TMS320C6x Evaluation Module Reference Guide

Literature Number: SPRU269A
April 1998

IMPORTANT NOTICE

Texas Instruments (TI) reserves the right to make changes to its products or to discontinue any semiconductor product or service without notice, and advises its customers to obtain the latest version of relevant information to verify, before placing orders, that the information being relied on is current.

TI warrants performance of its semiconductor products and related software to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are utilized to the extent TI deems necessary to support this warranty. Specific testing of all parameters of each device is not necessarily performed, except those mandated by government requirements.

Certain applications using semiconductor products may involve potential risks of death, personal injury, or severe property or environmental damage ("Critical Applications").

TI SEMICONDUCTOR PRODUCTS ARE NOT DESIGNED, INTENDED, AUTHORIZED, OR WARRANTED TO BE SUITABLE FOR USE IN LIFE-SUPPORT APPLICATIONS, DEVICES OR SYSTEMS OR OTHER CRITICAL APPLICATIONS.

Inclusion of TI products in such applications is understood to be fully at the risk of the customer. Use of TI products in such applications requires the written approval of an appropriate TI officer. Questions concerning potential risk applications should be directed to TI through a local SC sales office.

In order to minimize risks associated with the customer's applications, adequate design and operating safeguards should be provided by the customer to minimize inherent or procedural hazards.

TI assumes no liability for applications assistance, customer product design, software performance, or infringement of patents or services described herein. Nor does TI warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right of TI covering or relating to any combination, machine, or process in which such semiconductor products or services might be or are used.

Preface

About This Manual

This manual tells you how to install and operate the TMS320C6x ('C6x) evaluation module (EVM). It also provides support software documentation, application programming interfaces (APIs), and technical reference material for the 'C6x EVM.

The 'C6x EVM is a peripheral component interconnect (PCI) plug-in card that is compliant with the *PCI Local Bus Specification Revision 2.1*. The 'C6x EVM helps you evaluate characteristics of the 'C6x digital signal processor (DSP) to determine if it meets your application requirements. The 'C6x EVM is intended for use in a PCI expansion slot inside the PC™. It can also be operated outside the PC on a desktop or lab bench with the use of an external power supply and emulator (XDS510 or XDS510WS). The power supply and emulator are not included in the kit.

'C6x EVM support software and APIs enable you to use the board to create applications for the 'C6x. Software utilities are provided with the 'C6x EVM for board diagnostics, board configuration, and common object file format (COFF) DSP application loading. EVM schematics and logic equations are included in this manual to ease your hardware development efforts and reduce time to market.

This manual assumes that you are familiar with working in a Windows™ 95 or a Windows NT™ environment and understand general and technical PC terminology. This manual specifically addresses the 'C6x EVM and its support software. Detailed information about the 'C6x DSP and TI code development support tools is provided separately (see the *Related Documentation From Texas Instruments* section in this *Preface* for a list of documents and ordering information). For a summary of changes in this book, see Appendix H, *Summary of Updates in This Document*. For up-to-date information on the 'C6x EVM, as well as related products, visit the 'C6x EVM website at <http://www.ti.com/sc/c62xevm>.

How to Use This Manual

This reference guide provides the following types of information about the 'C6x EVM:

- **Introductory information**, consisting of Chapter 1, provides a high-level overview of the 'C6x EVM hardware and support software and describes how the product can be used during code development and debugging.
- **Installation information**, consisting of Chapters 2 and 3, provides hands-on information to help you get started using the 'C6x EVM.
 - Chapter 2 identifies the system requirements and 'C6x EVM kit contents. It also provides step-by-step hardware and software installation procedures.
 - Chapter 3 provides instructions for running the EVM confidence test.
- **Theory of operation**, consisting of Chapters 4 through 8, provides detailed information about the 'C6x EVM hardware and support software:
 - Chapter 4 describes the theory of operation for the 'C6x EVM hardware, including key component identification, detailed information about each functional area, and interface descriptions.
 - Chapter 5 provides a high-level overview of the C source debugger operation with the 'C6x EVM.
 - Chapter 6 describes the 'C6x EVM host software utilities.
 - Chapter 7 describes the host support software. It includes a complete API reference that allows you to write your own applications for the 'C6x EVM and also includes example applications that use the API calls.
 - Chapter 8 describes the DSP support software. It includes a complete API reference that allows you to write your own applications for the 'C6x EVM and also includes example applications that use the API calls.
- **Reference material**, consisting of Appendixes A through G, provides quick reference information for the 'C6x EVM:
 - Appendix A provides the EVM connector pinouts.
 - Appendix B contains the EVM DIP switch settings.
 - Appendix C contains the EVM schematics.
 - Appendix D provides the EVM complex programmable logic device (CPLD) equations.
 - Appendix E summarizes the EVM PCI configuration EEPROM.
 - Appendix F provides troubleshooting information.
 - Appendix G provides a glossary of terms used in this manual.

Notational Conventions

This document uses the following conventions:

- Program listings, program examples, and interactive displays are shown in a special typeface. Some examples use a **bold version** for emphasis; interactive displays use a **bold version** to distinguish commands that you enter from items that the system displays (such as prompts, command output, error messages, etc.).

Here is a sample program listing with the `evm6x_close()` function highlighted for emphasis:

```
#include <windows.h>
#include <evm6xdll.h>
. . .
HANDLE    h_board;
h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    exit(-1);
}
. . .
evm6x_close( h_board );
```

- In syntax descriptions, the instruction or command is in a **bold face**, and parameters are in *italics*. Portions of a syntax that are in **bold** should be entered as shown; portions of a syntax that are in *italics* describe the type of information that should be entered. Here is an example of a command syntax:

evm6xldr *filename*

- Square brackets (**[** and **]**) identify an optional parameter. If you use an optional parameter, you specify the information within the brackets; you do not enter the brackets themselves. Here is an example of a command that has optional parameters.

evm6xtst [*options*] [*log_filename*]

`evm6xtst` is the command. This command has two optional parameters, indicated by *options* and *log_filename*.

- Device pins often are represented in groups. Device pin group notation consists of the pin name followed by brackets containing the range of pins included in the group. A colon separates the numbers in the range. For example, `PDB[7:0]` represents the 8 peripheral data bus pins (PDB7 through PDB0) on a device.

- The TMS320C6x family of devices is referred to as the 'C6x. The following abbreviations are used in this manual for TI devices on the 'C6x EVM:

Abbreviation	Device Definition
'C6201	TMS320C6201
'ALB16244	SN74ALB16244
'CBT3257	SN74CBT3257
'CBTD3384	SN74CBTD3384
'LVT125	SN74LVT125
'LVTH162245	SN74LVTH162245

Information About Cautions and Warnings

This book contains cautions and warnings.

This is an example of a caution statement.
A caution statement describes a situation that could potentially damage your software or equipment.

This is an example of a warning statement.
A warning statement describes a situation that could potentially cause harm to you.

The information in a caution or a warning is provided for your protection. Please read each caution and warning carefully.

Related Documentation From Texas Instruments

The following books describe the 'C6x processor and related support tools. To obtain a copy of any of these TI documents, call the Texas Instruments Literature Response Center at (800)477–8924. When ordering, please identify the book by its title and literature number.

TMS320C6x Assembly Language Tools User's Guide (literature number SPRU186) describes the assembly language tools (assembler, linker, and other tools used to develop assembly language code), assembler directives, macros, common object file format, and symbolic debugging directives for the 'C6x generation of devices.

TMS320C6x C Source Debugger User's Guide (literature number SPRU188) tells you how to invoke the 'C6x simulator and emulator versions of the C source debugger interface. This book discusses various aspects of the debugger, including command entry, code execution, data management, breakpoints, profiling, and analysis.

TMS320C6x Optimizing C Compiler User's Guide (literature number SPRU187) describes the 'C6x C compiler and the assembly optimizer. This C compiler accepts ANSI standard C source code and produces assembly language source code for the 'C6x generation of devices. The assembly optimizer helps you optimize your assembly code.

TMS320C62x/C67x CPU and Instruction Set Reference Guide (literature number SPRU189) describes the 'C62x/C67x CPU architecture, instruction set, pipeline, and interrupts for these digital signal processors.

TMS320C6201/C6701 Peripherals Reference Guide (literature number SPRU190) describes common peripherals available on the TMS320C6201/C6701 digital signal processors. This book includes information on the internal data and program memories, the external memory interface (EMIF), the host port, multichannel buffered serial ports, direct memory access (DMA), clocking and phase-locked loop (PLL), and the power-down modes.

TMS320C62x/C67x Programmer's Guide (literature number SPRU198) describes ways to optimize C and assembly code for the TMS320C62x/C67x DSPs and includes application program examples.

TMS320C62x/C67x Technical Brief (literature number SPRU197) gives an introduction to the 'C62x/C67x digital signal processors, development tools, and third-party support.

XDS51x Emulator Installation Guide (literature number SPNU070) describes the installation of the XDS510™, XDS510PP™, and XDS510WS™ emulator controllers. The installation of the XDS511™ emulator is also described.

TMS320 DSP Development Support Reference Guide (literature number SPRU011) describes the TMS320 family of digital signal processors and the tools that support these devices. Included are code-generation tools (compilers, assemblers, linkers, etc.) and system integration and debug tools (simulators, emulators, evaluation modules, etc.). Also covered are available documentation, seminars, the university program, and factory repair and exchange.

TMS320C6x Peripheral Support Library Programmer's Reference (literature number SPRU273) describes the contents of the 'C6x peripheral support library of functions and macros. It lists functions and macros both by header file and alphabetically, provides a complete description of each, and gives code examples to show how they are used.

TMS320C6201 Digital Signal Processor Data Sheet (literature number SPRS051) describes the features of the TMS320C6201 fixed-point DSP and provides pinouts, electrical specifications, and timings for the device.

Related Documentation

You can use the following specification to supplement this reference guide:

PCI Local Bus Specification Revision 2.1, PCI Special Interest Group, June 1, 1995.

Obtaining Technical Support

Before contacting Texas Instruments Technical Support, please have the following information available:

- ☐ Assembly number of your 'C6x EVM (D600830-0001) located on the bottom side of the board
- ☐ Revision number of your 'C6x EVM located in parentheses next to the assembly number on the bottom side of the board
- ☐ Serial number located on the bottom side of the board
- ☐ Record of the 'C6x EVM confidence test utility results that identifies potential problems and other revision numbers (software, EEPROM, CPLD). Chapter 3, *Running the Board Confidence Test*, explains how to run the test.
- ☐ Computer's PCI BIOS brand name and version number
- ☐ Amount of memory in your computer system
- ☐ Version of the software and operating environment you are using such as Windows NT 4.0
- ☐ Version of the code generation tools your are using
- ☐ Version of the debugger you are using
- ☐ If you are using Windows 95, print out a report of your system configuration by performing the following steps:
 - 1) Right click on the My Computer icon on the desktop.
 - 2) Select the Properties menu item.
 - 3) Select the Device Manager tag.
 - 4) Select the Print button.
 - 5) Select the System summary radio button.
 - 6) Click on the OK button to print a system resource summary.

Have this system resource summary available when you contact technical support.

Note:

Check the system resource summary to see if the IRQ assigned to TI TMS320C6x EVM is shared with another device. If it is, this is probably the problem. See Appendix F, *Troubleshooting*, for the corrective action.

Once you have this information ready, contact Texas Instruments Technical Support as specified in the *If You Need Assistance* section that follows.

Contents

1	Introduction	1-1
	<i>Describes the TMS320C6x evaluation module (EVM) and introduces you to the topics of this book.</i>	
1.1	Key Features of the TMS320C6x EVM	1-2
1.1.1	User Controls and Indicators	1-3
1.1.2	External Interfaces	1-3
1.2	The TMS320C6x EVM Board	1-4
1.3	TMS320C6x EVM Hardware Functional Overview	1-7
1.4	TMS320C6x EVM Software Functional Overview	1-10
1.5	Operating Scenarios	1-13
2	Getting Started With the TMS320C6x EVM	2-1
	<i>Helps you get started using the TMS320C6x EVM; lists system requirements and provides hardware and software installation instructions.</i>	
2.1	EVM Kit Contents	2-2
2.2	System Requirements	2-4
2.2.1	PCI Operation	2-4
2.2.2	Stand-alone Operation	2-5
2.3	Before Starting the Installation Process	2-6
2.3.1	Controlling Static Electricity	2-6
2.3.2	Avoiding Obstructions to the EVM Board	2-7
2.4	EVM Hardware Installation for PCI Operation	2-8
2.4.1	Notice to Windows 95 Users	2-10
2.5	EVM Hardware Installation for Stand-Alone Operation	2-11
2.6	EVM Software Installation	2-13
3	Running the Board Confidence Test	3-1
	<i>Explains how to run the board confidence test included with the TMS320C6x EVM to verify that the board and software have been installed properly.</i>	
3.1	About the Board Confidence Test	3-2
3.2	Verifying the EVM Installation	3-2
4	TMS320C6x EVM Hardware	4-1
	<i>Describes the TMS320C6x EVM hardware components and how they operate.</i>	
4.1	TMS320C6x EVM Hardware Detailed Block Diagram	4-2
4.2	TMS320C6201 DSP	4-4
4.3	DSP Clocks	4-7

4.4	External Memory	4-8
4.4.1	SBSRAM	4-10
4.4.2	SDRAM	4-11
4.4.3	Expansion Memory	4-12
4.4.4	DSP Memory Maps	4-13
4.4.5	DSP EMIF Registers	4-16
4.5	Expansion Interfaces	4-18
4.5.1	Expansion Memory Interface	4-18
4.5.2	Expansion Peripheral Interface	4-19
4.5.3	Daughterboard	4-21
4.6	PCI Interface	4-23
4.6.1	PCI Interface Implementation	4-24
4.6.2	PCI Controller Operation Registers	4-28
4.6.3	PCI Add-On Bus Operation Registers	4-29
4.6.4	PCI Slave Support	4-30
4.6.5	PCI Master Support	4-33
4.7	JTAG Emulation	4-38
4.8	Programmable Logic	4-40
4.8.1	Reset Control	4-42
4.8.2	Power Management	4-44
4.8.3	Dual DSP Clock Oscillator Control	4-45
4.8.4	PCI Controller/JTAG TBC Interface Control	4-47
4.8.5	PCI Controller/DSP Interface Control	4-47
4.8.6	PCI Memory-Mapped Board Control/Status Registers	4-49
4.8.7	DSP Memory-Mapped Control/Status Registers	4-56
4.8.8	PCI and DSP Interrupt Control	4-62
4.8.9	CE1 Memory Decoding/Data Transceivers Control	4-65
4.8.10	User Options Control	4-66
4.9	Stereo Audio Interface	4-69
4.10	Power Supplies	4-74
4.10.1	3.3-V Voltage Regulator	4-74
4.10.2	1.8-V/2.5-V Voltage Regulator	4-75
4.10.3	5-V Voltage Regulator	4-75
4.10.4	External Power Connector	4-75
4.10.5	Fan Power Connector	4-76
4.11	Voltage Supervision	4-77
4.12	User Options	4-78
4.13	Indicators	4-79
5	TMS320C6x EVM Debugger	5-1
	<i>Provides an overview of the TMS320C6x EVM debugger capabilities and EVM-specific debugger configuration information.</i>	
5.1	Key EVM Debugger Features	5-2
5.2	EVM-Specific Debugger Configuration	5-4
5.2.1	Identification of Boards by Relative Index	5-4
5.2.2	Dedicated Test Bus Controller	5-5
5.2.3	Application Name Differences	5-5

6	TMS320C6x EVM Host Utilities	6-1
	<i>Describes the host utilities provided with the 'C6x EVM, including the EVM COFF loader, EVM confidence test, and 'C6x EVM board configuration utilities.</i>	
6.1	EVM COFF Loader	6-2
6.2	EVM Confidence Test	6-4
6.3	EVM Board Configuration	6-6
7	TMS320C6x EVM Host Support Software	7-1
	<i>Describes the EVM host support software components and low-level Windows drivers; provides an alphabetical summary of the Win32 DLL API functions and examples of how the EVM host support software can be used by user-generated Win32 applications.</i>	
7.1	Host Support Software Components	7-2
7.2	EVM Low-Level Windows Drivers	7-2
7.3	EVM Win32 DLL API	7-3
7.3.1	EVM Win32 DLL API Data Types	7-3
7.3.2	EVM Win32 DLL API Functions	7-5
7.4	EVM Host Support Software Example	7-42
8	TMS320C6x EVM DSP Support Software	8-1
	<i>Describes the EVM DSP support software components; provides an alphabetical summary of the McBSP driver, codec library, and board support library API functions and examples of how the EVM DSP support software can be used by user-generated DSP applications.</i>	
8.1	DSP Support Software Components	8-2
8.2	Using the DSP Support Software Components	8-3
8.3	McBSP Driver API	8-4
8.3.1	McBSP Driver Macros	8-4
8.3.2	McBSP Driver Data Types	8-5
8.3.3	McBSP Driver Functions	8-8
8.4	Codec Library API	8-22
8.4.1	Codec Library Macros	8-22
8.4.2	Codec Library API Functions	8-26
8.5	Board Support Library API	8-39
8.6	DSP Support Software Examples	8-45
A	TMS320C6x EVM Connector Pinouts	A-1
	<i>Identifies the connector pins on the TMS320C6x EVM.</i>	
A.1	TMS320C6x EVM Connector Summary	A-2
A.2	Stereo Microphone Input Jack	A-2
A.3	Stereo Line Input Jack	A-3
A.4	Stereo Line Output Jack	A-3
A.5	CPLD ISP Header	A-4
A.6	TMS320C6x JTAG Emulation Header	A-5
A.7	Expansion Memory Interface Connector	A-6
A.8	Expansion Peripheral Interface Connector	A-7
A.9	External Power Connector	A-8
A.10	DSP Fan Power Connector	A-8
A.11	PCI Local Bus Connector	A-9

B	TMS320C6x EVM DIP Switches	B-1
	<i>Describes the user-option DIP switches on the TMS320C6x EVM; identifies the factory default switch settings.</i>	
C	TMS320C6x EVM Schematics	C-1
	<i>Contains the schematics for the TMS320C6x EVM.</i>	
D	TMS320C6x EVM CPLD Equations	D-1
	<i>Contains the CPLD equations for the TMS320C6x EVM.</i>	
D.1	Overview of the EVM CPLD	D-2
D.2	EVM CPLD Equations	D-8
E	TMS320C6x EVM PCI Configuration EEPROM	E-1
	<i>Summarizes the contents of the EEPROM on the TMS320C6x EVM.</i>	
F	Troubleshooting	F-1
	<i>Lists error conditions and explains how to correct them.</i>	
G	Glossary	G-1
	<i>Defines acronyms and key terms used in this book.</i>	
H	Summary of Updates in This Document	H-1
	<i>Summarizes the updates in this version of the document.</i>

Introduction

This chapter lists the key features of the TMS320C6x evaluation module (EVM), provides functional overviews of the EVM hardware and software, and describes the EVM operating scenarios.

