TV broadcasting as well as AM, FM and various radio waves. These PLL IC’s were developed through high speed N-channel silicon gate MOS technology.

Features

• The maximum operating frequency is guaranteed as follows. CXD1225M } 300MHz
  Usage up to 1 GHz is possible when combined with an ECL (general purpose) prescaler.

• Programmable divider permits the division of a program frequency up to 1/262, 151

• Programmable reference divider permits the selection of comparison frequency at will. (E.G. Using a 4MHz crystal oscillator selection from 244Hz to 2MHz is possible)

• High-speed phase comparator provides high C/N ratio.

• Operation control through 3pins.

• 3 independent pins (AM1, FM1, TV1) are provided for the signal input at respective frequencies.

• Multipurpose output terminals are provided (AO, BO)

• Low consumption (Standard: 120W)

Structure

N-channel silicon gate MOS

Absolute Maximum Ratings (Ta = 25°C, Vss = 0V)

• Supply voltage \( V_{oo} \) —0.5 to +7 V

• Input pin voltage \( V_{in} \) —1 to +7 V

• Operating temperature \( T_{opr} \) —20 to +75 °C

• Storage temperature \( T_{stg} \) —55 to +150 °C

Operating Input Frequency Test Circuit

[Diagram of CXD1225M circuit]

Control input data to CX-7925B/CXD1225M: T1-H, T2-H, A-L, B-H
SG: HP's 8640B
(Input level read directly at built-in level meter)

Operation

[1] Signal input from the local oscillator
CXD1225M use 3 independent input pins according to frequency and application.
- AMI pin
  Reception pin for AM and TV broadcast. Signal input up to 40MHz is warranted for CXD1225M.
  Frequency division ratio when using this pin is 1/2 to 1/65537.
- FMI pin
  Reception pin for FM and TV broadcast. Signal input up to 150MHz is warranted for CXD1225M.
  Accordingly, the external prescaler is not required for FM reception. For TV reception, the entire TV band
  width can be covered through combination with an external prescaler up to 1/8. Frequency division ratio
  ranges from 1/12 to 1/262151. When not in use this pin stays open.
- TVI pin
  This pin is solely used for TV broadcast reception. With the built-in 1/2 prescaler signal input up to
  300MHz is warranted for CXD1225M. The entire bandwidth can be covered through combination with an
  external prescaler up to 1/4. Frequency division ratio ranges from 1/24 to 1/524302. When not in use
  this pin is grounded internally via a resistor of more than 100kΩ.

[2] Phase comparator output
The phase comparator output (PD pin) has a 3-level value. The pin is at High level when the input signal
is more advanced in phase than the reference signal. At Low level when the phase lags behind and at high
impedance when they are in phase.

[3] Control signal and control system
CX-7925B/CXD1225M are designed as controllers compatible with general 4 or 8-bit microcomputers.
There are 3 control input pins CLK, LAT, DIN and 2 control output pins AB and BO. Through the proper
combination of these pins, the simplification and multi-functionalization of the system can be realized.
CX-7925B/CXD1225M feature 3 data input modes, (normal mode), Up/Down mode and Data check
mode with different signal input patterns for each.
[3-1] Control signal input modes

(a) Data input mode (normal mode)
To set all initial values of CXD1225M a total of 40bit of data has to be input 20bits at a time. With LAT pin at Low, as data is input to DIN pin, data is input to the shift register 1 bit at a time with the rising edge of the clock input to CLK pin.

After 20bit of data has been transmitted to the shift register, with CLK at High as LAT pin is set to High, data is latched, (after data is latched, turn LAT pin back to Low, Varying DIN and CLK pins while LAT pin is at High may affect data internally).

As will be described in detail later on, input data is input either in the programmable divider or the reference divider according to the state of the last bitC. In practice input from the controller the 20bit of the data including first the reference divider frequency, input pin selection and AO, BO output pins data using the above method. Here the data last bit is set to Low.

Next input 20bit including data used to set the programmable divider, in the same way. Here set the last bitC to High. This sets all internal states. After that, to vary only the programmable divider value, varying only the latter 20bit of data will suffice (In this case too, C is to be set to High).

To vary the programmable divider value (channel selection, AFT) the usage of Up/Down mode mentioned hereafter will improve efficiency.

(b) UP/DOWN mode
After setting CLK pin to Low, the contents of UP/DOWN counter can be increased or decreased by one according to DIN pin High, Low level. This by turning LAT pin (normally at Low level) from High to Low. By repeating this process the setting value of the programmable divider can be varied as required.

(c) DATA CHECK mode
This mode is used to check if data has been correctly input from the controller to the data register. Data left in the shift register immediately after input data has been latched is output bit by bit from BO pin. This at the rising edge of a clock input pin and at to CLK pin while it is held to High and after LAT pin is set to Low. The shift register data can only be output from BO pin when bits T1 and T2 of the data are at High and Low, respectively.

[3-2] Control data assignment
CXD1225M is assigned in 20bits. The last 20bits are the data identification code. Identifying the code will tell the data contents. Though unrelated to users, switching to Test mode is also performed using this code. Each of the programmable divider and reference divider frequency number is given in binary value with LSB at the leading digit.

(a) Control input data of the Reference divider (C = Low)
This can be described as the initialization setting data. It is always input when power is fed or when a channel band is switched. The input data composition is as follows.

<table>

- 180 -
• A, B, T1; Each of A0 and B0 pins features 2 functions selected according to T1 value. When T1 is at Low, A and B values are output as they are to A0 and B0 pins. These signals can be used to select the prescaler frequency division, the filter constant, the channel band signal and various other purposes. When the prescaler M54465P (Mitsubishi) for TV reception is used the following selection codes for frequency division ratio apply.

<table>
<thead>

</tbody>
</table>
• T2: T2 is used for Test mode selection. Users usually set this data to Low. To test the frequency division output and reference output this T2 bit and aforementioned T1 bit are set to High while A and B bits are set to Low. Then, a reference output and a frequency division output can be observed at AO and Bo pins respectively.
• C: As described before, set to High in this case.

(3-3) Data input and control signal timing
(a) Data input mode (normal mode)

(b) UP/DOWN mode

(c) DATA CHECK mode (Shift register data check)

(*) Mark indicates data is output within this timing)
(4) Reference signal (Reference divider input signal)

The connection of a chrystal oscillator to X1 and X0 allow these IC's to generate reference signals. The input of an external clock signal to X1 pin permits the usage of an external clock as reference signal.

(4-1) Reference signal generation by means of built-in oscillator

Connect a chrystal oscillator with a frequency of 1MHz to 13MHz to X1 and X0 pins, as shown below. The diagram below shows an example where a standard 4MHz osillator is used. The capacitance ratio of C1, C0 should be 1 to 2:1 while their serial capacitance values should be the specific load capacitance of the chrystal oscillator.

(4-2) Reference signal generation by means of external clock

When an external clock signal, such as a clock signal obtained from the controller is to be used as reference clock, input it to X1 pin via a capacitor as shown below. The clock frequency range is guaranteed up to 13MHz. However, the usage of a signal with proper rise and fall (over 5V/µs) is recommended especially when the frequency is low. This is to prevent malfunction.

Sync Separation and AFC for Digital Video Processing

Description
The CXD1229Q consists of a sync separation circuit best suited for digital video processors and an AFC that outputs 910kHz clocks.

Features
- Double action sync separation circuit copes well with noise and APL fluctuations.
- Fully synchronous AFC circuit (910kHz generator)
- VD detection circuit does not malfunction when dealing with nonstandard signals.
- First field and second field (ODD/EVEN) discrimination circuit.

Applications
Digital video processor, digital VCR, digital TV

Block Diagram
Absolute Maximum Ratings (Ta=25°C)

- Supply voltage \( V_{DD} \) \( V_{SS} = -0.5 \) to +6.0 V
- Input voltage \( V_I \) \( V_{SS} = -0.5 \) to \( V_{DD} + 0.5 \) V
- Output voltage \( V_O \) \( V_{SS} = -0.5 \) to \( V_{DD} + 0.5 \) V
- Operating temperature \( T_{op} \) -25 to +85 °C
- Storage temperature \( T_{stg} \) -40 to +125 °C
- Output current \( I_O \) \( V_O = V_{DD} \) (Max.) +70mA \( V_O = 0V \) (Max.) -40mA

Recommended Operating Conditions

- Supply voltage \( V_{DD} \) 4.75 to 5.25 (Typ. 5.00) V
- Operating temperature \( T_{op} \) 0 to +70 °C
- H level output current \( V_{OH} \) - 0.4 (Max.) -0.4mA
- L level output current \( V_{OL} \) (Max.) +10mA

Description of Functions

1) Sync separation

The video input signal passes through feedback clamp, first sync separation and after noise elimination, clamp pulse is formed. With this clamp pulse, the video input signal is sync clamped and the second sync separation performed.

With this double sync separation circuit structure, a sync separation circuit resistant to noise and APL fluctuations is realized.
(2) Fully synchronous AFC circuit (910f₀ circuit)

Input H sync, that edge and VCO (≈ 910f₀) counted down to 1/910 are phase compared. There are 2 such error outputs: RPD: phase comparison output between all sync bottom line and the built-in H counter, and FPD: between sync rising edge and the built-in H counter. RPD output is a lag-lead filter and FPD output is an integrator. Both outputs are converted into DC error respectively.

The added value is applied to a variable capacitor and VCO oscillation frequency maintained at a stable 910f₀.

(3) VD detection circuit does not malfunction when dealing with nonstandard signals

CSYNC is integrated sliced and VD obtained. This VD is resampled at AFH and VD formed. With a standard signal, as shown in the above diagram, a stable VD is obtained. However, in nonstandard signals, the relation between H sync and V sync is not constant. VD rise and AFH overlap and in some cases a stable VD output cannot be obtained. In such cases, CXD1229 varies the slice level and automatically prevents AFH and VD from overlapping to obtain a stable VD output. During variable speed PB in personal computers and VCRs, a stable VD output can also be expected.

(4) First field and second field discrimination

When there is no H sync signal in the delay pulse that comes within a constant period from the V sync signal, it is discriminated as the first and third field. If there is a signal then it is discriminated as the second and fourth field and output from Pin WEVN (Pin32). (For “H”: first, third field)

48pin QFP (Plastic) 0.7g
Description

The CXA1496AQ is a 10-bit 20MSPS 2-step parallel type A/D converter for video signal processing. This A/D converter operates on a dual ±5V power supply. The external addition of sample and hold, reference power supply and clock timing circuits permit the conversion of analog signals into digital signals.

Features

- Maximum operating frequency: 20MHz (Min.)
- Integral linearity error: 10-bit ±1.5LSB
- Differential linearity error: 10-bit ±1LSB
- Low power consumption: 310mW (Typ.)
- Wide band analog input: 10MHz
- Low input capacity: 150pF (Typ.)
- Built-in digital correction (Compensation within a range of ±16LSB)
- TTL input (CLK only: ECL LIKE)
- TTL output (3-state control)
- Output code: Binary/2S complement/1S complement

Function

10-bit 20MSPS 2-step parallel type A/D converter

Structure

Bipolar silicon monolithic IC

Applications

High resolution video signal processing

Block Diagram

Sony reserves the right to change products and specifications without prior notice. This information does not convey any license by any implication or otherwise under any patents or other right. Application circuits shown, if any, are typical examples illustrating the operation of the devices. Sony cannot assume responsibility for any problems arising out of the use of these circuits.
High Speed Sample and Hold IC

Description
The CXA1693Q performs high speed sample and hold of video and various type of signals.

Features
- Maximum sampling frequency
  40MHz (Minimum)
- Built-in -2V constant voltage circuit.
- Built-in clock pulse generating circuit for
  A/D converter
- Low power consumption
  180mW (Typical)

Absolute Maximum Ratings (Ta=25 °C)
- Supply Voltage Vcc 7 V
- Vee -7 V
- Write current lW 50 mA
- Operating temperature Topr -20 to +75 °C
- Storage temperature Tstg -65 to +150 °C
- Allowable power dissipation PD 375 mW

Structure
BiPolar silicon monolithic IC.

Operating Conditions
- Supply Voltage Vcc 4.75 to 5.25 V
  Vee -4.75 to 5.25 V

Application
Usage in combination with the CXA1694Q or CXA1496Q can simplify peripheral circuit design for A/D conversion.
6-bit 20MSPS Video A/D Converter (CMOS)

Description
The CXD1172A is a 6-bit CMOS A/D converter for video use. The adoption of a 2-step parallel system achieves low power consumption at a maximum conversion speed of 20MSPS minimum, 35MSPS is typical.

Features
- Resolution 6-bit ± 1/2 LSB
- Max. sampling frequency 20MSPS
- Low power consumption 40mW (at 20MSPS Typ.) (Reference current excluded)
- Built-in sampling and hold circuit.
- 3-state TTL compatible output.
- Power supply 5V single
- Low input capacity 4pF
- Reference impedance 300Ω (Typ.)
- Pin replaceable with CXD1172.

Structure
Silicon gate CMOS monolithic IC.

Applications
TV, VCR digital systems and a wide range of fields where high speed A/D conversion is required.

Absolute Maximum Ratings (Ta=25 °C)
- Supply voltage VDD 7 V
- Reference voltage VRT, VRS VDD to VSS V
- Analog Input voltage VIN VDD to VSS V
- Digital Input voltage CLK VDD to VSS V
- Digital output voltage VCH, VCL VDD to VSS V
- Storage temperature Tstg -55 to +150 °C
8-bit 20MSPS Video A/D converter with Clamp Function

Description
The CXD1176Q is an 8-bit CMOS A/D converter for video use that features a sync clamp function. The adoption of a 2-step parallel method realizes low power consumption and a maximum conversion speed of 20MSPS.

Features
- Resolution power: 8-bit ± 1/2 LSB (DL)
- Max. sampling frequency: 20MSPS
- Low power consumption: 60mW (at 20MSPS Typ.)
  (Reference current excluded)
- Built-in sync type clamp function
- Built-in monostable multivibrator for clamp pulse generation
- Built-in sync pulse polarity selection function
- Clamp pulse direct input possible
- Built-in reference voltage self bias circuit
- Input CMOS compatible
- 3-state TTL compatible output
- Single 5V power supply
- Low input capacity: 11 pF
- Reference impedance: 300 Ω (Typ.)

Applications
TV and VCR digital systems and a wide range of applications where high speed A/D conversion is required.

Structure
Silicon gate CMOS IC

 Absolute Maximum Ratings (Ta = 25°C)
- Supply voltage VDD 7 V
- Reference voltage VRT, VRB VDD to Vss V
- Input voltage VIN VDD to Vss V
  (Analog)
- Input voltage VIH VDD to Vss V
- Output voltage VOH VDD to Vss V
  (Digital)
- Storage temperature Tstg  -55 to +150 °C

Recommended Operating Conditions
- Supply voltage AVDD, AVss 4.75 to 5.25 V
  DVDD, DVss
| DGND - AGND | 0 to 100 mV
- Reference input voltage VRB 0 to 2.7 V
  VRT to 2.7 V
- Analog input VINF 1.8Vp-p above
- Clock pulse width TPW1...25 (min) ns
  TPWO...25 (min) ns
- Operating ambient temperature Topr −20 to +75 °C
8-bit 35MSPS Video A/D Converter with Clamp Function

Description
The CXD1179Q is an 8-bit CMOS A/D Converter for video use that has a sync clamp function. The adoption of a 2-step parallel method realizes low power consumption and a maximum conversion speed of 35MSPS.

Features
- Resolution power; 8-bit + 1/2 LSB (DL)
- Max. sampling frequency; 35MSPS
- Low power consumption; 100mW (at 35MSPS Type.) (Reference current excluded).
- Built-in sync type clamp function.
- Built-in monostable multivibrator for clamp pulse generation.
- Built-in sync pulse polarity selection function.
- Clamp pulse direct input possible.
- Built-in clamp ON/OFF function.
- Built-in reference voltage self bias circuit.
- Input CMOS compatible.
- 3-state TTL compatible output.
- Single 5V power supply.
- Low input capacity; 11pF
- Reference impedance; 300Ω (Typ.)

Applications
Wide range of applications where high speed A/D conversion is required.

Structure
Silicon gate CMOS IC.

Absolute Maximum Ratings (Ta=25 °C)
- Supply voltage $V_{DD}$
- Reference voltage $V_{RT}, V_{RS}$
- Input voltage (Analog) $V_{IN}$
- Input voltage (Digital) $V_{IH} (V_{IL})$
- Output voltage (Digital) $V_{CH} (V_{OL})$
- Storage temperature $T_{stg}$

Description
The CXA1236Q is an ultra high-speed D/A converter that multiplexes two 8-bit input data. This IC realizes a maximum conversion speed of 500MSPS and is suitable for signal processings which require high speed and high resolution D/A conversions such as high quality displays, high definition video systems and others.

Features
- Ultra high-speed: 500MSPS, multiplexed input
- High resolution: 8bit
- Low power consumption: 1W (for VEE = -4.5V)
- Video control input: Sync, Blank, Ref. White, Bright
- ECL 100K and 10K compatible input
- Can drive 25Ω, 37.5Ω, 50Ω, and 75Ω loads
- Differential current output
- RS-343A compatible output
- -5.5 to -4.2V range single power supply operation

8-bit 40MSPS RGB 3-Channel D/A Converter

Description
The CXD1178Q is an 8-bit high-speed D/A converter for video band use. It has an input/output equivalent to 3 channels of R, G, and B. It is suitable for use of digital TV, graphic display, and others.

Features
- Resolution 8-bit
- Maximum conversion speed 40MSPS
- RGB 3-channel input/output
- Differential linearity error +0.25LSB
- Low power consumption 240mW (200Ω load at 2Vp-p output)
- Single 5V power supply
- Low glitch noise

Recommended Operating Conditions
- Supply voltage AVDD, AVSS 4.75 to 5.25 V
- DVDD, DVSS 4.75 to 5.25 V
- Reference input voltage VREF 0.5 to 2.0 V
- Clock pulse width Tpw1, Tpwo 12.5 (Min.) ns
- Operating temperature Topr -20 to +75 °C

Structure
Silicon gate CMOS IC

Absolute Maximum Ratings (Ta=25°C)
- Supply voltage VDD 7 V
- Input voltage VIN AVDD to AVSS V
- Output current IOUT 0 to 15 mA (Every each channel)
- Storage temperature Tstg -55 to +150 °C

Block Diagram

Sony reserves the right to change products and specifications without prior notice. This information does not convey any license by any implication or otherwise under any patents or other right. Digital Comb filter

Description
The CXD2011Q is an adaptive comb filter compatible with both NTSC and PAL systems and provides good Y/C separation capability.

Features
- Y/C separation by adaptive processing
- Has two built-in 1H delay lines
- Under the PAL system, a comb filter can be easily realized by combined use of the CXD2011Q with a CXK1202S or CXK1203Q.
- Clock 4fsc, 8-bit configuration

Absolute Maximum Ratings (Ta=25°C, Vss=OV)
- Supply voltage VDD Vss–0.5 to +7.0 V
- Input voltage V1 Vss–0.5 to VDD+0.5 V
- Output voltage Vo Vss–0.5 to VDD+0.5 V
- Operating temperature Topr –20 to +75 °C
- Storage temperature Tstg –55 to +150 °C

Recommended Operating Conditions
- Supply voltage VDD 4.5 to 5.5 V
- Operating temperature Topr –20 to +75 °C

Block Diagram

Structure
Silicon gate CMOS IC

Application
Y/C separation for color TV and VCR

Description of Functions

The CXD2011Q is an NTSC and PAL compatible digital Y/C separation IC which offers higher performance than the conventional line comb, thanks to adaptive (two-dimensional) processing. Two-dimensional processing, compared with three-dimensional processing, makes it possible to get a lower cost system.

In the case of NTSC, the conventional simple line comb always produces an error in the vertical non-correlated portion, because it calculates non-correlated signals together as shown in Fig. 1. In order to minimize the possibility of calculating non-correlated signals together, two line combs are provided for Y/C separation of signals of a line. One of the line combs (referred to as the upper line comb for the sake of convenience) is for calculation of signals of the line and the one above the line, whereas the other line comb (referred to as the lower line comb for the sake of convenience) is for calculation of signals of the line and the one below the line. These two line combs are separately used to ensure calculation of correlated signals together.

When only a line for example is colored as shown in Fig. 2, an error occurs in both the upper and lower line combs. In the case of signals like this where the vertical frequency is high but the horizontal frequency is low, the bandpass and trap are used for Y/C separation.
When both the vertical and horizontal frequencies are high and vertical correlation strong, the 2H comb output derived by averaging the upper and lower comb outputs is used.

In this manner the upper comb, lower comb, 2H comb or BPF output whichever is an optimum output is selected on the basis of signal correlation, thereby assuring much higher accuracy in Y/C separation than by the conventional line comb.

In addition, digital implementation eliminates ringing, etc. that used to occur in the conventional glass delay line.

In the case of PAL, Y/C separation by use of the conventional BPF and trap presented problems such as considerable cross color and poor frequency response. These problems can be solved by use of the CXD2011Q without causing any side effects.

Summary of Advantages Offered by CXD2011Q
(1) Accomplishes Y/C separation with much higher accuracy than the conventional line comb.
(2) Helps reduce the number of parts in sets because of compatibility with both NTSC and PAL.
(3) Reduces cross colors and improves the frequency response in the PAL system.
(4) Digital implementation eliminates ringing, etc. encountered in the glass delay line.
(5) Reduces the load on the manufacturing line because there is no need for comb adjustments.
Application circuits shown are typical examples illustrating the operation of the devices. Sony cannot assume responsibility for any problems arising out of the use of these circuits or for any infringement of third party patent and other right due to same.

**CXK1202Q**

**Digital Delay Line**

**Description**
CXK1202Q is a digital line memory pertaining to 8-bit structure which employs silicon gate CMOS process. It can easily be used to realize compensation for dropout of VTR and used as a digital filter, noise reduction, etc.

**Features**
- 1144 words x 8 bit structure
- Number of delay steps is 17 to 1144 bits and variable.
- Possible to select the following 16 delay lines (Peripheral circuit is unnecessary) for NTSC, PAL and SECAM
  - 905 to 912 bits
  - 1129 to 1136 bits
- High speed cycle time
  - Minimum write cycle time 25ns
  - Minimum read cycle time 25ns
- I/O level Compatible with TTL level
- Data output three-states
- 5V single power supply operation
- Low power dissipation (200mW typ.)

**Absolute Maximum Ratings**
- Supply voltage $V_{DD}$ -0.5 to +7.0 V
- Input voltage $V_{IN}$ -0.3 to +7.0 V
- Operating temperature $T_{OP}$ -10 to +85 °C
- Storage temperature $T_{ST}$ -55 to 150 °C
- Power consumption $P_{O}$ 500 mW

**Recommended Operating Conditions**
(Ta=0 to 70 °C)
- Supply voltage $V_{DD}$ 4.5 to 5.5 V (5.0V typ.)
- Supply voltage $V_{SS}$ 0 V
- Input voltage "H" level $V_{IH}$ 2.4 to $V_{DD}$ +0.3 V
- Input voltage "L" level $V_{IL}$ -0.3 to +0.8 V

Timing Chart

(1) The input signal levels are at the low level=0V and at the high level=3V, and 5ns for both rising and falling edges.

(2) The voltage judging level of the low and high levels is 1.5V.
Application

1. 1H delay line (Delay steps 905 to 912 bits, 1129 to 1136 bits)

Since a clear signal generation circuit is incorporated in the CXK1202Q, an external clear signal is unnecessary when it is used as an 1H delay line. By selecting the DEL pin (pin 19) to "H" level and the OE pin (pin 7) to "L" level, they can be used as the delay lines of the delay steps as shown in Tables 1 and 2.

A circuit and timing chart when they are used as the delay line of the delay step 908 bits are as shown in Figs. 1 and 2.

Table 2. Delay steps when PAL mode

Fig. 1. Circuit of 908 bits delay

Fig. 2. Timing chart of 908 bits delay
2. Delay line (Delay step 17 to 1144 bits)

By setting the DEL pin (pin 19), NTSC/PAL pin (pin 6), and OE pin (pin 7) to “L” level, they can be used as a delay line of delay steps 17 to 1144 bits.

The delay steps can be determined by the clear signal and the input level of S1 to S3. The clear signal is input always every 8n (n is an integer. n=1, 2, ... 141) clocks. At that time, the obtained delay step is either one from 8 steps of (n+1) +1 to 8 (n+2) bits. The selection is performed by S1 to S3 pins. The number of delay steps to be obtained by the input levels of S1 to S3 are tabulated in Table 3.

For example, when used as a delay line of delay step of 123, it is written as 123=8 (14+1) +3 and it becomes n=14. Accordingly, input the clear signal every 8x14=112 clocks and set the S1, S2 and S3 pins respectively to “L”, “H” and “L” levels and it can be used as a delay line of delay step of 123 bits. The circuit and timing chart at that time are respectively as shown in Figs. 3 and 4.

Special Application Example — Data Holding

Since SRAM is incorporated in the CXK1202Q, data holding can be carried out. However, it is unable to perform random access of the held data. The maximum data holding amount is 1120 words × 8 bit.

The data holding can be carried out by controlling the input timing and clock of the WCLR and RCLR signals. Set to WCLR and RCLR signals input modes by selecting the DEL pin (pin 19) to “L” level. By selecting the NTSC/PAL pin (pin 6) to “L” level, the maximum data holding amount of it becomes 1120 words × 8 bit.

- Data writing in
  When the WCLR signal is input so as to fetch it at the rising edge of the clock signal, the write address counter is cleared and the data input at that moment is written into the top address. After the WCLR signal has been transferred to “H” level from “L” level, the write address counter is incremented and the data are recorded in the order they have been input. If there are data, which are desired to be written in, up to i-th (i is an integer, i=0, 1, 2, … 1119) and when the condition is $8m \leq i \leq 8m+7$ (m is an integer, m=0, 1, 2, … 139), input the clock signals up to 8 (m+1) 2 to 8 (m+1) +7 counted from the WCLR signal input and it becomes necessary to stop the input of the clock signal there-after. (Fig. 6)

  **Note**
  - Be sure that if the clock signal after 8 (m+1) +7th clock signal is not stopped, it keeps counting on as if there are input data.
  - When the clock is stopped at other than 8 (m+1) +2 to 8 (m+1) +7, the power supply current is somewhat increased so it is desired not to stop it.

- Data read out
  When the RCLR signal is input so as to fetch it at the rising edge of the clock signal, the data having been held commence to output data after 8 to 15 clocks from that clock. The data are output in the same order as they have been written in. The data output commencing period is dependent on the levels of S1 to S3 as shown in Table 4.

  A circuit example when data is output from after 11 clocks is as shown in Fig. 5 and its timing chart is as shown in Fig. 7.

  Moreover, the data read out once is held unless it is rewritten.

  **Note**
  - If the RCLR signal is input during data writing, reading out from after 8 to 15 clocks is possible. At that time, input the RCLR signal after 8k clocks (k is an integer, k=1, 2, 3, … 141) from the WCLR signal input. (Fig. 8)
  - Do not stop the clock while reading the data is being performed.

![Fig. 5. A circuit from the RCLR signal is input to the data output commencement](image)

Digital Delay Line

Description
The CXK1202S is a digital line memory pertaining to 8-bit structure which employs silicon gate CMOS process. It can easily be used to realize compensation for dropout of VTR and used as a digital filter, noise reduction, etc.

Features
- 1144 words × 8 bit structure
- Number of delay steps is 17 to 1144 bits and variable.
- Possible to select the following 16 delay lines (Peripheral circuit is unnecessary) for NTSC, PAL and SECAM
  905 to 912 bits
  1129 to 1136 bits
- High speed cycle time
  Minimum write cycle time 25ns
  Minimum read cycle time 25ns
- I/O level Compatible with TTL level
- Data output three-states
- 5V single power supply operation
- Low power dissipation (200 mW typ.)

Structure
Silicon gate CMOS

Absolute Maximum Ratings
- Supply voltage \( V_{DD} \) -0.5 to +7.0 V
- Input voltage \( V_{IN} \) -0.3 to +7.0 V
- Operating temperature \( T_{opr} \) -10 to +85 °C
- Storage temperature \( T_{stg} \) -55 to 150 °C
- Power consumption \( P_{d} \) 500 mW

Recommended Operating Conditions (\( T_a = 0^\circ C \) to 70°C)
- Supply voltage \( V_{DD} \) 4.5 to 5.5 V (5.0V typ.)
- Supply voltage \( V_{SS} \) 0 V
- Input voltage “H” level \( V_{IH} \) 2.4 to \( V_{DD} +0.3 \) V
- Input voltage “L” level \( V_{IL} \) -0.3 to +0.8 V

2. Delay line (Delay step 17 to 1144 bits)

By setting the DEL pin (pin 2), NTSC/PAL pin (pin 8), and OE pin (pin 9) to "L" level, they can be used as a delay line of delay steps 17 to 1144 bits. The delay steps can be determined by the clear signal and the input level of S1 to S3. The clear signal is input always every 8n (n is an integer: n=1, 2, ..., 141) clocks. At that time, the obtained delay step is either one from 8 steps of 8(n+1)+1 to 8(n+2) bits. The selection is performed by S1 to S3 pins. The number of delay steps to be obtained by the input levels of S1 to S3 are tabulated in Table 3.

For example, when used as a delay line of delay step of 123, it is written as 123=8(14+1)+3 and it becomes n=14. Accordingly, input the clear signal every 8×14=112 clocks and set the S1, S2 and S3 pins respectively to "L", "H" and "L" levels and it can be used as a delay line of delay step of 123 bits. The circuit and timing chart at that time are respectively as shown in Figs. 3 and 4.

3. Special Application Example — Data Holding

Since SRAM is incorporated in the CXK1202S, data holding can be carried out. However, it is unable to perform random access of the held data. The maximum data holding amount is 1120 words × 8 bit.

The data holding can be carried out by controlling the input timing and clock of the WCLR and RCLR signals. Set to WCLR and RCLR signals input modes by selecting the DEL pin (pin 21) to “L” level. By selecting the NTSC/PAL pin (pin 8) to “L” level, the maximum data holding amount of it becomes 1120 words × 8 bit.

- Data writing in

When the WCLR signal is input so as to fetch it at the rising edge of the clock signal, the write address counter is cleared and the data input at that moment is written into the top address. After the WCLR signal has been transferred to “H” level from “L” level, the write address counter is incremented and the data are recorded in the order they have been input. If there are data, which are desired to be written in, up to i-th (i is an integer: i=0, 1, 2 ... 1119) and when the condition is 8m ≤ i ≤ 8m+7 (m is an integer: m=0, 1, 2 ... 139), input the clock signals up to 8(m+1)2 to 8(m+1)+7 counted from the WCLR signal input and it becomes necessary to stop the input of the clock signal there-after. (Fig. 6)

Note) • Be sure that if the clock signal after 8(m+1)+7th clock signal is not stopped, it keeps counting on as if there are input data.
• When the clock is stopped at other than 8(m+1)+2 to 8(m+1)+7, the power supply current is somewhat increased so it is desired not to stop it.

- Data read out

When the RCLR signal is input so as to fetch it at the rising edge of the clock signal, the data having been held commence to output data after 8 to 15 clocks from that clock. The data are output in the same order as they have been written in. The data output commencing period is dependent on the levels of S1 to S3 as shown in Table 4.
A circuit example when data is output from after 11 clocks is as shown in Fig. 5 and its timing chart is as shown in Fig. 7.
Moreover, the data read out once is held unless it is rewritten.

Note) • If the RCLR signal is input during data writing, reading out from after 8 to 15 clocks is possible. At that time, input the RCLR signal after 8k clocks (k is an integer: k=1, 2, 3, ... 141) from the WCLR signal input. (Fig. 8)
• Do not stop the clock while reading the data is being performed.
Fig. 5 A circuit from the RCLR signal is input to the data output commencement

Description
The CXK1206M is a 3-port VRAM capable of coping with both NTSC and PAL and of storing pictures for one 8-bit field with two chips, and is suitable as a memory for improving the picture quality including NR + TBC, and NR + double speed.

Features
• Asynchronous 3-ports, one for Write and two for Read.
• 960 column x 306 row x 4 bit structure (suitable for video signal processing).
• NTSC and PAL are respectively compatible with 4 fsc.
• Applicable to various uses in recursive mode/non-recursive mode.
• Random access: column → by block (Write only) row → by line.
• Transmission between I/O ports and the internal memory can be automatically controlled from the inside.
• Transfer synchronizing function.
• Power consumption: 100 mW (Typ.)
• Power supply: +5V ± 10%.
• I/O level: TTL Low input capacitance.
• Substrate bias generator built in.

Structure
Silicon gate three-layered polysilicon, CMOS

Applications
Video signal processing field memory

Absolute Maximum Ratings (Ta = 25°C, Vss = 0V)
• Supply voltage Vcc -1.0 to +7.0 V
• Operating temperature Töpr 0 to +70 °C
• Storage temperature Tstg -55 to +125 °C
• Allowable power dissipation PD 1.0 W

Recommended Operating Conditions (Ta = 0 to 70°C, Vss = 0V)
• Supply voltage Vcc 4.5 to 5.5 V
• Supply voltage VSS 0 V
• Input voltage "H level" VIH 2.4 to 6.5 V
• Input voltage "L level" VIL -2.0 to +0.8 V

</tbody>
</table>
According to the status of this pin, the CXK1206 operates in any of the two modes: one is the recursive mode with this pin set at high level, and the other is the non-recursive mode with this pin set at low level.

• Recursive mode: This mode permits sequential access to 960 x 306 memory cells up to 0 to 293759. Initialization is conducted by VCLR0, 1 and 2 pin input. In the case of Write, the serial data input when VCLR0 high level is latched by CKW is treated as the data input of Line 0 /Block 0. In the case of Read, the serial data output is given as the data for Line 0/Block 0 with a lag of 64 clocks from the moment when VCLR1 and 2 high level is latched by CKR1 and 2, respectively.

• Non-recursive mode: The mode treats 960 x 306 memory cells with a unit of 1 line/16 blocks (60 bits per block) and controls lines with VCLR0, 1 and 2 and INC0, 1 and 2 and blocks with HCLR0, 1 and 2. It is different from the recursive mode in that, in the case of Write, the serial data input when HCLR0 is latched by CKW is handled as the data input for Line 0 /Block 0, and in the case of Read, the serial data output is output from Read ports 1 and 2 as the data for line 0/Block 0 with a lag of 64 clocks from the moment when HCLR1 and 2 are latched by CKR1 and 2.

APM

This pin is necessary for the mode for presetting the block address in one line of the Write port, and the address preset mode is valid only when RM is set to low level (non-recursive mode). If this pin is at high level when HCLR0 is latched by CKW, one of 16 blocks is selected by four bits ADD0 to 3. When the address preset mode is not in use, do not fail to select low level, in which case, TSM, TR0, TR1 and TR2 become available from among the multi-functional pins (TR0/ADD0, TR1/ADD1, TSM/ADD2 and TR2/ADD3).

TR0/ADD0, TR1/ADD1, TSM/ADD2, TR2/ADD3

These pins serve as block address presetting pins when APM is at high level (address preset mode), (non-recursive mode) and as pins for transfer synchronization mode when APM is at low level.

• In the address preset mode, one of 16 line blocks of the Write port with the use of ADD0 to 3 four-bit binary data can be selected, and the data input is accepted as in the non-recursive mode.

• When TSM is at low level (master), signals for synchronizing other CXK1206s with master CXK1206 are output from TR0, TR1 and TR2, and when it is at high level (slave), in contrast, synchronizing signals are received. Also, use TSM pin with a fixed DC and does not change it during device operation.

• TR0 is the I/O pin for Write transfer synchronization of the Write port.

• TR1 is the I/O pin for Read transfer synchronization of the Read port 1.

• TR2 is the I/O pin for Read transfer synchronization of the Read port 2.

• When using in Transfer Synchronize mode, be sure to connect between master and slave for all of TR0, TR1 and TR2.

CKW

The rising edge of this pin issues a signal for latching data from input pins DIN0 to 3 into the shift register and input of internal address pointer control pins (VCLR0, HCLR0 and INC0). Since this signal serves also as the basic signal for start control of the internal clock synchronizing logical circuit and the dynamic RAM, it is necessary to cause clock operation irrespective of the presence of Write operation.

VCLR0

The pin plays different roles between high level (recursive mode) and low level (non-recursive mode) of pin RM.

The number of counts of VCLR0 is counted only for latch of high level after recognition of low level of the latched state by CKW. Continuation of high level is counted as one.
In recursive mode: When CKW latches VCLR0's high level, the then Serial write data input is taken in as the data of * (0, 0). From among the data entered so far data of less than a block as partitioned by block (60 bits) are rejected.
* (0, 0) means Line 0/Block 0; (v, h) means the number of lines and that of blocks upon input of control signal.

In non-recursive mode: When CKW latches high level of VCLR0, shift advances until the block (60 bits) during Serial write is filled up, and the line is cleared. More specifically, if VCLR0 is entered during Serial write, it is transferred to the (v, h) memory cell after the completion of input of 60 bits, and the data to be serially written are transferred to (0, h + 1) memory cell.

HCLR0
When high level of this pin is latched by CKW, the then input data is first taken in as (v, 0) data. Input data already entered and not sufficient to fill up a block (60 bits) are rejected. When pin RM is at high level (recursive mode), a signal to this pin has no meaning.

The number of counts of HCLR0 is counted only for the latch of high level after recognition of low level of the latched state by CKW for each time. Continuation of high level is counted as one.

INC0
When this pin is latched by CKW, the lines in the corresponding number are incremented. The incremented lines become valid in two cases: when HCLR0's high level is latched, or when VCLR0's high level is latched, and the shift register then advances to the end of that block. When pin RM is at high level (recursive mode), a signal to this pin has no meaning.

The number of counts of INC0 is counted only for the latch of high level after recognition of low level of the state latched by CKW. Continuation of high level is counted as one.

• When combining with VCLR0, the number of counts n of INC0 during the time from the state of VCLR0 latched by CKW until the shift register is filled up with 60 bits during Write causes Write of data input for the next 60 bits to be written into (n, h + 1) memory cell.

INC0 is invalid, however, when INC0 is used simultaneously with VCLR0.

• When combining with HCLR0, the number of counts n of INC0 during the period from HCLR0's state latched by CKW last time up to the current latch causes 60 bits of data input to be entered next to be written into (v + n, 0) memory.

INC0 is valid when INC0 is used simultaneously with HCLR0.

CKR1 and 2
The rising edge of these pins moves the shift register of the Read port and issues a signal for output of data to output pins D010 to 13 and D020 to 23 and a signal for latching the input of each internal address pointer control pin (VCLR1 and 2, HCLR1 and 2, and INC1 and 2).

VCLR1 and 2
The role of these pins is different between high level (recursive mode) and low level (non-recursive mode) of pin RM.

The number of counts of VCLR1 and 2 is counted only for latch of high level after recognition of low level of the state latched by CKR1 and 2, respectively. Continuation of high level is counted as one.

• In recursive mode: When CKR1 or 2 latches high level of VCLR1 or 2, (0, 0) data is output with a lag of 64 clocks from that moment. In the meantime, the shift register (60 bits) in shift is output to the full to retain the last output.

• In non-recursive mode: When CKR1 or 2 latches high level of VCLR1 or 2, it outputs the block currently in Serial read and 60 bits of the next block, and then output of consecutive blocks of the cleared line is started. More particularly, when VCLR1 or 2 is latched and the line of the internal address counter is hence cleared, the data (v, h + 1) for the next serial output have already been transferred from the memory cell to the data register, and while outputting the data, it transfers (0, h + 2) data and then outputs (0, h + 2) data.
SONY

HCLR1 and 2
When high level of this pin is latched by CKR1 or 2, (v, 0) data are output with a lag of 64 clocks from that moment. In the meantime, it outputs the shift register data in shift to the full to retain the final output. When pin RM is at high level (recursive mode), a signal to any of these pins has no meaning.

The number of counts of HCLR1 and 2 is counted only for high level latch after recognition of the state latched by CKR1 or 2. Continuation of high level is counted as one.

INC1 and 2
When high level of these pins is latched by CKR1 or 2, lines corresponding to the number of times of latching are incremented. The incremented lines become valid in two cases: when HCLR1 or 2 high level is latched, or when high level of VCLR1 or 2 is latched, and then the line address is latched at clock 57 of that block. When pin RM is at high level (recursive mode), a signal to any of these pins has no meaning.

The number of counts n of INC1 and 2 is counted only for the latch of high level after recognition of low level of the state latched by CKR1 or 2. Continuation of high level is counted as one.

- When combining with VCLR1 or 2, the number of counts n of INC1 and 2 prior to clock 56 of the block of VCLR1 or 2 latched by CKR1 or 2 causes (n, h + 2) memory cell data to become data to be output from the shift register for the 2'nd next time.
- When INC1 and 2 are used simultaneously with VCLR1 and 2, respectively, however, INC1 and 2 are invalid.

Data Input (DINO to 3)
Information to a data input pin is accepted at rising edge of CKW in the state of “L” of WE, and entered into the shift register. When WE is at “H”, input data are not accepted, without operation of the Write shift register (Write clock gate function).

Input into the shift register is accomplished immediately, whereas the information is loaded to the data register after completion of input of one block (60 bits) and transferred to the memory cell before the shift register is filled up with new data. Therefore, Serial write data input in the case of Serial write is transferred to the memory cell with a lag of one block.

Input control (WE)
Input control to DINO to 3 is conducted with WE. When WE is at “L”, synchronization with CKW enables input, and when WE is at “H”, input is not accepted and shift operation of the Write shift register is discontinued. This is used, for example, when thinning out data input (gate function of Write-side input clock (CKW) by WE).

Data output (DO10 to 13, DO20 to 23)
The three-state TTL level is adopted for the output buffer. When OE1 and 2 are at “L”, output is immediately enabled and data in synchronization with CKR1 and 2 are output. When OE1 and 2 are at “H”, output is in high impedance state, but the shift register operates in synchronization with CKR1 and 2 and conducts transfer between memory cell and data register and load between data register and shift register.

Output from the shift register is made from time to time. Data in output are those transferred from the memory cell to the shift register by one block prior to the block in current output.

Output control (OE1 and 2)
OE1 conducts output control of only output pins DO10 to 13, and OE2 conducts output control of only output pins DO20 to 23, without arresting shift operation of the shift register of Read port. Output control of DO10 to 13 and DO20 to 23 brings about output enable without being synchronized with CKR1 and 2 when OE1 and OE2 are at “L”, and brings the output to high impedance state without being synchronized with CKR1 and 2 at “H”.

Clock correlation

CXK1206M uses a DRAM in the memory block. Accordingly and in order to hold data, either of the following clock relations has to be satisfied. In NRM (Non Recursive Mode) and using HCLR with INC, keep access time to all memory zones utilized, within 21msec.

\[
T_{\text{MAX}} = \frac{21\text{msec}}{960 \text{ dots} \times 306 \text{ lines}} = 70\text{ns}
\]

Standby mode to hold image data

To reduce power consumption while image data is held, keep WE = H fixed and use only 1 port of the read side. In this case write in is not performed. Clock correlation turns out as either of the following cases. In NRM (Non Recursive Mode) and using HCLR with INC, keep access time to all memory zones utilized, within 21msec.

\[
T_{\text{MAX}} = \frac{21\text{msec}}{960 \text{ dots} \times 306 \text{ lines}} = 70\text{ns}
\]

Transfer synchronizing master chip

Transfer synchronizing slave chip

Description of Operation
CXK1206 has the following five operating modes. As to the details of timing, etc., refer to the separate description:

1. Recursive mode, transfer synchronous mode output:
   These modes handle the memory as a simple delay line. Control is accomplished via VCLR0, 1 and 2, WE, OE1 and OE2. The synchronizing signal for use of multiple chips is output (forming master chips).

2. Recursive mode, transfer synchronous mode input:
   A synchronizing signal is entered in the mode as described in 1 above (becoming slave chip).

3. Non-recursive mode, transfer synchronous mode output:
   This is the mode for controlling the memory by block or line. Control is accomplished via VCLR0, 1 and 2, INCO, 1 and 2, HCLR0, 1 and 2, WE, OE1 and OE2. The synchronizing signal for use of multiple chips is output (forming master chips).

4. Non-recursive mode, transfer synchronous mode input:
   A synchronizing signal is entered in the three modes as described above (becoming slave chips).

5. Non-recursive mode, address preset mode:
   This is the mode for controlling the memory by block or line, and permits setting any address by block when writing in the memory. Control is accomplished via VCLR0, 1 and 2, INCO, 1 and 2, HCLR0, 1 and 2, WE, OE1, OE2, and ADDO, 1, 2 and 3. A synchronizing signal cannot be entered or output when using multiple chips in this mode.

VRO: VCLRO
HRO: HCLRO
ICO: INCO
A0 to 3: ADDO to 3
(v, h), v: Number of the line for Write port upon input of control signal
h: Number of the block for Write port upon input of control signal
H: High level latched by CKW
nH: Number of times of high level latched by CKW is n.

Note: • This device is arranged in 306 lines, 16 blocks and 60 bits.
• For Write address counter reset, it is necessary to make at least one input of VCLRO in recursive mode, or VCLRO and HCLRO in non-recursive mode.
• It is necessary to set low or high in DC manner for pins RM and APM input.

*1. It is necessary to enter VCLRO and HCLRO at the same time, or to enter HCLRO prior to the first clock of the block next to the block containing VCLRO.
*2. nH: Number of times of “H” of INCO prior to HCLRO after the current HCLRO.
*3. nH: Number of times of “H” of INCO prior to the first clock of the block next to the h block containing VCLRO.
*4. It is necessary to enter INCO and HCLRO prior to the first clock of the block next to that containing VCLRO.
*5. When pin APM is at low level, pin TSM becomes valid, and the Read ports and the Write port are in transfer synchronous mode. When pin TSM is at low level, transfer output is provided (master), and when it is at high level, transfer input is accepted (slave).

</tbody>
</table>

**VR1:** VCLR1  
**HR1:** HCLR1  
**IC1:** INC1

(v, h) v: Number of the line for Read port upon input of control signal  
   h: Number of the block for Read port upon input of control signal  
   H: High level latched by CKR1  
   nH: Number of times of high level latched by CKR1 is n.

**Note:**  
* This device is configured with 306 lines, 16 blocks and 60 bits.  
* In Read, address preset cannot be done irrespective of pin APM control, but when pin APM is at low level, the mode becomes transfer synchronous mode.  
* For Read address counter reset, it is necessary to make at least one input of VCLR1 and HCLR1 in non-recursive mode.  
* It is necessary to set low or high in DC manner for pins RM and APM input.

*1. It is necessary to enter VCLR1 and HCLR1 simultaneously, or to enter HCLR1 prior to clock 55 of the block containing VCLR1. To enter VCLR1 before the lapse of 64 clocks from HCLR1 is unable.  
*2. nH: Number of times of "H" of INC1 prior to HCLR1 after the current HCLR0.  
*3. nH: Number of times of "H" of INC1 prior to the clock 55 of the h block after the current VCLR 1.  
*4. It is necessary to enter INC1 and HCLR1 prior to the clock 55 of the h block containing VCLR0.

### Function table 5  [Read 2]

The same particulars as those in Function table 4 apply also for VCLR2, HCLR2 and INC2.
Recursive mode, Write

1. Initial cycle  2. Normal cycle

---

**Note**  
- After Write of up to Line 0/block 15, the next 60 bits are automatically written in block 0 of the next line. 
- After Write of up to Line 305/block 15, the next 60 bits are automatically written in line 0/block 0. 
- 1. When pin TSM = "L", output is made through automatic synchronization with CKW from the interior of device. 
- 2. Transfer input should be completed within a block Write. In the case of synchronous transfer between two chips, processing is made automatically between devices.
**Recursive mode, Read**

1. Initial cycle  
2. Normal cycle

### Note
- After Read of up to Line 0/block 15, the next 60 bits are automatically read from block 0 of the next line.
- After Read of up to Line 305/block 15, the next 60 bits are automatically read from line 0/block 0.

*1. When pin TSM = "L", output is made through automatic synchronization with CKW from the interior of device.

*2. Transfer input should be completed within a block Read. In the case of synchronous transfer between two chips, processing is made automatically between devices.

*3. If VCLR comes before 55th clock of the block currently Read, the final data of the block is retained. If VCLR comes after 56th clock of the block currently Read, data of the next block are read, following the current block, and the data of block 0 are output with a lag of 64 clocks from VCLR.
Recursive mode (in non-recursive mode, VCLR in the figure below corresponds to HCLR)
New data access mode

Cycle description

<table>
<thead>
<tr>
<th>Cycle description</th>
<th>Line 0/block 0 Write</th>
<th>Line 0/block 1 Write</th>
<th>Line 0/block 2 Write</th>
<th>Line 0/block 3 Write</th>
<th>Line 0/block 0 Write</th>
</tr>
</thead>
</table>

Note 1.

Transfer description

Note) *1. In order to access new data, block Write transfer is conducted after Write of 60 bits, and readout is made after Read transfer of that block. A lag of more than 184 clocks is necessary for Read clock from Write clock.
Recursive mode (in non-recursive mode, VCLR in the figure below corresponds to HCLR)
Old data access mode

Note) • When the lag of Read clock from Write clock is more than 65 clocks and less than 183 clocks, Write of new data is guaranteed, although it is uncertain whether new data access or old data access.
• In order to access old data, Read transfer of that block should be accomplished before Write transfer of new data. A lag of less than 64 clocks is necessary for Read clock from Write clock.
Non-recursive mode, Write
1. Initial cycle (the cycle for Writing from line 0/block 0)
2. Normal cycle

*Note*  In the case of initial cycle, it is necessary to enter VCLRO and HCLRO simultaneously, or to enter HCLRO before the first clock of the block next to that containing VCLRO.
Non-recursive mode, Write
3. First block cycle (the cycle for Writing data from the start of block)

Note) *1. After Write of one block (60 bits), Write transfer is conducted in the next block.
*2. In non-recursive mode, after Write up to the final block of a line, no further Write is performed. Write transfer of the final block is accomplished during 60 clocks after the completion of final block Write.
Non-recursive mode, Write

4. Line address cycle (for address control in line direction)

Cycle description

TR0 (output)

TR0 (input)

Transfer description

- Line v/block h Write
- Line v/block 0 Write
- Line v/block 1 Write
- Line v+n/block 0 Write

Note) *1. n is the number of times of INCO.
*2. Latch of this HCLRO covers the range from the last HCLRO up to INCO entered at the same time as this HCLRO. Line address recursively circulates from the current address, depending upon the number of times of INCO.
Non-recursive mode, Write

5. VCLRO special cycle No. 1 and No. 2

Note) *1. VCLRO having entered after the 1st clock in the written block resets the line address, and is latched at the end of the block.

*2. When VCLRO enters after the 1st clock in the written block, followed by INCO, the line address is reset, and line address in the number equal to the number of times of INCO having entered block 1 Write are incremented, latching the line address at the beginning of the next block.

When VCLRO and INCO are simultaneously entered, only address reset becomes valid.
Non-recursive mode, Write
6. VCLRO special cycle No. 3

*Note* When VCLRO enters after the 1st clock in the written block, followed by INCO n times, and then by HCLRO, the line address is reset, and incremented in the number equal to the number of times of INCO. Latch of the line address and reset of the block address are carried out.
Non-recursive address preset mode, Write
1. Initial cycle   2. Normal cycle

*: irrespective of "H" or "L"

*Note* The block address is latched by HCLR0 in the case of address preset mode.

Non-recursive address preset mode, Write
3. Address preset cycle
4. Line address and block address preset cycle
5. VCLRO special cycles Nos. 1, 2 and 3

For these cycles, refer to non-recursive mode considering the difference from non-recursive mode lying in that the block address is latched by HCLR0.
Non-recursive mode, Read
1. Initial cycle (the cycle Reading data from line 0/block 0)
2. Normal cycle

Note) *1. When VCLR1 and HCLR1 are simultaneously entered, or HCLR1 is entered before clock 55 of the block containing VCLR1, the data of line 0/block 0 are output with a lag of 64 clocks from HCLR1.

*2. If HCLR enters before clock 55 of the block currently Read, the final data of the block is retained. If HCLR enters after clock 56 of the block currently Read, the next block data are read, following the current block, and the data of block 0 are output with a lag of 64 clocks from HCLR.
Non-recursive mode, Read

3. First block cycle

Note) *1. If HCLR enters before clock 55 of the block currently Read, the final data of the block is retained. If HCLR enters after clock 56 of the block currently Read, the next block data are read, following the current block, and the data of block 0 are output with a lag of 64 clocks from HCLR.

*2. In non-recursive mode, after Reading up to the final block of the line, the final data output is retained.
Non-recursive mode, Read

4. Line address cycle

---

Note) *1. n is the number of times of INC1.

*2. Latch by this HCLR1 covers the range from the clock next to the last HCLR1 up to INC1 having entered simultaneously with this HCLR1. The line address recursively circulates from the current address, depending upon the number of times of INC1.
Non-recursive mode, Read

5. VCLR1 special cycle Nos. 1 and 2

Note) *1. VCLR1 having entered before clock 56 in one block which has been read resets the line address and is latched at clock 57 of the block. In the next block, Read transfer of line 0/block h + 2 is carried out.

*2 When VCLR1 enters before clock 56 in one block which has been read, followed by INC1, the line address is reset, and the line address is incremented in the number equal to the number of times of INC1 having entered before clock 56 in the block which has been read. The line address is latched at clock 57 of the block. When VCLR1 and INC1 enter simultaneously, the address reset becomes valid.
Non-recursive mode, Read
6. VCLR1 special cycle No. 3

*Note) When VCLR1 enters in one block, followed by INC1 n times, and then followed by HCLR1 before clock 56 of the block, the line address is incremented in the number equal to the number of times of INC1 after reset, and line address latch and block address reset are carried out at the next clock.
Example of Application 1 Delay line, field memory in case of recursive mode

Note) • If the cycle time is equal between CKW and CKR1, this is possible also in the case of asynchronization.
• If the cycle time differs between CKW and CKR1, Read overtaking may occur. Refer to Example of Application 2.
• In non-recursive mode, it is necessary to advance the line for each line through combination of INC and HCLR input.
* When using 306 lines/16 blocks/60 bits, continuous Read is possible by only entering CKR1 and CKW without entering VCLR1.
Example of Application 2  Field double scan conversion in case of recursive mode

Block
Clock
Solid line: serial Write
Dotted line: serial Read

Field 0 Write  Field 1 Write  Field 0 Read/Field 2 Write  Field 1 Read/Field 3 Write  Field 2 Read

64 clocks 64 clocks 64 clocks 64 clocks 64 clocks

Note) Continuous input of CKWO and CKR1. WE = "L", OE1 = "L"

Description of circled drawing

- Read overtaking
  In order to Read data of written block in the case of field double scan conversion, the phase lag of Read as compared with write must be about three as converted into Write blocks (184 clocks in terms of CKW).
- When using two chips in 8-bit digitalized signal configuration, independent operation of the two chips may cause Read overtaking between the two chips. In order to synchronize Read overtaking between the two chips, use the transfer synchronous mode using one as the master chip, and the other as the slave chip.
Example of Application 3
Write of 1/2-compressed data in memory, non-recursive mode, address preset mode:

*Note* Use of the address preset mode permits Write to B, C and D areas. Write to area C is also possible by operating INCO in non-recursive mode.
3-port VRAM Application Example

1. NR + TBC

2. NR + double-speed

3. Monitor and Printer Concurrent Drive
Application Circuit (1)

Using recursive mode: The following diagram shows a circuit with:
1) 1 field delay
2) 1 frame delay

(1) 1 field delay:

Aperture Compensation for TV

Description
The CXA1387S is a bipolar IC for aperture compensation designed to improve TV picture quality.

Features
- Aperture compensation using built-in delay line.
- Luminance signal coring function.
- VM (velocity modulation) signal output.
- Tracking delay for luminance signal output, VM output and Chroma signal output.
- Chroma signal image interval gain control (excluding burst signal interval).

Applications
Improvement of picture quality for TV, monitor, etc.

Block Diagram

30pin SDIP (Plastic)

Structure
Bipolar silicon monolithic IC

SONY reserves the right to change products and specifications without notice.

Pin Configuration

Absolute Maximum Ratings (Ta = 25°C)
- Supply voltage \( V_{CC} \) 12 V
- Operating temperature \( T_{opr} \) -20 to +75 °C
- Storage temperature \( T_{stg} \) -65 to +150 °C
- Allowable power dissipation \( P_D \) 1.35 W
- Voltage impressed to pin \(-0.3 \) to \( V_{CC} + 0.3 \) V

Operating Conditions
- Supply voltage \( V_{CC} \) 8.5 to 9.5 V

Electrical Characteristics Test Circuit

Operation
1. Y coring

As shown in the above diagram, Y signal is passed through HPF, amplitude limitation is performed and the result subtracted from the original signal to execute Y signal coring.

Amplitude limitation performed through LMT.
Cut off frequency of the HPF (high pass filter) used for coring stands at approx. 1MHz (Typ.). The amplitude limiting range of the limiter stands within 0 to 400mV (Typ.). Control is performed through Pin 30 (SLICE).

- Raising the voltage of Pin 30 (SLICE) raises the limiter level and coring effect is more amply expressed.
- Coring is controlled through Pin 29. At L level, coring is OFF and at H, it is ON. At this threshold level, this pin is biased.

2. Aperture control
Y signal is attenuated by approx. -24.5dB passing through the coring (process) circuit to be output from Pin 23 as Y1 output. Y1 output passes through one built-in delay line to be output as Y2 output from Pin 20. Then Y2 output passes through still another delay line to be output as Y3 output from Pin 17. (See Block Diagram, P.4)

These three outputs (Y1, Y2, and Y3) are input to Pins 24 (Y1IN), 21 (Y2IN), and Pin 18 (Y3IN) through capacity coupling to start aperture control process.

Aperture control process controls preshoot/overshoot ratio through WGT pin (Pin 27) and sharpness level through SHP pin (Pin 25) respectively. This control process is indicated on the above diagram.

The basic principle of delay line aperture control is shown on the below diagram.

3. Chroma signal gain control
When CNR is ON, chroma signal gain control in executed at a timing other than that of burst signal. As a result, chroma signal is restrained and pales. In signals with numerous noise components, this gain control pales color to reduce conspicuous color noise and evenly distribute CNR (chroma noise reduction) effects.
(1) Timing
When CNR is ON, gain control is executed in the image section only (With the exception of burst section).
The timing is, therefore, formed by using H, BLK pulse input from Pin 3.
Simultaneously with the input of H, BLK pulse Tr, Q1 turns OFF and Pin 4 (NR1) voltage rises. Tr. Q1 turns ON again when H, BLK pulse turns to L level and Pin 4 voltage reaches the voltage set at Pin 9 (SET-P).
Gain control timing pulse is emitted during the period when H, BLK pulse is input (When it turns to H level) until Pin 4 voltage reaches the voltage set at Pin 9. During this period gain control is not performed.

(2) Gain control
When CNR is ON, gain control is performed according to the timing set in (1). The amount of gain control is set at Pin 7 (NR2).
Control range stands within 0dB to −26dB. (See Pin Description, P.5 ~)

4. VM output
CXA1387S features a VM (velocity modulation) signal output. (Pin 15)
Basically, it is similar to Y input. Since Y output is contour accentuated by means of the built-in delay line.
VM output has the same delay time as Y output. Changing the delay time of Y output delay (that is, changing Y output peak frequency), means simultaneously changing VM output delay time. This goes the same with C output, except that C output, can be canged independently.
Diagram of Operation

- **Corning level**: SLICE
- **Corning SW**: 1.5V to 6V
- **Bias**: HBLK
- **H, BLK pulse**: 5V to 0V
- **Gain control**: GAIN CONT TIMING
- **Gain control timing**: 2.78
- **Gain control suppressing**: 5.6K
- **Suppression control**: 2 to 7V
- **Delay time control**: 2 to 6V
- **FO**: Controlling all delay times
- **FOC**: Controlling only chroma signal independently
- **Y IN**: 2VP-p (MAX)
- **WEIGHTING/SHARPNESS**: 3 to 5V - Amount of sharpness
- **0 to 6V - Preshoot overshoot**
- **Y. OUT (Aperture control output)**
Notes on Operation
Consider the following points during usage.

1. Oscillation
   Output stage (YOUT, VMOUT, and COUT) in this IC is an emitter follower. When loads concerned with capacity are involved oscillation may occur. Use a buffer. Connect a by-pass capacitor to each of pins, FO (Pin 13) and FOC (Pin 14), that control the delay time of the built-in delay line.

2. Offset of chroma signal when CNR is ON
   There is an offset between where image signals are gain controlled and burst signal not gain controlled. (See Fig. below.)

![Diagram showing offset between gain control not performed and gain control performed.]

(This offset is specified in Item, No.18, Electrical Characteristics.)

When the changing offset applies to the image chroma signal, the TV screen is adversely affected. Adjust Pin 9 (SET. P) voltage, controlling Pin 9 voltage so that it does not apply to the image.

![Good example vs. Bad example showing the effect of the offset.]

3. Input signal dynamic range
   i) The max. input dynamic range of Y signal stands at 2Vp-p. This is the value from Sync to White peak. When the input signal exceeds 2Vp-p, it may be clipped and distorted.
   ii) The max. input dynamic range in the chroma signal stands at 500mVp-p (Max.). This is when the chroma signal is at burst signal. When a low frequency Y signal is mixed with the chroma input signal (CIN), this input dynamic range may reach a max. of 2Vp-p.)

**Description**

The CXA1451M is a wide-band switch and driver IC for application to video signals. It has 75Ω drivers for two channels.

**Features**

- Provided with 75Ω drivers for two channels with the same voltage gain.
- Capable of switching video signals at frequencies over a wide-band (up to 25MHz).
- 75Ω drivers with power save function.
- Low current consumption (16mA, Typ.)
- Frequency response: Relative to 500kHz;
  - Within ± 0.1dB (Typ.) at 5MHz
  - Within ± 0.3dB (Typ.) at 10MHz
  - Within ± 1dB (Typ.) at 25MHz

**Absolute Maximum Ratings (Ta=25 °C)**

- Supply voltage $V_{CC-VEE}$ 14 V
- Operating temperature $T_{OPR}$ -20 to +75 °C
- Storage temperature $T_{STG}$ -65 to +150 °C
- Allowable power dissipation $P_D$ 650 mW

**Operating Conditions**

- Supply voltage $V_{CC}$ 4.0 to 6.0 V
- $V_{EE}$ -4.0 to -6.0 V

**Block Diagram and Pin Configuration**

Electrical Characteristics Test Circuit
Application Circuit

When the TTL output is low, the IN1 signal is output.
When it is high, the IN2 signal is output.

Application circuits shown are typical examples illustrating the operation of the devices. Sony cannot assume responsibility for any problems arising out of the use of these circuits or for any infringement of third party patent and other right due to same.

Description of Operation

The IN1 and IN2 signals input to Pins 2 and 4 are switched by the control signal input to Pin 6.
When Pin 6 is open or low (<1.0V), the Pin 2 input signal is selected. When it is high (>2.0V), the Pin 4 input signal is selected. The selected input signal is output from driver output Pins 11 and 13 as well as SW output Pin 16.

Drivers 1 and 2 (DRV.1 and DRV.2) have power save control pins 14 and 10, respectively. Each driver operates only when its power save control pin is open or low (<1.0V), so that power is saved when its power save control pin is high (>2.0V).

This power saving corresponds to a reduction of about 5mA in current consumption per driver.

CXD1160AP/AQ

Digital Audio signal processing LSI

Description
CXD1160AP/AQ is a digital audio signal processing LSI.

Features
This LSI features built-in instruction RAM, coefficient RAM, multiplier, barrel shifter and others. With regards to peripheral interface usage, serial I/O, delay I/O (stereo delay for a max. of 1024 samples possible) and microcomputer interface provide excellent system cost performance.

Structure
Silicon gate CMOS

Functions
(1) Hardware
- Master clock 30.72MHz max. (during MCK1 input)
  15.36MHz max. (during MCK2 input)
- Machine cycle 130ns min.
  (160 cycle max. /fs=48KHz)
- Instruction 1 to 3 cycle (single precision/ double precision)
- Built-in RAM Instruction RAM 24bitx64w
  coefficient RAM 16bitx64w
  data RAM 16bitx64w
- Multiplying part 16bitx16bit
  built-in multiplier
  data coefficient
  (1) 16x16 (1 cycle)
  (2) 16x32 (2 cycle)
  (3) 32x16 (2 cycle)
  (4) 32x32 (3 cycle)
- Adder-Subtractor 34bit±34bit
  Acc 34bit with 2bit shifter
- Register For adder-subtractor R (H/L)
  Serial I/O I 1 (H/L) I 2 (H/L)
  O 1 (H/L) O 2 (H/L)
  Delay I/O D 1 (H/L) D 0 (H/L)
  Every register 32bit
  H/L can be used independently

(2) Interface
- Serial I/O Time-shared 2ch input
  2ch output
  Every channel data format
  32bit, (16bit+16bit), 24bit, 16bit,
  Every channel bit clock format
  32ck, 24ck MSB first
- Delay I/O Every channel variable delay (1 to 1024 samples)
  Usage also possible as serial I/O
- Microcomputer interface

Operation

Block Diagram Description

(1) I-RAM
I-RAM Instruction RAM with command word length of 24bit x 64 word. Write in from the exterior possible through microcomputer interface. Commands are divided into 1/2/3/ cycle commands according to type. Jumps to No. 0 every sampling cycle.