The TMS320C6x evaluation module (EVM) is a low-cost, general-purpose platform for the development, analysis, and testing of 'C6x digital signal processor (DSP) algorithms and applications. The 'C6x EVM allows you to evaluate the 'C6x DSP and algorithms to determine if they meet your application requirements. The 'C6x EVM hardware design information and software application programming interfaces (APIs) also provide a reference design that facilitates your own 'C6x-based hardware and software development.

The EVM is bundled with TMS320C6x code generation and source debugger tools, Windows 95 and NT drivers, host PC and DSP software APIs, example applications with source code, and various utility applications. The hardware and software bundle provides an integrated package that allows you to quickly evaluate the 'C6x DSP's performance and develop custom applications.

Topic	Page
1.1 Key Features of the TMS320C6x EVM	1-2
1.2 The TMS320C6x EVM Board	1-4
1.3 TMS320C6x EVM Hardware Functional Overview	1-7
1.4 TMS320C6x EVM Software Functional Overview	1-10
1.5 Operating Scenarios	1-13

1.1 Key Features of the TMS320C6x EVM

The 'C6x EVM has the following key features:

- ☐ 200-MHz 'C6201 DSP capable of executing 1600 million instructions per second (MIPS)
- ☐ Quad clock support (33.25 MHz, 40 MHz, 133 MHz, and 160 MHz)
- ☐ Peripheral component interconnect (PCI) interface with initiator/target (master/slave) support
- ☐ 256K bytes of 133-MHz synchronous burst static random-access memory (SBSRAM)
- ☐ 8M bytes of 100-MHz synchronous dynamic RAM (SDRAM)
- ☐ Embedded JTAG emulation via PCI and external XDS510 support
- ☐ Host port interface (HPI) access to all DSP memory via the PCI bus
- ☐ Stereo 16-bit audio codec that supports sample rates from 5.5 kHz–48 kHz
- ☐ Onboard switching voltage regulators for 1.8/2.5 volts direct current (V_{DC}) and 3.3 V_{DC}
- ☐ Onboard linear voltage regulator for analog 5 V_{DC}
- ☐ Three light emitting diode (LED) indicators (one power-on indicator and two user-defined indicators)
- ☐ Internal PCI operation
- ☐ External desktop operation (requires external power supply and XDS510 or XDS510WS emulator, which are not included in the 'C6x EVM kit)
- ☐ Expansion memory and DSP peripheral connectors for daughterboard support
- ☐ Plug-and-play PCI device

1.1.1 User Controls and Indicators

The 'C6x EVM has the following user controls and indicators:

- ☐ JTAG emulation (embedded or external)
- ☐ DSP oscillator clock selection (33.25 MHz or 40 MHz)
- ☐ Clock mode (multiply-by-1 or multiply-by-4 for 33.25-MHz, 40-MHz, 133-MHz, or 160-MHz DSP CLKOUT1)
- ☐ DSP boot mode selection:
 - None (no-boot mode)
 - HPI boot mode
 - Read-only memory (ROM) boot mode (requires optional daughter-board)
- ☐ Little- or big-endian memory addressing
- ☐ Three user-defined dual in-line package (DIP) switches
- ☐ Manual reset
- ☐ Power-on LED indicator
- ☐ Two user-defined LED indicators

1.1.2 External Interfaces

The 'C6x EVM has the following external interfaces:

- ☐ PCI revision 2.1-compliant interface (5 V, 32-bit)
- ☐ Molex 4-pin external power connector (5 V, 12 V, –12 V, and GND)
- ☐ 2-pin power connector for cooling fan (5 V)
- ☐ 14-pin external JTAG header
- ☐ 10-pin complex programmable logic device (CPLD) in-system programmable (ISP) header (not installed)
- ☐ Three 3.5-mm audio jacks (line in, line out, and microphone)
- ☐ Two low-profile 80-pin (.050-inch) daughterboard connectors (EMIF and DSP peripheral expansion)

1.2 The TMS320C6x EVM Board

The 'C6x EVM is a full-size PCI board with approximate dimensions of 4.2 inches wide, 12.28 inches long, and 0.49 inches high (excluding its bracket and retainer). The 'C6x EVM is intended for use in a PCI expansion slot on your computer's motherboard. The 'C6x EVM can be operated stand-alone on a desktop with the use of an external power supply and XDS510 or XDS510WS emulator. (The power supply and the emulator required for stand-alone operation are not included in the kit.)

Note:

If you are using the 'C6x EVM in a PCI expansion slot, make sure there is an unobstructed slot open for the full-length PCI card. See section 2.3.2, *Avoiding Obstructions to the EVM Board*, for more information.

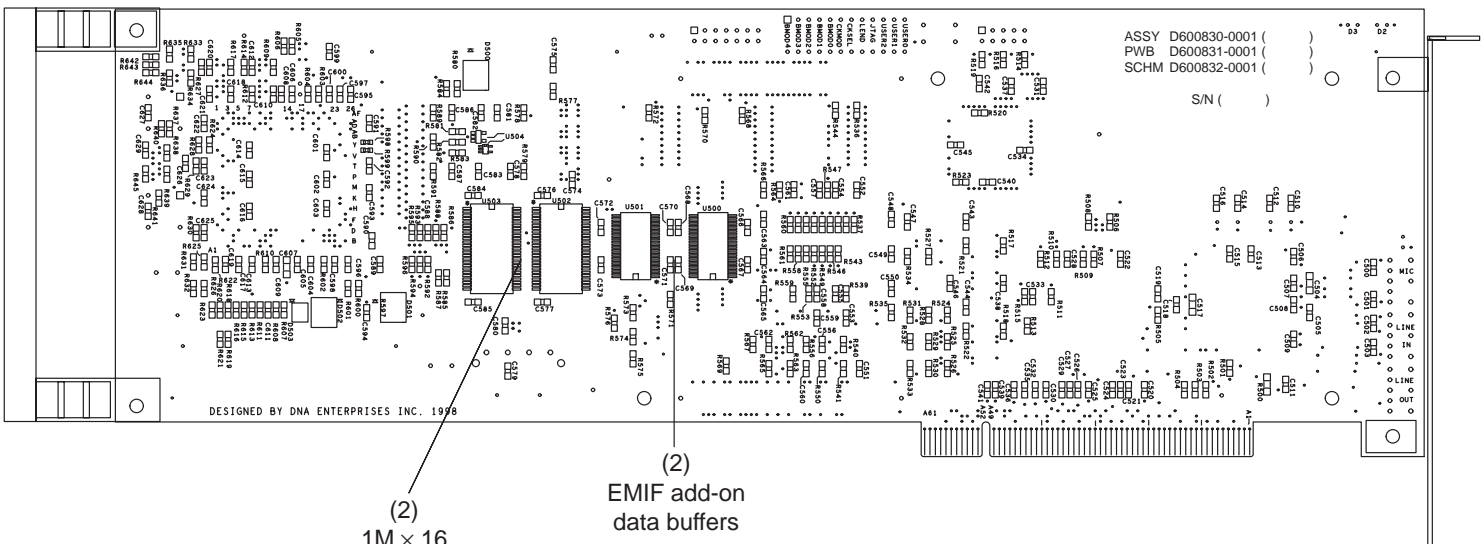

The 'C6x EVM has a 'C6201 DSP onboard that allows full-speed verification of 'C6x code with the included source debugger. The 'C6x EVM provides a PCI interface, SBSRAM and SDRAM, a 16-bit audio codec, and embedded JTAG emulation support. Connectors on the 'C6x EVM provide DSP external memory interface (EMIF) and peripheral signals that enable its functionality to be expanded with custom or third-party daughterboards.

The EVM provides a 'C6x hardware reference design that can assist you in the development of your own 'C6x-based products. In addition to providing a reference for interfacing the DSP to various types of memories and peripherals, the design also addresses power, clock, JTAG, and PCI controller interfaces.

Figure 1–1 and Figure 1–2 depict the top and bottom sides, respectively, of the 'C6x EVM. The figures identify the major components on the 'C6x EVM board.

Figure 1-1. TMS320C6x EVM Layout (Top Side)

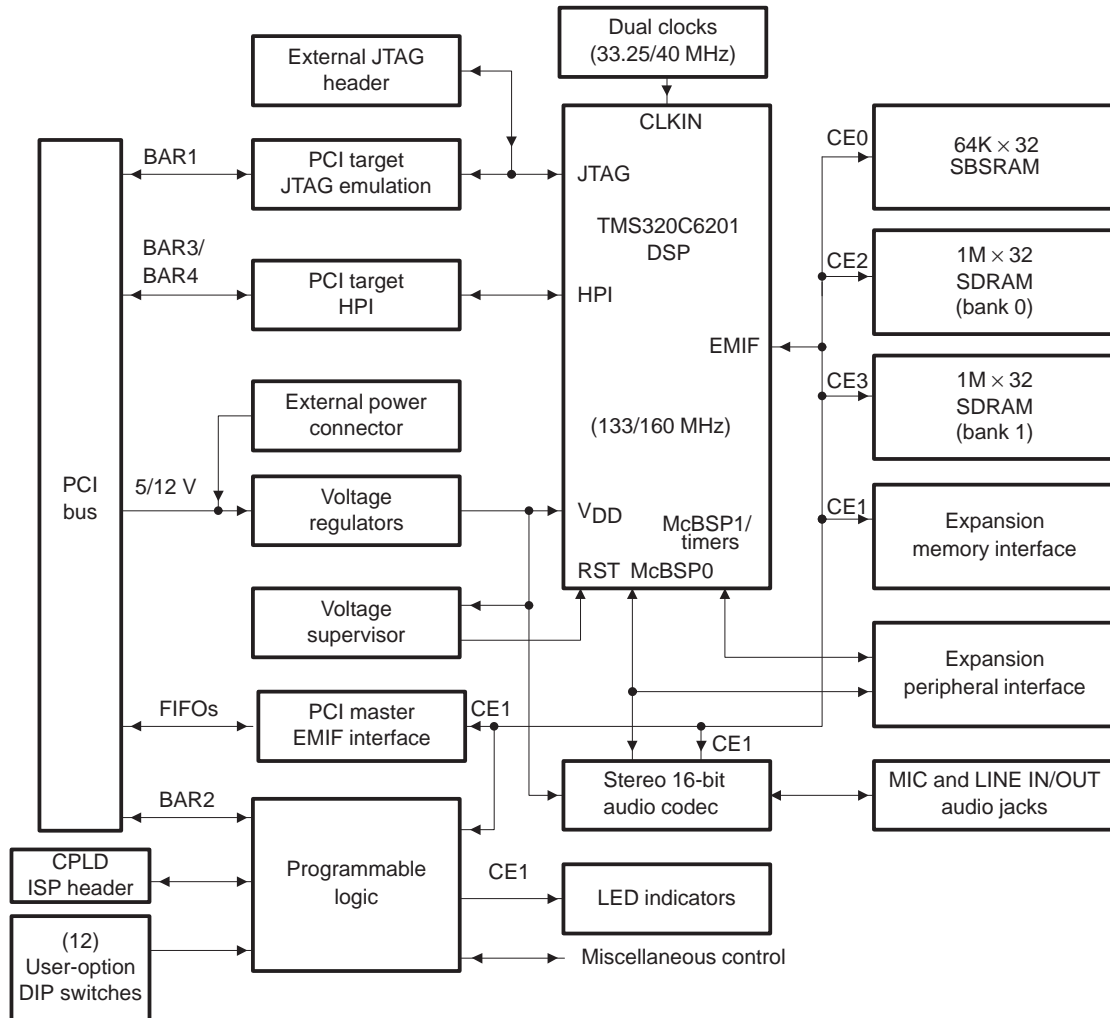

1.3 TMS320C6x EVM Hardware Functional Overview

Figure 1–3 shows the basic functional block diagram and interfaces of the 'C6x EVM.

Figure 1–3. TMS320C6x EVM Block Diagram

The 'C6x EVM hardware can be divided into 12 functional areas. This section provides an overview of each of these 12 areas. Detailed descriptions of the EVM hardware are provided in Chapter 4, *TMS320C6x EVM Hardware*.

- ❑ **DSP.** The 'C6x EVM is built around the 'C6201 DSP, which operates up to 1600 MIPS with a CPU clock rate of 200 MHz. For more information, see section 4.2, *TMS320C6201 DSP*.
- ❑ **DSP clocks.** The 'C6x EVM supports operation with two different onboard clock sources (33.25 MHz and 40 MHz) and two clock modes (multiply-by-1 and multiply-by-4). As a result, the DSP can operate at four different clock rates, including 33.25 MHz, 40 MHz, 133 MHz, or 160 MHz. For more information, see section 4.3, *DSP Clocks*.
- ❑ **External memory.** The 'C6x EVM provides one bank of 64K × 32, 133-MHz SBSRAM and two banks of 1M × 32, 100-MHz SDRAM. Additional asynchronous memory can be added with a daughterboard using the expansion memory interface. All external memory devices are byte-addressable. For more information, see section 4.4, *External Memory*.
- ❑ **Expansion interfaces.** The 'C6x EVM provides external memory interface and external peripheral interface connectors that enable the use of a custom or third-party daughterboard. The memory interface supports asynchronous memory transfers, and the peripheral interface provides daughterboard use of the DSP internal peripherals. For more information, see section 4.5, *Expansion Interfaces*.
- ❑ **PCI interface.** The 'C6x EVM includes a *PCI Local Bus Revision 2.1*-compliant interface that enables host access to the onboard JTAG controller, DSP host port interface (HPI), and board control/status registers. The 'C6x EVM's PCI interface allows source debugging with the 'C6x EVM without requiring an XDS510 emulator, as well as host software access to all of the DSP memory space via the PCI bus. The 'C6201 DSP can also master the PCI bus to transfer data to and from the host memory. For more information, see section 4.6, *PCI Interface*.
- ❑ **JTAG emulation.** The 'C6x EVM provides embedded JTAG emulation, using an onboard test bus controller (TBC), as well as a header to support an XDS510 JTAG emulator. This allows source debugging over the PCI bus without requiring an emulator or by using an XDS510 emulator when operating stand-alone on a desktop. For more information, see section 4.7, *JTAG Emulation*.
- ❑ **Programmable logic.** The 'C6x EVM's CPLD provides the board's glue-logic and control/status registers. For more information, see section 4.8, *Programmable Logic*.

- ❑ **Audio interface.** The 'C6x EVM includes a CD-quality, 16-bit audio interface with stereo microphone and line-level inputs and a stereo line-level output. A multimedia audio codec is used that supports all popular sample rates from 5.5kHz–48 kHz. The audio circuit includes an op amp based microphone preamplifier. Three 3.5-mm audio jacks are located on the board's mounting bracket. For more information, see section 4.9, *Stereo Audio Interface*.
- ❑ **Power supplies.** The 'C6x EVM uses voltage regulators to provide 1.8 V or 2.5 V for the 'C6201 core; 3.3 V for the 'C6201 I/O, memories, CPLD, and buffers; and 5 V for audio components. The PCI bus or external power connector's 5 V is used for all other digital components. The PCI bus or external power connector's 12 V is used for the input to the 5 V regulator. Efficient switching regulators are used for the 1.8/2.5 V and 3.3 V, and a low-power linear regulator is used to generate the analog 5 V. For more information, see section 4.10, *Power Supplies*.
- ❑ **Voltage supervision and reset control.** The 'C6x EVM uses a voltage supervisor to monitor the board's voltages and provide a board reset signal. The CPLD also includes logic related to reset control with inputs from a manual reset pushbutton, the PCI controller, and software reset control signals. For more information, see section 4.11, *Voltage Supervision*.
- ❑ **User options.** The 'C6x EVM supports user option control via 12 onboard DIP switches or with direct control by host software via the PCI bus. The user options include the boot mode, clock mode, clock select, JTAG select, and endian mode. Three user-defined options are also provided. For more information, see section 4.12, *User Options*.
- ❑ **LED indicators.** The 'C6x EVM provides three LED indicators. A single green LED is illuminated whenever 5 V is applied to the board. Two red LEDs can be used for user-defined status, with one located on the board's mounting bracket and the other located at the top of the board. For more information, see section 4.13, *Indicators*.

1.4 TMS320C6x EVM Software Functional Overview

The 'C6x EVM software consists of *host support software* and *DSP support software*.

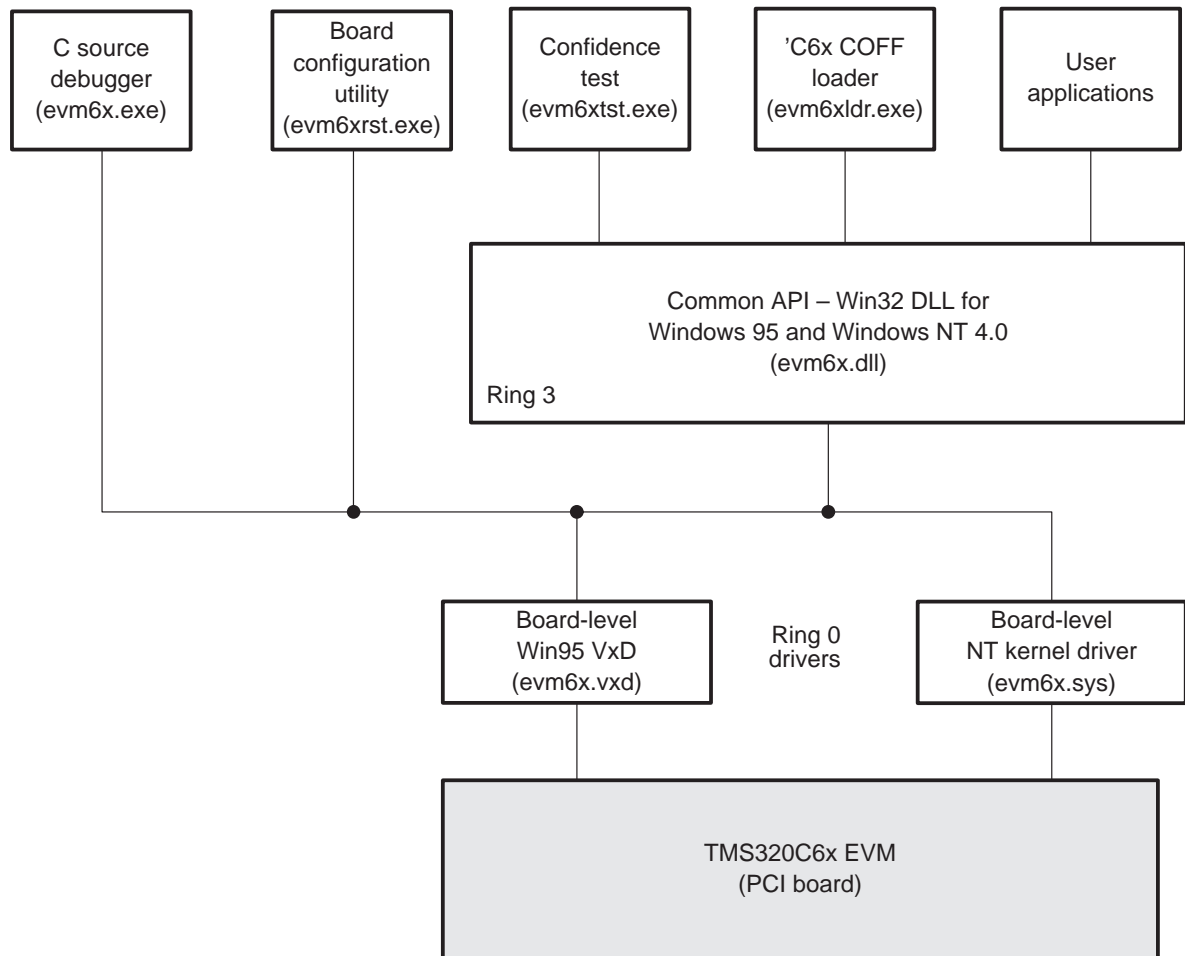

The host support software supplied with the 'C6x EVM board includes the following Win32 host utilities and libraries. The host utilities and host libraries run on an Intel™ PC under either Windows 95 or Windows NT 4.0.

- ❑ **C source debugger (evm6x.exe).** The debugger software tool helps you debug 'C6x software on the board. For more information, see Chapter 5, *TMS320C6x EVM Debugger*.
- ❑ **Board configuration utility (evm6xrst.exe).** This utility is used to reset and configure the board. For more information, see section 6.3, *EVM Board Configuration*.
- ❑ **EVM confidence test utility (evm6xtst.exe).** This utility tests the basic operation of the board. For more information about the EVM confidence test, see section 6.2, *EVM Confidence Test*. To use the EVM confidence test to verify the hardware and software installation, see Chapter 3, *Running the Board Confidence Test*.
- ❑ **'C6x COFF loader utility (evm6xldr.exe).** This utility is used to load and execute 'C6x software on the board. For more information, see section 6.1, *EVM COFF Loader*.
- ❑ **EVM Win32 DLL (evm6x.dll).** The Win32 host libraries consist of a Windows 95 and a Windows NT version of evm6x.dll, which provides user software access for control and communication with the EVM board. For more information, see Chapter 7, *TMS320C6x EVM Host Support Software*.
- ❑ **Example source code.** Example code that illustrates how to use the host Win32 dynamic link library (DLL) functions is provided with the 'C6x EVM. For more information, see section 7.4 *EVM Host Support Software Example*.

Figure 1–4 provides a block diagram of the EVM host software components and their relationships. The left side of the figure shows the C source debugger. The debugger makes direct calls to the low-level (ring 0) drivers to access the JTAG TBC device on the EVM board. The board configuration utility also makes direct calls to the drivers to access the board option registers on the EVM board.

The remainder of the figure shows the Win32 host utilities and the components they use to access the hardware. The Win32 applications call the Windows 95 or Windows NT DLL that implement a consistent user-mode (ring 3) API. These DLLs make calls to the low-level (ring 0) drivers that provide access to the hardware.

Figure 1–4. TMS320C6x EVM Host Support Software Block Diagram

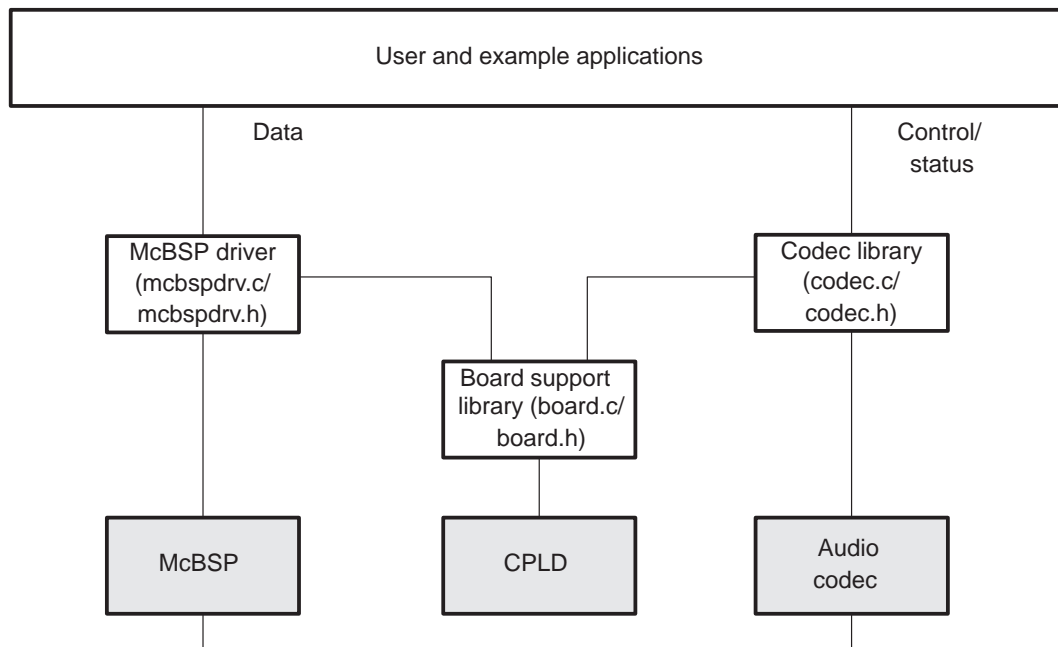

The DSP support software supplied with the EVM board includes the following components:

- ❑ **McBSP driver (mcbspdvr.c and mcbspdvr.h).** This driver is for the multichannel buffered serial port (McBSP) peripheral. For more information, see section 8.3, *McBSP Driver API*.
- ❑ **Codec library (codec.c and codec.h).** This library is a collection of routines that configures and controls the operation of the CS4231A audio codec device. For more information, see section 8.4, *Codec Library API*.
- ❑ **Board support library (board.c and board.h).** This library provides 'C6x board-specific routines for EVM configuration and control. For more information, see section 8.5, *Board Support Library API*.
- ❑ **Example source code.** Code examples are provided to demonstrate the use of the DSP McBSP, codec, and board support functions. For more information, see section 8.6, *DSP Support Software Examples*.

Figure 1–5 provides a block diagram of the EVM 'C6x software components and their relationships. For more information, see Chapter 8, *TMS320C6x EVM DSP Support Software*.

Figure 1–5. TMS320C6x EVM DSP Support Software Block Diagram

1.5 Operating Scenarios

The 'C6x EVM can operate in a computer motherboard's full-size PCI slot or stand alone on a desktop or lab bench. Because the 'C6x EVM does not have onboard ROM, applications are loaded by host software using the board's embedded JTAG or DSP HPI interfaces over the PCI bus or by an XDS510 emulator connected to the board's 14-pin JTAG header. A daughterboard with non-volatile memory can be designed to provide the 'C6x EVM with a ROM boot capability that enables it to boot an application itself upon reset in both operating scenarios.

Table 1–1 summarizes the various ways applications can be loaded into the 'C6x in the PCI and stand-alone operating scenarios.

Table 1–1. Operating Scenarios Application Loading Summary

Operating Scenario	JTAG TBC Via PCI Bus	DSP HPI Via PCI Bus	XDS510 Emulator	ROM Daughterboard
PCI slot	Yes	Yes	Yes	Yes
Stand-alone	No	No	Yes	Yes

The following paragraphs summarize the PCI and stand-alone operating scenarios.

- ❑ **PCI operation.** When the 'C6x EVM is installed in a PCI slot, host software can control and monitor it via memory-mapped registers. The host software can also access the onboard JTAG test bus controller (TBC) to download code and access the DSP, as well as transfer data to and from the DSP using the 'C6201 HPI. The C source debugger uses the JTAG TBC to access the board, and the 'C6x EVM COFF loader uses the HPI. An XDS510 can be used with the board in a PCI slot, but it is not needed because onboard emulation control is provided. An optional ROM-boot mode can be used in PCI operation if a daughterboard with nonvolatile memory is installed.
- ❑ **Stand-alone operation.** When the 'C6x EVM is operated in a stand-alone configuration on a desktop or lab bench, an XDS510 or XDS10WS emulator with the standard 'C6x C source debugger (not the 'C6x EVM debugger included in the kit) is typically used to load applications and control the board. In stand-alone operation, the PCI interface is disabled, so the onboard JTAG TBC and HPI interfaces are not available. An optional ROM-boot mode can be used in stand-alone operation if a daughterboard with nonvolatile memory is installed.

Getting Started With the TMS320C6x EVM

This chapter explains how to get started using the 'C6x EVM. It provides a list of EVM kit contents, system requirements, and step-by-step hardware and software installation instructions.

Before you begin the installation, verify that you received all of the EVM kit components listed in section 2.1 and that your PC hardware and software platforms meet the minimum requirements described in section 2.2.

Topic	Page
2.1 EVM Kit Contents	2-2
2.2 System Requirements	2-4
2.3 Before Starting the Installation Process	2-6
2.4 EVM Hardware Installation for PCI Operation	2-8
2.5 EVM Hardware Installation for Stand-Alone Operation	2-11
2.6 EVM Software Installation	2-13

2.1 EVM Kit Contents

The following checklist details items that are shipped with the 'C6x EVM kit.

- | | | |
|--------------------------|-------------------------|--|
| <input type="checkbox"/> | PCI plug-in card | TMS320C6x EVM PCI plug-in card |
| <input type="checkbox"/> | CD-ROMs | <p>Two CD-ROMs are included in the kit:</p> <p><i>TMS320C6x EVM Support Software</i>. This CD-ROM contains the following software:</p> <ul style="list-style-type: none"><input type="checkbox"/> Device driver for Windows 95. Includes common Win32 user-mode dynamic link library (DLL) with programmer API and low-level VxD driver<input type="checkbox"/> Device driver for Windows NT 4.0. Includes common Win32 user-mode DLL with programmer API and low-level kernel mode driver<input type="checkbox"/> Host example code. Example code that uses the Win32 user-mode DLL to access the EVM board resources<input type="checkbox"/> C source debuggers. Includes a C source debugger for Windows 95 and another for Windows NT 4.0<input type="checkbox"/> 'C6x COFF loader. A command-line utility that provides a means to configure the EVM board and load an application via the DSP HPI<input type="checkbox"/> Confidence test utility. A command-line utility that verifies proper operation of the EVM by testing the major components on the board<input type="checkbox"/> Board configuration utility. A command-line utility that resets and configures the EVM board.<input type="checkbox"/> 'C6x peripheral support library. 'C6x device library for DMA, timers, McBSPs, EMIF, HPI, and interrupt control<input type="checkbox"/> 'C6x McBSP driver. Stand-alone 'C6x McBSP driver in object and source formats<input type="checkbox"/> 'C6x codec device library. Audio codec device library in object and source formats<input type="checkbox"/> 'C6x board support library. EVM board support library in object and source formats.<input type="checkbox"/> 'C6x example code. Example DSP application using the McBSP driver, codec device library, and board support library |

**CD-ROMS
(continued)**

TMS320C6x DSP CD-ROM. This interactive CD-ROM features the 'C6x DSP generation. It also contains full information about DSP Solutions from the Texas Instruments website at <http://www.ti.com/dsps>, including 165M bytes of DSP technical documentation.

**TI code generation
tools**

A separate box is included that provides the 'C6x code generation tools. This box contains an additional CD-ROM and documentation.

**Documentation**

The following documentation is included:

- ☐ *TMS320C6x Evaluation Module Reference Guide* (this book)
- ☐ *TMS320C6x Peripheral Support Library Programmer's Reference*
- ☐ *TMS320C62x/C67x CPU and Instruction Set Reference Guide*
- ☐ *TMS320C6201/C6701 Peripherals Reference Guide*
- ☐ *TMS320C6x C Source Debugger User's Guide*
- ☐ *TMS320C6201 Digital Signal Processor Data Sheet*
- ☐ *Microprocessor Development Systems TI Customer Support Guide*
- ☐ *Government Compliance Card*
- ☐ *TMS320C6x EVM Registration Card*

2.2 System Requirements

The following sections list the system requirements for operating the 'C6x EVM in a PCI slot and in a stand-alone configuration.

2.2.1 PCI Operation

The following checklists detail the items that are required for operating the 'C6x EVM in a PCI slot.

Hardware checklist

- | | |
|---|--|
| <input type="checkbox"/> Host | Pentium™ PC |
| <input type="checkbox"/> Memory | Minimum of 16M bytes (32M bytes recommended) |
| <input type="checkbox"/> Hard disk space | Minimum of 20M bytes |
| <input type="checkbox"/> Monitor | Color |
| <input type="checkbox"/> Slot | One full-length revision 2.1-compliant PCI local bus slot (5 V, 32 bits) |
| <input type="checkbox"/> Board | TMS320C6x EVM board (included in the kit) |
| <input type="checkbox"/> Other hardware | CD-ROM drive |
| <input type="checkbox"/> Cables | 3.5-mm audio cables (optional) |

Software checklist

- | | |
|---|--|
| <input type="checkbox"/> Operating system | Windows 95 or Windows NT 4.0 |
| <input type="checkbox"/> PC software tools | Microsoft™ Visual C++ version 4.2 or greater (required for host-side user application development) |
| <input type="checkbox"/> Files | All other files are installed by the 'C6x EVM support software and the TI code generation tools CD-ROMs included in the kit. |

2.2.2 Stand-alone Operation

The following checklists detail the items that are required for operating the 'C6x EVM in a stand-alone configuration.

Hardware checklist

- | | |
|---|--|
| <input type="checkbox"/> Host | One of the following: <ul style="list-style-type: none"> <input type="checkbox"/> A 32-bit 486-based Pentium PC <input type="checkbox"/> Minimum of a SPARCstation™ compatible system equivalent to a SPARCstation 2 |
| <input type="checkbox"/> Memory | Minimum of 16M bytes of RAM |
| <input type="checkbox"/> Hard disk space | Minimum of 32M bytes of hard disk space for temp files and 15M bytes of hard disk space for software tools |
| <input type="checkbox"/> Monitor | Color |
| <input type="checkbox"/> Board | TMS320C6x EVM board (included in the kit) |
| <input type="checkbox"/> Other hardware | CD-ROM drive |
| <input type="checkbox"/> Power supply | 5 V _{DC} at 4 A
12 V _{DC} at 500 mA
–12 V _{DC} at 100 mA (optional for daughterboard) |
| <input type="checkbox"/> Cables | <input type="checkbox"/> Power cable with 4-pin Molex (disk-drive) connector

<input type="checkbox"/> 3.5-mm audio cables (optional) |
| <input type="checkbox"/> Emulator | XDS510 or XDS510WS |

Software checklist

- | | |
|--|---|
| <input type="checkbox"/> Operating system | One of the following: <ul style="list-style-type: none"> <input type="checkbox"/> For a PC platform, you need Windows NT 3.5.1 or higher or Windows 95 <input type="checkbox"/> For a SPARCstation platform, you need SunOS™ version 4.1.x or SunOS version 5.x (or Solaris™ 2.x) using an X Window System™ based window manager, such as OpenWindows™ version 3.0. |
| <input type="checkbox"/> Debugger | TMS320C6x C source debugger for an XDS510 or XDS510WS (not the EVM 'C6x debugger included in the kit) |

2.3 Before Starting the Installation Process

Before you begin installing the 'C6x EVM, perform the following tasks:

- ☐ Verify that you have received the items listed as part of the 'C6x EVM kit in section 2.1.
- ☐ Make sure that the system in which you are installing the EVM meets the hardware and software requirements listed in section 2.2.
- ☐ To help avoid equipment damage, read and follow the instructions in this section for controlling static electricity and avoiding obstructions that could prevent you from installing the 'C6x EVM.

Note:

If any items in the EVM kit are missing or damaged, contact Texas Instruments immediately. See *If You Need Assistance* in the *Preface* for the appropriate contact information.

2.3.1 Controlling Static Electricity

Minimizing Static Shock

Special handling methods and materials should be used to prevent equipment damage. You should be familiar with identification and handling of ESD-sensitive devices before attempting to perform the procedures identified in this manual.

To help avoid problems resulting from static electricity, follow these guidelines:

- ☐ Store the board in its antistatic bag until you are ready to use it.
- ☐ Keep the antistatic bag for storing or transferring the board between computers.
- ☐ Wear a properly connected ground strap at all times when handling the 'C6x EVM.