1-address stack 6bit address 2-stage stack. Combination with double sub routine or loop jump is possible.

Loop Counter 4bit loop counter. Loop jump possible from 0 to 15 times.

(2) K-RAM
K-RAM 16bit x 64 word coefficient RAM. Write in from the exterior can be performed through the microcomputer interface as well as write through execution command coefficient is in the format of complement on two while single precision (16b) and double precision (32b) are handled concurrently.

(3) D-RAM
D-RAM 16bit x 64 word data. Address space is ring shaped while the method adopted is for users to make access without knowledge of the physical address. Data in is in the format of complement on two with single (16b) and double precision (32b) are handled concurrently.

D-address Counter 6bit long address counter counted up every sampling cycle. Users are aware of the address relative to that of the address counter value. The counter indicates the actual physical address and can be handled as a delay tap fixed address.

(4) Data Register (all in complement on two format)
Sl1 Register This register (32b) stores CH1 data input from serial I/O used for read only. Upper 16bit (11H) and lower 16bit (11L) can be handled independently.

Sl2 Register This register (32b) stores CH2 data input from serial I/O used for read only. Upper 16bit (12H) and lower 16bit (12L) can be handled independently.

SO1 Register This register (32b) stores CH1 data output from serial I/O. Beside read/write, can also be handled as a temporary register. upper 16bit (01H), and lower 16bit (01L) can be handled independently.

SO2 Register This register (32b) stores CH2 data output from serial I/O. Beside read/write, can also be handled as a temporary register. Upper 16bit (02H) and lower 16bit (02L) can be handled independently.

DI Register This register (32b) stores CH1 or CH2 data input from delay I/O. Used for read only. Upper 16bit (DIH) and lower 16bit (DIL) can be handled independently.

DO Register This register (32b) stores CH1 or CH2 data output from delay I/O. Used for write only. Upper 16bit (DOH) and lower 16bit (DOL) can be handled separately.

P Register This register 33bit in length, stores the multiplied results of various bit lengths.

R Register Data set in this register (32b) through the transfer command can be utilized as one sided input to AV. Upper 16bit (RH) and lower 16bit (RL) can be set independently.
<table>
<thead>

During transfer or multiplying the upper 16bit of this output (ACCH) and the lower 16bit (ACCL) can be handled independently</td>
</tr>
<tr>
<td>Barrel Shifter</td>
<td>ACC value passed through the clipper can be handled as follows 1) converted into positive value floating point form 2) arithmetic left shift executed 3) arithmetic right shift executed.</td>
</tr>
</tbody>
</table>
Internal RAM structure

I-RAM

Instruction RAM (I-RAM) integrated in CXD1160AP/AQ is composed of address 0 to 63 (24b*64w) with a command word length of 24bit. Commands are transferred one (24bit) at a time through the microcomputer interface mode 1, from the exterior. Each transfer can be sent to the desired address.

External interrupt is executed at serial I/O LRCK and BCK. Every sampling cycle a jump is forcibly made to 0 address. That is, at every sampling the command is repeatedly executed from 0 address.

For executive commands there are, forced jump (JMP), condition jump, sub routine call (CAL), sub routine turn (RTN) and loop jump (LPJ). They all fly to the absolute address.

There are 2 stack stages and usage in conjunction with double sub routine or loop jump is possible.

Loop counter is composed of 4bit and loop jump can be executed up to 15 times.

Command execution cycle is given according to MPY mode in 1/2/3/ cycle time.

The number of cycles that can be executed within 1 sampling section depends on the sampling frequency (fs) and the cycle clock (fck=flck). Let's assume that at sampling section 1 we have L cycle (cycle 0 to cycle L-1). Here, the last cycle (L-1) called KSH cycle cannot be executed because of the command or coefficient transfer section of the microcomputer interface. Cycle (L-2) called KSL cycle can be executed with the exception of K-RAM handling.

Example 1) fs=48kHz \( f_{cycle} = \frac{1}{f_{ck}} = \frac{1}{f_{ckx}} = 8.144\text{MHz}(=48\times 128) \)

In this case \( f_{ck}/fs = 128 \). There are 128 cycles (cycle 0 to 127).

- Cycle 0 to cycle 125...Execution cycle
- Cycle 126 ......................Execution possible with the exception of K-RAM handling.
- Cycle 127 ......................Execution impossible

Example 2) fs=44.1kHz \( f_{cycle} = 8.144\text{MHz} \)

In this case at \( f_{ck}/fs = 139.3... \) both 139 cycle (cycle 0 to cycle 138) and 140 cycle (cycle 0 to cycle 139) exist.

- Cycle 0 to cycle 136......Execution cycle
- Cycle 137 ......................Execution possible with the exception of K-RAM handling
- Cycle 138, 139 .................Execution impossible.

The sequential execution address of 63 address is 0 address.

When Power is ON the contents of I-RAM are not determined.
K-RAM

Coefficient RAM (K-RAM) built-in CXD1160AP/AQ is composed of 16bit x 64 word (address 0 to address 63). Single precision coefficient 1w (16b), double precision coefficient are expressed by 2w (32b) in succession, and can coexist on K-RAM. In the operation system both are complement on 2 and MSB can be handled as 1 > K ≥ -1 at Sign bit.

\[ K_s = -K_{1s} + \sum_{i=1}^{16} 2^{-i}K_{1s-i} \]

\[ K_d = -K_{1d} + \sum_{i=1}^{32} 2^{-i}K_{1d-i} \]

Coefficient transfers from the exterior in the microcomputer interface K mode the required successive 2 addresses (32b) at one time. As there is also inside the execution command a command that serves to write in K-RAM, one part can be used as a temporary register. At Power ON K-RAM contents are undetermined.

Referring to the fig on the right the storage position can be defined as follows.
- When m address single precision is specified, the single precision coefficient Ks in m address can be used.
- When n address double precision is specified, the double precision coefficient kd in n address n@ address 1 can be used. Here low word Ks is stored in n address and high word Kh is stored in n@ 1 address.

K-RAM address specify can be mentioned in the command that actually handles K-RAM. There are 2 types of K-RAM address specify absolute address specify and relative address specify.
- Absolute address specify  Absolute address→addr
- Relative address specify  addr@relative address→addr

During commands that do not handle K-RAM, the present address addr does not change. (addr→addr)

At the forced 0 address jump every sampling cycle, reset is executed to addr=0. Accordingly and for the first time only, both the absolute address specify and relative address specify indicate the same physical address.

When double precision command is utilized with addr, after the command execution, addr+1→addr is obtained. Note that the present address obtained is 1 increment over that of the address specified from the user side.

Address 63 and address 0 are ring addresses. (0@-1=63, 63@1=0)

As a total of 2 cycles, the last cycle of the sampling section and the cycle before that, are coefficient transfer sections, K-RAM cannot be utilized.
D-ROM

Data RAM(D-ROM) built-in CXD1160AP/AQ is organized in 16 bit x 64 word (address 0 to address 63). Single precision data is indicated in 1W (16b) and double precision data at a 32 address distance in 2W (32b). Both can be disposed on D-ROM. For operations both are used with complement on two. MSB is at Sign Bit to be handled as 1>D~1. D-ROM contents is unspecified at Power On.

\[
Ds= -D_s + \sum_{i=1}^{16} 2^{-i} D_{s-i}, \quad Dd= -D_d + \sum_{i=1}^{16} 2^{-i} D_{d-i}
\]

Referring to the fig. on the right the storage position can be defined as follows.

- When m address single precision is specified, single precision data Ds can be used.
- When n address double precision is specified, double precision data Dd in n address 32 can be used. Here high word Dh is stored in n address and low word Dl in n address 32.

D-ROM address specification by users is a logical address and not a physical one. Inside the IC there is a 6 bit ring address counter that is incremented every I/O sampling. The logical address addr which is modulo added to this counter value DAC because the physical address.

Physical address=DAC \oplus addr

Example) Logical address is assigned to the respective data in the formula at right.

If \( y(n) \) is entered in addr=3 and \( X(n) \) in addr=1 then \( y(n-1) \) is constantly in addr=2 and \( X(n-1) \) in addr=0.

D-ROM address specify can be mentioned in the command that actually handles D-ROM. There are 2 types of address specify, absolute address specify and relative address specify.

- Absolute address specify Absolute address \( \rightarrow \) addr
- Relative address specify addr \( \oplus \) relative address \( \rightarrow \) addr

With commands where there is no D-ROM address specify, the present address addr remains unchanged. (addr \( \rightarrow \) addr).

Reset to addr=0 is effected at address 10 forable jump every sampling cycle. Accordingly and for the first time only, absolute address specify and relative address specify indicate the same logical address.

Address 63 and address 0 are ring addresses (0\( \oplus \)1=63, 63\( \oplus \)1=0)

Note that double precision data low word side is far away to determine all the data location.

The last cycle in the sampling section is a command transfer section and commands cannot be executed.
Interface

Clock circuit

There are 2 methods to generate the master clock ACK in this IC.

1. The clock input from MCK1 input pin is frequency divided by 2 internally to be ready for use.
2. The clock input from MCK2 input pin is directly used.

(1) When the input is from input pin MCK1
Fix input pin MCK2 to +5V

\[ f_{MCK1} = 2f_{ACK} \]

(2) When the input is from input pin MCK2
Fix input pin MCK1 to +5V or to GND

\[ f_{MCK2} = f_{ACK} \]

In any case the maximum frequency of master clock ACK is

\[ f_{ACK} \leq 15.36 \text{MHz} (=48 \text{K} \times 320) \]

Moreover as this IC makes use of a dynamic F/F internally, it is not possible to stop the master clock and keep the internal condition as it is.

Cycle clock ICK (or KCK) inside the IC is twice ACK master clock.

\[ f_{ICK} = f_{SS} = \frac{1}{2} f_{ACK} \]

Commands differ according to type. There are 1 cycle/2 cycle and 3 cycle commands.
Microcomputer Interface

There are 3 input pins used for microcomputer control. Those are used to rewrite in part or totally K-RAM or I-RAM inside the IC, as well as to execute the various settings of serial I/O and delay I/O.

- **SDT**: 40 bit in length of serial data per transfer.
- **SCK**: This serial clock transfers serial data to the internal shift register at the rising edge.
- **XSLO**: This gate pulse (active low level) latches in a lump the 40 bit serial data input to the shift register. At the same time and with this rising edge processing inside the IC is requested.

*When this IC is used as a multi-processor, all SDT pins or SCK pins on the respective IC's may be linked.*

The transfer format (shown later on) timing system features serial data from S0 (top bit) to S39 as shown in the big below.

By applying the below conditions to XSLO the above tLWH conditions can be prevented and the max. Transfer rate of 40 bit/LRCK realized.

The setting contents transferred through this microcomputer interface are undetermined inside the IC when Power is ON.
SDT, SCK and XSLO timing is regulated inside the IC before usage.

- In brackets < > respective modes proper value
- Between "- - -"=don't care
(1) K mode
This mode transfers the coefficient (complement on 2 and MSB at sign bit) to K-RAM (16bit x 64w). S39 is at 'L'.
With the 6 bits of KA5 (MSB) to KA0 K-RAM address (address 0 to 63) is specified. 16 bits, K15 to K0 are input from MSB side to KA address. 16 bits, K31 to K16 are input from MSB side to KA01 address. When KA specifies address 63, KA01 goes to 0 address.
When K31 to K0 are at double precision coefficient (32bits), handle through the low word side KA address for instructions.

\[ K_{KA} = -K_{31} + \sum_{i=1}^{16} 2^{-i}K_{31-i} \]

Then,
If K15 to K0 or K 31 to K 16 are at single precision coefficient (16bit)

\[ K_{KA} = -K_{31} + \sum_{i=1}^{16} 2^{-i}K_{31-i} \quad \text{or} \quad K_{KA} = -K_{31} + \sum_{i=1}^{16} 2^{-i}K_{31-i} \]

Then,
Whatever the contents be, there is no change as far as the transfer of a 2 word part to an address where KA and KA01 are in succession, is executed each time.
Moreover, note that there are write in commands to K-RAM in the instructions too.

(2) I mode
This mode transfers instructions to I-RAM (24 bit x 64W) S39 is at 'H' and S 31 at 'L'.
IA5 (MSB) to IA0 (LSB) 6 bit specify I-RAM address IA (address 0 to 63). To this IA address I23 to I0 24 bit are input.

(3) R mode
This mode transfers information relative to the setting of serial I/O and Delay I/O.
S39 is at 'H' and S31 at 'H' too.
Beside this, setting is executed at pins DYSL and SIO2 of the IC according to requirements.

☐ MUTE
Controls serial I/O output (SO) and output (XWSO) during delay I/O serial mode.
When delay I/O is in delay mode, only serial I/O is controlled.
The actual MUTE switching is synchronous with the rising edge of LRCK and serial output data. In any case, serial output data doesn't change in the middle of a bit.

Control bits not in usage may be set to either H or L.
For Serial I/O and Delay I/O see different paragraph for details.
Serial I/O

Serial data interface I/O corresponding to 16 bit stereo D/A converter (CX20152) format. One each for input and output, operate in common synchronously with external LRCK and BCK. Each inputs and outputs data for 2ch at every sample cycle. For bit clock BCK there are 2 kinds, 32 bit clock mode and 24 bit clock mode. Data format is in complement on 2 positive logic binary fixed decimal point type. There is 32 bit/24 bit/16 bit data according to the various modes. Transfer order for each and all is at the last LSB.

<table>

For Instructions read only available for input register. For output register either read or write available. For use as single precision (16 bit) register, the above 8 registers can all be handled independently. For instance when 11H is specified the numerical expression becomes, A31 at MSB (sign bit) and A16 at LSB

\[ A_s = A_{31} + \sum_{i=1}^{3} 2^{-i}A_{31-i} \]

For use as double precision (32 bit) register, 11H/L, 12H/L, 01H/L and 02H/L come in pairs. For instance when 11H is specified the numerical expression becomes, A31 at MSB (sign bit) and A0 at LSB.

\[ A_s = A_{31} + \sum_{i=1}^{3} 2^{-i}A_{31-i} \]

This is not usual but when 11L is specified at double precision, numerical expression becomes A15 at MSB (sign bit) and A16 at LSB.

\[ A_s = A_{15} + \sum_{i=1}^{15} 2^{-i}A_{15-i} + \sum_{i=1}^{15} 2^{-14-i}A_{31-i} \]
Outline of Serial I/O timing

First, during 1LRCK period, ch1/ch2 serial data that is input from SI is latched at ch1/ch2 input register with the rising edge of the following LRCK. Also, during 1LRCK, if the results of the calculating operations are enclosed into ch1/ch2 output registers, those are latched by the shift register at the following rising edge of LRCK to be respectively output as serial data from SO.

Detailed timing between Serial I/O and I/O register is as follows.

- **LRCK**
- **BCK**
- **SI/SO**

Period during which gate latch is applied to ch1/ch2 input registers.

ch1/ch2 output registers value latched at shift register.

Serial I/O and I/O register are dependent on the timing with LRCK and BCK from the exterior. Also the only interrupt is executed between this LRCK and BCK on the Instructions.

The IC operates on the master clock. Now, should the operation be going on in 1LRCK period at cycle 0 to cycle L (L+1 cycle), the following restrictions would apply to the I/O register handling.

**<Input register read command>**
- Cycle (L-3), (L-2), (L-1), L cannot read.
- Cycle 0 to cycle (L-4) can read.

**<Output register write command>**
- The following are standards of cycles where write cannot be executed in the output register. This is because of the frequency relationship between bit clock BCK and cycle clock KCK (ICK).

If all data is handled as 32 bit data then, we have 2ch IN 2ch OUT.
If all data is handled as 16 bit data, then we have 4ch IN 4ch OUT.
Mixed handling in single precision (16 bit) and double precision is possible.

Example of Single precision numerical expression

\[ \begin{align*}
1 & \_H = A_{16} + \sum_{i=1}^{15} 2^{-i} A_{15} \\

As the input register uses high word register only. Accordingly 11L and 12L are not use. 01L and 02L are used as temporary registers.

Example of single precision numerical expression.

\[ I1H = -A_{31} + \sum_{i=1}^{14} 2^{-i}A_{31-i} \]
There are 2 modes. When input pin \( \text{DYSL} \) is grounded serial mode is on. When it is set to +5V delay mode is ON.

Here serial mode means delay I/O operates similarly as serial I/O. Also, in delay mode DRAM is connected to the exterior and sample delay executed at will.

The following registers correspond to delay I/O inside the IC. Handling is either in units of 16 bit or 32 bit.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

In the instructions, input register is for read only while output register is for write only.

When used as single precision register (16 bit), the 4 registers shown above may be used individually. That is when DIH is specified, numerical expression turns out as MSB at \( E_{31} \) and LSB at \( E_{16} \).

For
\[
E_s = -E_{31} + \sum_{i=1}^{16} 2^{-i} E_{31-i}
\]

When used as double precision register (32 bit), DIH/L and DOH/L come in pairs. That is when DIH is specified, numerical expression turns out as MSB at \( E_{31} \) and LSB at \( E_{0} \).

For
\[
E_s = -E_{31} + \sum_{i=1}^{16} 2^{-i} E_{31-i}
\]

as much as similarity with serial I/O register is concerned. However there is a decisive difference where the following points are concerned.

In serial I/O register two 32 bit stereo for 1ch each, are available. The 2 input registers maintain the same value for about 1LRCK. That is from the time both are input near LRCK rising edge until around the next LRCK rising edge. During this period read is possible any time. Move over after both the 2 output registers are output to S/R around LRCK rising edge, until the following LRCK rising edge and for about the period of 1LRCK, the next value to be output should be input. During this period, usage as temporary register is possible.

On the other hand, delay I/O register has only 32 bit 1ch. to stereo operate that, the input register has to be input twice during 1LRCK period.

Similarly the output register is input twice. Accordingly programs have to be written along those lines.
Delay I/O serial mode

By fixing input pin DYSL to GND delay I/O turns to serial mode. In this case delay I/O operates as serial I/O. That is the timing system is regulated by LRCK and BCK and the format by SIO2, SIO1 and SIO0. Also serial input data is input and output through XWSO pin.

Delay I/O register is monoral. When it is input/output twice to 1LRCK, stereo operation is executed. An outline of delay I/O input/output system timing is as follows.

![Diagram of Delay I/O serial mode]

DI0(SI)  ch 2 data  ch 1 data
XWSO(SO)  ____
LRCK  ____
DI register
DO register

Calculating operation

The detailed timing of delay I/O input/output register is as follows.

![Detailed timing diagram]

LRCK  ___________
BCK  ___________
DIC/XWSO  ___________
(SI)  (SO)  ___________

2SB  LSB  ___________
2SB  LSB  ___________

Section where gate latch is applied to DI register.

DO register value is latched to shift register.

DI register value contained in the first half of 1LRCK calculating operations is the serial input data of the second half of the preceding LRCK. DI register value is similarly the serial input data of LRCK first half.

Also, the value entered to DO register in the first half becomes the serial output data of the same LRCK latter half in the 1LRCK calculating operations. The value entered in DO register during the second half becomes the serial output data in the first half of the following LRCK.

DI register read prohibit cycle around LRCK falling edge and DO register write prohibit cycle change in relation to LRCK, BC and the original oscillation. DI or DO registers handling around this area should be performed after due confirmation.

During delay I/O serial mode, turn open the external DRAM pins for delay mode, that is XRAS, XCAS and A7 to A0, 10 in all.
**Delay I/O delay mode**

By fixing input pin DYSL to +5V, delay I/O turns to delay mode. In this case, delay I/O composes the delay space by utilizing the 64K bit x 1 DRAM connected to the exterior.

64K x 1 = 1024 sample x (32 bit + 32 bit)

That is, 32 bit data 1 to 1024 sample stereo delay is performed. This stereo delay sample volume is set through the microcomputer interface R mode (R9 to R0).

<td>1 0 2 4</td>
</tr>
</tbody>
</table>

Outline of the timing system is as follows.

That is if data CH1 (n) is written in DO register of 1LRCK (calculating operations) first half, then data CH1 (n-r) can be read from DI register. If data CH2 (n) is written in DO register at the second half, then data CH2 (n-r) can be read from DI register.

Connection to the external DRAM is as seen on the fig at right fixed.

Fix addresses over A8 to +5V or GND.

Moreover, for addresses that move frequently the order is: Column A0 to A4, Row A0 to A7, and column A5 to A7.

There are 2 kinds of data bit length for delay 32 bit and 30 bit. Timing system differs according to type.
(1) 32bit delay mode

By turning DIO, of the microcomputer interface R mode to 'H', 32bit delay mode is set on. To realize this, the following hardware conditions should be met.

\[
\text{LRCK} = 136 \text{KCK} = 272 \text{ACK}
\]

With 32bit delay mode, delay for all 32bit DI/DO registers is possible.

<table>
<thead>
<tr>
<th>DIH</th>
<th>E_1, E_2, ..., E_16, E_17</th>
</tr>
</thead>
<tbody>
<tr>
<td>DOH</td>
<td>F_1, F_2, ..., F_16, F_17</td>
</tr>
</tbody>
</table>

Timing (LRCK=136KCK Example)

Should the data written last between cycle 0 to 66 in DO register be at CH1(n), data CH1(n-r) from the previous cycle 134 up to the present cycle 65 in DI register can perform read.

Similarly, should data written last between cycle 68 and last cycle 1 in DO register be at CH2(n), data CH2(n-r) between cycle 66 to 133 in DI register can perform read.
(2) 30bit delay mode

By turning DIO, of the microcomputer interface R mode to 'L', 30bit delay mode is set on. To realize this, the following hardware conditions should be met.

\[ LRCK \leq 128 \text{KCK} = 256 \text{ACK} \]

That is, 512 \( fs \leq \text{fMCK1} \) or 256 \( fs \leq \text{fMCK2} \)

30bit delay mode can perform the delay of DI/DO register upper 30bit.

<table>
<thead>
<tr>
<th>DIH</th>
<th>E2, E3, ..., E17, E16</th>
<th>DIL</th>
<th>E15, E14, ..., E3, E2, 0, 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>DOH</td>
<td>F2, F3, ..., F17, F16</td>
<td>DOL</td>
<td>F15, F14, ..., F3, F2, x, x</td>
</tr>
</tbody>
</table>

Here, DOL register lower 2bit are at don't care, DIL register lower 2bit contain 0.

Timing (LRCK=128KCK Example)

```
<table>
<thead>
<tr>
<th>KCK</th>
<th>125 127 0 29 30 31 32 61 62 63 64 93 94 95 96 125 126 127 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>KSL</td>

<td></td>
</tr>
<tr>
<td>A7-A5</td>
<td>X X X X X X X X X</td>
</tr>
<tr>
<td>A4-A0</td>
<td>X X 0 0 0 0 0 0 0</td>
</tr>
<tr>
<td>DO</td>
<td></td>
</tr>
<tr>
<td>DI</td>
<td></td>
</tr>
</tbody>
</table>

Calculating operations
```

Should the data written last between cycle 0 to 62 in DO register be at CH1(n), data CH1(n-r) from the previous cycle 126 up to the present cycle 61 in DI register can perform read.

Similarly, should data written last between cycle 64 and last cycle 1 in DO register be at CH(n), data CH2(n-r) between cycle 62 to 125 in DI register can perform read.
Instructions

Outline

In one 24bit word length command the following can be executed in parallel, ① K-RAM and D-RAM address setting, ② MPY Command, ③ AU Command ④ Transfer Command ⑤ Jump Command. Data handled include, single precision (16b), double precision (32b) or through a combination of the 2, from 1 cycle to 3 cycle commands are available.

① K-RAM and D-RAM address setting

Sets the RAM address to be handled by a given command. For address setting there are, absolute address specify and relative address specify.

• K-RAM Single precision coefficient and double precision coefficient (2W in succession) can be used in this order or otherwise. Write is also enabled through a command allowing for use as a temporary register

• D-RAM Ring address. The modulo added value of the address counter value incremented at each serial I/O sampling cycle and that of the address set by the user becomes the actual value. Single precision data and double precision data (2W mutually separated by 32 addresses.) can be used in this order or otherwise.

② MPY Command

4 Types (K*D, K*X, X*D, X*X) and 4 kinds of modes (16b*16b, 16b*32b, 32b*16b, 32b*32b) can be handled. Through the respective modes the execution cycle of the command is determined.

K....K-RAM value
D....D-RAM value
X....From the register related ones hanging to the main bus, those that can output Acc.

③ AU Command

Can perform addition, subtraction, absolute value and comparison. A 2bit shifter is also built-in.

④ Transfer Command

Single precision data internally transfers double precision data via the main bus. Barrel shifter operations are executed through this transfer command.

⑤ Jump Command

There are unconditional jump, conditional jump, subroutine call and return, loop jump. Stack features a 2-stage structure and combination with double sub routine or loop jump is possible. Loop counter can perform loop jump 0 to 15 times at 4b. At every serial I/O sampling cycle forced 0 address jump is executed.
Points in Execution Commands

Each execution command with a 24 bit word length can, widely speaking, process the following in parallel. RAM address setting, MPY command AU command, transfer command and jump command. Specially through MPY command, data to be handled is defined as single precision or double precision. According to what the execution cycle is determined.

Data register and data format

</tr>
</tbody>
</table>

From the above commands that can execute Read become the source of transfer of the transfer command through the main bus or the multiplicator input data of MPY command.

In single precision (16b) commands, respective registers are handled independently. In double precision commands (32b) high word registers and low word registers are handled in pairs.

At power ON the respective registers data value become indefinite.
RAM address setting

(1) K-RAM address setting

Absolute address specify

<table>
<thead>
<tr>
<th>addr</th>
<th>H</th>
<th>a5 a4 a3 a2 a1 a0</th>
</tr>
</thead>
<tbody>
<tr>
<td>I12</td>
<td>111 110 10 18 17 16</td>
<td></td>
</tr>
</tbody>
</table>

At absolute expression 0 to 63

Relative address specify

<table>
<thead>
<tr>
<th>addr</th>
<th>L</th>
<th>a5 a4 a3 a2 a1 a0</th>
</tr>
</thead>
<tbody>
<tr>
<td>I12</td>
<td>111 110 10 18 17 16</td>
<td></td>
</tr>
</tbody>
</table>

At complement on 2 expression -32 to +31

- addr@K - addr

<table>
<thead>
<tr>
<th>addr&lt;±JK,- addr</th>
<th>a5 a4 a3 a2 a1 a0</th>
</tr>
</thead>
<tbody>
<tr>
<td>I12</td>
<td>111 110 10 18 17 16</td>
</tr>
</tbody>
</table>

At complement on 2 expression -8 to +7

- addr©<.- addr K=1

<table>
<thead>
<tr>
<th>addr©&lt;.- addr K=1</th>
<th>a5 a4 a3 a2 a1 a0</th>
</tr>
</thead>
<tbody>
<tr>
<td>I12</td>
<td>111 110 10 18 17 16</td>
</tr>
</tbody>
</table>

At complement on 2 expression -2 to +1

- addr©<.- addr K+1

During single precision command, 1 word of K (addr) is handled.

\[ K_s = -d_{15} + \sum_{i=1}^{15} 2^{-i} d_{15-i} \]

During double precision command, 2 word (32b) of K (addr) and K (addr 0 1) are handled. Here,

\[ K_s = -d_{31} + \sum_{i=1}^{31} 2^{-i} d_{31-i} \]

With K (addr) at low word, K (addr 0 1) at high word, 1 increment from the addr specified by the user, (addr 0 1  addr) execution is completed.

For commands where K-RAM is not handled, the present address remains unchanged.

At the forced 0 address jump every sampling cycle, reset is performed to addr=0.

K-RAM address space is shaped as a ring. (63 0 0 0 0 63). During Power ON K-RAM contents are not defined.
(2) D-RAM address setting

D-RAM address specify by the user is a logical address and not a physical address. At the forced 0 address jump every sampling cycle, the ring address counter DAC is incremented by 6 bit.

The logical address addr modulo added to the ring address counter DAC is the physical address that actually points.

Physical addr=DAC⊕addr

What follows is all about logical address addr.

Absolute address specify  \[ D_6(d) \rightarrow addr \]

<table>
<thead>
<tr>
<th>112</th>
<th>15 14 13 12 11 10</th>
<th>At absolute expression 0 to 63</th>
</tr>
</thead>
<tbody>
<tr>
<td>H</td>
<td>a5 a4 a3 a2 a1 a0</td>
<td></td>
</tr>
</tbody>
</table>

Relative address specify  \[ \text{addr} \oplus D_6(r) \rightarrow addr \]

<table>
<thead>
<tr>
<th>112</th>
<th>15 14 13 12 11 10</th>
<th>At complement on 2 expression -32 to +31</th>
</tr>
</thead>
<tbody>
<tr>
<td>L</td>
<td>a5 a4 a3 a2 a1 a0</td>
<td></td>
</tr>
</tbody>
</table>

\[ \text{addr} \oplus D_4 \rightarrow addr \]

<table>
<thead>
<tr>
<th>13 12 11 10</th>
<th>At complement on 2 expression -8 to +7</th>
</tr>
</thead>
<tbody>
<tr>
<td>a3 a2 a1 a0</td>
<td></td>
</tr>
</tbody>
</table>

\[ \text{addr} \oplus D_2 \rightarrow addr \]

<table>
<thead>
<tr>
<th>11 10</th>
<th>At complement on 2 expression -2 to +1</th>
</tr>
</thead>
<tbody>
<tr>
<td>a1 a0</td>
<td></td>
</tr>
</tbody>
</table>

\[ \text{addr} \oplus D_1 \rightarrow addr \]

\[ D = +1 \]

During single precision command, 1 word of D (addr) is handled

\[ D_6 = d_1 + \sum_{i=1}^{6} 2^{-i} d_{i+1} \]

During double precision command, 2 word (32b) of D (addr) and D (addr + 1) are handled.

\[ D_6 = d_2 + \sum_{i=1}^{31} 2^{-i} d_{i+1} \]

D (addr) is high word and D (addr + 32) is low word.

When there is no D-RAM address specify command the present address remains unchanged. (addr → addr)

At the forced 0 address jump every sampling cycle, reset is executed to addr=0.

Address space between D-RAM is ring shaped. (63 ⊕ 1 → 0, 0 ⊕ (-1) → 63)

At Power ON, D-RAM contents are undefined.
MPY Command

With the 2 bit of instructions I23 and I22, data length that is input to the multiplicator, is determined. Through this 4 types of MPY mode can be handled. Also, the command execution cycle is regulated by each mode.

With the 2 bit of instructions I21 and I20, the type of data input to the multiplicator is determined. Here K indicates that the address specified with this command is from K-RAM data. Similarly, D indicates the address specified with this command is from D-RAM data.

X indicates this is the register assigned by the command. It is input to the multiplicator through the main bus. When X is double precision specified, respective H/L registers are handled in pairs. In this case the register assigned is handled in high word and the corresponding register in low word.

A more detailed table will turn out as follows.

<table>
<thead>
<tr>
<th>I21</th>
<th>I20</th>
<th>123</th>
<th>122</th>

</tr>
</tbody>
</table>

For X*X with MPY command, either 16b*16b or 32b*32b is used. However for transfers where double precision X is at the source, X16*X32 type can be used.

Multiplication results enter register P and can be used with the next command. P bit length is at 33 bit and (-1) * (-1) = +1 can also be stored.

\[ P = -2d_{31} + \sum_{i=1}^{31} 2^{-i} d_{31} ... = +1 \geq P \geq -1 + 2^{-31} \]

The multiplicator itself operates all the time. P is renewed with every command. In save commands where there is no X16*X32, X32*X16 or MPY command, P is undefined.
AU Command

<table>
<thead>
<tr>

<td>O</td>
</tr>
</tbody>
</table>

For the 4bit of Instructions 119 to 116 AU command is provided |R| and |4R| are absolute values. 'Acc-R' and 'Acc-4R' are absolute values. 'Acc-4R' and 'Acc-4R' are comparison commands. Multiplication results are not stored in Acc, and Acc holds the previous value.

Acc bit length is at 34bit.

\[ \text{Acc} = 4d_{33} + \sum_{i=1}^{31} 2^{-d_i} \geq -4 \quad \text{Min. resolution capability } 2^{-31} \]

P is at 33bit of multiplication results from the previous command. It is code expanded to 34bit for use. R stands at a 32bit value as entered in R register by transfer commands from the commands received up to that. It is similarly code expanded to 34bit for use.