2.3.2 Avoiding Obstructions to the EVM Board

Avoiding Obstructions

To minimize the risk of damage to the 'C6x EVM, avoid physical obstructions that may prevent insertion of the board. You must install the EVM in a full-length PCI slot only.

Before installing the EVM, make sure that your PC has a full-length PCI slot. Otherwise, obstructions could prevent you from fully inserting the EVM in the motherboard PCI-bus connector. For example, in some computer systems, the location or height of the central processing unit (CPU) or the location of the PCI-bus slot may prevent you from inserting the EVM. Possible obstructions also include memory modules, processor fans, power supply circuits, and cable connections. Failure to avoid obstructions when installing the EVM could permanently damage the card.

2.4 EVM Hardware Installation for PCI Operation

Minimizing Personal Injury Risk

To minimize the risk of personal injury, always turn off the power to your PC and unplug the power cord before installing the 'C6x EVM board.

To install the 'C6x EVM board into your PC, follow these steps:

- 1) Turn off your PC's power and unplug the power cord.
- 2) Remove the cover from your PC.
- 3) Locate an existing unused PCI slot. Make sure that this slot allows the installation of a full-length PCI card. If the slot is a shared ISA/PCI slot that shares mechanical space, make sure that an ISA card is not already installed.
- 4) If installed, remove the PCI slot's cover from the back of the computer by unscrewing it from the chassis.
- 5) Remove the 'C6x EVM from the antistatic bag. Keep the antistatic bag for storing or transferring the board in the future.
- 6) Insert the 'C6x EVM board into the empty, full-length PCI slot (see Figure 2–1). Secure its mounting bracket to the chassis with the previously removed screw. You do not have to set any jumpers or switches on the board for PCI operation.
- 7) Replace the PC cover.
- 8) Connect the 3.5-mm audio cables to the EVM's microphone, line in, and line out connectors as needed. The connectors are labeled with MIC IN, LINE IN, and LINE OUT designations (see Figure 2–2).
- 9) Plug in the PC's power cord and turn on the PC's power.
- 10) If your operating system is Windows NT, the hardware installation is finished. Proceed to section 2.6, *EVM Software Installation*. If your operating system is Windows 95, proceed to step 11.
- 11) When you turn on the PC's power, Windows 95 detects a newly installed EVM board and prompts you for the driver disk. Insert the EVM support software CD-ROM and follow the instructions on the screen. After the driver is installed, reboot the PC. To install the EVM support software, proceed to section 2.6, *EVM Software Installation*. For additional information about moving an EVM board to another PCI slot, adding another EVM board, and removing an EVM board, see section 2.4.1, *Notice to Windows 95 Users*.

Figure 2–1. TMS320C6x EVM PCI Installation

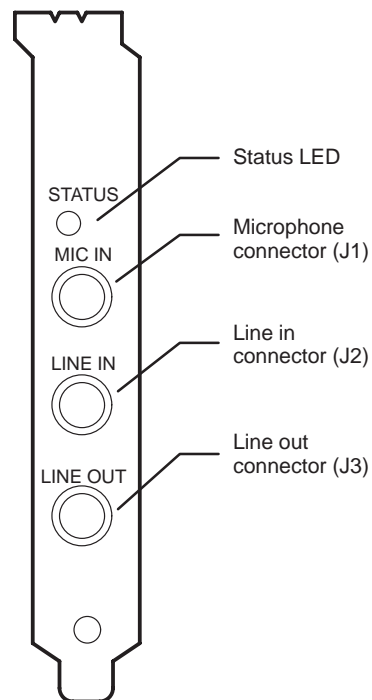

Figure 2–2. Audio Cable Connectors on the EVM Board Mounting Bracket

2.4.1 Notice to Windows 95 Users

If an EVM board is moved from one slot to another one that has never had an EVM board installed in it, or if a second EVM is installed into a PCI slot that has never had an EVM board installed in it, Windows 95 recognizes the board as new hardware and installs the driver for the EVM board using the previously installed driver files. In this situation, Windows 95 does not prompt for a system reboot, although one is required for proper operation with the EVM board in the new slot. Therefore, whenever an EVM board is installed in a PCI slot for the first time, you must reboot the system after the driver is installed.

At initial installation, if you cancel the driver installation when Windows 95 prompts for a driver disk, you must perform the following steps to reinstall the driver properly. The board is then accessible via the driver.

- 1) Perform a complete driver uninstall.
- 2) Reboot the system.
- 3) When prompted, reinstall the driver using the driver disk.
- 4) Reboot the system.

If you remove an EVM board from your system, or if you want to move it from one PCI slot to another one, you must perform a *remove hardware* operation as follows:

- 1) From the Windows 95 desktop, right click on the My Computer icon.
- 2) Select the Properties menu item.
- 3) Select the Device Manager tab.
- 4) Select the Other devices item in the list of devices in the system.
- 5) Select the TI TMS320C6x EVM device under the Other devices item.
- 6) Click on the Remove button to remove the EVM driver associated with the current PCI slot.

2.5 EVM Hardware Installation for Stand-Alone Operation

Minimizing the Risk of Equipment Damage

Never disconnect or reconnect any cables or other hardware devices while power is applied to the emulator or EVM. Doing so can cause damage to your EVM.

In stand-alone operation, the 'C6x EVM must be connected to an external power supply (which is not included in the 'C6x kit) and an emulator. To install the 'C6x EVM for stand-alone operation as depicted in Figure 2–3, follow these steps:

- 1) Install your emulation hardware and software.
- 2) Turn the power supply off and unplug its power cord from the wall outlet.
- 3) Connect the power supply's DC output cable with the 4-pin female connector to the 'C6x EVM external power connector (J8).
- 4) Connect the XDS510 or XDS510WS emulator's 14-pin connector to the EVM's JTAG header (J5) located at the top-center of the EVM board.

Note:

Pin 6 of the 14-pin XDS510 emulator connector is filled in and the corresponding pin 6 of the JTAG header (J5) on the EVM is missing to ensure proper connection.

- 5) Configure the 'C6x EVM DIP switches (SW2) for the desired mode of operation. See Appendix B for DIP switch settings. The JTAG selection must be used to select external emulation (SW2-9 ON).
- 6) Connect the 3.5-mm audio cables to the EVM's microphone, line in, and line out connectors as needed. The connectors are labeled with MIC IN, LINE IN, and LINE OUT designations (see Figure 2–2).
- 7) Plug the power supply's power cord into the wall outlet.
- 8) Turn on the power supply and verify that the 'C6x EVM's green power indicator is illuminated.
- 9) Power up the emulator.

Figure 2–3. TMS320C6x EVM Stand-Alone Installation

2.6 EVM Software Installation

On most Windows 95 or Windows NT 4.0 systems, Setup automatically starts when the *TMS320C6x EVM Support Software* CD-ROM is loaded. However, if AutoPlay is not enabled on your system, you need to explicitly run the setup.exe program in the top-level directory of the CD-ROM following these instructions:

- 1) Insert the *TMS320C6x EVM Support Software* CD-ROM in your CD-ROM drive.
- 2) Choose Run from the Start menu.
- 3) In the Open box, type the following command:
`d:\setup`
where d is the letter assigned to your CD-ROM drive.
- 4) Click on OK and follow the instructions on the screen.

By default, the installation program modifies the PATH environment variable:

```
PATH=c:\evm6x;%path%
```

In Windows 95, this is set up in the autoexec.bat file.

In Windows NT, this is set up in the registry under:

```
HKEY_CURRENT_USER\ENVIRONMENT
```

If you choose not to have the installation program modify your environment, you will need to modify it yourself as described. In addition to this modification of the PATH variable, you can set up or modify other environment variables for your convenience in accessing files, setting code generation options, and setting debugger options. The environment variables and their settings are described in the *TMS320C6x Optimizing C Compiler User's Guide* and the *TMS320C6x C Source Debugger User's Guide*.

After you have completed installation of the EVM hardware and software, follow the instructions in Chapter 3, *Running the Board Confidence Test*, to verify the correct installation of the EVM hardware and software. For more detailed information about the EVM confidence test, see section 6.2, *EVM Confidence Test*.

Running the Board Confidence Test

This chapter explains how to run the board confidence test included with the TMS320C6x EVM board. This test can only be run after the EVM board hardware and software have been installed. See Chapter 2, *Getting Started With the TMS320C6x EVM*, for installation instructions.

Topic	Page
3.1 About the Board Confidence Test	3-2
3.2 Verifying the EVM Installation	3-2

3.1 About the Board Confidence Test

The confidence test verifies proper operation of the major components of the EVM board and its support software. The test also displays board configuration information. These EVM hardware components are tested:

- ☐ SBSRAM
- ☐ SDRAM
- ☐ 'C6x interrupts
- ☐ 'C6x timers
- ☐ 'C6x DMA
- ☐ 'C6x McBSP serial ports
- ☐ PCI controller NVRAM (EEPROM)
- ☐ Audio codec
- ☐ Audio inputs and output
- ☐ LEDs
- ☐ Endian mode selection

The installation of these EVM software components is tested:

- ☐ Win32 DLL
- ☐ Host low-level board driver

The following section explains how to run the board confidence test utility to verify that the board and software have been installed properly. For additional information about the confidence test utility, see section 6.2, *EVM Confidence Test*.

3.2 Verifying the EVM Installation

To run the board confidence test utility to verify the installation of the board and software, follow these steps:

- 1) Install the 'C6x EVM board and supplied software as described in Chapter 2, *Getting Started With the TMS320C6x EVM*. If you want to verify the stereo audio capabilities of the EVM board during the confidence test, you must connect input sources to the microphone and line inputs and an amplified speaker to the line output.
- 2) Open a command window and change the directory to the conftest subdirectory of the EVM installation directory. This directory is created during the installation process and contains additional files needed for the execution of the confidence test utility.
- 3) Execute the confidence test utility in a command window by entering the following command on the command line:

```
evm6xtst test.log
```

This command starts the confidence test utility for the first EVM board and logs the test results to a file named test.log.

- 4) The output from the confidence test should be similar to the sample output provided in Example 3–1. If the test results in a failure message, see Appendix F, *Troubleshooting*.

Example 3–1. Sample Confidence Test Output

TMS320C6x EVM Hardware

This chapter describes the TMS320C6x EVM hardware, its key components and how they operate, and its various interfaces. Detailed programmer interface information such as memory maps, register definitions, interrupt usage, and required software initialization tasks are also provided.

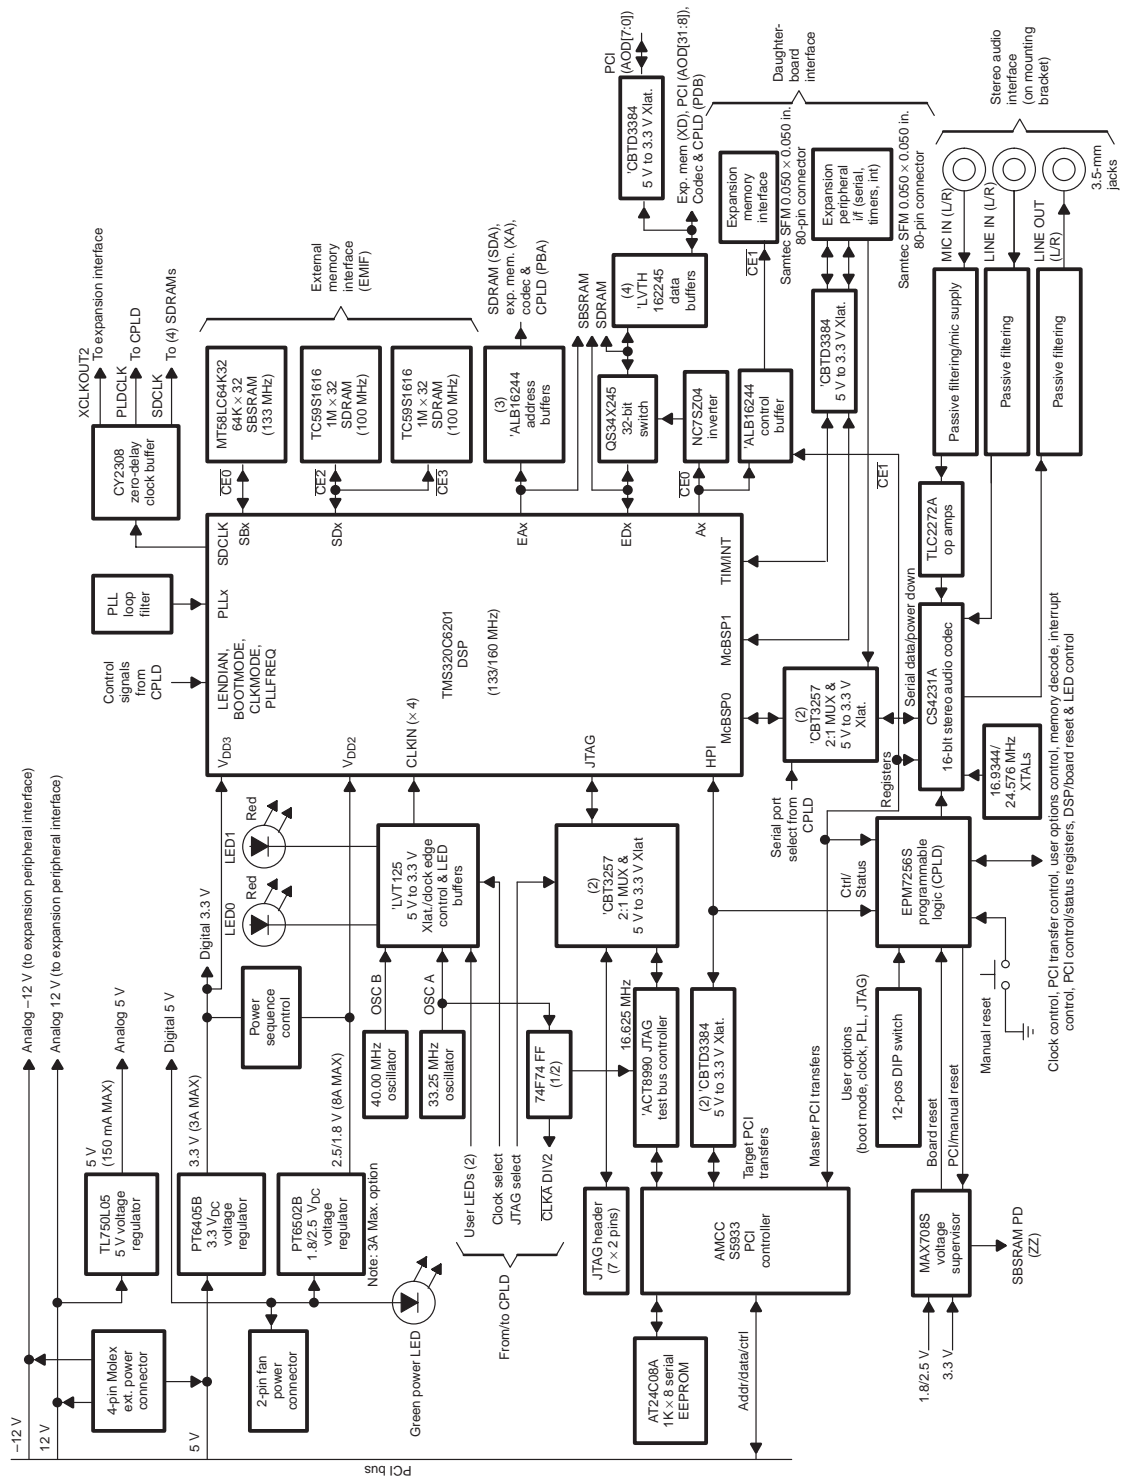

The hardware can be divided into 12 functional areas. Each of these areas is discussed in detail in this chapter.

4.1 TMS320C6x EVM Hardware Detailed Block Diagram

Figure 4–1 provides a detailed block diagram of the 'C6x EVM hardware. It identifies the key components described in this chapter and shows how they interface to each other.