There are 5 Flags for the multiplication results of AU commands to be used when the following command is a conditional jump command. However where X mark is shown on the above chart, it is undefined, so exercise care.

<table>
<thead>
<tr>
<th>Flag</th>
<th>Condition</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zero</td>
<td>Acc = 0</td>
<td></td>
</tr>
<tr>
<td>Non Zero</td>
<td>Acc ≠ 0</td>
<td></td>
</tr>
<tr>
<td>Plus</td>
<td>Acc ≥ 0</td>
<td></td>
</tr>
<tr>
<td>Minus</td>
<td>Acc &lt; 0</td>
<td></td>
</tr>
<tr>
<td>Over Flow</td>
<td>Acc ≥ 1 or Acc &lt; -1</td>
<td></td>
</tr>
</tbody>
</table>

Only for comparison commands Flag is raised for 'Acc-R' and Acc-4R. XOVF output pin turns to active L during the command in execution after OVF has turned to true.

When Acc value is used for MPY, transfer or barrel shifter, it passes through clipper to be used in 32bit length.

Assuming clipper output=A, we have:

\[
\text{IF Acc} \geq 1 \text{ then } A = 1 - 2^{-31} \\
\text{else } 1 > \text{Acc} \geq -1 \text{ then } A = \text{Acc} \\
\text{else } -1 > \text{Acc} \text{ then } A = -1
\]
Transfer command

(1) Source and Destination

For the origin (source) of Transfer command K-RAM, D·RAM and X are provided.
Similarly, for the destination of transfer command K-RAM, D·RAM and Y are provided.

Accordingly, K-RAM and Serial I/O output registers (O1H-O2L) can be used as temporary registers.

Combinations are provided as follows.

<table>
<thead>
<tr>
<th>(K-RAM, D-RAM) → Y</th>
<th>X → (K-RAM, D-RAM)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

In between RAM there is no direct transfer.

Even if there is a transfer command to Y, incase it is not actually used, Y assignment uses 0 or 1.

BO1H to BO2L for X and B11H to B12H for Y, relate to the barrel shifter and will be referred to later on. X and Y assignment can be set independently for the transfer command of single precision data.

For the transfer command of double precision data, X and Y came in pair as H/L registers. The one assigned is processed as high word register.

Whether the transfer command is of single precision or double precision depends on the transfer origin (source). That is determined through 123 and 122bit of MPY command.

MPY command uses for X*X,

16b*16b (123, 122=LL, 1 cycle) or
32b*32b (123, 122=HH, 3 cycle). Should the multiplication be ignored, double precision transfer can be executed at 16b*32b (123, 122=LH, 2 cycle).

Be careful with 2 the following types of transfer commands that are prohibited.

1. Between serial I/O output register of the same register (EX) O1H → O1H
2. Respective registers relating to the barrel shifter B2H → B1L

<table>
<thead>
<tr>
<th>19 18 17 16</th>
<th>X</th>
</tr>
</thead>
<tbody>
<tr>
<td>13 12 11 10</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>19 18 17 16</th>
<th>Y</th>
</tr>
</thead>
<tbody>
<tr>
<td>13 12 11 10</td>
<td></td>
</tr>
</tbody>
</table>

H H L L (keep)
H H L L (keep)
H H L L (keep)
(2) Barrel Shifter
Barrel shifter operation command is inserted in the transfer commands.
There are 3 types of barrel shifter operation commands depending on the transfer destination Y register.

<table>
<thead>
<tr>
<th>Barrel shifter operation command</th>
<th>Transfer destination (16b)</th>
<th>Transfer data (16b)</th>
</tr>
</thead>
<tbody>
<tr>
<td>(1) Positive value floating-point type conversion</td>
<td>BI1H</td>
<td>d15 d14 d13 d12 d11 d10 ~ d0</td>
</tr>
<tr>
<td>(2) Arithmetic left shift</td>
<td>BI1L</td>
<td>S3 S2 S1 So ~ ~</td>
</tr>
<tr>
<td>(3) Arithmetic right shift</td>
<td>BI2H</td>
<td>S3 S2 S1 So ~ ~</td>
</tr>
</tbody>
</table>

As a rule those are single precision transfer commands. As for transfer data in the case of (1) Positive value floating-point type conversion, anything will do. For (2) Arithmetic left shift and (3) Arithmetic right shift the amount of shift S is specified in the 4 bit d14 to d11.
Conversion scale is, for (1) also included, 0 to 15 bit.

\[
S = \sum_{i=0}^{3} 2^i S, \quad 15 \geq S \geq 0
\]

Input data to be converted is 31 bit data \( A' \), excluding LSB, taken from value A (32b) or the result value Acc from the previous command, passed through a clipper.

\[
A' = -a_{31} + \sum_{i=1}^{10} 2^{-i}a_{31-i}, \quad 1.2^{-30} \leq A' \leq 1
\]

The converted results can be observed from the following 4 registers. The value is kept until the following barrel shifter operation command is issued. B01H is the respective data converted value.

\[
B01H = d_{15} + \sum_{i=1}^{13} 2^{-i}d_{15-i}
\]

B01L shows input A with the exclusion of sign bit, where the upper 4 bit are inverted and the rest is filled with zero.
B02H and B02L apply a only during floating-point type conversion. The amount of shift Q is included.

\[
Q = \sum_{i=0}^{3} 2^i q_i, \quad 15 \geq Q \geq 0
\]
① Positive value floating-point type conversion

Positive value $A^\ast$ (≥0, $a_{31}=0$) is converted to floating-point type ($A^\ast\approx BO1H+2^q$).

**Case I** $A^\ast \geq 2^{-1}\alpha$

$$A^\ast = -0 + \sum_{i=1}^{15} 2^{-a_{31-i}} \quad \text{for} \quad 15 \geq Q \geq 0, a_{31-x+1} = 1$$

$$= \sum_{i=1}^{15} 2^{-a_{31-i}} \cdot 2^{-Q} \approx (-0 + \sum_{i=1}^{15} 2^{-a_{31-i}}) \cdot 2^{-Q} = BO1H \cdot 2^{-Q}$$

This, to turn into the regular form $BO1H \geq \frac{1}{2}(b_{17}=1)$

**Case II** $2^{-16} > A^\ast$

$$A^\ast = -0 + \sum_{i=1}^{15} 2^{-a_{31-i}} = \sum_{i=1}^{15} 2^{-a_{31-i}} \times (-0 + \sum_{i=1}^{15} 2^{-a_{31-i}}) \cdot 2^{-Q} = BO1H \cdot 2^{-Q}$$

This becomes $\frac{1}{2} > BO1H(d_{17}=0), Q=15$

② Arithmetic left shift

With sign bit fixed, $S$ bit of $A^\ast$ is shifted left

$$01H = a_{31} + \sum_{i=1}^{15} 2^{-a_{31-i}}$$

**Case I** $2^{-15} > A^\ast \geq 0$

$$A^\ast \cdot 2^5 = (-0 + \sum_{i=1}^{15} 2^{-a_{31-i}}) \cdot 2^5 = \sum_{i=1}^{15} 2^{-a_{31-i}} \cdot 2^5 = \sum_{i=1}^{15} 2^{-a_{31-i}}$$

$$\approx -0 + \sum_{i=1}^{15} 2^{-a_{31-i}} = BO1H$$

**Case II** $0 > A^\ast \geq -2^{-15}$

$$A^\ast \cdot 2^5 = (-1 + \sum_{i=1}^{15} 2^{-a_{31-i}}) \cdot 2^5 = -\left(\sum_{i=1}^{15} 2^{-a_{31-i}} + 2^{-15}\right) \cdot 2^5$$

$$= -(\sum_{i=1}^{15} 2^{-a_{31-i}} + 2^{-15}) \cdot 2^5 = -\sum_{i=1}^{15} 2^{-a_{31-i}} + 2^{-15}$$

$$= -1 + \sum_{i=1}^{15} 2^{-a_{31-i}} \approx -1 + \sum_{i=1}^{15} 2^{-a_{31-i}} = BO1H$$

**Case III** $A^\ast \geq 2^{-1}$ or $-2^{-1} > A^\ast$

In this case conversion cannot be executed correctly
Arithmetic right shift
With sign bit fixed, $S$ bit of $A'$ is shifted right.

$$BO1H = -a_{31} + \sum_{i=1}^{16} 2^{-i}a_{31-i} + \sum_{i=1}^{15} 2^{-i}a_{31-i}$$

However,

$$S=0 \quad BO1H = -a_{31} + \sum_{i=1}^{16} 2^{-i}a_{31-i} = A'$$

$$S=15 \quad BO1H = -a_{31} + \sum_{i=1}^{16} 2^{-i}a_{31-i} + 2^{-14}a_{31}$$

$$A' \cdot 2^{-2} = \left(-a_{31} + \sum_{i=1}^{16} 2^{-i}a_{31-i}\right) \cdot 2^{-2} = -2^{-15}a_{31} + \sum_{i=1}^{15} 2^{-i}a_{31-i} + 2^{-14}a_{31}$$

$$\approx -a_{31} + \sum_{i=1}^{16} 2^{-i}a_{31-i} + \sum_{i=1}^{15} 2^{-i}a_{31-i} = BO1H$$

Flag BSQ

This flag is renewed with every barrel shifter operation command. This applies only during positive floating-point conversion.

When positive value floating-point conversion is executed, from that bit shift $Q$

$$Q = \sum_{i=0}^{31} 2^{i}q_{i}$$

$q_{0}$ becomes the Flag BSQ.

That flag value is kept until the following barrel shifter operation command comes.

When condition jump command and barrel shifter operation command are on the same command, Flag BSQ that is utilized for condition jump, is the flag value of the previous barrel shifter operation command.

BSQ=ON The bit shift amount of the positive value floating-point conversion is an odd number

BSQ=OFF The bit shift amount of the positive value floating-point conversion is an even number
Jump system command

Jump commands for the instruction address include: conditional jump, unconditional jump and sub routine call. They all jump to addresses expressed in 6bit and containing an A.

\[ A = \frac{1}{2} A, \quad 63 \leq A \leq 0 \]

Sub routine call and loop jump can stack instruction address. They are formed by a 2-address FILO and can execute up to a double combination. When stack performs a forced 0 address jump, it also keeps the previous condition.

(1) Conditional jump
   JP(F)

When the condition is met, the following command executes the command of the address ahead of the jump.
When the condition is not met, the command after that executes the command of the address in the order.

(2) Non conditional jump
   JMP

Elements from this command, execute the command of the address ahead of the jump, unconditionally

(3) Sub routine call
   CAL

This command executes the command of address ahead of the jump for the sub routine. Also it pushes to the stack the address following this command.

Next this command pops out the address from the stack and executes the command of that address.
(4) Loop jump
Sets the number of loops (0 to 15) in the 4 bit loop counter to repeatedly execute a certain

group of commands (1 to 16 times).

<table>
<thead>
<tr>
<th>Loop counter set</th>
<th>LCS (C)</th>
</tr>
</thead>
<tbody>
<tr>
<td>115 114 113 112</td>
<td>111 110 115 114</td>
</tr>
<tr>
<td>H L L L C3 C4 C5 C6</td>
<td></td>
</tr>
</tbody>
</table>

Number of loops
$C = \frac{1}{15} 2^{L-C} , \quad 15 \geq C \geq 0$

Sets the number of loops in the loop counter

<table>
<thead>
<tr>
<th>Loop counter and loop address set</th>
<th>LTS (C)</th>
</tr>
</thead>
<tbody>
<tr>
<td>115 114 113 112</td>
<td>111 110 115 114</td>
</tr>
<tr>
<td>H L L H C3 C4 C5 C6</td>
<td></td>
</tr>
</tbody>
</table>

Sets the number of loops in the loop counter and also pushes into the stack the next instruction address (loop head address)

<table>
<thead>
<tr>
<th>Loop address set</th>
<th>LPS</th>
</tr>
</thead>
<tbody>
<tr>
<td>115 111 110 15 14</td>
<td></td>
</tr>
<tr>
<td>L H H</td>
<td></td>
</tr>
</tbody>
</table>

Pushes the next instruction address (loop head address) into the next instruction address

<table>
<thead>
<tr>
<th>Loop jump</th>
<th>LPJ</th>
</tr>
</thead>
<tbody>
<tr>
<td>115 111 110 15 14</td>
<td></td>
</tr>
<tr>
<td>L L H</td>
<td></td>
</tr>
</tbody>
</table>

Decrements the loop counter value
① $C \geq 0$ jumps to the address in the stack
② $C < 0$ Pops out the stack and proceeds in order to the command of the following address

Example) Program

<table>
<thead>
<tr>
<th>Execution</th>
</tr>
</thead>
<tbody>
<tr>
<td>LTS (1) LTS 1→C</td>
</tr>
<tr>
<td>Command group A Command group A</td>
</tr>
<tr>
<td>Command group A</td>
</tr>
<tr>
<td>LPJ LPJ C-1= 0→C ( ≥0 )</td>
</tr>
<tr>
<td>Command group A</td>
</tr>
<tr>
<td>LPJ LPJ C-1= -1→C ( &lt;0 )</td>
</tr>
<tr>
<td>Command group B</td>
</tr>
</tbody>
</table>

The stack has a double structure. Accordingly, the following can be executed.

- The subroutine inside the subroutine
- The loop jump inside the subroutine
- The subroutine inside the loop jump

The loop jump inside the loop jump cannot be executed

Points on Execution Commands

Execution cycle

A command can be repeatedly executed from the command 0 address by means of the forced 0 address jump every Serial I/O sampling cycle.

Now, Assume that from the time 0 address has started, up until just before 0 address jump the number of cycles is N. [Cycle 0 to cycle (N-1)]

<table>
<thead>
<tr>
<th>Cycle</th>
<th>Description</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Normal cycle: Execution possible</td>
<td></td>
</tr>
<tr>
<td>(N-2)</td>
<td>KSL cycle: with the exception of K-RAM access, execution possible</td>
<td></td>
</tr>
</tbody>
</table>
| (N-1) | KSH cycle: Execution impossible (Any command will do) | *

* To provide time for K-RAM, I-RAM and the micro computer to interface (2) and (3) are available.

The number of cycles N is given through the following formula, with fs for sampling frequency and fck as cycle clock frequency.

\[
\frac{f_{ck}}{f_s} \frac{-1 < N < \frac{f_{ck}}{f_s} + 1}{f_{ck}} \quad \text{for} \quad f_{ck} = \frac{1}{2}f_{cck} = \left\{ \begin{array}{ll}
\frac{1}{2}f_{cck} & \\
\frac{1}{2}f_{cck} & \end{array} \right.
\]

If fck is a whole number \( N = f_{ck}/f_s = N_1 \). Cycle 0 to cycle (N-1)
If fck is not a whole number there are 2 cycle patterns

\[
N = \begin{cases} 
N_1, & \text{Cycle 0 to Cycle (N-1)} \\
N_1+1, & \text{Cycle 0 to Cycle N_1} 
\end{cases}
\]

<table>
<thead>
<tr>
<th>General expression</th>
<th>Normal cycle</th>
<th>KSL cycle</th>
<th>KSH cycle</th>
</tr>
</thead>
<tbody>
<tr>
<td>( f_{ck}/f_s ) whole number</td>
<td>( N = N_1 )</td>
<td>Cycle 0 to cycle (N-3)</td>
<td>Cycle (N-2)</td>
</tr>
<tr>
<td>( f_{ck}/f_s ) not a whole number</td>
<td>( N = N_1 )</td>
<td>Cycle 0 to cycle (N-3)</td>
<td>Cycle (N-2)</td>
</tr>
<tr>
<td></td>
<td>( N_1+1 )</td>
<td>Cycle 0 to cycle (N-3)</td>
<td>Cycle (N-2)</td>
</tr>
</tbody>
</table>
Therefore when \( \frac{f_{ck}}{f_s} \) is a whole number

1. Cycle 0 to cycle (N1-3) .......... Normal cycle: Execution possible
2. Cycle (N1-2) .......................... KSL cycle: with the exception of K-RAM access, execution possible
3. Cycle (N1-1) .......................... KSH cycle: Execution impossible (Any command will do)

Or when \( \frac{f_{ck}}{f_s} \) is not a whole number

A Cycle 0 to cycle (N1-3) : Execution always possible at normal cycle.
B cycle (N1-2) : Turns into normal cycle or KSL cycle.
C cycle (N1-1) : Turns into KSL cycle or KSH cycle.
D cycle N1 : Turns into KSH cycle or does not exist.

Example 1) When \( f_{ck}=6.144 \text{ MHz} \) \( f_s=48 \text{ KHz} \)

\[
\frac{f_{ck}}{f_s} = 128 \quad \therefore N = N1 = 128 \text{ Cycle 0 to cycle 127}
\]

Example 2) When \( f_{ck}=6.144 \text{ MHz} \) \( f_s=44.1 \text{ KHz} \)

\[
\frac{f_{ck}}{f_s} = 139.3... \quad \therefore N = \begin{cases} N1 = 139 \text{ cycle 0 to cycle 138} \\
N1+1 = 140 \text{ cycle 0 to cycle 139}
\end{cases}
\]

A Cycle 0 to cycle 136
B Cycle 137
C Cycle 138
D Cycle 139
Serial I/O and Register

(1) Serial I/O input register
The conditions for transfers with serial I/O input register as source or for cycle $n$ without MPY are:

$$N-\frac{1}{4} < n < N-\frac{3}{4} + M$$

SIN delay from $M \cdots BCK$ falling edge

As $N=2\frac{3}{4} (KCK)$

$$N-\frac{1}{4} < n < N : N-4 \leq n \leq N-1$$

- $\frac{f\text{CK}}{fS}$ for whole number $n \equiv (N-4 \leq n \leq N-1) = (N-4 \leq n \leq N-1)$

Cycle 0 to cycle (N1-5) ............. Serial input data transferred to the previous sampling space is in this space register and can be handled freely.

Cycle (N1-4) to cycle (N1-1) ...... In this space usage of serial I/O input register is prohibited.

* In certain cases cycle (N1-2) can be used. Check when necessary.

- $\frac{f\text{CK}}{fS}$ for whole number $n \equiv (N-4 \leq n \leq N-1) = (N-4 \leq n \leq N-1)$

Cycle 0 to cycle (N1-5) ............. Serial input data transferred to the previous sampling space is in this space register and can be handled freely.

Cycle (N1-4) to cycle (N1-1) ...... In this space usage of serial I/O input register is prohibited.

(2) Serial I/O output register
Cycle $n$ conditions for transfers that can not be executed with serial I/O output register as destination

$$N-\frac{1}{4} + \frac{f\text{CK}}{fB} \cdot M \leq n < N-\frac{3}{4} + \frac{f\text{CK}}{fB}$$

$fB \cdots \text{bit clock frequency}

$M$ is a delay margin to be ignored here $n \equiv (N-4 \leq n \leq N-1) = (N-4 \leq n \leq N-1)

24 bit clock system

$$N-\frac{1}{4} + \frac{1}{48} \frac{f\text{CK}}{fS} \leq n < N-\frac{3}{4} + \frac{1}{48} \frac{f\text{CK}}{fS}$$

32 bit clock system

$$N-\frac{1}{4} + \frac{1}{64} \frac{f\text{CK}}{fS} \leq n < N-\frac{3}{4} + \frac{1}{64} \frac{f\text{CK}}{fS}$$

* As no margin is taken for the left side, in certain cases prohibited cycles are not included. Check when necessary.
Example 1) f_{\text{ck}} = 6.44 \text{ MHz} \quad f_s = 48 \text{ KHz} \quad N = N_1 = 128 \quad (\text{Cycle 0 to cycle 127})

Serial I/O input register

\[ n = (N_1 - 4 \leq n \leq N_1 - 1) = \{ 124 \leq n \leq 127 \} \]

\[ \begin{align*}
\text{Cycle 0 to cycle 123} & \quad \text{usable} \\
\text{Cycle 124 to cycle 127} & \quad \text{unusable}
\end{align*} \]

Serial I/O output register 24 clock system

\[ \frac{1}{4} \leq \frac{1}{48} \quad 128 < n < \frac{3}{4} + \frac{1}{128} \]

\[ \frac{12}{12} < n < \frac{1}{12} \]

\[ n \leq N - 1 \]

\[ n = N - 1 = N_1 = 127 \]

\[ \begin{align*}
\text{Cycle 0 to cycle 126} & \quad \text{usable} \\
\text{Cycle 127} & \quad \text{unusable}
\end{align*} \]

Serial I/O output register 32 clock system

\[ \frac{1}{4} \leq \frac{1}{64} \quad 128 < n < \frac{3}{4} + \frac{1}{64} \]

\[ \frac{3}{4} < n < \frac{3}{4} \]

\[ n = (N - 2 \leq n \leq N - 1) = (126 \leq n \leq 127) \]

\[ \begin{align*}
\text{Cycle 0 to cycle 125} & \quad \text{usable} \\
\text{Cycle 126 to cycle 127} & \quad \text{unusable}
\end{align*} \]
Example 2) \( f_{CK} = 6.144 \text{ MHz} \quad f_s = 44.1 \text{ KHz} \quad N_n = \begin{cases} N_1 = 139 \text{ (Cycle 0 to cycle 138)} \\ N_1+1 = 140 \text{ (Cycle 0 to cycle 139)} \end{cases} \)

Serial I/O input register \( n = (N_i - 4 \leq n \leq N_i) \cdot (135 \leq n \leq 139) \)
- Cycle 0 to cycle 134 .......... usable
- Cycle 135 to cycle 139 .......... unusable

Serial I/O output register 24 clock system \( \frac{1}{4} + \frac{1}{48}(139.3...) < n < \frac{3}{4} + \frac{1}{48}(139.3...) \)
- \( N_i - 1.3... < n < N_i + 0.1... \)
- \( n = (N_i - 1.0) = (N_i - 1, N_i, 0) = (138, 139, 0) \)
- Cycle 1 to cycle 137 .......... usable
- Cycle 137, 139, cycle 0 ......... unusable

Serial I/O output register 32 clock system \( \frac{1}{4} + \frac{1}{64}(139.3...) < n < \frac{3}{4} + \frac{1}{64}(139.3...) \)
- \( N_i - 2.0... < n < N_i - 0.5... \)
- \( N_i - 2 \leq n \leq N_i - 1 \)
- \( n = (N_i - 2, N_i - 1, N_i) = (137, 138, 139) \)
- Cycle 0 to cycle 136 .......... usable
- Cycle 137 to cycle 139 .......... unusable

Delay I/O (Serial mode) and register
(1) Delay I/O input register
Delay I/O input register is input twice during 1 sampling period. For one of those 2 instances the timing is the same as for serial I/O. For the other instance the conditions for the transfer with this register as source or the cycle \( n \) when MPV cannot be executed are:

\[
\frac{1}{2} f_{CK} - \frac{1}{4} f_s < n < \frac{1}{2} f_{CK} - \frac{3}{4} f_s + M
\]

as \( N_n = \frac{1}{2} f_{CK} \)

\[
\frac{1}{2} f_{CK} - \frac{1}{4} f_s < n < \frac{1}{2} f_{CK} - \frac{1}{4} f_s
\]

accordingly \( n = \text{max} : n < \frac{1}{2} f_{CK} - \frac{1}{4} f_s \)

<table>
<thead>
<tr>
<th>Cycle 0 to cycle ( n_2 ) ..........</th>
<th>data transferred during LRCK L level of the previous sampling level is in the register and can be handled freely.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cycle ((n_2+1)), cycle ((n_2+2)) ..........</td>
<td>Usage prohibit cycle</td>
</tr>
<tr>
<td>Cycle ((n_2+3)) to cycle ((N_i-5)) ........</td>
<td>data transferred during LRCK H level of the present sampling period is in the register and can be handled freely</td>
</tr>
<tr>
<td>Cycle ((N_i-4)) to cycle ((N_i-1)) ..........</td>
<td>Usage prohibit cycle</td>
</tr>
</tbody>
</table>

*In certain cases cycle \((n_2+3)\) also becomes usage prohibit cycle. Please check when necessary.
(2) Delay I/O output register
Delay I/O output register outputs twice during 1 sampling period. For one of those 2 instances the timing is the same as for serial I/O. For the other instance, the conditions for cycle \( n \) where transfer with this register as destination can not be executed are

\[
\frac{1}{2} \frac{f_{CK}}{f_S} - \frac{4}{4} < n < \frac{1}{2} \frac{f_{CK}}{f_B} - \frac{3}{4} + \frac{f_{CK}}{f_B}
\]

as \( M=0 \) \( [KCK] \)

\[
\frac{1}{2} \frac{f_{CK}}{f_S} - \frac{4}{4} < n < \frac{1}{2} \frac{f_{CK}}{f_B} - \frac{3}{4} + \frac{f_{CK}}{f_B}
\]

24 bit clock system

\[
\frac{25}{48} \frac{f_{CK}}{f_S} - \frac{4}{4} < n < \frac{25}{48} \frac{f_{CK}}{f_S} - \frac{3}{4}
\]

32 bit clock system

\[
\frac{33}{64} \frac{f_{CK}}{f_S} - \frac{4}{4} < n < \frac{33}{64} \frac{f_{CK}}{f_S} - \frac{3}{4}
\]

*In certain cases, as the left side margin is not included, cycles that become prohibited are not included. Please check when necessary.

Example 1) \( f_{CK}=6.144 \) MHz \( f_S=48 \) kHz \( N-N_1=128 \) (Cycle 0 to cycle 127)

Delay I/O input register \( n_1<\frac{1}{2} \frac{128-4}{4} = 60- \frac{1}{4} \)

\[\therefore n_1=59\]

\[
\begin{align*}
\text{Cycle 0 to cycle 59} & \quad \text{usable} \\
\text{Cycle 60 to cycle 61} & \quad \text{ unusable} \\
\text{Cycle 62 to cycle 123} & \quad \text{ usable} \\
\text{Cycle 124 to cycle 127} & \quad \text{ unusable}
\end{align*}
\]

Delay I/O output register 24 clock system

\[
\frac{25}{48} \frac{128-4}{4} < n < \frac{25}{48} \frac{128-3}{4}

Delay I/O (delay mode) and register

(1) 32 bit delay mode
32 bit Conditions where delay mode can be realized

\[ fS \leq \frac{1}{136} \text{ fCK} \quad \text{that is} \quad N_i \geq 136 \]

The relation between data to write in DO register and data to read from DI register is.

• DO register
  - Cycle 0 to cycle 66: data written last in this period is set as CH1 (n)
  - Cycle 67: write prohibit
  - Cycle 68 to cycle (N1-2): data written last in this period is set as CH2 (n)
  - Cycle (N1-1), (N1): write prohibit

• DI register
  - Previous cycle 134 to cycle (N1-2), cycle 0 to cycle 65
    - In this period CH1 data (n-r) can read
  - Cycle 62 to cycle 125: In this period CH2 data (n-r) can read.
  - Cycle (N1-1), (N1): read prohibit

(2) 30 bit delay mode
30 bit Conditions where delay mode can be realized

\[ fS \leq \frac{1}{128} \text{ fCK} \quad \text{that is} \quad N_i \geq 128 \]

The relation between data to write in DO register and data to read from DI register is.

• DO register
  - Cycle 0 to cycle 62: data written last in this period is set as CH1 (n)
  - Cycle 63: write prohibit
  - Cycle 64 to cycle (N1-2): data written last in this period is set as CH2 (n)
  - Cycle (N1-1), (N1): write prohibit

• DI register
  - Previous cycle 126 to cycle (N1-2), cycle 0 to cycle 61
    - In this period CH1 data (n-r) can read
  - Cycle 62 to cycle 125: In this period CH2 data (n-r) can read.
  - Cycle (N1-1), (N1): read prohibit

CXD1244S

Digital Filter for CD Player

Description
CXD1244S is a digital filter LSI with 4-times/8-times over sampling rate, developed for compact disc player.

Features
• Built-in 4-times/8-times sampling digital filter for 2 channels.
• Ripple within 0.00001dB
• Attenuation within -100dB(24.1kΩ).
• Noise shaping, Attenuator
• Soft muting, de-emphasis and a wide variety of built-in functions.

Application
Compact disc player

Structure
Silicon gate CMOS IC

Absolute Maximum Ratings (Ta=25°C)
• Supply voltage $V_{DD}$ -0.5 to +6.5 V
• Input voltage $V_1$ -0.5 to $V_{DD} +0.5$ V
• Storage temperature $T_{stg}$ -55 to +150°C
• Allowable power dissipation $P_D$ 500 mW (Ta=60°C)

Recommended Operating Conditions
• Supply voltage $V_{DD}$ 4.75 to 5.25 V
• Operating temperature $T_{opr}$ -10 to +60°C
• OSC frequency $f_X$ 12.0 to 18.5 MHz

Functions
Conceptual block diagram
An outline block diagram of this LSI is shown below.

1. Noise shaping
   For respective outputs FIR 1 to 3, IIR, SOFT/ATT figures are usually rounded off. However, by
turning NS to "H" noise shaping can be applied.
   NS register is cleared when INIT is at "L" or NS at "L".

2. Soft muting
   By turning SOFT to "H"/"L", data can be smoothly muted or demuted.

   ![Output amplitude graph]
   Output amplitude
   T = 256/FS (S)

3. Digital attenuator
   Can attenuate output data by means of transfer data from an external microcomputer.
1) Command and Audio output

Attenuate data is in 12 bit and can be set in 1024 steps. The relationship between command and output is shown in the chart below.

<table>
<thead>
<tr>
<th>Attenuate data</th>
<th>Audio output</th>
</tr>
</thead>
<tbody>
<tr>
<td>400 (H)</td>
<td>0 dB</td>
</tr>
<tr>
<td>3FF (H)</td>
<td>-0.0085 dB</td>
</tr>
<tr>
<td>3FE (H)</td>
<td>-0.017 dB</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>001 (H)</td>
<td>-60.206 dB</td>
</tr>
<tr>
<td>000 (H)</td>
<td>-∞</td>
</tr>
</tbody>
</table>

The attenuate value from 001 (H) to 3FF (H) can be obtained through the following formula.

\[ \text{ATT} = 20 \log \left( \frac{\text{Input data}}{1024} \right) \text{ dB} \]

Example: Attenuate data for 3FA (H)

\[ \text{ATT} = 20 \log \left( \frac{1018}{1024} \right) \text{ dB} = -0.051 \text{ dB} \]

2) Attenuator operation

Suppose that there are pieces of attenuator data ATT1, ATT2 and ATT3 and that ATT1 > ATT3 > ATT2 and that the place of attenuator data ATT1 is transferred first and ATT2 transferred next. If ATT2 is transferred before, the value of ATT2 is reached (during the state of A in Fig.1), the attenuation directly approaches the value of ATT2. If ATT3 is transferred before the value of ATT2 is reached (during the state of B or C in Fig.1), the attenuation is carried on from the value at the time (B or C) to approach the value of ATT3. Transition from one piece of attenuator data to another is the same as in the case of softmuting.

![Fig.1 Transition from one attenuator value to another](image-url)
3) Input data timing

Attenuate function can be activated by means of ATT, Shift and Latch.
Transfer format is indicated as follows.

(1) ATT data is a 12 bit word length and LSB first transfer ATT data is available 000(H) to 400(H).
(2) When Latch is at "L", ATT cannot be transferred.
(3) With INIT at f, 400 (H) is set as ATT data.

- The transition from ATT1 to ATT2 takes place in soft muting operation.
- During attenuate operation SOFT is set to either ON or OFF, it turns back to the original ATT data.
- When ATT data =400 (H) Noise shaping is not applied regardless of NS ON or OFF.
  When ATT data =400 (H) Noise shaping is applied regardless of NS ON or OFF.

4. Digital deemphasis

By turning EMP to "H", deemphasis can be applied by means of IIR filter.
Time constant of de-emphasis are $\tau_1=50\mu$s and $\tau_2=15\mu$s at $f_s=44.1kHz$. 
5. Offset
Offset can be applied to the output data by means of OFST and OPOL.
Pos/Neg selection of the offset value is possible as indicated in the following chart.

<table>
<thead>
<tr>
<th>OFST</th>
<th>OPOL</th>
<th>OUT 16/18</th>
<th>Offset value</th>
</tr>
</thead>
<tbody>
<tr>
<td>L</td>
<td>X</td>
<td>L</td>
<td>0000 (H)</td>
</tr>
<tr>
<td>L</td>
<td>X</td>
<td>H</td>
<td>00000 (H)</td>
</tr>
<tr>
<td>H</td>
<td>H</td>
<td>L</td>
<td>02AA (H)</td>
</tr>
<tr>
<td>H</td>
<td>H</td>
<td>H</td>
<td>02AA8 (H)</td>
</tr>
<tr>
<td>H</td>
<td>L</td>
<td>L</td>
<td>FD55 (H)</td>
</tr>
<tr>
<td>H</td>
<td>L</td>
<td>H</td>
<td>FD554 (H)</td>
</tr>
</tbody>
</table>

6. Muting
By turning MUTE to “H” or INIT to “L”, the output can be muted. Then, the offset value set at the offset is output. When INIT is at “L”, 0 data is input to this LSI.