Figure 4-1. TMS320C6x EVM Detailed Block Diagram

4.2 TMS320C6201 DSP

The TMS320C6201 DSP is the brain of the 'C6x EVM. The 'C6201 DSP has the following key features:

- ❑ **VelociTI™ advanced very long instruction word (VLIW) architecture**
 - Load/store architecture
 - Instruction packing for reduced code size
 - 100% conditional instructions for faster execution
 - Intuitive, reduced instruction set computing with RISC-like instruction set
- ❑ **CPU**
 - Eight independent functional units (including two 16-bit multipliers with 32-bit results and six arithmetic logic units (ALUs) with 32/40 bit results)
 - 32 32-bit registers
 - 1600 million instructions per second (MIPS)
 - 5-ns cycle time
 - Up to eight 32-bit instructions per cycle
 - Byte-addressable with 8-, 16- and 32-bit data
 - 32-bit address range
 - Little- and big-endian support
 - Saturation
 - Normalization
 - Bit-field instructions (extract, clear, left-most bit detection)
- ❑ **Memory/peripherals**
 - Glueless external memory interface to synchronous memories such as SBSRAM and SDRAM
 - Glueless external memory interface to asynchronous memories such as SRAM and EPROM
 - 4-channel direct memory access (DMA)
 - Host port interface (HPI) with dedicated auxiliary DMA channel providing access to entire processor memory space
 - Two multichannel buffered serial ports (McBSPs) for direct interfacing to telecommunication, audio, and other serial devices

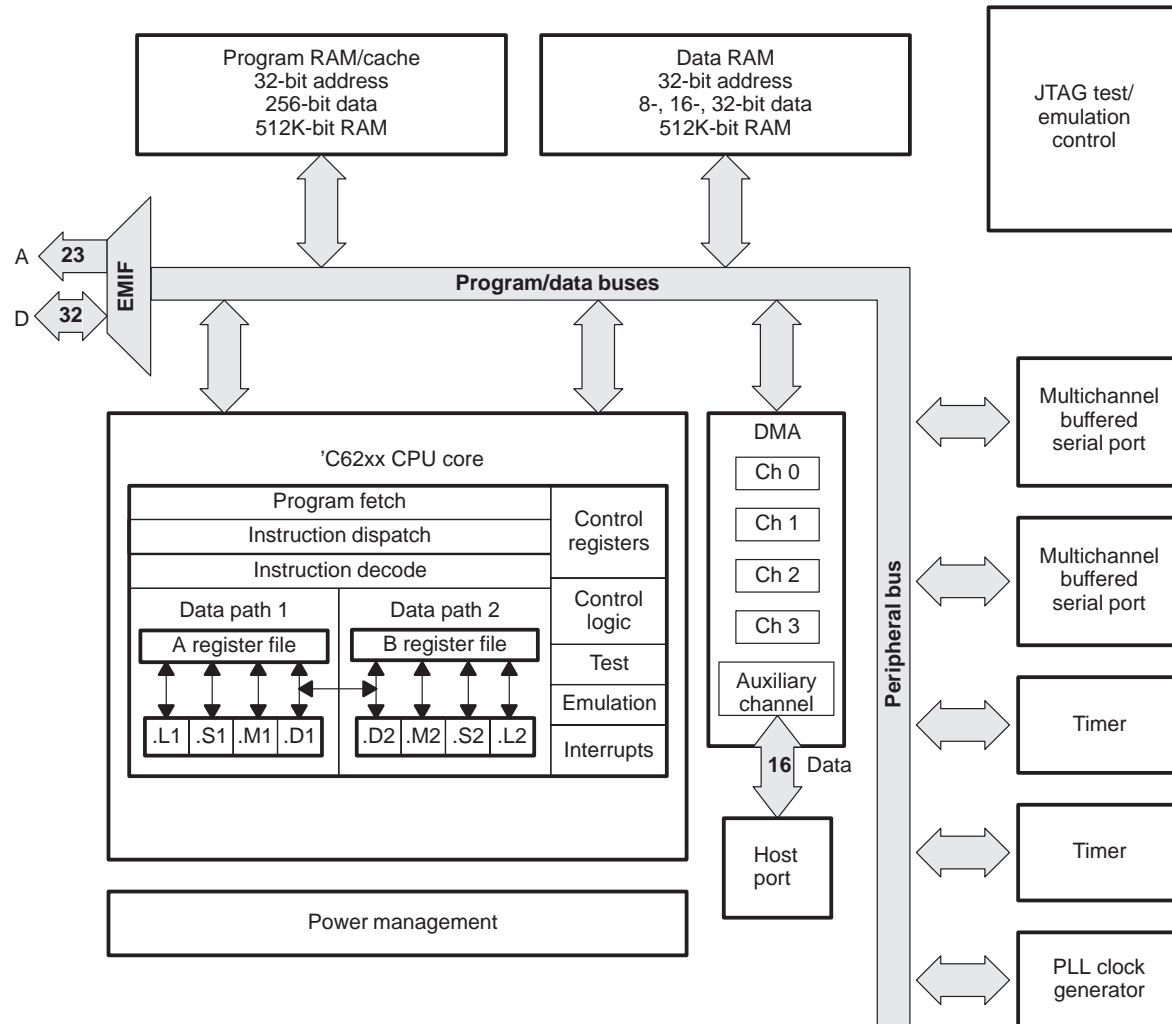

- Two general-purpose timers
- Multiply-by-4 phase locked loop (PLL) and multiply-by-1 PLL-bypass options
- 1M-bit on-chip memory (2K × 256 bits of program memory/64K bytes of data memory)
- Miscellaneous
 - IEEE-1149.1 (JTAG) boundary-scan compatible for emulation and test support
 - 352-lead ball grid array (BGA) package
 - 0.25-micron/5-level metal process with CMOS technology
 - 3.3-V I/O and 2.5-V internal core voltages

Figure 4–2 shows the 'C6201 core, peripherals, and external interfaces.

Because the 'C6x EVM is a hardware reference design intended to provide you with maximum flexibility, it supports all of the DSP's external interfaces. The 'C6x EVM uses the PLL clock generator interface to support multiply-by-1 and multiply-by-4 clock modes with CPU clock rates of 33.25 MHz, 40 MHz, 133 MHz, and 160 MHz. The JTAG test/emulation interface supports both embedded and external emulation for source code debugging. The control interface resets the DSP, provides external interrupts, chooses data endian mode, and selects the DSP's boot method. The external memory interface (EMIF) supports synchronous SDRAM and SDRAM memories and asynchronous accesses to the CPLD registers, stereo audio codec, PCI controller, and expansion memory. The EMIF is also brought out to an expansion memory interface connector for daughterboard use. The host port interface (HPI) is used for bidirectional data transfers between the PC and the DSP. The timer interfaces are provided on the expansion peripheral interface connector for daughterboard use. The multichannel buffered serial ports provide interfaces to an onboard stereo audio codec and/or a daughterboard connected to the expansion peripheral interface.

An extremely low-profile, integrated heat sink/fan cools the 'C6201 DSP for maximum performance and reliability. This 7.5-mm-high unit is designed for the 'C6201's 35-mm × 35-mm BGA package. It requires 5 V_{DC} at 100 mA and reduces the temperature rise on the device by 50–80% to handle the maximum dissipation of the DSP in a PCI environment that has little or no air flow. The 'C6x EVM provides a small 2-pin power connector (J9) to supply the fan's power.

Figure 4–2. TMS320C6201 Core, Peripherals, and External Interfaces

4.3 DSP Clocks

The 'C6x EVM provides quad DSP clock support, which allows you to run the DSP core at these rates:

- ☐ Full speed (160 MHz)
- ☐ Speed of the SBSRAM (133 MHz)
- ☐ Multiply-by-1 clock modes (33.25 MHz and 40 MHz)

Typically, you will use either the full-speed or SBSRAM-speed DSP clock. Depending on the application, one speed may be more efficient than the other. You can perform benchmarks using both clocks to determine optimal performance for a particular application.

The EVM uses two half-size oscillators, along with a TI SN74LVT125 quad bus buffer device, to provide 33.25- and 40-MHz CLKIN signals to the 'C6201. The use of the 'LVT125 device provides multiple functions, including 5-V to 3.3-V signal level translation, clock selection, and clock edge control with fast rise and fall times required by the DSP.

The clock selection is made via a DIP switch during external operation or via a software switch for internal PCI operation. Clock select control logic in the complex programmable logic device (CPLD) controls the 'LVT125 buffer output enable that corresponds to the selected clock oscillator. The CPLD provides break-before-make clock switching between the two clock oscillators to prevent any output contention.

The EVM provides user options for selecting the CLKIN frequency (33.25 or 40 MHz) and the clock mode (multiply-by-1 or multiply-by-4), so the CLKOUT1 (CPU clock) frequency can be 33.25 MHz, 40 MHz, 133 MHz, or 160 MHz (see Table 4–1). The SBSRAM clock (SSCLK) can be configured by the DSP software to be one-half the CPU clock (CLKOUT1) or the same as CLKOUT1. The SDRAM clock (SDCLK) is always one-half of CLKOUT1. The CPLD also controls the DSP's CLKMODE and PLLFREQ control inputs based on the clock mode selection.

Table 4–1. DSP Clock Summary

Clock Source	Clock Mode	CLKOUT1	SSCLK (1/2 rate/1× rate)	SDCLK
33.25 MHz	Multiply-by-1	33.25 MHz	16.625/33.25 MHz	16.625 MHz
40.00 MHz	Multiply-by-1	40.00 MHz	20/40 MHz	20 MHz
33.25 MHz	Multiply-by-4	133 MHz	66.5/133 MHz	66.5 MHz
40.00 MHz	Multiply-by-4	160 MHz	80 MHz [†]	80 MHz

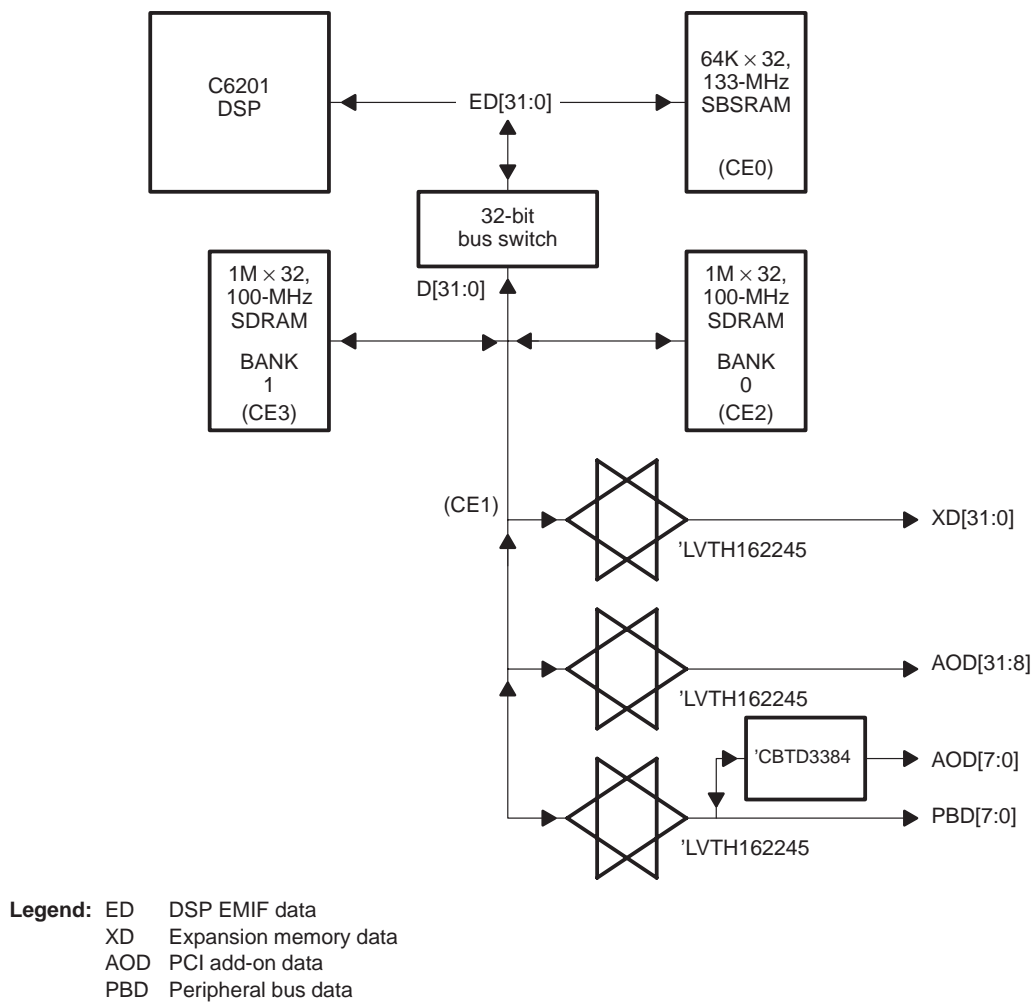

[†] 1× SSCLK rate is invalid when CLKOUT1 is 160 MHz.

4.4 External Memory

The 'C6x EVM provides one bank of $64K \times 32$ -bit words of 7.5-ns (133-MHz) SBSRAM and two banks of $1M \times 32$ -bit words of 10-ns (100-MHz) SDRAM. An expansion memory connector is also provided to enable asynchronous memory and memory-mapped devices to be added using a daughterboard. The external SBSRAM and SDRAM devices on the board are 3.3-V devices. The expansion memory connector is able to support both 3.3-V and 5-V devices because 'LVTH162245 5-V-tolerant buffers are used.

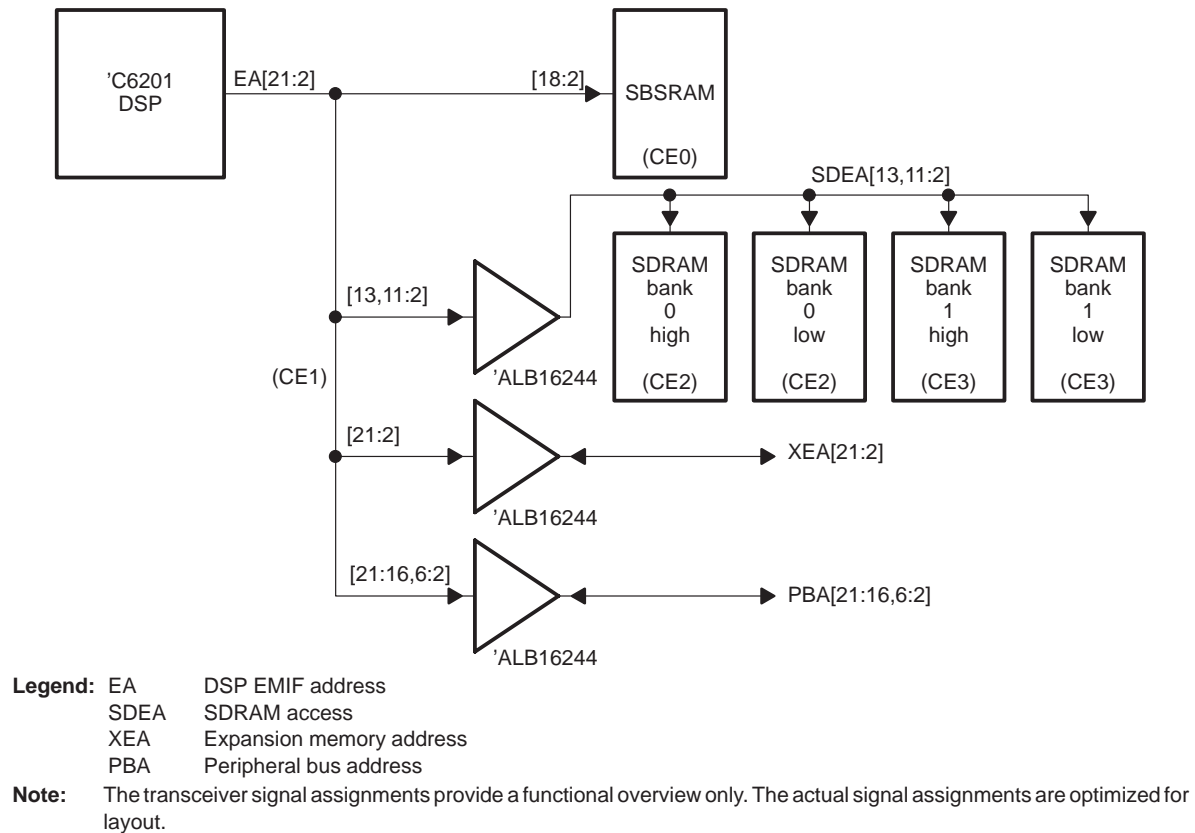

The EMIF address and data busses are buffered (except to the SBSRAM) to preserve signal integrity, limit loading on the 'C6201 outputs, and provide the necessary drive to meeting timing requirements. A 32-bit bus switch device is used to isolate the rest of the data bus during SBSRAM accesses. This isolation preserves signal integrity and allows the EVM to run the SBSRAM at the full 133-MHz bus speed. Very fast line drivers are used to buffer the address and control signals, which limits the loading on the DSP's outputs. Fast data transceivers are used to provide voltage translation and the necessary drive to a daughterboard. Figure 4–3 and Figure 4–4 show the configuration of the EMIF data and address bus buffering, respectively.

Figure 4–3. EMIF Data Bus Topology

Note: The transceiver signal assignments provide a functional overview only. The actual signal assignments are optimized for layout.

Figure 4–4. EMIF Address Bus Topology

4.4.1 SBSRAM

The EVM provides $64K \times 32$ -bit words of SBSRAM. The SBSRAM used on the EVM is directly connected to the DSP with no glue logic or buffers required, because the 'C6201 EMIF provides a direct interface to industry-standard SBSRAM devices. The bank of SBSRAM is mapped into the DSP's CE0 memory space, allowing it to be used for program booting, assuming that it has been initialized by host software or the emulator. It has a 7.5-ns cycle time (133 MHz) and provides $64K \times 32$ -bit words of memory in a single 100-pin thin quad flat pack (TQFP) package. The pinout of this package is the same for the $128K \times 32$ -bit word device, but it uses one extra address line. The EVM layout supports the use of $128K \times 32$ -bit devices.

The SBSRAM device can be clocked by the 'C6201 at the CPU clock speed when operating at 133 MHz, one-half the clock speed when operating at 160 MHz, or at either the same as or one-half the clock speed when operating in the multiply-by-1 clock mode (33.25 MHz and 40 MHz). This selection is

made based on the setting of the SSCRT bit in the EMIF global control register. Additionally, various boot modes inherently select the clock speed used for the SBSRAM interface. You must correctly select the SBSRAM clock rate for the selected CPU clock rate.

The 'C6201 EMIF provides signals that directly correspond to the SBSRAM pins. Because the 'C6201 can generate a new address every cycle, the SBSRAM's \overline{ADV} control input, which allows the device to generate its own addresses internally, does not have to be used. This SBSRAM control input is pulled high on the EVM.

The SBSRAM device supports a snooze power-down mode when its ZZ input signal is a logic high. The ZZ input is controlled directly by the voltage supervisor's logic high reset output; so, when the board is held in reset, the SBSRAM is disabled and placed into a power-down mode. With this power management feature, the maximum current is reduced from 110 mA to 0.5 mA. Data in the SBSRAM is retained during the snooze mode.

4.4.2 SDRAM

The EVM provides two banks of $1\text{M} \times 32\text{-bit}$ words of SDRAM. Each bank is comprised of two $512\text{K} \times 2$ banks \times 16-bit devices. The 3.3-V SDRAM used on the 'C6x EVM requires no glue logic to interface to the DSP because the 'C6201 EMIF generates all the required SDRAM control and refresh signal sequences. The two banks of SDRAM are mapped into the DSP's CE2 and CE3 memory spaces. Each bank uses 4M bytes of the 16M-byte address space. One of the banks of SDRAM (CE3) resides on the back side of the board to optimize signal routing and signal integrity.

The SDRAM devices are always clocked at one-half the CPU clock rate. This means that when the DSP core runs at 133 MHz, the SDRAM runs at 66.5 MHz (15 ns), and when the DSP core runs at 160 MHz, the SDRAM runs at 80 MHz (12.5 ns). The EVM's SDRAM devices are rated for 100-MHz operation.

The four SDRAM devices have dedicated point-to-point clocks that are driven by a clock driver device. The clock driver provides near zero-delay PLL buffering of the DSP's SDCLK. Two clock driver outputs are routed to the expansion peripheral interface connector and the CPLD. Address and control signals are buffered with TI 'ALB16244 buffers to manage the loading of these 'C6201 signals properly.

The SDRAM must be refreshed periodically to maintain its data. The 'C6x EVM uses the DSP's SDRAM refresh capability so the RFEN bit in the DSP's SDRAM control register must be set to 1. The refresh period can be a maximum of 15.625 μs .

The EVM's CPLD includes SDRAM enable bits that are controlled via the DSP memory-mapped SDCNTL register. After reset is released, these SDRAM enables, which are connected to the SDRAM clock enable (CKE) pins, default to active, enabling the SDRAMs. When the board is held in reset or DSP software explicitly clears the register control bits, the SDRAMs are disabled and placed into a power-down mode. With this power management feature, the maximum per-device current is reduced from 120 mA to 3 mA.

An additional use of the CPLD SDRAM enable bits is the ability to independently disable the CE2 and CE3 SDRAM banks to allow these memory spaces to be used for asynchronous expansion memory on a daughterboard. When an SDRAM bank is disabled, the respective memory space can be used for asynchronous expansion memory.

4.4.3 Expansion Memory

The EVM provides an asynchronous expansion memory interface connector (J6) to allow you to add memory or memory-mapped devices via a daughterboard. The expansion memory interface is mapped into the lower 3M bytes of the DSP's 4M-byte asynchronous CE1 memory space. Expansion memory in the CE1 space is addressed from 0x1000000–12FFFFFF in MAP 0 and 0x1400000–16FFFFFF in MAP 1 mode. The upper 1M bytes of the CE1 memory space is allocated for onboard peripherals. This division of the CE1 memory space allows both the onboard devices and the expansion memory interface to coexist without conflicts.

Because the EVM's stereo audio codec, PCI controller, and CPLD registers are also accessed in the DSP's asynchronous CE1 memory space, the CPLD provides transceiver control logic that prevents the expansion memory space from conflicting with the onboard use of the CE1 space. The CPLD monitors the CE1 signal along with the upper address signals (EA[21:20]) to determine when the lower 3M-byte expansion memory space is being accessed and enables the expansion memory transceivers accordingly. CE1 decoding in the upper 1M byte is handled by the CPLD for control of onboard peripherals.

The EMIF CE2 and CE3 memory space enables are available on the expansion peripheral interface connector (J7). These two memory spaces can also be used for asynchronous memory on the daughterboard when their respective SDRAM enable bits are not asserted in the CPLD register. The SDRAM enable bits control the SDRAM clock enables, as well as enabling the expansion memory transceivers to be turned on during CE2 and CE3 memory space accesses. This capability supports applications that do not require one or both banks of SDRAM, but need to interface to faster or additional asynchronous memory on a daughterboard.

All expansion memory interface signals are buffered using TI 'LVTH buffers/transceivers to allow both 3.3- and 5-V devices to be used on the daughterboard and to isolate the daughterboard from the onboard EMIF. The three memory space enables (CE1–CE3) are buffered versions of the DSP outputs and are not generated by decode logic. This allows fast daughterboard logic to be used as required for the application without incurring additional delay. The expansion memory transceivers isolate the daughterboard and onboard data busses to prevent bus contention.

One potential use of the expansion memory interface is to provide nonvolatile memory such as ROM or Flash memory on a daughterboard that can be used for ROM boot operation. This allows the EVM to be autobooted at power up and reset with an application stored in nonvolatile memory. The EVM can operate in this mode inside the PC or, more typically, in an external operating environment.

4.4.4 DSP Memory Maps

Table 4–2 and Table 4–3 show the 'C6x EVM DSP memory maps for MAP 0 and MAP 1 modes, respectively.

Table 4–2. TMS320C6x EVM DSP Memory Map (MAP 0)

Start Address	End Address	External Memory Space	Size (Bytes)	Description
00000000	0003FFFF	CE0	256K	SBSRAM

4.4.5 DSP EMIF Registers

The DSP EMIF registers must be initialized before the external memory on the 'C6x EVM can be accessed by DSP or host software. The DSP EMIF registers must be initialized by the DSP software before it accesses external memory in the no-boot and ROM-boot modes. When HPI-boot mode is selected, the host software must initialize the EMIF registers via the HPI before HPI memory accesses are performed on external memory. This section identifies the required and recommended EMIF register values for proper EVM operation.

The EMIF global control register must be initialized to enable the various DSP output clocks and select clock polarities, the SBSRAM clock rate (one-half the CPU clock or the same as the CPU clock), and the requester arbitration mode. The 'C6x EVM does not use the CLKOUT1 and CLKOUT2 outputs, so these clocks should be disabled to minimize EMI emissions. The SDCLK output (which is used to clock the EVM's four SDRAM devices, the CPLD, and the daughterboard circuitry) should have its polarity identical to the DSP's internal SDCLK. The SBSRAM clock rate (SSCLK) can be either one-half the CPU clock or the same as the CPU clock when the CPU clock rate is 33.25 MHz, 40 MHz, or 133 MHz. When the CPU clock rate is 160 MHz, only one-half the CPU clock rate is valid for SSCLK. The requester arbitration mode selection is application dependent. For a one-half-rate SSCLK operation, a value of 0x3060 is recommended. For a full-rate SSCLK operation, a value of 0x3064 is recommended.

The EMIF CE space control registers for the CE0–CE3 must be initialized to select the external memory configuration of the 'C6x EVM. *The CE1 memory space control register must be configured for a strobe period of 3 CLKOUT1 cycles for proper operation.* Table 4–4 summarizes the CE space allocation of the 'C6x EVM.

Table 4–4. TMS320C6x EVM CE Memory Space Initialization Summary

CE Memory Space	Memory Type	Memory Characteristics	Control Register Address	Control Register Value
CE0	SBSRAM	133 MHz maximum	0x1800008	0x40
CE1	PCI controller, CPLD registers, audio codec, and expansion memory	32-bit async, strobe = 3	0x1800004	160 MHz: 0x30F30323 133 MHz: 0x20E20322 40 MHz: 0x10D10321 33.25 MHz: 0x10D10321
CE2	SDRAM (bank 0)	100 MHz maximum	0x1800010	0x30
CE3	SDRAM (bank1)	100 MHz maximum	0x1800014	0x30

Because the 'C6x EVM includes SDRAM, the EMIF SDRAM control and timing registers must be initialized to select timing and device width, enable refresh, initialize the SDRAM devices, and control the SDRAM refresh period. The SDRAM timing selection is dependent on the CPU clock speed, so the host or DSP software must determine its clock speed to properly initialize the timing control bits. The host and DSP can each read CPLD registers to determine the CPU clock speed based on the clock selection (33.25 MHz or 40 MHz) and clock mode (multiply-by-1 or multiply-by-4). The SDRAM devices have a t_{RC} (refresh/active-to-refresh/active) period of 100 ns, a t_{RP} (precharge-to-active) period of 30 ns, and a t_{RCD} (active-to-read/write) period of 30 ns. Based on the determined CPU clock period, the TRC, TRP, and TRCD fields of the EMIF SDRAM control register can be initialized based on the CLKOUT2 period, as summarized in Table 4–5.

Table 4–5. EMIF SDRAM Control Register Timing Fields

CPU Clock (MHz)	CLKOUT2 Period (ns)	TRC Field	TRP Field	TRCD Field
33.25	60	1	0	0
40	50	1	0	0
133	15	6	1	1
160	12.5	7	2	2

The SDRAM control register's INIT bit must be set to 1 to initialize the SDRAM in each CE space configured for SDRAM (CE2/CE3). The RFEN bit must be set to 1 to enable EMIF SDRAM refreshes. The SDWID bit must also be set to 1 to select two, 16-bit SDRAM devices per SDRAM CE space.

The SDRAM timing register, which selects the SDRAM refresh period, must be initialized for a maximum period of 15.625 μ s. The refresh period is based on CLKOUT2 cycles, so the SDRAM timing register period must have maximum values as summarized in Table 4–6.

Table 4–6. EMIF SDRAM Timing Register Values

CPU Clock (MHz)	CLKOUT2 Period (ns)	Maximum Register Value
33.25	60	0x103
40	50	0x138
133	15	0x410
160	12.5	0x4E1

See the *TMS320C6201/C6701 Peripherals Reference Guide* for detailed information about the DSP's EMIF registers.

4.5 Expansion Interfaces

The 'C6x EVM provides two expansion connectors that allow a daughterboard to be connected to the board. Daughterboards can be used to extend the capabilities of the EVM and to provide custom and application-specific I/O. One expansion connector provides the DSP's asynchronous EMIF, and the other provides access to the DSP's peripherals and control/status signals. Both connectors also provide power to the daughterboard.

Most of the expansion connector signals are buffered so that the daughterboard cannot directly influence the operation of the EVM board. The use of TI 'LVTH and 'CBT family interface devices allows the use of either 5- or 3.3-V devices to be used on the daughterboard.

The 'C6x EVM's expansion memory and peripheral interfaces are provided with two dual-row, 80-pin connectors. These surface-mount connectors are low profile and have a 0.050-inch (1.27-mm) pitch. The recommended mating connectors provide 0.465-inch board spacing, allowing ample space for daughterboard components.

The expansion memory interface connector has a reference designator of J6 on the EVM. The expansion peripheral interface connector is J7. See Appendix A for the pinouts of the expansion connectors.

4.5.1 Expansion Memory Interface

The expansion memory interface provides the DSP's asynchronous EMIF signals to a daughterboard. External asynchronous memories and memory-mapped devices can be added to the EVM, including nonvolatile memory that can be used to boot the EVM upon reset.

The expansion memory interface includes:

- ❑ **20 external address signals (EA[22:2]).** All of the DSP's 20 external address signals are available on the expansion memory interface, allowing up to 4M bytes of external memory to be addressed. However, because the CE1 memory space must be shared with onboard peripherals, only the lower 3M bytes are available to a daughterboard. If CE2 or CE3 is used for external asynchronous memory instead of SDRAM, an additional 4M bytes in each memory space can be addressed.
- ❑ **32 external data signals (ED[31:0]).** All of the DSP's 32 external data signals are available on the expansion memory interface to support full 32-bit word accesses to the daughterboard.
- ❑ **CE1 memory space enable.** The DSP's CE1 memory space enable is available on the expansion memory interface to allow asynchronous accesses to daughterboard memory and memory-mapped devices.

- ❑ **Four byte enables (BE[3:0]).** The DSP's four byte enables are available on the expansion memory interface to support byte (8-bit), halfword (16-bit), and word (32-bit) daughterboard memory accesses.
- ❑ **Four asynchronous control signals.** The DSP's asynchronous control signals ($\overline{\text{ARE}}$, $\overline{\text{AWE}}$, $\overline{\text{AOE}}$, and $\overline{\text{ARDY}}$) are provided to control asynchronous memory accesses to a daughterboard.
- ❑ **Power signals.** The expansion memory interface also provides ground, 5-V, and 3.3-V power signals to the daughterboard.

4.5.2 Expansion Peripheral Interface

The expansion peripheral interface provides the DSP's peripheral signals to a daughterboard. This peripheral expansion capability allows serial devices such as other codecs and communication devices to be added to the EVM via a daughterboard.

The expansion peripheral interface includes:

- ❑ **Seven signals for each of the serial ports (McBSP0 and McBSP1).**

The DSP's seven McBSP1 signals are available on the expansion peripheral interface. These signals are buffered by a 'CBTD3384 device to support both 5- and 3.3-V serial devices using McBSP1 on a daughterboard.

The DSP's seven McBSP0 signals are also available when the DSP software controls onboard 'CBT3257 multiplexers that connect them to the expansion connector rather than the audio codec. This architecture provides a daughterboard with access to both of the DSP's serial ports, which is useful in many DSP applications. Because a 'CBT3257 multiplexer is used, both 5- and 3.3-V serial devices can use McBSP0 on a daughterboard.
- ❑ **Two input/output signals for each of the timers (timer 0 and timer 1).**

The expansion peripheral interface includes each of the DSP timers' input and output signals. This allows timer signals to be sent to the daughterboard, or timer input or events to be counted to come from the daughterboard. Each timer has one input and one output signal.
- ❑ **Interrupt, interrupt acknowledge, and identification signals.** A DSP external interrupt (XEXT_INT7) is included on the expansion peripheral interface to allow the daughterboard to interrupt the 'C6201 to notify it of data transfers and other significant events. This interrupt is pulled down on the EVM, so the daughterboard must drive it high to interrupt the DSP. Additionally, the DSP's interrupt acknowledge (IACK) and interrupt identification number signals (INUM[3:0]) are available to the daughterboard.

- ❑ **Four DMA completion flags.** The DMA action complete flags (DMAC[3:0]) are available to the daughterboard on the expansion peripheral interface. These pins provide a method of feedback to external logic generating an event for each DMA channel. The DMAC pins can also be used for general-purpose output control signals controlled from the DSP's DMA channel secondary control register.
- ❑ **Four general-purpose input/output flags.** Two general-purpose control inputs and two status outputs are brought to the expansion peripheral interface to allow the DSP to control and monitor various signals on a daughterboard. The XCNTL[0:1] and XSTAT[0:1] signals can be controlled with DSP software by accessing the CPLD's DSP memory-mapped CNTL and STAT registers, respectively.
- ❑ **Power-down signal.** The DSP's power-down indication signal (DSP_PD) is also brought to the expansion peripheral interface so that a daughterboard can be powered down, if desired.
- ❑ **Reset signal.** The expansion peripheral interface also provides a reset signal that is active low when the board is in the reset state. This allows circuitry on the daughterboard to be set in a known state. The reset signal is asserted for a minimum of 140 ms upon power up, via a manual reset pushbutton or under software control. A memory-mapped register bit in the CPLD's CNTL register allows DSP software to directly control this reset signal.
- ❑ **CLKOUT2 signal for the synchronization clock.** The DSP's CLKOUT2 signal (CPU clock divide by 2) is brought out to the peripheral expansion interface for synchronization needs on daughterboards.
- ❑ **Buffered CE2 and CE3 signals for possible memory space use when the respective SDRAMs are disabled.** The DSP's CE2 and CE3 memory space decodes are buffered and brought out to the expansion peripheral interface to provide additional fast memory decodes. This can be useful on daughterboards that have multiple devices that need fast memory decodes. The CE2 and CE3 are dedicated to SDRAM use on the EVM board, but the EMIF control registers can be initialized for asynchronous operation, which disables the respective SDRAM banks and allows expansion asynchronous memory to be used instead. The CE2 and CE3 SDRAM enable bits in the CPLD's DSP memory-mapped registers must also be used to shut down the respective SDRAM bank and allow the CPLD logic to enable the external data transceivers for the CE2/CE3 accesses.
- ❑ **Power signals.** The expansion peripheral interface also provides ground, 12-V, -12-V, 5-V, and 3.3-V power signals to the daughterboard.

4.5.3 Daughterboard

The 'C6x EVM supports the mating of a daughterboard that has two 80-pin 0.050-inch \times 0.050-inch TFM-series connectors from Samtec. The recommended mating connector (part number TFM-140-32-S-D-LC) is a surface-mount connector that provides a 0.465-inch mated height.

The EVM supports two sizes of daughterboards that both use the two 80-pin connectors. The small daughterboard measures approximately 3.15 inches \times 3.4 inches and mounts in the center of the board over the low-profile buffers and memories. This format is intended for daughterboards that do not require an I/O connection on the mounting bracket.

The large daughterboard measures approximately 7.5 inches \times 3.4 inches and mounts from the center of the board over to the mating connector end of the board. This format is intended for daughterboards that require an I/O connection on the mounting bracket or need more space than the small daughterboard provides.

A daughterboard mounts with its component side down. This ensures that the PCI height requirement is met and no components are exposed to possible damage due to board insertions and extractions.

The EVM provides four standoff mounting holes to support daughterboard connections. Mounting holes MT1 and MT2 support small daughterboards, and all four mounting holes support large daughterboards. The MT1, MT2, and MT3 mounting holes are electrically connected to the digital ground plane to provide additional daughterboard grounding. MT4 is not electrically connected on the EVM.

Figure 4–5 shows the small and large daughterboard envelopes, the relationship between the two expansion connectors, and the relative location of the four mounting holes on the component side of the 'C6x EVM board.

Figure 4–5. Daughterboard Envelopes and Connections on the TMS320C6x EVM

- Notes:**
- 1) All dimensions are shown in millimeters. Inch dimensions are shown in parentheses.
 - 2) Drawing shows daughterboard envelopes and connections on the component side of EVM board.
 - 3) Standard-size daughterboard is 80.0 mm x 86.2 mm (3.15 in. x 3.39 in.).
 - 4) Full-size daughterboard is 191.0 mm x 86.2 mm (7.52 in. x 3.39 in.).
 - 5) Daughterboard connectors are Samtec .050-in. x .050-in. Micro Strips (SFM-140-L2-S-D-LC).
 - 6) Daughterboard mating connectors are Samtec TFM-140-32-S-D-LC.
 - 7) Mating height is 0.465 in. (11.81 mm).
 - 8) There are four plated holes (MT1–MT4) on the EVM for standoff mounting.
 - 9) Mounting holes MT1–MT3 are electrically connected to digital ground.
 - 10) Mounting hole MT4 is floated with no electrical connection.

4.6 PCI Interface

The 'C6x EVM's peripheral component interconnect (PCI) interface provides plug-and-play functionality along with the ability to support high-speed target (slave) and initiator (master) modes of data transfers.

The plug-and-play feature of PCI is intended to eliminate the resource conflicts associated with ISA cards that result from user configuration of addresses and interrupts. PCI devices each provide a configuration register space within the system that can be accessed by the host prior to it being mapped into the system memory or I/O space. Access to the configuration registers is the key to PCI's plug-and-play functionality. The PC's BIOS executes configuration cycles after reset to identify devices on the PCI bus and to determine each of their system resource requirements, such as I/O and memory space and interrupts. PCI devices are automatically configured by the PC BIOS, to prevent system resource conflicts. The EVM's Windows drivers obtain information from the EVM's PCI controller's configuration registers to determine where the board is located and what interrupt it uses. This allows you to simply plug the board into a PCI slot without setting any jumpers or switches.