7. Data polarity
Inversion and non inversion of the output data can be selected by means of DPOL.

When DPOL is at “H”, non inversion.
when DPOL is at “L”, inversion.

8. I/O synchronizing circuit
1) Principle
A window featuring 10 internal system clocks (XIN/2) is set. The sync circuit observes whether the rising edge (LRCK f) of LRCK that is input, has entered the window or not. When the power supply is turned on, should LRCK f be out of the window the sync circuit stops the internal processing in timing with the center of the window. Synchronously with the appearance of the next LRCK f the processing is started. Through this operation synchronization between the exterior system and this LSI is established.

2) Resynchronization by means of INIT
Even when LRCK f is inside the window but located close to one of the 2 edges of the window, the sync may miss with the mingling of external noise or other Re sync operation. To this effect it is necessary to apply resync, without fault, after supply is turned on. ReSync operation is executed with the INIT f timing. Sync. circuit is initialized and LRCK is located in the center of the window.
Moreover, when the sync falls out of the window, INAF output turns to “H” level.

3) Non synchronous MUTE
When INAF is at H, 0 data is output regardless of offset ON/OFF.
9. Output format
The output format of this LSI can be selected as shown in the chart below.

<table>

10. I/O signal latch timing
1) Input
   DPOL, SOFT, MUTE, OFST, QPOL, INIT, SONY/12S, LFS, OUT16/18, NS, EMP
   The above indicated input signals are latched by means of internal clocks equivalent to LRCK.

2) Output
   LRCKO, DATAL, DATAR, APT.WS, LE/WS
   The above indicated output signals are latched by means of internal clocks equivalent to BCKO.

CXD2552Q

Pulse D/A Converter*

Description
The CXD2552Q is a pulse D/A converter developed for digital audio products; compact disc player and others.

Features
- PLM pulse converter
- 3rd order noise shaper
- Direct digital sync
- Master clock 1024Fs
- 2 channel built in

Absolute Maximum Ratings
- Supply voltage \( V_{reb} \) -0.5 to +6.5 V
- Input voltage \( V_{in} \) -0.3 to \( V_{reb} +0.3 \) V
- Allowable power dissipation \( P_{d} \) 500 mW (Ta=60°C)
- Storage temperature \( T_{stg} \) -55 to +150 °C

Recommended Operating Conditions
- Supply voltage \( V_{reb} \) 4.75 to 5.25 V
- Operating temperature \( T_{opr} \) -10 to 60 °C
- OSC frequency \( f_{x} \) 32.0 to 49.7 MHz
- Supply voltage difference \( V_{reb} - V_{reb}, V_{reb} - D_{reb}, V_{reb} - X_{reb} \) ± 0.1V
  \( V_{ss} - V_{ss}, V_{ss} - D_{ss}, V_{ss} - X_{ss} \) ± 0.1V

Structure
Silicon gate CMOS IC

Applications
Compact disc player, digital amplifier, BS tuner

Block Diagram and Pin Configuration

* Sony Corporation developed the Pulse D/A converter and designed the LSI circuitry that incorporates the Multi-Stage Noise Shaping technique originated by NTT (Nippon Telegraph and Telephone Corporation).

Sony reserves the right to change products and specifications without prior notice. This information does not convey any license by any implication or otherwise under any patents or other right. Application circuits shown, if any, are typical examples illustrating the operation of the devices. Sony cannot assume responsibility for any problems arising out of the use of these circuits.

**Electrical Characteristics Testing Method**

The testing of total harmonic distortion and S/N ratio is shown in Fig. 1. and 2.

**Fig. 1.**

**Fig. 2.**
Description of Function

I/O Synchronizing Circuit

1) Theory of operation
   A window featuring 8 internal clocks (256Fs) is set. The sync circuit observes whether the rising edge (LRCK) of the LRCK input has entered the window or not. When power supply is turned on, should LRCK be out of the window, the sync circuit stops the internal processing in timing with the center of the window. The processing is started synchronously with the appearance of the next LRCK. Synchronization between the exterior system and this LSI is established through this operation.

2) Resynchronization by means of INIT
   Even when LRCK is inside the window but located close to one of the two edges of the window, synchronization may be upset by the mingling of external noise. To this effect, it is necessary to apply resync without fail after power supply is turned on. Resync operation is executed from the rising edge of INIT and timed after 4 periods of Fs rate LRCK. The sync circuit is initialized and LRCK is located at the center of the window.
   Moreover, when synchronization falls out of the window, INAF output turns to “H” level.

Input Timing (8fs rate)

![Input Timing Diagram]
Application circuits shown are typical examples illustrating the operation of the devices. Sony cannot assume responsibility for any problems arising out of the use of these circuits or for any infringement of third party patent and other right due to same.
Package Outline  Unit: mm

44pin QFP (Plastic) 1.1g

SONY NAME QFP-44P-L122
EIAJ NAME *QFP044-P-1414-AX
JEDEC CODE

CX025520
CXD2555Q is a delta sigma type (2nd order delta sigma noise shaping) A/D & D/A with a digital filter.

Features
- Two Channel A/D, D/A with over-sampling, Decimation digital filter.
- Analog circuit for A/D included
- Distortion level: 0.01% (A/D, D/A)
- S/N: 90dB for D/A
  80dB for A/D

Functions
- 1 Fs data rate I/O possible
- Multi chip system possible
- Serial data interface: 32 slot
  Right/Left Adjusted Data
  MSB/LSB first in selections
- Master clock Selection:
  256Fs/512Fs/768Fs/1024Fs
- Fs selection:
  8KHz/16KHz/32KHz/44.1KHz/48KHz
- Provides several clock outputs, devided by a masterclock

Description of Operation
1. Serial Data Interface LRCK, BCK, SOUT, SIN, MASL, MLSL
   Serial data format is same for both SIN and SOUT - 2’s complementary 2 channel serial data. Each channel has 16bit data at 32bit slot. MASL mode select the 16bit data timing - data comes first or later. MLSL mode select MSB first or LSB first.

<table>
<thead>
<tr>

<th>MASL</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>H</td>
<td>MSB first</td>
</tr>
<tr>
<td>L</td>
<td>LSB first</td>
</tr>
</tbody>
</table>

2. Master Mode/Slave Mode MS, LRCK, BCK
   When multiple chips are used together, one of the ICs is used as "Master" and output LRCK, BCK. Other ICs are receiving these clocks as "Slave" chips.

<table>
<thead>
<tr>
<th>MS</th>
<th>Mode</th>
<th>LRCK, BCK I/O</th>

</table>
2. (Con't) Slave Mode

(Example)

3. Crystal Oscillation Frequency Select XTLI, XTLO, XSLO, XSL1, UCLK, XCLK.
If XSL2 = "L" the crystal frequency is selected by XSLO and XSL1 as shown in Table 1.
If XTLI receives CMOS level input signal, XTLO should open.

<td>H</td>
<td>H</td>
<td>512x32KHz</td>
<td>8KHz</td>
</tr>
</tbody>
</table>

Table 2 - Low Frequency Fs Mode Select.

32KHz based crystal frequency gives these Fs frequencies.
If 44.1KHz is base frequency then Low Frequency Fs are either 22.05KHz or 11.025KHz.
If 48KHz is base frequency then Low Frequency Fs are either 24KHz or 12KHz.

5. D/A Output Mode Selection

<table>
<thead>
<tr>

SCSI Controller LSI

Description

The CXD1185AQ is a high performance CMOS SCSI controller LSI that conforms to ANSIX3.131-1986 standards. The CXD1185AQ is capable of operating in both initiator and target modes. It satisfies all standard SCSI bus features, such as arbitration, selection and parity generation/check functions. A 24-bit data transfer byte counter and 16-byte FIFO are built into the hardware. Two separate buses for data and processor makes high speed data transfer possible. 48 mA (sinking) port is built-in to achieve reduction in the number of external components.

The chip offers a set of high level commands at SCSI phase level. It is also possible to read/write all individual SCSI signals. The combination of the above two makes programs simpler and at the same time improves programability.

Features

- Satisfies all SCSI bus features, including arbitration, selection, parity generation/check and synchronous data transfer mode.
- Maximum synchronous data transfer rate of 4.0MB/sec and maximum asynchronous data transfer rate of 2.5 MB/sec.
- Provides two separate parts for the data bus and the CPU bus.
- Built-in user-programmable timer for selection/reselection timeout operation.
- Supports 8-bit microcomputer bus.
- Supports programmed I/O and DMA transfer modes.
- Built-in 48mA (sinking) SCSI port. The SCSI port can be used as either single-ended port or differential port.

Absolute Maximum Ratings (Ta=25°C, $V_{SS}=0V$)

</tbody>
</table>

<Note 1> All VDD and VSS pins should be connected to the power supply and ground, respectively.

<Note 2> Items in parentheses ( ) indicate the meaning of the signal when operating in the SCSI differential mode.

<Note 3> In systems where the CPU and data buses are not separate, connect the WED and RED pins to WE and RE, respectively, and Pins D7-D0 to Pins C7-C0.

<Note 4> If the data bus parity signal is not used, pull up the DP pin using a resistor.

Description of Functions

1. Internal registers

CXD1185AQ possesses 16 internal registers. The CPU can control CXD1185AQ by reading and writing these registers.

A summary of the registers is provided below.

<table>
<thead>
<tr>
<th>Address</th>

</tbody>
</table>

< * > No register assigned to this address.

1-1. Status register (R0 : R)

This register is used to monitor the status of CXD1185AQ.

<table>
<thead>
<tr>
<th>7 6 5 4 3 2 1 0</th>
</tr>
</thead>
</table>
| MRST  MDBP INIT  TARG TRBZ  MIRQ  CIP |}

MRST : Monitors the SCSI bus RST signal, positive logic.
MDBP : Monitors the SCSI bus DBP signal, positive logic.
INIT : “1” when CXD1185AQ is in initiator status.
When this bit is set to “1”, all commands except ones which are valid in target status and in disconnected status are accepted.
TARG : “1” when CXD1185AQ is in target status.
When this bit is set to “1”, all commands except ones which are valid in initiator status and in disconnected status are accepted.
TRBZ : When this bit is set to “1”, it indicates that the transfer byte counter count is zero.
MIRQ : Monitors the interrupt request signal (IRQ signal).
This bit is set whenever interrupt request occurs and cleared once interrupt request 1 register and interrupt 2 register are read. This bit is not affected by the content of the interrupt authorization register. The logic level of this bit is not affected by the SIRM bit in the environment setting register.
CIP : Indicates that a chip command is being executed.
While this bit is “1”, no new commands can be written to the command register, with the exception of the “Reset Chip” command.
1.2. Command register (RO: W)
This is the register to which CXD1185AQ commands are written.
When a command is written to this register, status register bit 0 (CIP) is set. When the command is executed and terminated, interrupt request register bit 7 (FNC) is set, and the CIP bit and command register are cleared.

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>CAT1</td>
<td>CAT0</td>
<td>DMA</td>
<td>TRBE</td>
<td>CMD3</td>
<td>CMD2</td>
<td>CMD1</td>
<td>CMD0</td>
</tr>
</tbody>
</table>

**CAT1, CAT0:**
Sets the category code given to CXD1185AQ.
CXD1185AQ commands are divided into the following four categories:

<table>
<thead>
<tr>
<th>CAT1</th>
<th>CAT0</th>
<th>Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>Commands which are valid in any status</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>Commands which are valid in disconnected status</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>Commands which are valid in target status</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>Commands which are valid in initiator status</td>
</tr>
</tbody>
</table>

If the current status of CXD1185AQ does not match with the category code in the command received, the CIP and command registers are cleared. No interrupt is generated in this case.

**DMA:**  DMA mode
When this bit is set to “1” and a transfer command is executed, DMA transfer takes place via the data bus (D7-D0). During the DMA transfer, any attempts by the CPU to read/write SCSI data register via CPU bus is ignored.

**TRBE:**  Activates the transfer byte counter.
When this bit is set to “1” and a transfer command is executed, the transfer byte counter value is decremented each time a byte of data is transferred.
When the counter reaches “0” the next data request is stopped. At this point, if the data transfer mode is output to SCSI or in DMA mode, CXD1185AQ will continue to transfer any data remaining in FIFO until it is empty. If a transfer command is executed when this bit is set to “0”, 1 byte of data will be transferred regardless of the value of the transfer byte counter. In this case the transfer byte counter is not decremented. When DMA bit is set, TRBE bit must also be set. These two bits can be set simultaneously during command write.
CMD3, CMD2, CMD1, CMD0:
Indicates the command code.

CXD1185AQ responds to the following commands. See the command description section for detailed information.

<table>

</table>

(*) Don't care, except that if DMA bit is set to "1", TRBE bit must be set to "1".

1-3. SCSI data register (R1: R/W)
This register is used when transferring data between the SCSI bus and the CPU bus.
When data is output to the SCSI bus via the CPU bus, data can be written to this register if the FIFO status register bit 4 (FIF) is "0".
When data is input from SCSI bus, data can be read from this register if the FIFO status register bit 7 (FIE) is "0".
When "Assert SCSI data" is executed the 16 byte FIFO becomes a 1 byte FIFO. Any value written to the register will be on the SCSI bus instantly and a read operation will return the current SCSI data bus value.
When a DMA transfer is performed via the data bus, reads and writes to the SCSI data register are performed using the WED, RED and DACK signals.

1-4. Interrupt request registers 1 and 2
These registers show the cause of the interrupt.
When an interrupt authorized by interrupt authorization registers 1 or 2 is generated, the IRQ pin is set immediately.
Bits in the interrupt request registers 1 and 2 are cleared once the registers are read by the CPU. When all interrupt bits are cleared, MIRQ bit (in the status register) and the IRQ pin are cleared.
Note that interrupt bits in these registers are set regardless of the values in the interrupt authorization registers. If interrupt requests are software polled, interrupt request registers 1 and 2 should only be read
when the MIRQ bit, in the status register, is "1".

1-4-1. Interrupt request register 1 (R2 : R)
This register's interrupt conditions can be masked in the interrupt authorization register 1.
When one of the bits in this register is set, MIRQ bit in the status register is set. If the interrupt bit is authorized in the interrupt authorization register 1, the IRQ pin is activated simultaneously.

<table>

<tbody>
<tr>
<td>STO</td>
<td>RSL</td>
<td>SWA</td>
<td>SWOA</td>
<td>ARBF</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

STO : Selection Time Over
Indicates a time out error during selection. Also, indicates that the SCSI bus RST signal has been driven for the time set in the selection/reset timer if the mode register bit 4 (TMSL) is set to "1". The selection time out time and SCSI bus RST signal drive time are determined by the value of the selection/reset timer register.

RSL : Reselected
Indicates that reselection has taken place. FNC bit in the interrupt register 2 is set after reselection. The CPU may not write new commands to the command register until the FNC bit is set. This bit is not set unless the "Enable Selection/Reselection" command is executed.

SWA : Selection With ATN
Indicates that selection has taken place with the SCSI bus ATN signal driven. FNC bit in the interrupt register 2 is set after selection. The CPU may not write new commands to the command register until the FNC bit is set. This bit is not set unless the "Enable Selection/Reselection" command is executed.

SWOA : Selection Without ATN
Indicates that selection has taken place. FNC bit in the interrupt register 2 is set after selection. The CPU may not write new commands to the command register until the FNC bit is set. This bit is not set unless the "Enable Selection/Reselection" command is executed.

ARBF : Arbitration Fail
Indicates that CXD1185AQ lost in the arbitration for the right to use the SCSI bus. This bit is set when, after receiving a selection/reselection command, the chip waited for bus free and entered arbitration only to be encountered by another device with higher priority. As soon as this bit is set the selection/reselection command is terminated. To participate in another arbitration a new selection/reselection command must be written to the command register.

1-4-2. Interrupt request register 2 (R3 : R)
This register's interrupt conditions can be masked in the interrupt authorization register 2.
When one of the bits in this register is set, MIRQ bit in the status register is set. If the interrupt bit is authorized in the interrupt authorization register 2, the IRQ pin is activated simultaneously.

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>FNC</td>
<td>DCNT</td>
<td>SRST</td>
<td>PHC</td>
<td>DATN</td>
<td>DPE</td>
<td>SPE</td>
<td>RMSG</td>
</tr>
</tbody>
</table>

FNC : Function Complete
Indicates that the received command was executed and terminated.

DCNT : Disconnected
Indicates that a disconnect has taken place in the initiator mode.

SRST : SCSI Reset
Indicates that the SCSI bus RST pin was driven. This bit is also set when the "Assert RST" command is executed.

PHC : Phase Change
Indicates that the SCSI phase has been changed. This bit is set if CXD1185AQ is operating in the initiator mode and the target has changed the SCSI phase (MSG, I/O, C/D signal), and drove REQ.
DATN : Drive ATN  
Indicates that the SCSI bus ATN signal has been driven. This bit is set if the CXD1185AQ is operating in the target mode and the initiator has driven the ATN signal.

DPE : Data bus Parity Error  
Indicates a parity error on the data bus. This bit is only set if environment setting register bit 5 (DPEN) is set to "1". In initial status odd parity (environment register bit 6 set to "0") is selected.

SPE : SCSI bus Parity Error  
Indicates a parity error on the SCSI bus. Parity check takes place during the selection phase and data transfer phases.

RMSG : REQ in Message Phase  
Indicates that the REQ signal has been driven during the message phase when the CXD1185AQ is in initiator mode. This bit is used when two different batches of message data have been received during the message phase or if the target requests that a message be resent.

1-5. Environment setting register (R3: W)  
This register is used to set the operating mode of the CXD1185AQ. Normally, some value must be written to this register immediately after a hardware reset from the CPU.

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>DIFE</td>
<td>SDPM</td>
<td>DPEN</td>
<td>SIRM</td>
<td></td>
<td>FS1</td>
<td>FS0</td>
<td></td>
</tr>
</tbody>
</table>

DIFE : Selects the differential mode.
When this bit is set to "1", general-use I/O port Pins P3-P0 are assigned for differential mode bits.

SDPM : Selects the data bus parity condition.
This bit is set to "0" for odd parity and to "1" for even parity. However, its value is irrelevant if the DPEN bit is set to "0".

DPEN : Enables parity generation/check for the data bus.
If this bit is set to "1", data bus parity signal is input/output via the DP pin.

SIRM : Selects the IRQ signal logic level.
After a hardware reset is performed, the IRQ signal output is positive logic. To change the IRQ signal to negative logic, "1" must be set in this bit.

FS1, FS0 :  
Used to select the CXD1185AQ clock division ratio.
The appropriate values, as shown in the table below, must be written into these bits to match the external clock frequency applied to the CXD1185AQ:

<table>
<thead>
<tr>
<th>Input frequency (MHz)</th>
<th>FS1</th>
<th>FS0</th>
<th>Clock division ratio</th>
</tr>
</thead>
<tbody>
<tr>
<td>16·13</td>
<td>0</td>
<td>0</td>
<td>4</td>
</tr>
<tr>
<td>12·9</td>
<td>0</td>
<td>1</td>
<td>3</td>
</tr>
<tr>
<td>8·5</td>
<td>1</td>
<td>*</td>
<td>2</td>
</tr>
</tbody>
</table>

For the changes made to these bits to be effective, "Chip Reset" command must be executed. Bits FS1 and FS0 are set for a clock division ratio of "4" after a hardware reset.
1-6. SCSI control monitor register (R4 : R)
Current status of all SCSI control signals can be read directly from this register.

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>MBSY</td>
<td>MSEL</td>
<td>MMSG</td>
<td>MCD</td>
<td>MIO</td>
<td>MREQ</td>
<td>MACK</td>
<td>MATN</td>
</tr>
</tbody>
</table>

MBSY : Monitors the SCSI bus BSY signal. Positive logic.
MSEL : Monitors the SCSI bus SEL signal. Positive logic.
MMSG : Monitors the SCSI bus MSG signal. Positive logic.
MCD : Monitors the SCSI bus C/D signal. Positive logic.
MIO : Monitors the SCSI bus I/O signal. Positive logic.
MREQ : Monitors the SCSI bus REQ signal. Positive logic.
MACK : Monitors the SCSI bus ACK signal. Positive logic.
MATN : Monitors the SCSI bus ATN signal. Positive logic.

1-7. Selection/reset timer register (R4 : W)
This register is used to set the selection time out time or the SCSI bus RST drive time.
The real selection time out time can be calculated by the following equation:

\[
\text{TIME} (\mu s) = \frac{\text{Div}}{f_{\text{cyc}}} \times (\text{VAL} + 1) \times 8,192
\]

\( f_{\text{cyc}} \) : Input frequency (MHz)
\( \text{Div} \) : Clock division ratio (See section on Environment setting register)
\( \text{VAL} \) : Value written to the selection/reset timer register

Generally the selection time out time is set to 250ms.
When the selection/reset timer register is used to set the drive time for the RST signal a "1" must be written to mode register bit 4 (TMSL).
The real RST signal drive time can be calculated by the following equation:

\[
\text{TIME} (\mu s) = \frac{\text{Div}}{f_{\text{cyc}}} \times (32 \times \text{VAL} + 38)
\]

\( f_{\text{cyc}} \) : Input frequency (MHz)
\( \text{Div} \) : Clock division ratio (See section on Environment setting register)
\( \text{VAL} \) : Value written to the selection/reset timer register

1-8. FIFO status register (R5 : R)
This register is for monitoring the FIFO status.

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>FIE</td>
<td>FIF</td>
<td>FC3</td>
<td>FC2</td>
<td>FC1</td>
<td>FC0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

FIE : FIFO Empty
Indicates that the FIFO is empty.
FIF : FIFO Full
Indicates that the FIFO is full.
FC3, FC2, FC1, FC0 :
Indicate the number of bytes of data stored in the FIFO.
1-9. SCSI ID register (R6 : R/W)
This register is used to set the SCSI owner ID and the target ID for selection.
The upper three bits in this register have different meanings during reads and writes.

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>SID2</td>
<td>SID1</td>
<td>SID0</td>
<td></td>
<td>OID2</td>
<td>OID1</td>
<td>OID0</td>
<td>(Read)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>TID2</td>
<td>TID1</td>
<td>TIDO</td>
<td></td>
<td>OID2</td>
<td>OID1</td>
<td>OID0</td>
<td>(Write)</td>
</tr>
</tbody>
</table>

SID2, SID1, SID0:
Indicates which device last selected/reselected the CXD1185AQ.

TID2, TID1, TIDO:
The target ID is written to these bits prior to selection.

OID2, OID1, OIDO:
The owner ID is written to these bits.

1-10. Transfer byte counter (high, middle, low) (R9, R8, R7 : R/W)
The 24-bit counter calculates the number of remaining bytes of transfer data during data transfer between
SCSI bus and the CPU bus or data bus. To activate the transfer byte counter, command register bit 4 (TRBE)
must be set when writing to the command register.
When data is output to the SCSI bus, the transfer byte counter is decremented at each rise of the WE or
WED signal. When data is input from the SCSI bus, is decremented at each fall of the ACK signal when in
the initiator mode and at each fall of the REQ signal when in the target mode.

1-11. Interrupt authorization registers 1 and 2 (RA, RB : R/W)
These registers are used to determine on which interrupt the IRQ pin should be activated.
The bit positions in these two registers correspond to the bit positions in the interrupt request registers. The
IRQ pin will be activated if an interrupt bit becomes “1” and the corresponding bit in the interrupt authorization
register is also set to “1”.

1-12. Mode register (RC : R/W)
This register is used for setting the modes of CXD1185AQ.

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>HDPE</td>
<td>HSPE</td>
<td>HATN</td>
<td>TMSL</td>
<td>SPHI</td>
<td></td>
<td>BDMA</td>
<td></td>
</tr>
</tbody>
</table>

HDPE: When this bit is set to “1”, data transfer will be terminated if a parity error is detected on the data
bus during a data transfer. However, this bit is irrelevant if environment setting register bit 5 (DPEN) is
set to “0”.

HSPE: When this bit is set to “1”, data transfer will be terminated if a parity error is detected on the SCSI
bus during a data transfer.

HATN: When this bit is “1” in target mode, data transfer will be terminated if an ATN signal is driven on the
SCSI bus.

TMSL: When this bit is set to “1”, the selection/reset timer register is used to set the duration of the SCSI
bus RST signal.
This bit must not be overwritten with a new value if status register bit 0 (CIP) is set to “1”. If it is
required to drive RST signal when the CIP bit is “1”, first execute “Reset Chip” command, then
overwrite this bit.
When this bit is set to "0", if target changes the phase signal during the execution of a transfer command and the REQ pin is active, interrupt request register 2 bit 4 (PHC) is set immediately. If this bit is set to "1", in the mode in which data is input from the SCSI bus, the PHC bit is not set until all the FIFO contents are transferred to the CPU bus or the DMA bus.

BDMA : Burst DMA mode. When this bit is set to "1", the DRQ pin be "1" for the whole of the DMA transfer.

1-13. Synchronous transfer control register (RD : R/W)
This register is used to set the transfer period and the offset for synchronous transfers.

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>TPD3</td>
<td>TPD2</td>
<td>TPD1</td>
<td>TPD0</td>
<td>TOF3</td>
<td>TOF2</td>
<td>TOF1</td>
<td>TOF0</td>
</tr>
</tbody>
</table>

TPD3, TPD2, TPD1, TPD0 :
Bits used to set the transfer period for synchronous transfers.
The transfer period is designated according to the following equation:

\[
\text{RATE (µs)} = \frac{\text{Div}}{f_{\text{cyc}} \times 2 \times (\text{VAL}+1)}
\]

fcyc : Input frequency (MHz)
Div : Clock division ratio (see section on Environment setting register)
VAL : Value written to TPD3-0
TOF3, TOF2, TOF1, TOF0 :
Bits used to set the offset for synchronous transfers.
The asynchronous transfer mode is selected by writing "0" to all of these bits.

1-14. SCSI bus control register (RE : R/W)
This register is used to control the control signals used by the SCSI bus. Reading this register consists simply of reading the value which was written there previously. However, if the "Assert SCSI Control" command is executed, "0"s will be read out. The "Assert SCSI Control" command must be executed in order to output this register's value to the SCSI bus.

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>ABSY</td>
<td>ASEL</td>
<td>AMSG</td>
<td>ACD</td>
<td>AIO</td>
<td>AREQ</td>
<td>AACK</td>
<td>AATN</td>
</tr>
</tbody>
</table>

ABSY : When this bit is set to "1", the SCSI bus BSY signal is driven.
ASEL : When this bit is set to "1", the SCSI bus SEL signal is driven.
AMSG : When this bit is set to "1", the SCSI bus MSG signal is driven.
However, it is not driven unless CXD1185AQ is in the target mode.
ACD : When this bit is set to "1", the SCSI bus C/D signal is driven.
However, it is not driven unless CXD1185AQ is in the target mode.
AIO : When this bit is set to "1", the SCSI bus I/O signal is driven.
However, it is not driven unless CXD1185AQ is in the target mode.
AREQ : When this bit is set to "1", the SCSI bus REQ signal is driven.
However, it is not driven unless CXD1185AQ is in the target mode.
AACK : When this bit is set to "1", the SCSI bus ACK signal is driven.
However, it is not driven unless CXD1185AQ is in the initiator mode.
AATN : When this bit is set to "1", the SCSI bus ATN signal is driven.
However, it is not driven unless CXD1185AQ is in the initiator mode.
1.15. I/O port (RF: R/W)
This register is used for input/output switching of the general-use 4-bit port and for reading/writing the contents of the port.

<table>
<thead>
<tr>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>PCN3</td>
<td>PCN2</td>
<td>PCN1</td>
<td>PCN0</td>
<td>PRT3</td>
<td>PRT2</td>
<td>PRT1</td>
<td>PRT0</td>
</tr>
</tbody>
</table>

PCN3, PCN2, PCN1, PCN0:
These bits are used for input/output switching of individual bits when Pins P3-P0 are used as a general-use port. When a “1” is written to any of these bits, the corresponding port is set to the output mode.
All these bits are cleared when a hardware reset is performed. Note that first “0” must be written to all these bits before writing a “1” to environment setting register bit 7 (DIFE).

PRT3, PRT2, PRT1, PRT0:
This is the 4-bit I/O port.
The values written to whichever of these four bits have been set to output mode by PCN3-PCN0 are output via Pins P3-P0. By reading these bits it is possible to monitor the values of Pins P3-P0 directly.

2. Command Description
This section gives description of all the commands supported by the CXD1185AQ.
With the exception of “Reset Chip”, the following commands can only be written to the command register when the ClP bit in the status register (bit 0) is “0”.

2.1. Commands valid in any status
The following commands can be issued when the CXD1185AQ is in any of its three statuses: disconnected, initiator or target.
The chip is, at any given time, in one of the three status disconnected, initiator or target. This section is divided into following subsections.
• Commands valid in any status
• Commands valid in disconnected state
• Commands valid in initiator mode
• Commands valid in target mode

• No Operation
This command has no effect on the CXD1185AQ.
However, the FNC bit is set when the command is completed.

• Reset Chip
This command initializes the CXD1185AQ.
Except for the environment setting register, all registers of the CXD1185AQ are cleared. If the clock division ratio is changed in the environment setting register, this command must be executed.
This command can be executed regardless of the value of the CIP bit.

• Assert RST
This command drives the SCSI bus RST pin.
When this command is executed, interrupt request register 2 bit 5 (SRST) is set and an interrupt is generated. The SCSI RST signal is active for 25 µs. However, if the RST signal drive duration needs to be changed, it is necessary to set mode register bit 4 (TMSL) to “1” and write the drive duration to the selection/reset timer register before executing this command.

• Flush FIFO
Initializes FIFO.
• Assert SCSI Control
  Outputs the value of the SCSI bus control register to the SCSI bus.
  In initiator mode ACK and ATN signals can be asserted.
  In target mode REQ, MSG, C/D and I/O signals can be asserted.
  This instruction is only needed in program I/O transfer.
  On program I/O, see 5-1.

• Deassert SCSI Control
  Prohibits the content of the SCSI bus control register from being output to the SCSI bus.
  Once the “Assert SCSI Control” command is executed, some of the SCSI bus control signals are output from the SCSI bus control register until this command is executed.

• Assert SCSI Data
  Outputs the value of the SCSI data register to the SCSI bus.
  However, data is not output in the following circumstances:
  i) A phase change interrupt (PHC) is generated in initiator mode.
  ii) In initiator receive mode (SCSI bus I/O signal is high).
  iii) In target receive mode (SCSI bus I/O signal is low).
  iv) The mode is neither initiator nor target.
  This instruction is only needed in program I/O transfer.
  On program I/O, see 5-1.

• Deassert SCSI Data
  Prohibits the value of the SCSI data register from being output to the SCSI bus.
  Once the “Assert SCSI Data” command is executed, the SCSI bus data signals are output from the SCSI data register until this command is executed.

2.2. Commands valid in disconnected status
The following commands are valid only in disconnected status. If any of these commands are issued in any other state, the CIP bit and the content of the command register are cleared immediately.

• Reselect
  This command executes arbitration/reselection from disconnected status.
  When this command is executed, the CXD1185AQ switches to the target mode.
  Before issuing this command, the owner ID (OID 2-0) and target ID (TID 2-0) values must be written in the SCSI ID register.

• Select without ATN
  This command executes arbitration/selection from disconnected status.
  When this command is executed, the CXD1185AQ switches to the initiator mode. Before issuing this command, the owner ID (OID 2-0) and target ID (TID 2-0) values must be written in the SCSI ID register.

• Select with ATN
  This command executes arbitration/selection from disconnected status.
  During selection the ATN signal is driven on the SCSI bus.
  When this command is executed, the CXD1185AQ switches to the initiator mode. Before issuing this command, the owner ID (OID 2-0) and target ID (TID 2-0) values must be set in the SCSI ID register. If, after this command is executed, message-out phase is to be terminated, the “Deassert ATN” command must be executed prior to the transfer of the last message byte.
**Enable Selection/Reselection**
Activates selection/reselection interrupts.
When this command is executed, the FNC bit is set immediately and the contents of the CIP bit and command register are cleared. Once this command is executed, RSL/SWA/SWOA interrupts (in interrupt request 1 register) are set during selection/reselection phase. When one of the selection/reselection is executed this will occur before the FNC interrupt.

Selection/reselection is also enabled after the following events.
- Hardware reset
- Execution of “Reset Chip”
- Assertion of SCSI bus RST signal
- Disconnect in initiator mode

**Disable Selection/Reselection**
Prohibits any response to selection/reselection.
Once this command is executed, the RSL/SWOA/SWA interrupts in interrupt request register 1 will not be generated.

### 2-3. Commands valid in target status
The following commands are valid only in target status.
If any of these commands are issued in any other state, the CIP bit and the Content of the command register are cleared immediately.
In the case of data send commands, the transfer data must not be written before the command is written in the command register and the necessary SCSI phase change is confirmed by software. In target mode, handshaking on the SCSI bus is terminated under the following conditions:

1. The REQ signal is in any state and if:
   - a hardware reset is performed.
   - the “Reset Chip” command is executed.
   - the SCSI bus RST pin is driven.

2. The command completes with REQ inactive if:
   - a parity error is generated on the SCSI bus or the data bus. (However, this is not the case if the mode register HDPE and HSPE bits are set to “0”.)
   - the SCSI bus ATN signal is driven. (However, this is not the case if the mode register HATN bit is set to “0”.)
   - while the transfer byte counter is in use:
     - the DMA bit is set to “1”, the status register TRBZ bit is set to “1” and the FIFO status register FIE bit is set to 1, or in receive mode, the DMA bit is set to “0” and the status register TRBZ bit is set to “1”.
     - While executing a single byte transfer:
       - the mode is send and the FIE bit is set to “1”,
       - or the mode is receive and FIFO status register bits FC3-FC0 are all set to “1”.

3. Handshaking is temporarily interrupted with REQ inactive if:
   - while the transfer byte counter is in use:
     - the mode is send and the FIFO status register FIE bit is set to “1”,
     - or the mode is receive and the FIFO status register FIF bit is set to “1”.
   - during synchronous transfer, the difference in the number of REqs and ACKs reaches the offset specified in the synchronous transfer register.
   - the mode is receive, during synchronous transfer, the number of FIFO bytes remaining is fewer than the offset specified in the synchronous transfer register.
• Send Message
The CXD1185AQ changes the phase to Message In by making the SCSI bus MSG and I/O signals active and the C/D signal inactive. The message bytes are then sent.
If there is more than one message byte or if the message must be sent all at once, the transfer byte counter must be used.

• Send Status
The CXD1185AQ changes the phase to Status and sends the status byte to the initiator.
It makes the SCSI bus I/O and C/D signals active and the MSG signal inactive.

• Send Data
The CXD1185AQ changes the phase to Data In and sends the data bytes to the initiator.
It makes the SCSI bus I/O signal active and MSG and C/D signals inactive.
If more than one data byte must be sent all at once, the transfer byte counter must be used.

• Disconnect
Makes all SCSI signals inactive, except for the RST signal.

• Receive Message Out
The CXD1185AQ changes the phase to Message In and receives the message bytes from the initiator.
It makes the SCSI bus MSG signal active and the I/O and C/D signals inactive.
If there is more than one message byte or if the message must be received all at once, the transfer byte counter must be used.

• Receive Command
The CXD1185AQ changes the phase to Command and receives the command bytes from the initiator.
It makes the SCSI bus C/D signal active and the MSG and I/O signals inactive.
If the command bytes must be received all at once, the transfer byte counter must be used.

• Receive Data
The CXD1185AQ changes the phase to Data Out and receives the data bytes from the initiator.
It makes the SCSI bus MSG, C/D and I/O signals inactive and received the data bytes.
If more than one data byte must be received all at once, the transfer byte counter must be used.

2.4. Commands valid in initiator status
The following commands are valid only in initiator status.
If any of these commands are issued in any other state, the CIP bit and the content of the command register are cleared immediately.
In the case of data send commands, the transfer data must not be written before the command is written in the command register.
Once the execution of a transfer command is commenced in initiator mode, handshaking on the SCSI bus is terminated under the following conditions:

1. The ACK signal is in any status and if:
   o a hardware reset is performed.
   o the "Reset Chip" command is executed.
   o the SCSI bus RST pin is driven.

2. The command completes with ACK inactive if:
   o phase change occurs and PHC bit in interrupt request register 2 is set to "1".
     If this is the case and the DMA bit is set to "1", the DRQ signal also remains inactive.
   o while the transfer byte counter is in use:
     the DMA bit is set to "1", the status register TRBZ bit is set to "1" and the FIFO status register FIE
bit is set to 1, or in receive mode, the DMA bit is set to “0” and the status register TRBZ bit is set to “1”.

- while executing a single byte transfer:
  - the mode is send and the FIE bit is set to 1,
  - or the mode is receive, FIFO status register FIE bits FC3-FC0 are all set to “1”.

3. The command completes with ACK active if:
   - the mode is receive and a parity error occurs on the SCSI bus. (However, this is not the case if the mode register HSPE bit is set to “0”.)
   - status is message-in phase, the TRBE bit is set to “0”, the REQ signal is active and a 1-byte message is received.
   
   Note that in the above two cases the “Deassert ACK” command must be executed afterwards.

4. Handshaking is temporarily interrupted with ACK inactive if:
   - while the transfer byte counter is in use:
     - the mode is send and the FIFO status register FIE bit is set to “1”.
   - during synchronous transfer, the difference in the number of REQs and ACKs reaches the offset specified in the synchronous transfer register.
   - during synchronous transfer, the number of FIFO bytes remaining is fewer than the offset specified in the synchronous transfer register.

5. Handshaking is temporarily interrupted with ACK active if:
   - while the transfer byte counter is in use:
     - the mode is receive and the FIFO status register FIF bit is set to “1”.

• Transfer Information
  In the initiator mode, causes data transfer to take place.

• Transfer Pad
  In the initiator mode, causes data transfer to take place.

  Note that unlike “Transfer Information”, the data output by the CXD1185AQ are all “0”'s and parity generation is not performed.

  In addition, no parity check is performed on any data input to the CXD1185AQ.

  Except for these two exceptions, this command is identical to the “Transfer Information” command.

• Deassert ACK
  Makes the SCSI ACK signal inactive.

• Assert ATN
  Makes the SCSI ATN signal active.

• Deassert ATN
  Makes the SCSI ATN signal inactive. After executing the “Select with ATN” or “Assert ATN” command, the SCSI bus ATN signal remains active until this command is executed.

3. Reset Operation
There are four initializing methods for the CXD1185AQ:

• hardware reset
• execution of the “Reset Chip” command
• assertion of RST signal on the SCSI bus
• disconnection
3-1. Hardware reset
This returns the CXD1185AQ to its initial status. However, environment setting register bit 1 (FS1) is set to "1", making the initial clock division ratio to "4". All of the internal circuits are also initialized.

3-2. Execution of the "Reset Chip" command
CXD1185AQ can be initialized by "Reset Chip" command (command code "01"). This command is effective regardless of the CIP bit in the status register. This command resets all registers with the exception of the environment setting register. All read only registers except for bits 7 and 6 of the status register and the SCSI control monitor register are cleared. Since the "Reset Chip" command clears all write registers, any SCSI bus signal it used to drive will also be cleared.

3-3. Assertion of RST signal on the SCSI bus
When the SCSI bus RST signal is active, signals on the SCSI bus being driven by the CXD1185AQ are made inactive with the exception of the RST pin. Bits 4 and 3 (INIT and TARG bits) are also cleared.

3-4. Disconnection
If the CXD1185AQ is operating in initiator mode and a disconnect interrupt is generated, a reset identical to the one in 3-3 takes place.

4. Interrupt Operation
In this section various interrupts, generated by the CXD1185AQ, are discussed in greater detail. If the internal interrupt conditions of the CXD1185AQ are satisfied, "1"s are written to the appropriate bits in interrupt request registers 1 and 2 and the MIRQ bit in the status register. IRQ pin becomes active only if the interrupt is authorised in the interrupt authorization registers.

4-1. Arbitration interrupts
When a selection command is executed, the CXD1185AQ waits for bus free. Once bus free is detected it outputs the BSY signal and the owner ID to the SCSI bus and enters arbitration. If, during arbitration, another device with higher priority enters arbitration or if the SEL signal is driven on the SCSI bus, arbitration fails and ARBF is set to "1". The FNC bit is also set a while later. If arbitration is successful it enters selection phase.

4-2. Interrupts when selected/reselected
After "Enable Selection / Reselection" is executed, if the owner ID and the SEL signal appear on the SCSI bus, SWOA bit is set to "1". If ATN signal also appear at the same time, SWA bit is set instead. If I/O signal appears instead of ATN signal, then, RSL is set.

4-3. Interrupts when selection/reselection command is executing
CXD1185AQ enters arbitration and after obtaining the right to use the SCSI bus it enters selection/reselection phase by sending the target ID, the owner ID and SEL signal onto the bus. At this point, the value of the selection/reset timer register is loaded into the hardware timer (not user accessible) and decrementing begins. Note that TMSL bit in the mode register must be "1" for the loading to take place. If there is no response from the target device by the time the hardware timer reaches "0", selection time over occurs and the STO bit is set to "1" and, afterward, the FNC bit is set to "1".
4.4. Data transfer phase interrupts

- The RMSG and PHC bits are valid interrupts only when INIT bit (status register bit 4) is set to “1”. Also, the DATN bit is valid only when the TARG bit (status register bit 3) is set to “1”. The SPE and OPE bits are valid both in initiator and target modes.
- The RMSG bit is set to “1”, if, in initiator mode, the target device activates REQ after changing the SCSI bus phase to either Message-In or Message-Out. If the message is of multiple byte, it is set each time REQ is activated.
- The PHC bit is set to “1”, if, in initiator mode, the target device activates REQ after changing the SCSI bus phase. If the new phase is either Message-In or Message-Out, RMSG bit is also set to “1”.
- The DATN bit is set to “1”, if, in target mode, the initiator asserts ATN on the SCSI bus. Once the interrupt request register 2 is read by the CPU the bit is cleared even if ATN continues to be active.
- The SPE bit is set when a parity error is detected on the SCSI bus during receive mode data transfer in both initiator and target mode. In initiator mode, it is set on receiving the REQ. In target mode it is set on receiving the ACK. The SPE bit is also set if parity error is detected during selection/reselection.
- DPE bit is set when a parity error is detected on the data bus while writing data into FIFO. It is set at the rise of the FIFO write signal, WED. This bit is valid only if the DPEN bit in the environment setting register is set to “1”. If the SDPM bit in the environment register is “1”, even parity check is carried out. Otherwise odd parity check is carried out.

4.5. Other interrupts

- The SRST bit is set to “1” when the SCSI bus RST signal becomes active. It is also set if the “Assert RST” command is executed and the CXD1185AQ drives the RST pin.
- The DCNT bit is set to “1” if the CXD1185AQ is operating in the initiator mode and the target device makes the BSY signal on the SCSI bus inactive. Normally, in initiator mode, this bit is set at the end of a series of SCSI operation when the SCSI bus phase becomes bus free.

5. Data Transfer

In this section procedures for transferring data to and from the CXD1185AQ is described. Data can be transferred between the CPU and the CXD1185AQ in the following three ways:

1. Program I/O transfer
2. CPU I/O transfer
3. DMA transfer

5.1. Program I/O transfer

This method is used to transfer data between the CPU bus and the CXD1185AQ. The CPU manages SCSI handshaking entirely through software. By issuing the “Assert SCSI Control” and “Assert SCSI Data” commands, all of the SCSI bus bits can be software controlled. After the above two commands are issued, values can be written to the SCSI bus control register and the SCSI data register to carry out the SCSI handshake.

When the “Assert SCSI Data” command is issued, the CXD1185AQ internal FIFO counter is fixed at “0”. As a result, only one byte of data can be received by the data register. Reading the SCSI data register results in reading the SCSI data bus directly. If the CXD1185AQ is in neither initiator nor target mode (status register bits 4 and 3 both set to “0”), none of the bits in the SCSI bus control register can be output to the SCSI bus except ABSY and ASEL. If the CXD1185AQ is in initiator mode, the AACK and AATN bits are output to the SCSI bus. In the target mode, the AMSG, ACD, AIO and AREQ bits are output.

When phase change (PHC) interrupt occur in initiator mode, output to the SCSI data bus is inhibited. In such case, read the SCSI control monitor register and watch the phase in the SCSI control register with that of the SCSI bus. When “Assert SCSI Control” instruction is executed in target mode, pins on the SCSI bus, except BSY, are released.
The phase can be controlled by setting appropriate values to the SCSI bus control register. The contents of the SCSI control register and/or SCSI data register are output continually after "Assert SCSI Control" and/or "Assert SCSI data". Therefore, when program I/O transfer is completed the "Deassert SCSI Control" or "Deassert SCSI Data" command must be written to the command register.

5-2. CPU I/O transfer
This method is used to transfer data between the CPU bus and the CXD1185AQ without using DMA. Transfer commands can be issued when the CPU is in either the initiator or the target mode. When issuing these commands, command register bit 5 (DMA) must be set to "0".

• Outputting data to the SCSI bus
During the transfer, the CPU must monitor the FIFO status and make sure that it does not attempt to write to the FIFO when it is full (FIFO is full when F1F bit in the FIFO status register is "1") (*). In target mode, after issuing the transfer command, the CPU must check that the SCSI bus phase is changed to the appropriate phase, by software, before any transfer data is written.

(*) Before writing a value to the data register a transfer command must be written to the command register.

• Reading data from the SCSI bus
After a transfer command is written to the command register, the CPU must monitor the FIE bit in the FIFO status register so as to make sure that it does not attempt to read an empty FIFO. The CPU must monitor the FNC bit in the status register to detect the end of transfer. The CPU, at the end of the transfer, must continue to read any remaining data in the FIFO.

5-3. DMA transfer
This method is used to transfer data between the Data bus and the CXD1185AQ. Transfer commands can be issued when the CPU is in either the initiator or the target mode. When issuing commands command register bits 5 (DMA) and 4 (TRBE) must be set to "1". When a transfer is initiated the DRQ pin (Pin 43) becomes active. Then, when the DACK pin (Pin 44) becomes active, the DRQ pin becomes inactive (when mode register bit 0 (BDMA) is set to "0") and one byte of data is either written to or read from the FIFO. If the environment setting register bit 5 (DPEN) is set to "1", the data bus parity is calculated from the DP pin (Pin 55). During reads the parity bit is generated, and during writes parity bit check takes place. During DMA transfer, the CPU bus and data register are cut off. Hence, data register reads/writes from the CPU are ignored.

6. Programming Overview
The CXD1185AQ supports SCSI phase level commands. As a result, when it is operating it is possible to perform programming without imposing a burden on the software. In this section actual methods for programming CXD1185AQ are introduced along with an explanation of all SCSI phases, assuming that the CXD1185AQ is in the initiator mode.

< Initial settings >
The CXD1185AQ is completely initialized when the power is turned on or after a hardware reset. Therefore, the following initial settings must be performed.

① Environment setting register initialization
The environment setting register is set to an initial value and initial clock division ratio of "4". Therefore, a new appropriate value must be written to match the external clock frequency as described in section 1-5. If required, "1"s must be written to the other bits at the same time.
２ "Reset Chip" command execution
The new clock division ratio becomes valid only after executing the "Reset Chip" command. (The other bits are valid as soon as they are written.) Therefore, if the clock division ratio is to be changed, the "Reset Chip" command must be executed after changing the FSI and FSO bits in the environment setting register.

＜Arbitration/selection execution＞

３ SCSI ID setting
The owner ID and target ID must be written to the SCSI ID register to prepare for selection.

４ Arbitration/selection
Write "1"s to some of the bits of interrupt authorization registers 1 and 2 (ARBF, STO, FNC, etc.) as required. Write "Select with ATN" command into the command register. If message-out phase is not necessary after selection, instead, write "Select without ATN" command. In this example "Select with ATN" is assumed. Wait for the CIP bit in the status register to become "1" and read the interrupt request registers.
If arbitration failed and ARBF bit is "1", repeat ４. Normally, if selection time over occurs and STO bit set to "1", "Assert RST" command is executed.

＜Message-out phase execution＞

５ Switching to the message-out phase
Wait until the target device switches the SCSI bus to the message-out phase (PHC bit set to "1").

６ Halting ATN signal drive
Execute "De-assert ATN" command to inactivate the ATN signal on the SCSI bus.

７ Sending message byte
Confirm that the CIP bit is "0" in the status register. Write "Transfer Information" command to the command register (DMA bit and TRBE bit are set to "0"s for a single byte message). Write the message byte into the SCSI data register. After confirming that the CIP bit is to "0", read interrupt request registers 1 and 2.

＜Command phase execution＞

８ Switching to the command phase
Wait until the target device switches the SCSI bus to the command phase (PHC bit set to "1").

９ Command send
Set the number of command bytes in the transfer byte counter. Write "Transfer Information" command into the command register. (this time set the TRBE bit to "1" and DMA bit to "0"). Write the command bytes into the SCSI data register. After confirming that the CIP bit is set to "0", read interrupt request registers 1 and 2.
< Data-in phase execution >

10. Switching to the data-in phase
  Wait until the target device switches the SCSI bus to the data-in phase (PHC bit set to “1”).

11. Data receive
  Set the number of transfer data bytes in the transfer byte counter. Write “Transfer Information” command into the command register (with both DMA bit and TRBE bit set to “1”). Note that programming of DMA controller is also required before starting DMA transfer. After confirming that the CIP bit is set to “0”, read interrupt request registers 1 and 2.

< Status phase execution >

12. Switching to the status phase
  Wait until the target device switches the SCSI bus to the status phase (PHC bit set to “1”).

13. Status receive
  Write “Transfer Information” command in the command register (both DMA bit and TRBE bit are “0”). After confirming that the CIP bit is set to “0”, read interrupt request registers 1 and 2. The status byte is read from the data register.

< Message-in phase execution >

14. Switching to the message-in phase
  Wait until the target device switches the SCSI bus to the message-in phase (PHC bit set to “1”).

15. Message receive
  Write “Transfer Information” command in the command register (both DMA bit and TRBE bit are “0”). After confirming that the CIP bit is set to “0”, read interrupt request registers 1 and 2. The message byte is read from the data register.

16. Halting ACK signal drive
  Message-In is exceptional in that after the message byte is read, ACK is not inactivated automatically. “Deassert ACK” command must be executed to inactivate ACK signal.
  Write “Deassert ACK” command in the command register. After confirming that the CIP bit is “0”, read the interrupt request registers.

< Disconnect >

17. Wait until the DCNT bit is set to “1”.
  All SCSI phases are covered in 1 - 17 above. If a disconnect message is sent from the target device when in the data phase, the status phase is skipped and processing continues with the message in phase. When reselection is performed from the target device (RSL bit set to “1”), it is necessary to wait until the FNC bit is set to “1”. Then read the monitor SCSI control register and perform the processing appropriate for the current SCSI phase.

< * > Don’t care.

However, if the DMA bit is set to "1", the TRBE bit is always also set to "1".
Package Outline  Unit: mm

64pin QFP (Plastic)  1.5g

SONY®
CXD1185AQ

- 412 -
CD-ROM Decoder

Description
CXD1186Q is a CD-ROM decoder LSI.

Features
• Corresponds to CD-ROM, CD-I and CD-ROM XA formats.
• Real time error Correction. (Erasure Correction using C2 pointer from CD player.)
• Double speed playback.
• Connection to standard SRAM up to 64K bytes, as buffer memory, possible.

Applications
CD-ROM driver

Structure
Silicon gate CMOS IC

Absolute Maximum Ratings (Ta=25°C)
- Supply voltage $V_{DD}$ -0.5 to +7.0 V
- Input voltage $V_I$ -0.5 to $V_{DD} + 0.5$ V
- Output voltage $V_O$ -0.5 to $V_{DD} + 0.5$ V
- Operating temperature $T_{opr}$ -20 to +75 °C
- Storage temperature $T_{stg}$ -55 to +150 °C

Recommended Operating Conditions
- Supply voltage $V_{DD}$ +4.5 to +5.5 (standard +5.0) V
- Operating temperature $T_{opr}$ -20 to +75 °C

Description of Function
1. Pin description
   Below is a description of pins by function.

1.1 CD player interface (4 pins)
   (1) DATA (input)
       Serial data from CIRC LSI (digital signal processing LSI for CD)
   (2) BCLK (input)
       Bit clock. Clock for DATA Strobe.
   (3) LRCK (input)
       LR clock. Indicates $L_{CH}$ and $R_{CH}$ of Data input.
   (4) C2PO (positive logic input)
       C2 pointer signal from CIRC. Indicates an error is included in the Data input.
       Interface mode with the CD player is controlled at DRVIF register.

1.2 Buffer memory interface (27 pins)
   (1) XMWR (memory write, negative logic output)
       Data write strobe signal of the buffer memory.
   (2) XMOE (memory output enable, negative logic output)
       Data read strobe signal of the buffer memory.
   (3) BAO to 15 (Buffer memory address, output)
       Address signal of the buffer memory.
   (4) BDB0 to 7 (Buffer data bus, I/O)
       Data bus signal of the buffer memory.
   (5) BDBP (Buffer data bus, I/O)
       Buffer memory data bus signal for error pointer.

1.3 CPU interface (16 pins)
   (1) XWR (CPU write, negative logic input)
       Write strobe signal of the CPU register.
   (2) XRD (CPU read, negative logic input)
       Read out strobe signal of the CPU register.
   (3) XCS (CPU chip select, negative logic input)
       Chip select negative logic signal from the CPU.
   (4) A0 to 3 (CPU address, input)
       Address signal for the CPU selection of the IC internal register.
   (5) DBO to 7 (CPU data bus, I/O)
       CPU data bus signal.
   (6) INT (CPU interrupt, output)
       Interrupt request output to the CPU. This pin polarity is controlled at the CONFIG register.

1.4 Host interface (19 pins)
   (1) HMDS (Host mode select, input)
       Signal for the host mode selection. This pin is pulled down inside the IC by means of a resistor at a standard 50kΩ.
       "L" or open: connected to Intel 80 type host Bus.
       "H": connected to SCSI controller IC.
   (2) HDRQ/XSAC (Host data request/SCSI acknowledge, output)
       When HMDS is at "L", DMA data request positive logic signal to host.
       When HMDS is at "H", DMA acknowledge negative logic signal to SCSI control IC.
(3) XHAC/SDRQ (Host DMA acknowledge/SCSI data request, input)
When HMDS is at “L”, DMA acknowledge negative logic signal from host.
When HMDS is at “H”, DMA data request positive logic signal from SCSI control IC.

(4) XHWR (Host write, negative logic I/O)
When HMDS is at “L” and ADMAEN also at “L”, data write strobe input from host.
When HMDS is at “H” and ADPCMEN at “L”, data write strobe output to SCSI control IC.
When ADMAEN is at “H”, data write strobe output to audio processor (ADP).

(5) XHRD (Host read, negative logic I/O)
When HMDS is at “L” and ADMAEN also at “L”, data read strobe input from host.
When HMDS is at “H” and ADMAEN at “L”, data read strobe output to SCSI control IC.
When ADMAEN is at “H”, data read strobe output to ADP.

(6) XHCS (Host chip select, negative logic input)
This pin is pulled up inside the IC by means of a resistor at a standard 50kΩ.
When HMDS is at “L”, chip select input from host.
When HMDS is at “H”, this signal is not used. Either fix to “H” or keep open.

(7) HAO and 1 (Host address, input)
These pins are pulled up inside the IC by means of a resistor at a standard 50kΩ.
When HMDS is at “L”, address input from the host.
When HMDS is at “H”, these signals are not used. Either fix to “H” or keep open.

(8) HDB0 to 7 (Host data bus, I/O)
Host data bus signal.

(9) HDBP (Host data bus, I/O)
Host data bus signal for error pointer.

(10) HINT (HOST interrupt, output)
This pin is an open drain output.
When HMDS is at “L”, interrupt request negative logic output to host.
When HMDS is at “H”, this signal is not used.

(11) XTC (Terminal count, negative logic output)
This is pulled up inside the IC by means of a resistor at a standard 50kΩ.
When HMDS is at “L”, data transfer complete instruction negative logic input from the host.
When HMDS is at “H”, this signal is not used. Either fix to “H” or keep open.

1.5 Audio processor (ADP) interface (2 pins)
(1) ADRQ (audio processor DMA request, positive logic input)
This pin is pulled down inside the IC by means of a resistor at a standard 50kΩ.
DMA data request signal to ADP. When not connected to ADP and CXD1186Q, either fix to “L” or keep open.

(2) XAAC (audio processor DMA acknowledge, negative logic output)
DMA acknowledge signal from ADP.

1.6 Others (4pins)
(1) XTL1 (Crystal1, input)
(2) XTL2 (Crystal2, output)
Crystal oscillator connecting pin for master clock oscillation.
(3) HCLK (halfclck, output)
Half frequency divided clock of the master clock.
(4) XRST (Reset, negative logic input)
Chip reset signal.

Pins BDB0 to 7, DBP to 7, HDB0 to 7 and HDBP are pulled up inside the IC by means of a resistor at a standard 25kΩ.
2. Register function

This IC is controlled from the CPU by means of 19 registers for each of write and read, respectively.

2.1 Write register

2.1.1 Drive Interface (DRVIF) register

<table>

(Note 1) * at normal speed PB set to “L”, at double speed PB set to “H”.
(Note 2)

CDL30 series  CXD1125Q/QZ, CXD1130Q/QZ, CXD1135Q/QZ, CXD1241Q/QZ, CXD1245Q, CXD1246Q/QZ, CXD1247Q/QZ/R and others.
CDL35 series  CXD1165Q, CXD1167Q/QZ/R and others.
CDL40 series  CXD2500Q/QZ and others.

2.1.2 Decoder Control (DECCTL) register

bit0 to 2:  DECMDSL2, 1, 0
(Decoder Mode Select 2, 1, 0)

DECMDSL2  1  0
“L” “L” “X”  Decoder disable
“L” “H” “X”  Monitor only mode
“H” “L” “L”  Write only mode
“H” “L” “H”  Real time correction mode
“H” “H” “L”  Repeat correction mode
“H” “H” “H”  CD-DA mode

bit3 : AUTODIST (Auto Distinction)
“H” : Error Correction performed according to the Mode byte and FORM bit read from Drive.
“L” : Error Correction is performed according to the following MODESEL and FORMSEL bits.

bit4 : FORMSEL (Form Select)
bit5 : MODESEL (Mode Select)
When AUTODIST is at “L” the sector is corrected as the following MODE or FORM.

MODESEL  FORMSEL
“L” “L” MODE1
“H” “L” MODE2, FORM1
“H” “H” MODE2, FORM2

bit6 : ECCSTR (ECC Strategy)
“H” : Error correction is performed with consideration to respective data error flag.
“L” : Error correction is performed without consideration to respective data error flag. When an 8bit/Word RAM is connected, turn this bit to “L”.

bit7 : ENDLADR (Enable DLADR)
“H” : When this bit is set to “H”, DLADR is enabled.
When, either write only mode, real time correction, or CD-DA mode is being executed, the decoder stops the buffer write as DADRC and DLADR turn equal.
"L" ; When this bit is set to "L", DLADR is disabled.
During the execution of write only mode or real time corection, even if DADR and DLADR turn
equal, the decoder does not stop buffer write.
(See paragraph 4 for details)

2.1.3 DMA Control (DMACCTL) register

bit0 : HSRC (Host Source)
"H" ; Data is transferred from the host to the buffer memory.
"L" ; Data is transferred from the buffer memory to the host.

bit1 : HDMAEN (HOST DMA Enable)
"H" ; DMA of the host port is enabled.
"L" ; DMA of the host port is prohibited.

bit2 : ENXTC (Enable XTC)
"H" ; DMA completion of the host port through XTC pin input is enabled.
"L" ; DMA completion of the host port through XTC pin input is disabled.

bit3 : ENHFRRC (Enable XFRRC)
"H" ; DMA Completion of the host port through HFRRC is enabled.
"L" ; DMA completion of the host port through HFRRC is disabled.

bit4 : ADMAEN (ADP DMA Enable)
"H" ; DMA of the audio processor port is enabled.
"L" ; DMA of the audio processor port is prohibited.
Also, prohibits turning HDMAEN and ADMAEN simultaneously to "H".

bit5 : CSRC (CPU Source)
"H" ; Data is transferred from the CPU to the buffer memory.
"L" ; Data is transferred from the buffer memory to the CPU.

bit6 : CDMAEN (CPU DMA Enable)
"H" ; DMA of the CPU port is enabled.
"L" ; DMA of the CPU port is prohibited.

bit7 : RESERVED
Unused, Keep set to "L".

2.1.4 Configuration (CONFIG) register

bit0 : RESERVED
Unused, Keep set to "L".

bits 1 and 2 : SDMACYCl, 0 (SCSI DMA CYCLE)
DMA transfer between this IC, SCSI control IC and ADPCM processor is executed in the following cycle.

SDMACYCl 0
"L" "L" 3 cycle.
"L" "H" 4 cycle,
"H" "X" 5 cycle,

bit3 : SBSCTL (SCSI Bus Control)
Setting this bit to "H" forces XHWR, XHRD, HDBO to 7 and HDBP into high impedance condition.

bit4 : CINTPOSI (CPU Interrupt Positive)
"H" ; INT pin turns to High active.
"L" ; INT pin turns to Low active.

bit5 : 9 BITRAM
"H" ; When a 9 bit/word RAM is connected, this bit is turned to "H".
"L" ; When a 8 bit/word RAM is connected, this bit is turned to "L".

bits 6 and 7 : RESERVED
Unused, Keep set to "L".
2.1.5 Interrupt Mask (INTMSK) register

Turning the respective bits of the register to "H" enables interrupt request from this IC to the CPU by means of the corresponding interrupt status (That is, When interrupt status is turned on, INT pin is activated) The value of the respective bits in this register does not affect the corresponding interrupt status.

- bit0 : DECINT (Decoder Interrupt)
  When the Decoder is executing one of the respective modes, write only, monitor, or real time correction, if Sync mark is detected or introduced, DECINT status is turned on. However, When Sync detection window is open, if sync interval is less than 2352 byts, Decint status is not turned on.
  Also, when Decoder repeat correction mode is being executed, everytime one correction is completed DECINT status is turned on.

- bit1 : HDMACMP (Host DMA Complete)
  When DMA of the host port is completed through HXFRC or XTC pins, HDMACMP status is turned on.

- bit2 : DRVOVRN (Drive Over Run)
  When ENDLADR bit (bit7) of DECC TL register is set to "H", and the DECODER has executed write only, real time correction mode or CD-DA mode, as DADRC and DLADR become equal, DRVOVRN status is turned on.
  However, in CD-DA mode, even when ENDLADR bit is turned to "L", DRVOVRN status is turned on.

- bit3 : HSTCMND (Host Command)
  As the host writes a command in the Command register, HSTCMND status is turned on.

- bit4 : HCRISD (Host Chip Reset Issued)
  By having the host write "H" in CHPRST bit (bit7) of the Control register, this IC is reset and HCRISD status is turned on.

- bit5 : RSLTEMPT (Result Empty)
  The host reads the Result register, As the Result register becomes empty RSLTEMTS status turns on.

- bit6 : DECTOUT (Decoder Timeout)
  After setting the Decoder to either, monitor only, write only or real time correction modes, if, even after sector 3 time (normal speed PB 40.6ms) passes, sync is not detected, DECTOUT status is turned on.

2.1.6 Clear Interrupt Status (INTCLR) register

When any of the respective bits of this register is set to "H", the corresponding interrupt status is cleared. After the interrupt status clearance, the bit automatically turns to "L". Accordingly there is no need for the CPU to set to "L" again.

- bit0 : DECINT (Decoder Interrupt)
- bit1 : HDMACMP (Host DMA Complete)
- bit2 : DRVOVRN (Drive Over Run)
- bit3 : HSTCMND (Host Command)
- bit4 : HCRISD (Host Chip Reset Issued)
- bit5 : RSLTEMPT (Result Empty)
- bit6 : DECTOUT (Decoder Timeout)

2.1.7 Drive•Last•Address register Low (DLADR-L)

2.1.8 Drive•Last•Address register High (DLADR-H)

When the Decoder is executing either of write only, real time correction mode or CD-DA mode, CPU sets the last address that writes into the buffer, data from the drive. When ENDLADR bit of DECC TL register is set to "H" and the Decoder is executing the above modes, if data from the drive is written into the buffer at the address specified from DLADR, all writing into the buffer is prohibited after that.
2.1.9 Drive Address Counter Low (DADRC-L)

2.1.10 Drive Address Counter High (DADRC-H)

This counter keeps the address that writes data from the drive into the buffer. When drive data is written into the buffer, DADRC contents is output from BA0 to 15. For every byte written in the buffer, DADRC is incremented. Before the Decoder executes either write only, real time correction mode or CD-DA mode, CPU sets the buffer write head address to DADRC.