The PCI bus operates synchronously at up to 33 MHz with a multiplexed 32-bit address/data bus. The power of PCI is its support for multiple devices to master the bus and communicate in bursts at up to 132M bytes/second ($33 \text{ MHz} \times 4 \text{ bytes/word}$). A burst consists of a single 32-bit address phase, followed by sequential 32-bit data words. Only one device can be mastering the bus at any one time, but for the period that it does, it can burst data at that rate if its hardware can keep up. If it is not fast enough, a ready signal is used to throttle the transfer at the rate at which it can read or write data. Because there are typically multiple devices on the PCI bus, such as the video controller, they must all timeshare the bandwidth, so the effective transfer rate for each device is typically much lower than 132M bytes/second. The key to maximizing transfer throughput on the PCI bus is to use burst transfers when possible to avoid repetitive PCI bus arbitration and the overhead associated with single-word transfers. The PCI bridge provides a hidden central arbitration mechanism where multiple bus masters can request and be granted the bus. It also controls the length of the bursts that each device can generate. PCI transfer rates are very machine-dependent because burst transfer support varies among the various bridges used in different PCs.

4.6.1 PCI Interface Implementation

The 'C6x EVM implements a fully-compliant PCI Revision 2.1 interface using an industry-standard application-specific integrated circuit (ASIC) (AMCC™ part number S5933). The S5933 PCI controller interfaces directly to the PCI bus connector (P1) and handles all of the PCI-side transactions, freeing the EVM hardware from having to handle them directly. The 'C6x EVM's 32-bit PCI interface operates at up to 33 MHz in a 5-V signaling environment. The EVM cannot be used in a 3.3-V PCI slot.

The S5933 provides PCI configuration registers that are always accessible to host software—even before the board has been mapped into the system resources. Accesses to these configuration registers are made by host software by specifying the device's bus number, device number, and function number. The PCI configuration registers are in a unique address space, so they are not directly mapped into either the host's I/O or memory spaces. Nonvolatile, serial EEPROM memory on the 'C6x EVM is used to store PCI configuration information for the board including its vendor and device IDs, memory space requirements, and operational parameters. The EVM's vendor ID is 0x104C (Texas Instruments), and its device ID is 0x1002.

The S5933 provides a glueless interface to the serial EEPROM that can be accessed from both the host and DSP software via memory-mapped register access. The contents of the EEPROM are automatically loaded into S5933 configuration registers at power-up reset to identify the system resource requirements and operating characteristics of the EVM. This information is used by the PC BIOS for system resource allocation.

The EVM uses an AT24C08A 1Kx8 serial EEPROM. The S5933 only requires 64 bytes for configuration information. Another 64 bytes is reserved for future use, so there are 896 free bytes, located from offsets 0x80 to 0x3FF, that can be used to store miscellaneous information, if desired.

The S5933 provides five base address registers (BARs). Each BAR is initialized upon power up by the nonvolatile memory to the desired size of a memory-mapped region for the device. The BIOS overwrites the BAR values with the address that it allocates to each region. The 'C6x EVM takes advantage of all five BARs. The first BAR (BAR0) is reserved for the PCI controller's operation registers. The other four BARs (BAR1–BAR4) are used to interface to the JTAG test bus controller (TBC), EVM control and status registers, and the 'C6201 HPI. Table 4–7 summarizes the 'C6x EVM PCI BAR definitions.

Table 4–7. TMS320C6x EVM PCI BAR Definitions

BAR Number	Size (Bytes/DWORDS)	Bus Width/Bits Used	Description
0	64/16	32/32	S5933 PCI operation registers
1	128/32	32/16	JTAG TBC registers
2	128/32	32/8	EVM board control/status registers
3	16/4	16/32	HPI control, address, and data registers
4	256K/64K	16/32	HPI data register (with autoincrement)

The S5933 provides three physical interfaces:

- ☐ PCI bus
- ☐ Add-on bus
- ☐ A nonvolatile memory interface

Data movement can occur between the PCI bus and the add-on bus, as well as between the add-on or PCI bus and the nonvolatile memory. Data transfers between the PCI and add-on buses can take place through mailbox registers, FIFOs, or the pass-through data path, which is a generic memory-mapped interface.

Mailbox registers are used to pass single 32-bit values between the host and DSP. Interrupts can be used to indicate when the mailbox registers are full and empty. The S5933 has eight mailboxes that are useful for passing command and status information between the host and the DSP. There are four incoming (host-to-DSP) and four outgoing (DSP-to-host) mailboxes. The host incoming and the DSP outgoing mailboxes are the same internally. The DSP incoming and the host outgoing mailboxes are the same internally. The mailbox status can be monitored from both sides in two ways. A mailbox status register available to both sides indicates the empty/full status of bytes within the mailboxes. The mailboxes may also be configured to generate interrupts to the host and DSP. One outgoing and one incoming mailbox on each side can be configured to generate interrupts.

FIFO transfers between the PCI and add-on buses can be performed under software control or directly by hardware using the device as a bus master. This means that the DSP software can access the S5933 FIFOs directly to read and write data from and to the PCI bus, or it can program its DMA controller to handle the transfers automatically in the background.

The pass-through data path is used when the EVM is a PCI target for JTAG TBC and DSP HPI transactions.

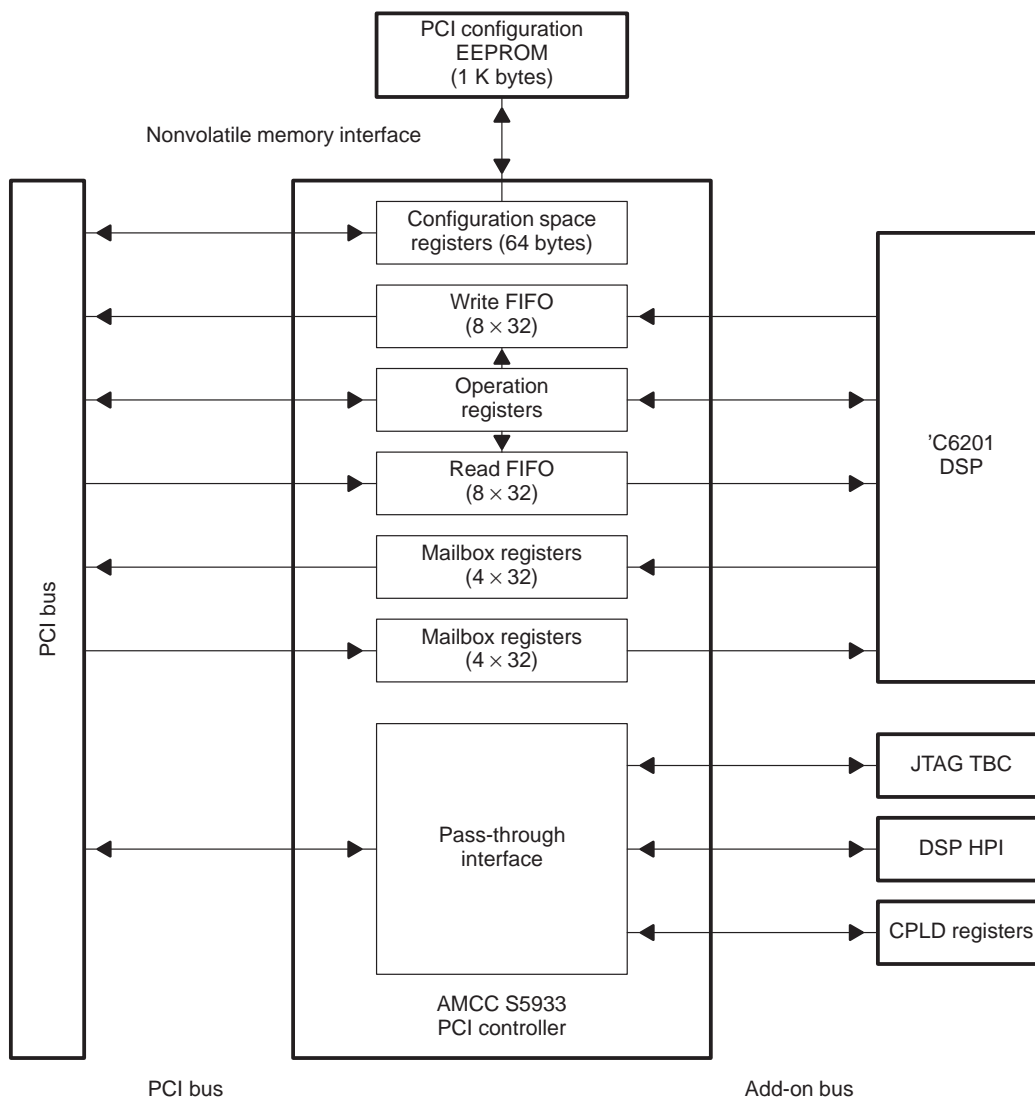

The S5933 registers and FIFOs are memory mapped into both the host and DSP memory spaces. The host can read the S5933 configuration registers to determine where the EVM is located in physical memory and what host interrupt has been assigned to it. The host software also configures the S5933 through the registers for master bus transfers because it knows the physical addresses of its memory buffers and other PCI devices.

The EVM is configured for PCI-initiated bus master transfers. In this configuration, the DSP cannot access the master read/write address and transfer count registers, and the DSP cannot be interrupted when the transfer counts reach 0. The DSP can access the other S5933 registers to read/write mailboxes, determine interrupt status, and read/write the FIFOs. Because the DSP typically uses DMA to control bus master transfers, a 'C6x DMA interrupt can be used to indicate the end of a transfer.

The S5933 supports both PCI (INTA#) and add-on interface (IRQ#) interrupts. This allows the host software and DSP software to be notified upon PCI events, such as the end of bus master transfers (host only), mailbox empty/full, and bus errors. The DSP is interrupted via its EXT_INT4 interrupt when the S5933 asserts its IRQ interrupt. The device also allows the host to control the system reset (SYSRST#) signal directly from software, so a software board reset can be invoked via the PCI bus.

Figure 4–6 provides a block diagram that shows the 'C6x EVM's PCI interface implementation based on the S5933 PCI controller.

Figure 4–6. PCI Interface Implementation

4.6.2 PCI Controller Operation Registers

The S5933 PCI operation registers allow the host software to:

- ☐ Configure the device and monitor its status
- ☐ Read and write mailboxes
- ☐ Reset the board
- ☐ Initiate bus master transfers
- ☐ Access the FIFOs

Table 4–8 identifies the S5933 PCI operation registers, along with their BAR0 offsets and access types. All registers are 32 bits wide and are addressed on doubleword (DWORD) boundaries.

Table 4–8. S5933 PCI Bus Operation Registers

Host Byte Address	PCI Operation Register	Description	Access
BAR0 + 0x00	OMB1	Outgoing mailbox register 1	Read/write
BAR0 + 0x04	OMB2	Outgoing mailbox register 2	Read/write
BAR0 + 0x08	OMB3	Outgoing mailbox register 3	Read/write
BAR0 + 0x0C	OMB4	Outgoing mailbox register 4	Read/write
BAR0 + 0x10	IMB1	Incoming mailbox register 1	Read only
BAR0 + 0x14	IMB2	Incoming mailbox register 2	Read only
BAR0 + 0x18	IMB3	Incoming mailbox register 3	Read only
BAR0 + 0x1C	IMB4	Incoming mailbox register 4	Read only
BAR0 + 0x20	FIFO	FIFO register port (bidirectional)	Read/write
BAR0 + 0x24	MWAR	Master write address register	Read/write
BAR0 + 0x28	MWTC	Master write transfer count register	Read/write
BAR0 + 0x2C	MRAR	Master read address register	Read/write
BAR0 + 0x30	MRTC	Master read transfer count register	Read/write
BAR0 + 0x34	MBEF	Mailbox empty/full status register	Read only
BAR0 + 0x38	INTCSR	Interrupt control/status register	Read/write
BAR0 + 0x3C	MCSR	Bus master control/status register	Read/write

4.6.3 PCI Add-On Bus Operation Registers

The S5933 add-on bus operation registers allow the 'C6201 DSP software to:

- ☐ Read and write mailbox messages
- ☐ Read and write FIFO data
- ☐ Control interrupts
- ☐ Provide read and write access to the PCI controller's configuration EEPROM

The PCI add-on bus operation registers are mapped into the DSP's CE1 asynchronous memory space starting at 0x01300000 (MAP 0) or 0x01700000 (MAP 1).

Table 4–9 summarizes the S5933 PCI controller's 64-byte bank of add-on bus operation registers. Registers in the address offset range of 0x24–0x33 are not available because they are either under direct hardware control or are inaccessible with PCI-initiated bus mastering.

Table 4–9. PCI Add-on Bus Operation Registers Summary

DSP Byte Address MAP 1 (MAP 0)	Add-on Bus Operation Register	Description	Access
01700000 (01300000)	AIMB1	Add-on incoming mailbox register 1	Read only
01700004 (01300004)	AIMB2	Add-on incoming mailbox register 2	Read only
01700008 (01300008)	AIMB3	Add-on incoming mailbox register 3	Read only
0170000C (0130000C)	AIMB4	Add-on incoming mailbox register 4	Read only
01700010 (01300010)	AOMB1	Add-on outgoing mailbox register 1	Read/write
01700014 (01300014)	AOMB2	Add-on outgoing mailbox register 2	Read/write
01700018 (01300018)	AOMB3	Add-on outgoing mailbox register 3	Read/write
0170001C (0130001C)	AOMB4	Add-on outgoing mailbox register 4	Read/write
01700020 (01300020)	AFIFO	Add-on FIFO register port	Read/write
01700024–01700033 (01300024–01300033)	–	Unavailable	None
01700034 (01300034)	AMBEF	Add-on mailbox empty/full status	Read only
01700038 (01300038)	AINTE	Add-on interrupt control	Read/write
0170003C (0130003C)	AGCSTS	Add-on general control/status	Read/write

The PCI add-on FIFOs can be accessed at offset 0x20 of the PCI add-on register address space (AFIFO) for general-purpose data transfers. However, the dedicated FIFO access addresses (0x01710000/0x01310000) must be used during PCI bus master transfers.

4.6.4 PCI Slave Support

The 'C6x EVM's PCI slave support enables the host, or other PCI device, to access its PCI controller, JTAG TBC, CPLD, and DSP HPI registers. Once the base addresses of these devices are obtained by the host driver upon initialization, their registers can be accessed like system memory. When the host accesses the EVM's slave devices, the S5933 PCI controller activates the pass-through bus to indicate that a data transfer is to take place. A state machine controller implemented in the EVM's CPLD manages the interface between the S5933 and the three targets. This state machine monitors and asserts signals that result in the transfer of data between the S5933's pass-through data register and the target interfaces. The S5933 decouples the state machine from the PCI bus by handling all the PCI-side transactions, so it only has to manage the reading and writing of data between the S5933 and the targets via the pass-through interface.

4.6.4.1 JTAG TBC

The 'C6x EVM's onboard JTAG TBC enables host software to control the 'C6201 JTAG interface for testing and emulation purposes. The debugger uses this interface to control and monitor the DSP. The 'C6x EVM debugger shipped with the EVM kit can be used for source code debugging on the board without requiring any additional hardware, such as an XDS510.

The JTAG TBC has 24 registers that are memory mapped at DWORD offsets starting at the address defined by the S5933's base address register 1 (BAR1). The TBC is a 16-bit device, so the upper 16 bits of data transfers are not used.

4.6.4.2 CPLD Registers

The 'C6x EVM's CPLD provides nine memory-mapped board control and status registers that the host software accesses via the PCI bus. The registers are located at DWORD offsets starting at the address defined by the S5933's BAR2. These registers allow the host software to control and monitor the 'C6x EVM board. Host software can reset the TBC and the DSP, configure and poll interrupts, monitor several board status signals, control software switches, observe DIP switch and DSP option signals, and check the revision number of the CPLD. The CPLD registers are only eight bits wide, so the upper 24 bits of data transfers are not used.

See section 4.8.6, *PCI Memory-Mapped Board Control/Status Registers*, for details on the PCI memory-mapped CPLD registers.

Similar to the other target interfaces, the add-on bus state machine provides the control signals that enable data transfers between the PCI controller and the board control and status registers. Whenever the S5933 indicates either a PCI read or write access to the board control and status registers (BAR2), the state machine acknowledges it by asserting S5933 and register control signals required to complete the data transfer. The lower eight bits of the S5933 add-on data bus are connected to the registers. The CPLD latches the register address during the PCI address phase and the state machine asserts register clock enable and output enable signals. The register address decoding and enable signals are used to clock data into and read data from the nine registers.

No voltage translation is required because the CPLD has 5-V tolerant inputs.

4.6.4.3 DSP HPI Interface

The 'C6x EVM provides DSP host port interface (HPI) access from the PCI bus, giving host software read and write access to all of the DSP's memory space. The 'C6x EVM supports both random and sequential accesses using the PCI controller's BAR3 and BAR4 memory regions, respectively.

The three 'C6201 HPI registers are memory mapped on the 'C6x EVM at DWORD offsets starting at the address defined by the S5933's base address register 3 (BAR3). The fourth address in the BAR3 region simply aliases to the HPID register. The three registers map directly to the DSP's HPI control (HPIC), address (HPIA), and data (HPID) registers. Table 4–10 summarizes the HPI registers mapped into BAR3.

Table 4–10. DSP HPI Registers (BAR3)

Host Byte Address	HPI Register	Description	Access
BAR3 + 0x00	HPIC	HPI control register	Read/write
BAR3 + 0x04	HPIA	HPI address register	Read/write
BAR3 + 0x08	HPID	HPI data register	Read/write
BAR3 + 0x0C	HPID	HPI data register (alias)	Read/write

Before HPI data transfers are performed successfully, the HPIC register must be properly initialized. The 'C6x EVM handles HPI data transfers with the first half-word being the least significant word for compatibility with the little-endian PCI bus. The 'C6201 HPIC register bit HWOB must, therefore, be set to 1 to select this data ordering. A value of 0x00010001 should be written to the HPIC register at BAR3 offset 0. Any subsequent writes to the HPIC register, such as controlling host and DSP interrupts, must keep bits 0 and 16 high in the HPIC to maintain the low-word/high-word transfer order.