This counter can also be used as the DMA address of the CPU port. During DMA execution of the CPU port, DADRC contents is output from BA0 to 15, DADRC is incremented at every byte of DMA execution.

CPU can read or set DADRC contents at any time. Do not alter DADRC contents during either write only, real time correction or CD-DA mode and the DMA execution of CPU port.

2.1.11 Host Address Counter Low (HADRC-L)

2.1.12 Host Address Counter High (HADRC-H)

This counter keeps the address that writes data from the host into the buffer or reads from the buffer. During execution of the host port DMA, HADRC contents are output from BA0 to 15. The counter is incremented at every DMA of the host port.

Before execution of the host port DMA, CPU sets the DMA head address to HADRC.

CPU can read or set HADRC contents at any time. Do no alter HADRC contents during host port DMA execution.

2.1.13 Host Transfer Counter Low (HXFRC-L)

2.1.14 Host Transfer Counter High (HXFRC-H)

This counter indicates the number of host port DMA transfers. It is decremented at every host port DMA. When ENHXFRC bit (bit3) of DMACCTL register is set to "H" and HXFRC value turns to 0, the host port DMA is disabled. At that time it is possible to send an interrupt request from this IC to the CPU.

CPU can read and set HXFRC contents at any time. Do not alter HXFRC contents during Host port DMA execution.

2.1.15 Chip Control (CHPCTL) register

<table>
<thead>
<tr>

</tr>
<tr>
<td>4-7</td>
<td>Do not fail to set to &quot;L&quot;. If set to &quot;H&quot; IC operation is not guaranteed.</td>
</tr>
</tbody>
</table>

2.1.16 CPU Buffer Write Data (CPUBWDT) register

With the CPU port DMA (buffer and write), data is written into this register. When CDMAEN of DMACCTL register=CSRC="H", write into this register is subject to the request of CPU port DMA (buffer write). See paragraph 6 for details.
2.1.17 Host Interface Control (HIFCTL) register
When HMDS is at "L", this register controls the hardware of the host interface.

bit0 : HINT #1 (Host Interrupt #1)
This bit value becomes the value of HINTSTS #1 (bit0) from STATUS register on the host side.

bit1 : HINT #2 (Host Interrupt #2)
This bit value becomes the value of HINTSTS #2 (bit1) from STATUS register on the host side.

bit2 : HINT #3 (Host Interrupt #3)
This bit value becomes the value of HINTSTS #3 (bit2) from STATUS register on the host side.

(Note) Once "H" is written, until bits 0 to 2 are cleared from the host or the chip is reset, keep at "H".
It is not possible to access the register from the CPU and turn bits 0 to 2 from "H" to "L".
Accordingly, to set any of these bits, it is not necessary to take into consideration the value of other bits.
When HINTSTS bits #1 to 3 from HIFSTS register that corresponds to the above bits are at "H",
it is prohibited to write "H" in the above bits. Therefore, before the CPU writes "H" in the above bits
HIFSTS register should be read, and confirmation made that corresponding HINTSTS bits #1 to 3
are at "L".

bit3 to 5: RESERVED
Unused. Keep set to "L". If set to "H" the IC operation is not guaranteed.

bit6 : CLRRLST (Clear Result)
When this bit is set to "H", the result register is cleared. When these register's clearance is
completed, this bit automatically turns to "L". Therefore, there is no need for the CPU to set back
to "L".

bit7 : CLRBSY (Clear, Busy)
When this bit is set to "H", BUSYSTS bit of HINTSTS register is cleared. When these register's
clearance is complete, this bit turns automatically turns to "L". Therefore, there is no need for
the CPU to reset to L.

2.1.18 Drive Result (DRVRLST) register
This register is utilized to transfer the command execution result to the host, when HMDS="L". This register
is composed of a 10 byte FIFO. For details see 4.2.1.

2.1.19 Register Address (REGADR) register
bit0 to 6: Do not fail to set to "L". If set to "H" the IC operation is not guaranteed.

bit7 : REGADR0 (Register Address0)
This bit is used for the register address expansion.

2.2 Read out register

2.2.1 Current Minute Address Low (CMADR-L) register

2.2.2 Current Minute Address High (CMADR-H) register
Indicates the buffer memory address where the current sector (after correction is completed) minute bytes
are written.

2.2.3 Header (HDR) register
A 4 byte register that indicates the current sector Header byte.
By reading address OH successively 4 times the CPU can know the Header byte value of the current sector,
starting from the MINUTE byte.

2.2.4 Sub Header (SHDR) register
A 4 byte register that indicates the current sector Sub Header byte.
By reading address 1H successively 4 times, the CPU can know the Sub Header byte value of the current
sector, starting from the File byte.
2.2.5 Header Flag (HDRFLG) register
Indicates the Header and Sub Header error pointer value.

2.2.6 Interrupt Status (INTSTS) register
The value of the respective bits in this register indicates the condition of the corresponding interrupt status.
The bit value of INTMSK register does not affect the above mentioned bits.

- bit0 : DECINT (DECODER Interrupt)
- bit1 : HDMACMP (Host DMA Complete)
- bit2 : DRVOVN (Drive Over Run)
- bit3 : HSTCMND (Host Command)
- bit4 : HCRISD (Host Chip Reset Issued)
- bit5 : RSLTEMP (Result Empty)
- bit6 : DECTOUT (Decoder Timeout)

2.2.7 DECODER Status (DECSTS) register
- bit0 : NOSYNC
  Indicates that Sync Mark could not be detected and that SYNC was inserted.
- bit1 : SHRTSCT (Short Sector)
  Indicates the Sync Mark interval was within 2352 bytes. This sector does not execute ECC and EDC.
- bit2 : ECCOK (ECC OK)
  Indicates there are no more errors from the header of the sector where error correction was completed up to P Parity byte.
  (In FORM2, this bit turns to don’t care.)
- bit3 : EDCOK
  Indicates EDC check showed there were no errors.
- bit4 : CORDONE (Correction Done)
  Indicates that sector contains bytes that were error corrected.
- bit5 : CORINH (Correction Inhibit)
  Indicates there was an error flag at MODE (and FROM) bytes when AUTODIST bit of DECODER register was turned to “H”. This sector does not execute ECC and EDC.
- bit6 : ERINBLK (Erasure in Block)
  Turns to “H” when C2 pointer from CIRC LSI stood in 1 byte or more of all the bytes, with the exception of current sector sync byte.
- bit7 : EDCALLO (EDC ALL ZERO)
  This bit turns to “H” when there are no error flags in any of EDC parity bytes of current sector, and the value is at OOH.

2.2.8 MODEFORM (MDFM) register
This register is effective only during the execution of Real time correction mode or Repeated correction mode.

- bit0 : CFORM (Correction FORM)
- bit1 : CMODE (Correction MODE)
  These bits indicate whether this IC identified MODE or FORM in that sector and executed error correction.

<table>
<thead>
<tr>
<th>CMODE</th>
<th>CFORN</th>
<th>MODE</th>
</tr>
</thead>
<tbody>
<tr>
<td>“L”</td>
<td>“L”</td>
<td>MODE1</td>

<td>“L”</td>
<td>MODE2, FORM1</td>
</tr>
<tr>
<td>“H”</td>
<td>“H”</td>
<td>MODE2, FORM2</td>
</tr>
</tbody>
</table>

- bit2 to 4: RMODE0, 1, 2 (Raw MODE)
- RMODE1, 0 : Indicates the lower 2 bits value of raw MODE byte.
- RMODE2 : Indicate the logical sum of the upper 6 bits and pointer in raw MODE byte.
2.2.9 DMA Status (DMASTS) register

bit0 : CBFWRDY (CPU Buffer Write Ready)
This bit turns to "H" when data written from CPU into CPUBWDT register is written in the buffer memory. As CPU writes the next data into CPUBWDT register, it turns to "L" until that data is written into the buffer memory. Also, when CSRS is set to "H" and CDMAEN to "H" (DMACTL register), this bit turns to "H".
CPU confirms this bit is at "H" and writes in the data into CPUBWDT register.

bit1 : CBFRRDY (HPU Buffer Read Ready)
When data read from buffer memory is kept ready in CPUBRDT register, this bit turns to "H". When CPU reads CPUBRDT register out it turns to "L".
CPU confirms this bit is at "H" and reads out data from CPUBRDT register.

bit2 : CBFRDPO (CPU Buffer Read Pointer)
Indicates the value of the pointer bit read from the buffer memory.

bit7 : REGADR (Register Address)
This bit indicates the value of bit7 from Register Address register.

2.2.10 DADRC-L

2.2.11 DADRC-H

2.2.12 HADRC-L

2.2.13 HADRC-H

2.2.14 HXFRC-L

2.2.15 HXFRC-H

2.2.16 CPU Buffer Read Data (CPUBRDT) register
CPU port DMA (buffer read) data is read out from this register. When CDMAEN of DMACTL register is at "H" and CSRC at "L", the read out of this register is set for the DMA (buffer read) request of the next CPU port.

2.2.17 Host Parameter (HSTPRM) register
When HMDS is at "L", this register is used to know the command parameter from the host. This register is composed of 10 byte FIFO.

2.2.18 Host Command (HSTCMD) register
When HMDS is at "L", this register is used to know the command from the host.

2.2.19 Host Interface Status (HIFIFS) register
When HMDS is at "L", this register is used to know the host interface condition.

bit0 : HINTSTS #1 (HOST Interrupt Status #1)
This bit turns to "H" as CPU writes "H" into HINT #1 (HIFCTL register bit0). It turns to "L" when the host writes "H" into CLRINT #1 (Control register bit0). This bit is used as interrupt status monitor to the host.

bit1 : HINTSTS #2 (Host Interrupt Status #2)
This bit turns to "H" as CPU writes "H" into HINT #2 (HIFCTL register bit1). It turns to "L" when the host writes "H" into CLRINT #2 (Control register bit1). This bit is used as interrupt status monitor to the host.
bit2 : HINTSTS #3 (Host Interrupt Status #3)
This bit turns to "H" as CPU writes "H" into HINT #3 (HIFCTL register bit2). it turns to "L"
when the host writes "H" into CLRINT #3 (Control register bit2). This bit is used as interrupt
status monitor to the host.

bit3 : PRMRRDY (Parameter, Read Ready)
This bit at "H" indicates that HSTPRM register is not empty, so that Parameter data can be
read out from the CPU. When this bit is at "L", HSTPRM register is empty and Parameter data
cannot be read out from the CPU.

bit4 : PRMFULL (Parameter Full)
This bit at "H" indicates HSTPRAM register is full.

bit5 : RSLWRDY (Result Write Ready)
This bit at "H" indicates that HSTPRM register is not full, so that the CPU can write Result
data. When this bit is at "L" DRVRSLT register is full and the CPU can not write Result data.

bit6 : RSLEMPT (Result Empty)
This bit at "H" indicates DRVRSLT register is empty.

bit7 : BUSYSTS (Busy Status)
This bit has the same value as that of BUSYSTS (bit7) of the status register on the host side.
This bit turns to "H" as the host writes a command in the Command register. It turns to "L",
as the CPU sets CLRBUSY bit of HIFCTL register.

3. **DECODER Operation**

Hereafter, the block containing functions 1 and 2 is called DECODER.

1. **Interface with CIRC LSI**

   The data stream from CIRC LSI is taken in, while sync detection, descramble and data write to the buffer are executed.

2. **Error correction**

   Executes error correction of the sector written in the buffer.

3.1 **DECODER operation mode**

The Decoder features 4 operation modes set by means of DECMDSEL0 to 2 bits of DECCTL register.

<table>
<thead>
<tr>
<th>DECMDSEL2</th>

</tr>
<tr>
<td>&quot;H&quot;</td>
<td>&quot;L&quot;</td>
<td>&quot;L&quot;</td>
</tr>
<tr>
<td>&quot;H&quot;</td>
<td>&quot;L&quot;</td>
<td>&quot;H&quot;</td>
</tr>
<tr>
<td>&quot;H&quot;</td>
<td>&quot;H&quot;</td>
<td>&quot;L&quot;</td>
</tr>
<tr>
<td>&quot;H&quot;</td>
<td>&quot;H&quot;</td>
<td>&quot;H&quot;</td>
</tr>
</tbody>
</table>

(1) **Decoder disable**

   DECODER operation is disabled.

(2) **Monitor only mode**

   Data from the drive is not written in the buffer. Raw data from the drive is written in the Header, Sub Header and HDRFLG registers.
(3) Write only mode
Set to this mode, first Sync pattern detection is performed. As sync pattern is detected, write from that sector into the buffer starts from minute byte. The buffer memory address of this minute byte, is the value set to DADRC though the CPU before setting the DECODER mode. Sectors after that, and the Sync pattern too, are written into the buffer.
This buffer write continues until either ① Decoder is disabled or ② when ENDLADR is at “H”, DLADR value becomes equal to that of DADRC.

(4) Real time correction mode
Buffer write works the same as write only mode.
At the same time, error correction of the sectors already written in the buffer is executed in real time.
(When this mode is set and while the first sector is being written in the buffer, as long as a whole sector is not yet stored in the buffer, correction is not executed.)

(5) Repeat correction mode
Data from the drive is not written in the buffer. Error Correction of sectors already written in the buffer can be executed repeatedly. This way, errors that could not be corrected during real time correction mode, can now be corrected.

(6) CD-DA mode
To write CD-DA (Digital audio) Disc data into the buffer, this mode is set. As this mode is set, write into the buffer is executed from the lower byte of LCH.
This buffer write continues until either ① Decoder is disabled, or ② When ENDLADR is at “H”, DLADR value becomes equal to that of DADRC.

3.2 DADRC (Drive Address Counter)
DADRC is the counter that holds the address when data from the drive is written into the buffer. When data from the drive is written into the buffer, the contents are output from BA0 to 15 as buffer memory address. CPU can set or read DADRC contents. CPU sets the buffer write head address in DADRC before the setting of Decoder write only mode, real time correction mode and CD-DA mode.

3.3 DLADR (Drive Last Address)
DLADR is the register that indicates in bytes the value of DADRC that stops the drive data buffer write during the execution of write only mode, real time correction mode and CD-DA mode. When ENDLADR bit of DECTRL register is at “H” and the above modes are being executed, if DADRC value becomes equal to DLADR, it stops the buffer write data from the drive. Then, DRV0VRN status is on. When sync interrupt applies and DRV0VRN bit is at “H”, have CPU disable the DECODER. When ENDLADR bit is at “L”, even if DADRC value becomes equal to DLADR, buffer write of the data from the drive is not stopped and DRV0VRN status does not turn on.
Through the usage of DLADR, buffer overran of the drive can be prevented.
When a value is set to DLADR, make sure to set the upper byte first and the lower byte next in the order. (Even in case only the value of one of the bytes is to be changed, set both bytes in the mentioned order. If this is not performed, IC operation can not be guaranteed.) The DLADR upper byte is first set then the lower byte is set and until data from the drive is written in the buffer, the above function is disabled. DLADR setting should be made carefully.

3.4 Error correction
(1) MODE FORM discrimination
Mode and Form discrimination in the sector that performs error correction is executed in bits AUTODIST, FORMSEL and MODESEL of DECTRL register, as indicated in Fig. 3.5.
(2) ECC strategy can be chosen through ECCSTR bit of DECCTL register.
   At "H", error correction is performed taking into consideration error flags from respective data.
   At "L", error correction is performed without taking into consideration error flags from respective data.
   For systems using 8 bit word RAM, turn ECCSTR to "L".
   When double speed PB is executed (DBLSPD of DRVIF register is at "H"), transfer speed to the host slows down. Data transfer speed to the host when XTL1 frequency is set to 16.9344MHz is shown below, Moreover, this data transfer speed is the value obtained when data buffer write from the drive, error correction and data transfer to the host are executed at the same time.

<table>
<thead>
<tr>
<th>ECCSTR</th>
<th>Data Transfer Speed</th>
</tr>
</thead>
<tbody>
<tr>
<td>Normal PB speed</td>
<td></td>
</tr>
<tr>
<td>L</td>
<td>2.1MB/S</td>
</tr>
<tr>
<td>H</td>
<td></td>
</tr>
<tr>
<td>Double PB speed</td>
<td></td>
</tr>
<tr>
<td>L</td>
<td>0.7MB/S</td>
</tr>
<tr>
<td>H</td>
<td></td>
</tr>
</tbody>
</table>

From the above table, it appears that during double speed PB, data transfer speed to the host decreases. During double speed PB, Read data speed from the Drive is at 176.4KB/S. Data transfer speed to the host at 0.7MB/S is quite faster than this Read speed. Actually, transfer speed to the host does not decrease and as Read data speed from the drive doubles, transfer speed to the host also approximately doubles.

3.5 CPU control of the IC during Real time correction
   CPU control of the IC during the IC execution of Real time correction mode is shown in Fig. 3.6.

3.6 CPU control of the IC during Repeat correction
   CPU control of the IC during the IC execution of Repeat correction mode is shown in Fig. 3.7.

4. Host interface

4.1 Host I/F mode
   This IC can be connected to the following, as the host interface.
   ① SCSI controller IC (CXD1180AQ, CXD1185DQ and others)
   ② Intel 80 type host bus
   This mode is set by means of HMDS pin, as shown below.

   When Type 80 is connected, HMDS input is at "L". Otherwise, HMDS pin is set to open. When SCSI control IC is connected, HMDS input is at "H".

4.2 Connected to Intel 80 type host bus
   When this IC is connected to Intel 80 type host bus either "L" is input to pin HMDS or it is left open. This connection is shown on Fig. 4.2.

4.2.1 Command/Status transfer between the Host and the CPU.
   (1) Register
       The host can access each of the 4 write and read registers. Using pins XHCS, HAO, HA1, XHRD and XHWR, it reads and writes their registers. DMA transfer is also possible with RDDATA and WRDATA registers despite XHCS, HAO and HA1 values. Their registers are selected by means of XHAC, XHRD, XHWR and DMA transfers performed with the host. Parameter register and Result register are 10 bytes FIFO registers. "L" input to XHAC and XHCS is prohibited at the same time.
**Write register**

- **Command register (address 0)**
  The host writes commands in this register. As the host writes in this register, interrupt request is applied from this IC to the CPU. Bit assignment and function attribution is performed by means of a control program.

- **Parameter register (address 1)**
  To execute commands, the host writes into this register command parameters. This is a 10 bytes FIFO register.

- **Write Data (WRDATA) register (address 2)**
  This register serves to write data from the host into the buffer memory. Data can be written into either I/O mode or DMA mode. This register is composed of a 2 x 9 bits FIFO.

- **Control register (address 3)**
  This register is for the direct control of the hardware in this IC by the host.
  
  bit0 to 2: INTCLR #1 to 3 (Clear Interrupt #1 to 3)
  Setting these bits to “H” will clear the corresponding interrupt status, After the clearance of interrupt status in these bits, they automatically go back to “L”.

  bit3 to 5: ENINT #1 to 3 (Enable Interrupt #1 to 3)
  Setting these bits to “H” will enable the corresponding interrupt status.
  The host can read the respective bits value from the status register.
  When the corresponding interrupt status is at “H”, it is prohibited to write “H” to these bits, accordingly, before the host sets these bits to “H”, the status register should be read out and interrupt status confirmed.

  bit6 : CLRPRM (Clear FIFO)
  Setting this bit to “H” clears the Parameter register, After these registers are cleared, this bit automatically goes back to “L”.

  bit7 : CHPRST (Chip Reset)
  Setting this bit to “H” initializes the inside of this IC. As the inside of this IC initialization is completed, this bit automatically return to “L”. Setting this bit to “H” enables interrupt request to the CPU.

**Read out register**

- **Status register (Address 0)**
  The host uses this register to read this IC status.
  
  bit0 to 2: INTSTS #1 to 3 (Interrupt Status #1 to 3)
  The value of the respective bits is the same as that of the bits corresponding to HIFCTL register of the sub CPU. When interrupt corresponding to the respective bits is enabled, they turn to “H” and interrupt request to the host is output.

  bit3 to 5: ENINTST #1 to 3
  (Enable Interrupt Status #1 to 3)
  The value of the respective bits is the same as that of the bits corresponding to Control register.

  bit6 : DREQSTS (Data Request Status)
  Indicates this IC is in buffer memory data transfer request condition versus the host. This bit has the same value as that of pin HDRQ. In I/O mode, when buffer memory data transfer is executed, access WRDATA register or RDDATA register after the host confirms this bit is at “H”.

  bit7 : BUSYSTS (Busy Status)
  This bit turns to “H” as the Host writes a command into the command register. It turns to “L” as the CPU sets CLRBUSY bit of HIFCTL register.

- **Result register (address 1)**
  The Host reads the results after the command execution from this register. This is a 10 bytes FIFO.
• Read Data (RDDATA) register (address 2)
  This register is for the Host to read data from the buffer memory. Data can be read in I/O mode or DMA mode. It is composed of a 2×9 bits FIFO.

• FIFO Status register (address 3)
  This register is for the HOST to read the status of Parameter or Result register.
  
  - bit0 : PRMWRDY (Parameter Write Ready)
    When this bit is at "H" it indicates that parameter register is not full, and that the Host can write parameter data.
  - bit1 : PRMEMEEMPT (Parameter Empty)
    This bit at "H" indicates Parameter register is empty.
  - bit2 : RSLRRDY (Result Read Ready)
    This bit at "H" indicates that Result register is not empty, and that the Host can read Result data.
  - bit3 : RSLFULL (Result Full)
    This bit at "H" indicates Result register is full.
  - bit4 to 7: RESERVED
    Unused.

(2) Host and sub CPU controlling order
An example of the Host and CPU controlling order is shown in Fig. 4.2.1.
In this case the host gets to know interrupt status by polling Status register, Interrupt request can also be enabled.

4.2.2 Data transfer between the Host and the buffer memory.
Data transfer between the Host and the buffer memory is executed through this IC. This IC incorporates a 2 x 9 bits FIFO (WRDATA, RDDATA register) to speed up data transfer.

(1) Data transfer in DMA mode
Data transfer between the Host and FIFO inside this IC, is performed through handshake utilizing HDRQ/XSAC and XHAC/SDRQ.
    HDRQ/XSAC becomes the HDRQ data transfer request signal from this IC to the host while XHAC/SDRQ becomes the corresponding acknowledge signal XHAC.

(1) Data transfer from the Host to the buffer memory (HSRC at "H")
    When HDMAEN is at "H" while FIFO in not FULL and XHAC is at "H", this IC activates HDRQ. As acknowledge signal XHAC comes back from the host, HDRQ is inactivated. With the rising edge of XHAC, data is written into FIFO. Data written into FIFO is written in the buffer memory address in the order prescribed by HADRC.

(2) Data transfer from the buffer memory to the host (HSRC at "L")
    When HDMAEN is at "H", buffer read data from the address prescribed by HADRC is written into the FIFO. As data is written into FIFO, if XHAC is at "H", this IC activates HDRQ. As the acknowledge XHAC comes back from the host, HDRQ is inactivated. During the period when XHAC is at "L", This IC outputs the FIFO data to HDBO to 7.

(2) Data transfer in I/O mode
The host can transfer data to and from the buffer memory, by writing or reading registers WRDATA and RDDATA. In this case the control of CXD1186Q by the CPU is the same as during DMA transfer mode.

Fig. 4.2.2 indicates the Host control flow when data transfer is performed in I/O mode between the Host and the buffer memory.

(3) Data transfer completion
The 3 following methods are for data transfer completion.
• HXFRC is used.
• XTC pin is used.
• HDMAEN bit is set to "L".

(1) When HXFRC is used
When HXFRC is used for data transfer completion, perform the following before the CPU starts data transfer.
    • Set the number of data transfer bytes at HXFRC.
    • Set ENHXFRC=HDMAEN="H" and the data transfer direction (HSRC bit). This starts data transfer.
    HXFRC is decremented every time data is written into FIFO.
    When HXFRC turns to 0, writing of data into FIFO after that is not performed. Then, when all the FIFO data is transferred to the buffer memory or the Host, HDMACMP status (DMASTS register) sets on. When HDMACMP bit of INTMSK register is set to "H", this IC outputs interrupt request (INT output) to the CPU.
When XTC pin is used

When XTC pin is used for data transfer completion, perform the following before the CPU starts data transfer.

- Set ENXTC=HDMAEN="H" and the data transfer direction (HSRC bit). This status data transfer.

During the Host final DMA byte transfer, turn XTC pin and XHAC, XHAC, XHWR, XHRD to "L". This way, data transfer to the host is no more performed. (HDRQ is not output to the host.) When HSRC is at "L" and XTC turns to "L", after XHAC becomes inactive, this IC turns to HDMACMP status. In this case, 1 byte of unnecessary data from the buffer memory may already be written in the FIFO.

There, care should be exercised as the last address of HADRC transfer + 2 is indicated. When HSRC is at "H", the IC turns to HDMACMP status, when the writing into the buffer memory of data written into the FIFO as XTC at "L", is completed.

In either case, as HDMACMP status sets on, and HDMACMP bit of INTMSK register is set to "H", this IC outputs interrupt request (INT output) to the CPU.

Both ENXTC and ENHXFRG bits of DMACTL register, can simultaneously be set to "H".

(Note) In either ① or ② case, after HDMACMP sets on, before starting up data transfer again, turn bit 1 of INTCLR register to "H" and clear HDMACMP register.

③ When HDMAEN bit is set to "L"

When HDMAEN bit is set to "L" during data transfer with the Host, data transfer is stopped. There data transfer between this IC and the Host or the buffer memory may be stopped half-way. The value of HADRC and HXFRC after that is not guaranteed. Also, in this case, HDMACMP status does not set on.

(4) CPU control of the IC

CPU control of the IC when data transfer is performed between the Host and the buffer memory is illustrated as follows. (In this example execute data transfer completion using HXFRC)

① The number of transfer bytes is set to HXFRC.
② HADRC is set at the DMA head address.
③ HDMAEN and ENHXFRG bits of DMACTL register are set to "H".
④ As the transfer of the specified number of bytes is completed, HDMACMP bit of DMASTS register turns to "H". (There, this IC can output an interrupt request to the CPU)
⑤ Also, HXFRC is at 0000H, while HADRC value stands as the value next to that of the buffer memory address transferred last.

4.3 When connected to SCSI control IC

When this IC is connected to SCSI control IC, HMDS pin is set to "H".

4.3.1 Connection method to SCSI control IC

- An example for the connection of this IC to an SCSI control IC where CPU bus and DMA bus are not separated (IE CXD1180AQ) is shown in Fig. 4.3.1.

To switch CPU and DMA buses, an external circuit is required.

- An example for the connection of this IC to an SCSI control IC where CPU and DMA buses are separated (IE CXD1185AQ) is shown in Fig. 4.3.1-2.

4.3.2 Data transfer between SCSI control IC and the buffer memory

Data transfer between SCSI control IC and buffer memory is performed through this IC.

(1) Data transfer handshake

XHAC/SDRQ become the data transfer request signal SDRQ from SCSI control IC to this IC. HDRQ/XSAC become the corresponding acknowledge signal XSAC.

① Data transfer from SCSI control IC to this IC (HSRC at "H")

When HDMAEN is at "H", SDRQ input while FIFO is not Full will make this IC activate XSAC. Data is written into FIFO with the rising edge of XHWR.

- 446 -
2. Data transfer from this IC to SCSI control IC (HSRC at “L”)
   When HDMAEN is at “H”, SDRQ input while FIFO is not EMPTY will make this IC activate XSAC. It also outputs data from FIFO to HDBO to 7 during the period XHAC is at “L”.

(2) Completion of data transfer
   The 2 following methods are for the completion of data transfer.
   • HXFRC is used.
   • HDMAEN is set to “L”.
   For either method refer to paragraph 4.2.2.

(3) Data transfer cycle
   The data transfer cycle between this IC and SCSI control IC can be controlled through SDMACYC 0 and 1 bits from CONFIG register. CPU sets these bits in coordination with the speed of SCSI control IC (See A. C characteristics)
   SDMACYC1  0
   “L” “L” 3 cycles.
   “L” “H” 4 cycles.
   “H” “X” 5 cycles.

(4) CPU control of the IC
   For CPU control of the IC when data transfer is executed between SCSI control IC and the buffer memory, see paragraph 4.2.2.

5. Data transfer between audio processor and buffer memory
   Data transfer between ADP and the buffer memory is performed through this IC.

(1) Data transfer handshake
   ADRQ pin is the data transfer request signal from ADP to this IC. XAAC pin becomes the corresponding acknowledge signal. When ADMAEN is at “H” and ADRQ is input while FIFO is not Empty, this IC activates XAAC and outputs FIFO data to HDBO to 7 during the period where XAAC is at “L”.
   (Note 1) HADRC and HXFRC are used for the transfer of data between both this IC and the host and this IC and ADP. Accordingly, HDMAEN and ADDMAEN cannot be set to “H” simultaneously. In case both are set to “H” simultaneously, HDMAEN will turn to “H” and admaen to “L”, inside the IC.
   (Note 2) Even When HMDS is at “L” (connected to Intel 80 type host bus), turning ADMAEN to “H” will make XHWR and XHRD pins change from input to output. Therefore access from the host to this IC register is not possible. Watch out for signals collision.

(2) Completion of data transfer
   There are 2 ways to complete data transfer.
   • Using HXFRC.
   • Turning ADMAEN bit to “L”.
   For details on the 2 methods refer to Paragraph 4.2.2.

(3) Data transfer cycle
   The data transfer cycle between this IC and ADP can be controlled using bits SDMACYC 0 and 1 from CONFIG register. CPU sets these bits to match ADP transfer speed.
   (See figure)
   SDMACYC1  0
   “L” “L” 3 cycles.
   “L” “H” 4 cycles.
   “H” “X” 5 cycles.

(4) CPU control of the IC
   For CPU control of the IC when data is transferred between ADP and the buffer memory, refer to Paragraph 4.2.2.
6. CPU port DMA
   - CPU control of the IC

   An example on CPU control of the IC when CPU port performs DMA is indicated in Fig. 5.1.2. When CPU port performs DMA, the address uses DADRC. Accordingly, when the Decoder is performing any of the following modes write only, real time correction, CD-DA, CPU cannot access the buffer memory.

   When CSRC is at "L", turning CDMAEN to "H" (DMACTL register) will cause data from the buffer memory to be read and written into CPUBRDT register.

   When CDMAEN is turned to "H", it is prohibited to change CSRC value. To change CSRC value turn CDMAEN to "L".

Package Outline  unit: mm

80pin QFP (Plastic)  1.6g
CD-ROM Decoder

Description
The CXD1196R is a CD-ROM decoder LSI with a built-in ADPCM decoder.

Features
- CD-ROM, CD-I, CD-ROM XA format compatible
- Real time error correction
- Double speed reproduction compatible (when VDD=5.0±10%)
- Can be connected to a standard SRAM up to 32Kbytes (256 Kbits)
- All audio output sampling frequency of 132.3kHz (Built-in oversampling filter)
- Built-in de-emphasis digital filter
- Capable of VDD 3.5V operation

Application
CD-ROM drive

Structure
Silicon gate CMOS IC

Absolute Maximum Ratings (Ta=25 °C)
- Supply voltage VDD
  - VSS -0.5 to +7.0 V
- Input voltage VI
  - VSS -0.5 to VDD +0.5 V
- Output voltage VO
  - VSS -0.5 to VDD +0.5 V
- Operating temperature Topr
  - -20 to +75 °C
- Storage temperature Tstg
  - -55 to +150 °C

Recommended Operating Conditions
- Supply voltage VDD
  - +3.5 to +5.5 (+5.0 Typ.) V
- Operating temperature Topr
  - -20 to +75 °C

**CD Digital Signal Processor**

**Description**

The CXD2500AQ/AQZ is a digital signal processing LSI designed for use in compact disc players. It has the following functions:

- A wide frame jitter margin (±28 frames) realized by a built-in 32K RAM.
- Generation by the use of a digital PLL of bit clock pulses for strobing the EFM signal with a capture range of ±150kHz or more.
- EFM data demodulation
- Enhanced protection of EFM Frame Sync signals
- Powerful error correction based on a refined super strategy
  - Error correction C1: Double correction C2: Quadruple correction
- Double-speed play back and vari-pitch play back
- Reduced noise generation at track jumping
- Auto zero-cross muting
- Subcode demodulation and subcode Q data error detection
- Digital spindle servo system (incorporating an oversampling filter)
- 16-bit traverse counter
- Built-in asymmetry correction circuit
- CPU interface using a serial bus

**Features**

- Servo auto sequencer
- Output for digital audio interface
- Digital level meter and peak meter
- Bilinguality

**Structure**

Silicon-gate CMOS IC

Sony reserves the right to change products and specifications without prior notice. This information does not convey any license by any implication or otherwise under any patents or other right. Application circuits shown, if any, are typical examples illustrating the operation of the devices. Sony cannot assume responsibility for any problems arising out of the use of these circuits.
**Pin Configuration**

![Pin Configuration Diagram]

**Absolute Maximum Ratings**
- Supply voltage \( V_{DD} \): -0.3 to +7.0 V
- Input voltage \( V_I \): -0.3 to +7.0 V
- Output voltage \( V_O \): -0.3 to +7.0 V
- Operating temperature \( T_{opr} \): -20 to +75 °C
- Storage temperature \( T_{stg} \): -40 to +125 °C

**Recommended Operating Conditions**
- Supply voltage \( V_{DD} \): 4.75*1 to 5.25*2 (5.0V typ.) V
- Operating temperature \( T_{opr} \): -20 to +75 °C
- Input voltage \( V_{IN} \)
  - \( V_{SS} - 0.3V \) to \( V_{DD} + 0.3V \) V
- Supply voltage differences
  - \( V_{SS} - AV_{SS} \): -0.1 to +0.1 V
  - \( V_{DD} - AV_{DD} \): -0.1 to +0.1 V

* 1 The minimum \( V_{DD} \) value of 4.75V is for the double-speed play back mode with vari-pitch control reset. It is 3.6V in the low power consumption, special regeneration mode.* 2 In normal-speed play back mode the minimum \( V_{DD} \) value is 4.5V

* 2 Low power consumption, special play back mode
  This is a normal-speed play back mode entered when the LSI is set for double-speed internal operation whereas the crystal oscillation frequency is halved.

* 3 The maximum \( V_{DD} \) value of 5.25V is for the double-speed play back mode with vari-pitch control reset. For normal-speed play back and low power consumption special play back mode, the maximum \( V_{DD} \) value is 5.5V.

**I/O Capacity**
- Input pins \( CI \): 12pF max.
- Output pins \( CO \): 12pF max. at high impedance

Note: Test Conditions
\[ V_{DD} = V_I = 0V \]
\[ f_M = 1MHz \]

Notes:  
- The data at the 64-bit slot is output in 2\(^\text{nd}\) complements on an LSB-first basis. The data at the 48-bit slot is output in 2\(^\text{nd}\) complements on an MSB-first basis.  
- GTOP monitors the state of Frame Sync protection. ("H": Sync protection window released)  
- XUFG is a negative Frame Sync pulse obtained from the EFM signal before Frame Sync protection is effected.  
- XPLCK is an inversion of the EFM PLL clock. The PLL is designed so that the falling edge of XPLCK coincides with a change point of the EFM signal.  
- The GFS signal turns "H" upon coincidence between Frame Sync and the timing of interpolation protection.  
- RFCK is a signal generated at 136-\(\mu\)s periods using a crystal oscillator.  
- C2PO is a signal to indicate a data error.  
- XRAOF is a signal issued when a jitter margin of \(\pm 28F\) is exceeded by the 32K RAM.

Description of Functions

§ 1 CPU Interface and Commands

○ CPU interface

This interface is used to set various modes using DATA, CLK, and XLAT.

The interface timing chart is shown below.

○ The command addresses of the CXD2500 and the data that can be set there are shown in Table 1-1.

○ When XRST is set to 0, the CXD2500 is reset, causing its internal registers to be initialized to the values listed in Table 1-2.

<td>1</td>
<td>1</td>
<td>1</td>
<td>RXF</td>
</tr>
</tbody>
</table>

RXF=0 FORWARD
RXF=1 REVERSE

- If a Focus-ON command ($47$) being executed is canceled, $02$ is issued and the auto sequence operation is discontinued.
- If a Track Jump or Track Move command ($48$ to $4F$) being executed is canceled, the auto sequence operation is discontinued.

$5X$ Command

Used to set timers for the auto sequencer.
Timers set: A, E, C, and B

<table>
<thead>
<tr>
<th>Command</th>
<th>D3</th>
<th>D2</th>
<th>D1</th>
<th>D0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Blind(A,E), Over flow(C)</td>
<td>0.18ms</td>
<td>0.09ms</td>
<td>0.045ms</td>
<td>0.022ms</td>
</tr>
<tr>
<td>Brake(B)</td>
<td>0.36ms</td>
<td>0.18ms</td>
<td>0.09ms</td>
<td>0.045ms</td>
</tr>
</tbody>
</table>

Example: D2=D0=1, D3=D1=0 (Initial Reset)
A=E=C=0.112ms
B=0.225ms

$6X$ Command

Used to set a timer for the auto sequencer.
Timer set: D

<table>
<thead>
<tr>
<th>Command</th>
<th>D3</th>
<th>D2</th>
<th>D1</th>
<th>D0</th>
</tr>
</thead>
<tbody>
<tr>
<td>KICK(D)</td>
<td>11.6ms</td>
<td>5.8ms</td>
<td>2.9ms</td>
<td>1.45ms</td>
</tr>
</tbody>
</table>

Example: D3=0 D2=D1=D0=0 (Initial Reset)
D=10.15ms

$7X$ Command

Used to set the number (N) of auto sequencer track jumps/moves.

<table>
<thead>
<tr>
<th>Command</th>
<th>Data 1</th>
<th>Data 2</th>
<th>Data 3</th>
<th>Data 4</th>
</tr>
</thead>
<tbody>
<tr>
<td>Auto sequencer track jump number setting</td>
<td>2&lt;sup&gt;16&lt;/sup&gt;</td>
<td>2&lt;sup&gt;14&lt;/sup&gt;</td>
<td>2&lt;sup&gt;12&lt;/sup&gt;</td>
<td>2&lt;sup&gt;10&lt;/sup&gt;</td>
</tr>
</tbody>
</table>

This command is used to set the value of “N” for execution of a 2N track jump or N track move.
- The maximum number of tracks that can be counted is 65,535. However, in the case of 2N track jumps, it is subject to the mechanical restrictions due to the optical system.
- When the number of tracks to be jumped is smaller than 16, the signals input from the CNIN pin are counted. When it is 16 or larger, the signals input from the MIRR pin are counted. This count signal selection contributes toward improving the accuracy of high-speed track jumping.
## $8X$ Command

### Mode Specification

<table>
<thead>
<tr>
<th>Command bit</th>
<th>CDROM</th>

<td>0</td>
<td>D. OUT</td>
<td>WSEL</td>
<td>Audio mode is entered. In this mode, average value interpolation and preceding value holding are performed.</td>
</tr>
<tr>
<td>CDROM=1</td>
<td></td>
<td>0</td>
<td></td>
<td></td>
<td>CDROM mode is entered. In this mode, average value interpolation and preceding value holding are not performed.</td>
</tr>
</tbody>
</table>

### Command bit Processing

<table>
<thead>
<tr>
<th>Command bit</th>
<th>Processing</th>
</tr>
</thead>
<tbody>
<tr>
<td>D.out Mute F=1</td>
<td>When Digital Out is ON (pin MD2=1), DA output is muted.</td>
</tr>
<tr>
<td>D.out Mute F=0</td>
<td>DA output muting is unaffected by the setting of Digital Out.</td>
</tr>
</tbody>
</table>

### D/A Out D.out Mute with F=1

<table>
<thead>
<tr>
<th>MD2=1</th>
<th>MD2=0</th>
</tr>
</thead>
<tbody>
<tr>
<td>(D. out-ON)</td>
<td>(D. out-OFF)</td>
</tr>
<tr>
<td>Mute ON</td>
<td>$-\infty$dB</td>
</tr>
<tr>
<td>Mute OFF</td>
<td>$-\infty$dB</td>
</tr>
</tbody>
</table>

### Sync Protection Window Width

<table>
<thead>
<tr>
<th>Command bit</th>
<th>Sync protection window width</th>
<th>Application</th>
</tr>
</thead>
<tbody>
<tr>
<td>WSEL=1</td>
<td>±26 channel clock pulses *</td>
<td>Antirollingness is enhanced.</td>
</tr>
<tr>
<td>WSEL=0</td>
<td>±6 channel clock pulses</td>
<td>Sync window protection is enhanced.</td>
</tr>
</tbody>
</table>

* In normal-speed play back, the channel clock frequency is 4.3218MHz.
## $9X$ Command

<table>
<thead>
<tr>
<th>Command</th>
<th>Data 1</th>
<th>Data 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>D3</td>
<td>D2</td>
<td>D1</td>
</tr>
</tbody>
</table>

### Func specification

<table>
<thead>
<tr>
<th>Command</th>
<th>Data 1</th>
<th>Data 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>DCLV ON-OFF</td>
<td>DSPB ON-OFF</td>
<td>A.SEQ ON-OFF</td>
</tr>
</tbody>
</table>

### Command bit

<table>
<thead>
<tr>
<th>Command bit</th>
<th>CLV mode</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>DCLV ON-OFF=0</td>
<td>In CLVS mode</td>
<td>FSW=L, MON=H, MDS=Z, MDP= servo control signal with carrier frequency of 230Hz at T_R=0 or 460Hz at T_R=1</td>
</tr>
<tr>
<td></td>
<td>In CLVP mode</td>
<td>FSW=Z, MON=H, MDS= speed control signal with carrier frequency of 7.35kHz, MDP=phase control signal with carrier frequency of 1.84kHz</td>
</tr>
<tr>
<td>DCLV ON-OFF=1</td>
<td>In CLVS or CLVP mode</td>
<td>DCLV When PWM, MD=1</td>
</tr>
<tr>
<td>(FSW and MON are unnecessary)</td>
<td></td>
<td>DCLV When PWM, MD=0</td>
</tr>
</tbody>
</table>

In the Digital CLV servo mode with DCLV ON-OFF set to 1, the sampling frequency of the internal digital filter is switched at the same time as switching between CLVP and CLVS. Therefore, for CLVS, the cut-off frequency fC is 70Hz with T_R set to 0 or 140Hz with T_R set to 1.

### Command bit Processing

<table>
<thead>
<tr>
<th>Command bit</th>
<th>Processing</th>

### Level Meter Mode (See timing chart 1-4.)

- This mode makes the digital level meter function available.
- Inputting 96 clock pulses to SQCK causes 96bits of data to be output to SQSO. Of the output data, the first 80bits comprise Sub-Q data communicating the data format to the Sub Code interface. The next 15 bits constitute PCM data (absolute value) ordered LSB-first. The last bit identifies the channel involved. That is, if the last bit is “H”, the PCM data has been generated in L-ch. If it is “L”, the data has been generated in R-ch.
- The PCM data is reset once it is read. At the same time, the L/R flag is reversed. While this state is kept until the next read operation is started, maximum value detection is continued; the detected maximum value is subsequently output.
SONY

CXD2500AQ/AQZ

Peak Meter Mode (See timing chart 1-5.)
○ In this mode, the maximum value of PCM data is detected whether the channel involved is L·ch or R·ch. To read the detected maximum value, it is necessary to input 96 clock pulses to SQCK.
○ When 96 clock pulses have been input to SQCK, 96 bits of data is output to SQSO. At the same time, the data is re-set in an internal register of the LSI.
That is, the PCM peak detection register is not reset when it is read.
○ To reset the PCM peak register, set both PCT1 and PCT2 to 0. Or, Set $AX mute.
○ In this mode, the absolute time of Subcode Q is controlled automatically.
Namely, every time a peak value is detected, the absolute time when the CRC was passed is stored. The program time operation is performed in the normal way.
○ The last bit (L/R flag) of the 96-bit data stays 0.
○ In this mode, the preceding value holding and average value interpolation data are fixed to level ($-\infty$).

§ 2 Subcode Interface

In this section, the subcode interface will be explained.
The contents of the subcode interface can be externally read in two ways. The subcodes P through W totaling 8 bits can be read from SBSO by inputting EXCK to the CXD2500.
Sub Q can be read after conducting a CRC check on the 80 bits of information in the subcode frame.
First, check SCOR and CRCF, then input 80 clock pulses to SQCK and read the data.

§ 2-1 P-W Subcode Read

These subcodes can be read by entering EXCK immediately after the fall of WFCK. (See Figure 2-1).

§ 2-2 80-bit Sub Q Read

Figure 2-2 shows a block diagram of the peripheral part of the 80-bit Sub Q register.
- The Sub Q regenerated on a bit-per-frame basis is input to the 80-bit serial/parallel register and the CRC circuit.
- When the results of a CRC on the 96 bits of Sub Q are OK, CRCF is set to 1 and the 96-bit data is output to SQSO.
  Furthermore, the 80-bit data is loaded into the 80-bit, parallel/serial register.
  If SQSO is found "H" after the output of SCOR, the CPU realizes that a new set of data has been loaded after passing a CRC.
- When 80-bit data is loaded CXD2500A, the bit arrangement is reversed within each byte of the data.
  Therefore, the bits are ordered LSB-first within each byte, even though the byte arrangement is kept unchanged.
- When 80 bits of data are confirmed to have been loaded, SQCK is input to read the data. Subsequently in the CXD2500A, the input of SQCK is detected and the retriggerable Mono/Multi is reset during Low.
- The time constant of the retriggerable Mono/Multi ranges from 270 to 400 µs. During SQCK High if it is less than this time constant, the Mono/Multi is kept being reset, preventing the contents of the P/S register from being loaded into the P/S register.
- While the Mono/Multi is kept reset, data loading into the peak detection parallel/serial register and 80-bit parallel/serial register is forbidden.
  Therefore, while data read operation is carried out at clock periods not exceeding the time constant for the Mono/Multi, the contents of these registers are retained without being rewritten, for example, when a CRC is passed.
- The CXD2500A permits the peak detection register to be connected to the shift-in of the 80-bit P/S register.
  The input and output terminals of Ring Control 1 are interconnected in the peak meter mode as well as level meter mode, while those of Ring Control 2 are interconnected only in the peak meter mode.
  The purpose of these Ring Control arrangements is to reset the registers every time their contents are read in the level meter mode, while preventing their contents from being destroyed by read operation during the peak meter mode.
  To enable this control, it is essential to input 96 clock pulses for read operation in the peak meter mode.
- As mentioned earlier, the detection of a peak value in the peak meter mode is followed by the storing of the next absolute time.
  A timing chart for these operations is shown in Figure 2-3.

Note: The "H" as well as "L" duration of the clock pulses to be input to the SQCK pin to perform the above-described operations must be between 750ns and 120 µs.

§ 3 Other Functions

§ 3-1 Channel Clock Regeneration Using Digital PLL Circuit

- Demodulation of the EFM signal regenerated using an optical system requires the use of channel clock pulses. The EFM signal to be demodulated has been modulated into an integer multiple of the channel clock period T, ranging from 3T to 11T.

- To read the information conveyed by the EFM signal, it is essential to correctly recognize the value of the integer and, hence, to use channel clock pulses.

- In a real CD player, the pulse width of the EFM signal fluctuates being affected by fluctuations of the disc rotation. For this reason, it is necessary to use a PLL in regenerating channel clock pulses.

Figure 3-1 shows a block diagram of the 3-stage PLL contained in the CXD2500A.

- The 1st-stage PLL is used for vari-pitch regeneration. To use this PLL, it is necessary to prepare an LPF and a VCO as external parts.

- The minimum pitch variation achievable is 0.1%. The output of this 1st-stage PLL is used as the base signal for all the clock pulses to be used in the LSI.

- When vari-pitch control is not performed, connect the output pin of XTAO to the VCKI pin.

- The 2nd-stage PLL generates R.F. clock pulses for use by the 3rd-stage digital PLL.

- The 3rd-stage comprises a digital PLL used to regenerate channel clock pulses. It realizes a capture range of ±150kHz (normal condition) or more.

- The digital PLL features a secondary loop. It is controlled through the primary loop (phase) and secondary loop (frequency).

- When FLFC=1, the secondary loop can be turned off.

- When high frequency components such as 3T, 4T or else, are offset, turning off the secondary loop will provide better play ability.

- In this case, however, capture range reaches 50kHz.

- 1/1000 divider
- LPF (Low Pass Filter)
- VCO (Voltage Controlled Oscillator)
- FIL1, FIL2
- CLTV: CLock Terminal Voltage

Overall Control:
- Digital PLL
- RFPLL (RF Phase Locked Loop)
§ 3-2 Frame Sync Protection

- During CD player operation at normal speed, Frame Sync is recorded about every 1.36 µs (at 7.35 kHz). This signal can be used to identify the data within each frame. When Frame Sync cannot be recognized for any data, the data cannot be identified and, as a result, it is treated as an error. Therefore, correct Frame Sync recognition is very important to ensure high playability for the CD player.

- For Frame Sync protection, the CXD2500A employs window protection, front protection, and rear protection. These measures combined realize powerful Frame Sync protection. The CXD2500 offers two window widths, one for use when the player is subjected to rotational disturbance and the other for use without such disturbance involved (WSEL = 0/1).

The front protection counter is fixed at count 13 and the rear protection counter at 3. Therefore, if, while Frame Sync signals are regenerated normally, regenerated signals cannot be detected, for example, due to flaws on the disc, up to 13 frames can be interpolated. If the number of frames with undetected Frame Sync exceeds 13, the window is released and the Frame Sync signals are re-synchronized. If no Frame Sync is correctly detected in 3 successive frames immediately after Frame Sync re-synchronization performed following a window release, the window is released at once.

§ 3-3 Error Correction

- On CDs, each data unit (8 bits) is formatted so that it is contained in two correction codes, C1 and C2. C1 consists of 28 bytes of information and a 4-byte parity, whereas C2 are made up of 24 bytes of information and a 4-byte parity. Both C1 and C2 comprise a reed Solomon code with a minimum distance of 5.

- C1 realizes double corrections and C2 quadruple corrections, both, by the refined superstrategy method.

- When correction by C1 is made, a C1 pointer determined according to the contents of the error, the status of EFM signal regeneration and the condition of CD player operation is attached to the corrected data so as to prevent erroneous correction by C2.

- The status of error correction can be monitored from outside the LSI. It is indicated as shown in Table 3-2.

- If an uncorrectable data error is detected, the previous data that has been held is substituted for the erroneous data or substitute data is created by average-value interpolation. In either case, a C2 pointer attached to the substitute data is set high.

§ 3-4 DA Interface

The CXD2500A has two modes of DA interface.

a). 48-bit slot interface
This is an MSB-first interface made up of LRCK signals with 48bit clock cycles per LRCK cycle. While the LRCK signal is high, the data going through this interface is of the left channel.

b). 64-bit slot interface
This is an LSB-first interface made up of LRCK signals with 64bit clock cycles per LRCK cycle. While the LRCK signal is low, the data going through this interface is of the left channel.

§ 3-5 Digital Out

There are three digital-out formats: type 1 for use at broadcasting stations, type 2, form 1 for use in general civil applications, and type 2, form 2 for use in software production. The CXD2500A supports type 2, form 1.

The clock accuracy for the channel status is automatically set at level II when the Xtal clock is used or level III when vari-pitch control is made.

CRC checks are conducted on the Sub Q data on the first 4 bits (bits 0-3). The data is input only after two checks are passed in succession.

The Xtal clock is set to 32MHz, and variable pitch is reset. When DSPB is set to 1, as D out is output, set MD2 to 0 and D out to off.

§ 3-6 Servo Auto Sequencer

The servo auto sequencer controls a series of operation including auto-focusing and track jumping. When an auto sequence command is received from the CPU, the servo auto sequencer automatically executes auto-focusing, 1-track jumping, 2N track jumping and N track moving.

During auto sequence execution (X Busy = Low), as SSP (servo signal processing LSI) is used exclusively, commands from the CPU are not transferred to SSP. Still, commands can be sent to CXD2500A.

To make this servo auto sequencer usable, connect a CPU, RF and SSP to the CXD2500Q as shown in Figure 3-7 and set A.SEQ ON-OFF of register 9 to ON.

When X Busy is at Low, as the clock turns from Low to High, from there and for a maximum of 100μsec, X Busy does not turn to High.

As this clock is at Low (when X Busy is at Low), and through the monostable multivibrator that is reset, when X Busy changes from Low to High, transfer of error data to SSP is prevented.

(a) Auto Focus ($47)

In auto focus operation, 'focus search up' is performed, FOK and FZC are checked, and the focus servo is turned on. When a $47 is received from the CPU, the focus servo is turned on through the steps shown in Figure 3-8. Since this auto focus sequence begins with 'focus search up,' it requires the pickup to be put down (focus search down) beforehand.

Blind E of register 5 is used to prevent FZC from flapping. The focus servo is turned on when FZC goes low after staying high for a period longer than E.

Figure 3-8 (a) Flowchart of auto focus operation
(b) Track Jump

Track jump operation includes 1, 10 and 2N track jumps. Do not perform this track jump unless the focus, tracking and sled servos are on. Such steps as tracking gain up and braking are not included in this track jump. Therefore, the commands for tracking gain up and brake on ($17) must be issued in advance.

- 1-track jump

When a $48 (or a $49 for a REV jump) is received from the CPU, the servo auto sequencer executes a FWD (REV) 1-track jump as shown in Figure 3-9. The values of blind A and brake B must be set in register 5.

- 10-track jump

When a $4H (or a $4B for a REV jump) is received from the CPU, the servo auto sequencer executes a FWD (REV) 10-track jump as shown in Figure 3-10. The principal difference between the 1-track and 10-track jumps is whether the sled is kicked or not. In the 10-track jump, the actuator after being kicked is braked when CNINs have been counted for 5 tracks. When the actuator has adequately slowed down as a result of braking, the tracking and sled servos are turned on (this actuator slow-down is detected by checking whether the CNIN period has exceeded the time specified as overflow C in register 5).

- 2N track jump

When a $4C (or a $4D for a REV jump) is received, the servo auto sequencer executes a FWD (REV) 2N track jump. The number of tracks to be jumped is determined by N whose value is to be set in register 7 beforehand. The maximum permissible number is $2^{14}$. In reality, however, it is subject to limitation imposed by the actuator.

When N is smaller than 16, the jumps are counted by means of counting CNIN signals. If N is not smaller than 16, MIRR signals are counted instead of the CNIN signals.

The 2N track jump sequence is basically the same as the 10-track jump sequence. The only difference between them is that, in the 2N track jump sequence, the sled is kept moving for time D specified in register 6 after the tracking servo is turned on.

- N track move

When a $4E (or a $4F for a REV move) is received from the CPU, the servo auto sequencer executes a FWD (REV) N-track move as shown in Figure 3-12. The maximum value that can be set for N is $2^{14}$. The track moves are counted in the same way as for 2N track jumps. That is, when N is smaller than 16, the moves are counted by means of counting CNIN signals. If N is not smaller than 16, MIRR signals are counted instead of the CNIN signals. In this N track move, only the sled is moved. This method is suitable for a large track move ranging from several thousand to several tens of thousand of tracks.

§ 3-7 Digital CLV

The digital CLV is a digital spindle servo, a block diagram of which is shown in Figure 3-14. It is capable of outputting MDS or MDP error signals by the PWM method after raising the sampling frequency up to 130kHz based on the normal speed in the CLVS, CLVP or another appropriate mode. It permits gain setting, also.

1. Minimum requirement for ADC input.
The external Low Pass Filters are used for eliminating aliasing noise, because there is a decimation filter (128fs sampling). This IC only needs to cut off more than 64fs frequency component. The sampling frequency (Fs) is more than 8KHz. Therefore, the roll off can be more than 500KHz. Only 1st order filter is required.

2. MAF (Moving Average Filter)
This block is down sampling, PDM (Pulse Density Modulation) data which is filtered at 128 times over sampled. The data rate will be 4 times fs. 32 input data are manipulated, averaged and transferred to the next stage.

3. PDM Output
Output data rate is 128fs. If fs=48KHz, the rate is 6.144MHz. The Wave form is as follows: A middle level represents high impedance output. The number of "1" and "0" pulses give the analog output level. If its analog output level is at center level, the number of "1" and "0" are equal.

Filtering is necessary to eliminate 128fs component. Attenuation level for stop band frequency component is -45dB level. If it is necessary to increase this level, additional LPF is recommended to be used.

4. Simple External Circuit (See attached circuit diagram)
It is recommended that the two peripheral chips to be used for computer applications, and the Common mode DAC output may simplify your system.

- Control logic
- Para. S.R.
- SN74HC299 x2

Diagram showing the external circuit example of the CXD2555Q.
RGB encoder - CXA1145P/M can provide Y, C output. The following is the circuit diagram to apply this output. S-VHS requires 75ohm drive capability for Y, C output. Output level should be adjusted with 1K ohm potentiometers. Recommended parts are the following, and are available from TOKO America (Telephone: 708/297-0070).

- 3.58MHz Band Pass Filter H286BAIS-6276DCD
- 4.43MHz Band Pass Filter H286BAIS-4963DCD
- Delay Line H288LSMS-3245PKD
1. **NTSC Composite Video Y/C Separation**

Because NTSC composite video signal is a modulated signal of Y and C, the following crosstalk may occur in signal process:

- **Cross Color**    Y to C Crosstalk
- **Dot Crawling**   C to Y Crosstalk

To avoid above errors, normally 1H delay line is used for Y/C separation. The chroma signal phase has a 180 degree shift in every H interval (Interlaced), the Y and C signal can be separated in the following way:

![Diagram of NTSC Composite Video Y/C Separation](image)

However, the low frequency components concentrated on harmonics of the sub carrier frequency will be combed away, and it will reduce the vertical resolution and decrease the sharpness of image in the vertical direction.
The following scheme can improve the vertical resolution:

Amplitude Vertical Resolution Chrominance

Spectrum (NTSC/PAL composite signal)

This can improve both cross color error and vertical resolution, but requires more components. Sony Digital comb filters can be recommended if the digital signal processor converting the digital Y, C data to RGB is available (See Application Note CAV04).

The simple solution may be the combination of BPF (Band Pass Filter) and Notch filter as mentioned in Sony NTSC/PAL decoder data sheet. It is better in video applications because there are more low frequency components existing in the sub carrier harmonics \((n + 1/2) x f_h\).

The comb filter is suitable for the still picture application, it can increase SNR. CXL5504M is NTSC CCD delay line recommended for Y/C separation.

### 3. PAL Decoder

4.43MHz trap and BPF (Band Pass Filter) combination are used for the PAL system. Besides, DAT and 1H delay line (Glass delay type) for chroma demodulation, Ultrasonic Delay line is also recommended. A supplier for the 1H delay line and a notch filter is Panasonic (Telephone: 201/348-5200). 1H CCD delay line can not be used for this application because there is no sync signal added on the chroma output signal at pin 21. Asahi Glass Corporation (Telephone: 011-81-3-3218-5781)

1. What is the digital comb filter?
The NTSC/PAL digital video system requires many ICs to compensate for several errors - cross color, dot crawling, interline flickers, and so on. Y/C separation process is the key to eliminate these errors. The 1H comb filter is used for eliminating cross color, and dot crawling because these errors are caused by Y to C or C to Y crosstalk (See Application Note CAV03).

The current digital TV system uses interframe Y/C separation, which is superior for the still video application. However the number of field memories are necessary and the noise from the moving picture can not be eliminated. (Therefore, 1H comb filter is used together with the interframe Y/C separators and the detector circuit for movement detection decide to switch between two Y/C separators.) But, the simple 1H comb filter can not compensate the cross color when there is no correlation in the adjacent lines. It is better to use BPF in such a case.

The digital comb filter - CXD2011Q is developed for improving the quality of the moving picture Y/C separation, combining together with the interframe Y/C separation. Both still video and moving picture quality can be improved.

In typical video applications (VCR, TV), the CXD2011Q alone can fulfill the function of noise compensation. IC switches 1H comb and BPF by detecting the difference in the adjacent line data.

2. How to use CXD2011Q in the computer system.
Combination of 8 bit 20MSPS A/D - CXD1176Q, the digital Y/C data (8 bit) can be generated. This example shows the overlay application with VGA controller IC. 1H Digital delay line - CXK1202S/Q are utilized to change the H sync frequency from 15.743KHz to 31.486KHz for NTSC system.
Double Scan Speed Converter

The VGA chip does not have H, V sync input to synchronize with the external video sync. The future VGA chip may have the internal PLL to lock the pixel clock with the external sync signal. The Gen Lock circuit example will be described in Application note - CAV06. The Digital mixer circuit, and Y/C to RGB conversion circuit may be necessary. The double scan method can be used for converting external H sync frequency to that of VGA.

Y, C signals from Digital Comb filter are interlaced signals with 15.743KHz sync cycle.

Double scan means interlace to non-interlaced conversion - Read one line and write 2 lines with double speed. 2 ICs can be switched Read and Write Cycle each other. However, this method cause flicker between the fields. Recommendation is using just one field (even or odd).
1. VGA Interface
Utilizing the NTSC/PAL encoder, RAMDAC output can be stored into the VCR and/or can be displayed on a TV monitor. However, the non-interlaced signal should be converted to the interlaced video. One way of doing this, is by using the 1H digital delay lines in the following circuit:

Timing Diagram
1. Gen Lock System
The Sync separator - CXA1365S and the Sync generator - CXD1030M are recommended to be used together. When the H sync drop happens in the VCR signal source, CXD1030 can generate H sync during the lack of sync period. Also 4fsc (4 times sub carrier frequency) generated in Gen Lock circuit. (Detail circuit diagram is shown on page 6-11).

2. VGA Sync Lock Circuit
The software solution may work in V sync lock with the external video. The future VGA chip needs to have V reset input at least to simplify the interface circuit. Because of lack of V, H sync input the VGA chip should be locked with the pixel clock. The hardware solution; H sync from both VGA and video are compared together with PLL and lock the pixel frequency. To adjust the timing difference in V sync, H sync from either VGA or video is taken away in each V interval, if there is more than 1 H time difference. The following is the diagram for this PLL circuit:

- Pixel CLK
- VCO
- PLL
- LPF
- VGA
- Gen lock block
- Comp video in
- CLK (4fsc)
- Vs
- Hs
- 31.5 KHz
- H extraction timing (1H shift/V interval)
- Hs + 2
- Hout
- VCO
- Pixel CLK
- PLL
- LPF
- VGA
- Gen lock block
- Comp video in
- CLK (4fsc)
- Vs
- Hs
- 31.5 KHz
- H extraction timing (1H shift/V interval)
- Hs + 2
- Hout
Normally the Gen Lock circuit does synchronize the sub carrier of the video to that of the internal clock generator. A H delay line (CXL5504M or CXK1202S/Q type) requires an accurate, 4 times sub carrier frequency; the NTSC/PAL signal process needs this frequency clock. However, it is not necessary to be locked with Y sync in the computer applications. Instead, H sync must be locked with the pixel clock for Graphic displays. The pixel clock frequency is quite different from Video sub carrier (See Application note CAV07).

The actual video signal sometimes has the unstable H sync signal - jitter and tracking error. Loosing H sync in several H sync intervals may occur, so extracting H from video can not fulfill the Gen Lock function. Gen Lock circuit "generates" the H sync; CXD1030M is used for this purpose. Simplified Gen Lock block is as shown here:

\[ f_1 = 14.31818 \text{ MHz (NTSC) } \]
\[ f_2 = 14.1875 \text{ MHz (PAL) } \]
1. **Computer Video In Applications**

Digital interface to the computer requires A to D converters (A/D’s). The speed range is 12-18 MHz, the resolution is 5-10 bit. RAMDAC requires RGB input with 5 bit resolution for video. XGA requires additional bit for B. Possibly the 6 bit 20 MHz A/D is the best choice for VGA overlay application. Teleconference type applications require Y/U/V (Y/R-Y/B-Y) digital interface. The sampling frequency is chosen by the display resolution. (Typically 640x480) D1 (4:2:2) format set the sampling frequency 13.5 MHz both for NTSC and PAL system.

2. **NTSC/PAL Digital decoder with D1/Square pixel mode selection.**

The circuit example is on page 6-13 (A).

3. **RGB Digital Interface for VGA.**

Compared with YUV interface, each R, G, B have up to 4.5 MHz signal band width (U, V have less than 1.5 MHz band width). The 6 bit 20 MHz A/D - CXD1172AM/AP is recommended to be used. The replacement of CXD1179Q circuit can be found in the drawing on page 6-13(B).

(B). The replacement block for RGB interface (VGA Application)
The Sony CD-ROM chip set is developed for PC, Workstation applications. On the other hand there are simple applications like computer games. They normally use the inexpensive storage device inside; however this does not use SCSI interface.

So, Sony developed the simplified version of CXD1186Q CD-ROM decoder. This new IC -CXD1196R is a CD-ROM decoder with ADPCM decoder and Digital filter for Audio out. The package is 20mil center 80pin Quad flat package. It is very small outline package.

The block diagram shown here is a proposed Computer game system; where CD or DAT are used as a storage devices outside: CD or DAT media should be developed by the customers.