The 'C6x EVM CPLD accepts data transfer requests from the S5933 PCI controller and asserts the DSP's HPI control signals required to transfer two 16-bit words. The CPLD also handles the HPI ready control signal monitoring, so software handshaking is not required.

Byte enables asserted during the host write to the HPID register are transferred to the HPI byte enables ($\overline{\text{HBE}}[1:0]$) by the 'C6x EVM's CPLD. The 'C6x EVM therefore supports byte, word, and doubleword data writes to anywhere in the DSP's memory space. This capability is useful for modifying individual bytes and words in memory or memory-mapped registers without corrupting the other bytes in a 32-bit word. A standard 32-bit access to the HPID register results in all four bytes being modified in the DSP memory space. From a software perspective, the pointer to the HPID register is simply modified and cast accordingly to perform byte and word write operations. Assuming a doubleword pointer to the HPID register is named HPI_DATA, a write access to byte 3 (MSbyte) of a 32-bit word would be performed as follows in C:

```
*((*unsigned char)(((unsigned long)HPI_DATA)+3)) = ByteValue;
```

Host access to the HPI via the BAR3 memory region therefore allows random read and write accesses anywhere in the DSP memory space with byte, word, and doubleword support. BAR3 accesses require that the HPIA register be updated for each transfer to a different address.

The 'C6x EVM also provides support, using the BAR4 memory region, for sequential data transfers between the host and the DSP by taking advantage of the HPI support for read and write autoincrement accesses. This capability allows blocks of data to be moved more efficiently between the host and the DSP without incurring the overhead associated with passing the memory address each time.

The HPI data registers in BAR4 are used when data is transferred between the host and DSP in autoincrement mode. This separate region eases the decoding and makes the transfers more efficient over the PCI bus with support for sequential and burst transfers. The HPI controller in the CPLD does not care about the addresses in this range, only that an access is within the address range. All accesses to BAR4 are written directly to the HPID register, assuming that the HPIA and HPIC registers have been initialized previously with autoincrement mode selected.

Sequential HPI data accesses with burst support is provided with host accesses to the memory-mapped region defined by BAR4. BAR4 provides a 64K DWORD (256K byte) memory window that can be addressed as a linear array or a circular buffer by host software. Accesses to the BAR4 memory region result in sequential data words being transferred to the HPI data register. The BAR4 offset address is ignored, since it is assumed that the HPI's address autoincrement feature has been selected. If the host cannot access memory past the 256K byte BAR4 allocation, the PCI controller ignores the request. The 'C6x EVM's sequential address burst support eliminates the need for the host to arbitrate for the PCI bus as often and eliminates the need to pass the board for every data transfer.

The burst transfers to the HPI cannot occur at the full 132M bytes/s PCI data rate because the 'C6201 HPI is not a 32-bit-wide, synchronous interface. The HPI presents only a 16-bit interface; hardware handshaking via its ready signal requires multiple PCI clocks per 32-bit data transfer.

Because the 'C6201 is not 5-V signal tolerant, the S5933 outputs are translated to 3.3-V-compatible signals using two TI 'CBTD3384 buffer devices.

4.6.5 PCI Master Support

The 'C6x EVM supports bus mastering of the PCI bus, enabling the EVM to take control of the PCI bus and transfer data between the host and EVM memory. The S5933 PCI controller handles the bus mastering transfers on the PCI bus. Transfers can be driven directly by 'C6201 software or automatically in the background with the DMA controller. This bus mastering support allows data transfers to be under EVM control without continuous host intervention. The host does need to get involved initially to configure the S5933's PCI address and transfer counters and initiate the transfer, but it is not involved at all in the actual data transfers. The host initialization is required because only the host knows the address of its, and other PCI devices', memory buffers.

Bus master transfers are supported by the S5933 using two on-chip FIFOs for read and write transfers between the 'C6201 and the PCI bus. Each FIFO is 32 bits wide and 8 words deep. These FIFOs are addressed asynchronously from the DSP-side because the PCI controller and the DSP operate at different rates. The S5933 provides two FIFO flags that indicate the status of each FIFO (RDEMPTY/WRFULL). These FIFO flags are used to control the flow of data to and from the DSP.

The S5933 registers and FIFOs are memory mapped into the DSP's CE1 asynchronous memory space, along with the audio codec control registers, DSP memory-mapped CPLD registers, and asynchronous expansion memory. State machines in the CPLD manage the interface between the 'C6201 and the S5933 read and write FIFOs. They monitor S5933 FIFO flags and accesses by the DSP to the S5933 FIFO at address 0x1310000 (0x1710000) and generate the external interrupts to the DSP to control the data transfers. The FIFOs must be accessed using the dedicated memory-map address, rather than the PCI add-on register offset, for the external interrupts to be generated.

Master read transfer support and master write transfer support are independently enabled by the DSP by setting two bits in the CPLD's memory-mapped FIFOSTAT register. When the PCIMREN bit (bit 1) is set, the CPLD generates EXT_INT5 interrupts to the DSP whenever data is available to be read in the PCI controller's read FIFO. When the PCIMWEN bit (bit 0) is set, the CPLD generates EXT_INT6 interrupts to the DSP whenever the write FIFO is not full and can accept data. Typically, the DSP triggers DMA read and write transfers on these interrupts for the most efficient transfers. However, the FIFO flags in the CPLD's FIFOSTAT register or the interrupts themselves can also be polled to drive the data transfers. The PCIMREN and PCIMWEN bits must be disabled at the completion of a bus master transfer and reenabled before the next one begins.

Both the host and DSP software must perform certain initialization and control actions to configure the 'C6x EVM for PCI bus master transfers. The host and DSP software actions can be performed independently and do not require any synchronization. Depending on the application, it may be necessary for the host software to notify the DSP software about the DSP memory space source/destination address and number of words to be transferred. The PCI bus mastering operation begins only when both sides have completed their actions.

The following subsections identify the actions that must be performed by the host and DSP software to perform PCI bus master transfers.

4.6.5.1 Host Software Actions

The 'C6x EVM is factory-configured for PCI (host) initiated bus master transfers. This means that only the host software can enable, control, and monitor the S5933 PCI controller's FIFO bus master on the PCI bus. The EVM uses the PCI-initiated configuration because only the host software knows the physical memory addresses of its memory, as well as other PCI devices' memory. For PCI-initiated bus mastering, the host software must complete certain actions to set up the FIFO bus mastering.

- ☐ **Define interrupt capabilities.** The host can be interrupted independently at the end of read and write transfers when the transfer counters reach 0. The S5933 INTCSR register's bits 14 and 15 must be set accordingly.
- ☐ **Reset FIFO flags.** The FIFO state must be initialized to empty by resetting the FIFO flags. The S5933 MCSR register's bits 25 and 26 can be set to reset these flags.
- ☐ **Define FIFO management scheme.** The FIFOs must be configured for the desired times that the S5933 should request mastering the PCI bus. For reads, the PCI bus can be requested when there are at least one or at least four vacant FIFO locations. For writes, the PCI can be requested when there are at least one or at least four filled FIFO locations. The S5933 does not have to request the bus as often when four or more data words are transferred during each bus grant period; using this FIFO management scheme improves throughput in most applications. The FIFO management scheme is selected by initializing the S5933's MCSR register's bits 9 and 13.
- ☐ **Define PCI-to-EVM and EVM-to-PCI priority.** It is recommended that write versus read priority be set equal by setting bits 8 and 12 of the S5933's MCSR register.
- ☐ **Define transfer source/destination address.** The start of the PCI-side source address must be written to the S5933's MRAR register for bus master reads, and the destination address must be written to the MVAR register for bus master writes. This address is the system's physical memory address that is presented on the PCI bus. This address must be on a 32-bit word address (lower two address bits 0).
- ☐ **Define transfer byte count.** The S5933's MWTC and MRTC registers must be initialized with the number of bytes to be transferred for bus master writes and bus master reads, respectively. The number of bytes must be a multiple of four because the 'C6x EVM only supports 32-bit, bus master data transfers.

- ❑ **Enable bus mastering.** After the other actions have been done, the read and write bus master operations can be independently enabled by setting bits 10 and 14 of the S5933's MCSR register. This enables the S5933's hardware to begin requesting the PCI bus to move data to and from its FIFOs.
- ❑ **Provide DSP software with data transfer information.** In most applications, the host software must notify the DSP software of the data transfer information, such as the DSP memory space source or destination address and the number of 32-bit words to be transferred. This allows the DSP software to initialize its DMA controller to handle the transfers from the S5933 to its memory space properly. This data transfer information can be sent to the DSP via the HPI or, more commonly, through the mailbox.
- ❑ **Provide application-specific response to end of transfer interrupt.** If interrupts were enabled, the host software must provide an interrupt service routine to handle PCI interrupts. The host software can perform an application-specific action in response to the end-of-transfer interrupt generated by the S5933. One example action is to prepare for the next data transfer.

The DSP must also perform certain actions in order to for the bus mastering to begin.

4.6.5.2 DSP Software Actions

The 'C6x EVM's DSP software is responsible for moving the data between its memory space and the S5933 PCI controller's bidirectional FIFO to complete the data transfers. The DSP typically uses DMA to handle the reading and writing of the data from and to the S5933's FIFO. Optionally, the DSP software can perform this data movement itself using an interrupt service routine or by polling the status of the interrupts or FIFO flags themselves.

The 'C6x EVM uses EXT_INT5 to control read bus master transfers from the S5933 read FIFO to the DSP memory space and EXT_INT6 to control write bus master transfers from the DSP memory space to the S5933 write FIFO. Logic in the CPLD, when explicitly enabled by the DSP software, monitors the FIFO flags and DSP accesses to the S5933 FIFO and controls the interrupts to the DSP.

The DSP software must perform the following actions to support PCI bus mastering:

- ☐ **Initialize 'C6x DMA control registers.** The primary DMA control register must be configured for incrementing address modification, 32-bit elements, and split-mode disabled. The transfers must be synchronized for reads or writes by initializing the RSYNC and WSYNC bits appropriately. For bus master reads, read synchronization based on EXT_INT5 must be selected. For bus master writes, write synchronization based on EXT_INT6 must be selected.

The secondary DMA control register can be configured to interrupt the DSP upon the transfer completion.

- ☐ **Initialize 'C6x DMA source/destination address register.** The source address register must be initialized for bus master writes, and the destination address register must be initialized for bus master reads.
- ☐ **Initialize 'C6x DMA transfer counter register.** The transfer counter register's FRAME COUNT and ELEMENT COUNT values must be set to select the number of frames and 32-bit elements that are to be transferred. This value must match the number of transfers that the host software indicates.
- ☐ **Start the 'C6x DMA controller.** The DMA controller can be started by writing 01b to the START bits of the primary DMA control register.
- ☐ **Enable CPLD master transfer support.** Before bus master transfer interrupts are generated to the DSP, the respective CPLD control bits must be set to 1 as needed. For bus master writes, the CPLD's FIFOSTAT PCIMWEN bit must be set to 1. For bus master reads, the PCIMREN bit must be set to 1. These enables activate a state machine in the CPLD that generates the external interrupts to the DSP.
- ☐ **Provide application-specific response to end-of-transfer interrupt.** If interrupts were disabled, the DSP software must provide an interrupt service routine to handle internal DMA block transfer complete interrupts. The DSP software can perform an application-specific action in response to the interrupt generated internal to the DSP. One example action is to prepare for the next data transfer.
- ☐ **Disable CPLD master transfer support.** To disable the bus master interrupts to the DSP and put the CPLD state machine in an idle state, the PCI bus master enable bits in the CPLD's FIFOSTAT register must be cleared to 0. The bus master enable bits must be disabled before another master transfer is started.

4.7 JTAG Emulation

The EVM provides embedded JTAG emulation, which is accessible via the PCI bus, as well as support for an external XDS510 emulator. The selected JTAG method is user configurable via the DIP switches when the board is operated outside the PC or via the software switches when it is in the PC.

The TI SN74ACT8990 JTAG test bus controller (TBC) provides memory-mapped control of the 'C6201's JTAG interface. This allows the 'C6x EVM C source debugger to be used with the EVM without an external emulator.

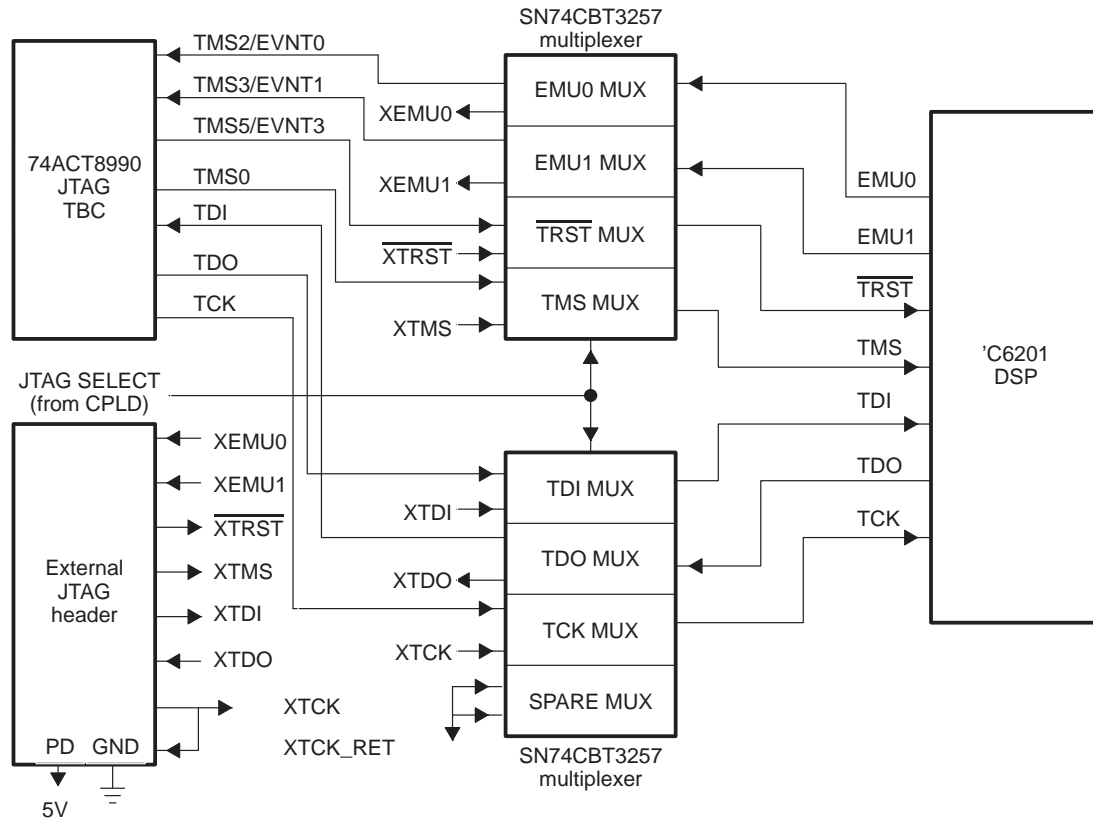

The 'C6x EVM's embedded emulation support provides several benefits:

- ☐ Emulation is supported without external cabling, monitor software, or consumption of user resources.
- ☐ Easy access to the 'C6201 supports high-level language (HLL) debuggers, factory testing, and field diagnostics.
- ☐ System boot ROMs are not needed. The host can download all necessary program and data information through the emulation port.

The TBC is presented to the PC host software as 24 memory-mapped registers. Each register is mapped at 32-bit (DWORD) address boundaries, but only the lower 16 bits of data words are connected to the 16-bit TBC device. The PCI controller's pass-through interface is used to access the slave TBC. The CPLD includes a state machine that manages the S5933-to-TBC data transfers via the pass-through interface.

A 14-pin (two rows of seven pins) header on the EVM (J5) supports an external XDS510 or XDS510WS emulator connection. This connection is required for debugging the EVM outside of a PC. Two TI CBT quad 2:1 multiplexer devices (SN74CBT3257) are used to provide the 5-V to 3.3-V translation required from the TBC to the 'C6201 and the selection between internal and external JTAG emulation. The JTAG interface to the 'C6201 consists of seven signals: TMS, TDO, TDI, TCLK, $\overline{\text{TRST}}$, EMU1, and EMU0. The two quad multiplexer devices are required to switch and translate seven signals. The use of the CBT devices also allows 3.3- or 5-V external emulator connections. Figure 4–7 shows how the DSP's JTAG signals are selected between the TBC and the external JTAG header using the CBT multiplexers.

Figure 4–7. JTAG Emulation Selection

The TBC does not directly provide pins dedicated for the EMU0, EMU1, and $\overline{\text{TRST}}$ signals that are present on the external JTAG header. However, the TBC can control and monitor these signals using the available TMSx pins. The TMS2 and TMS3 signals are used to monitor the EMU0 and EMU1 signals from the 'C6201, respectively. The TMS5 signal is used to control the DSP's $\overline{\text{TRST}}$ signal. The host emulation software monitors and controls these signals via the TBC's PCI interface.

You can select between internal and external JTAG emulation via DIP switch SW2–9 during external operation or via a software switch for internal PCI operation. The selection controls the multiplexers' select input signal accordingly.

A 10.368-MHz JTAG clock (TCK) is provided by the XDS510 or XDS510WS when external JTAG emulation is selected. The EVM provides a 16.625-MHz clock when the JTAG TBC is used for embedded emulation. The 16.625-MHz clock is derived from the EVM's 33.25-MHz oscillator output using a single SN74F74 D-type flip-flop device configured for a divide-by-2 operation.

4.8 Programmable Logic

The 'C6x EVM uses a CPLD (Altera™ part number EPM7256S) to implement the board's required glue logic and to provide control and status interfaces for both host and DSP software. The CPLD provides the following functions:

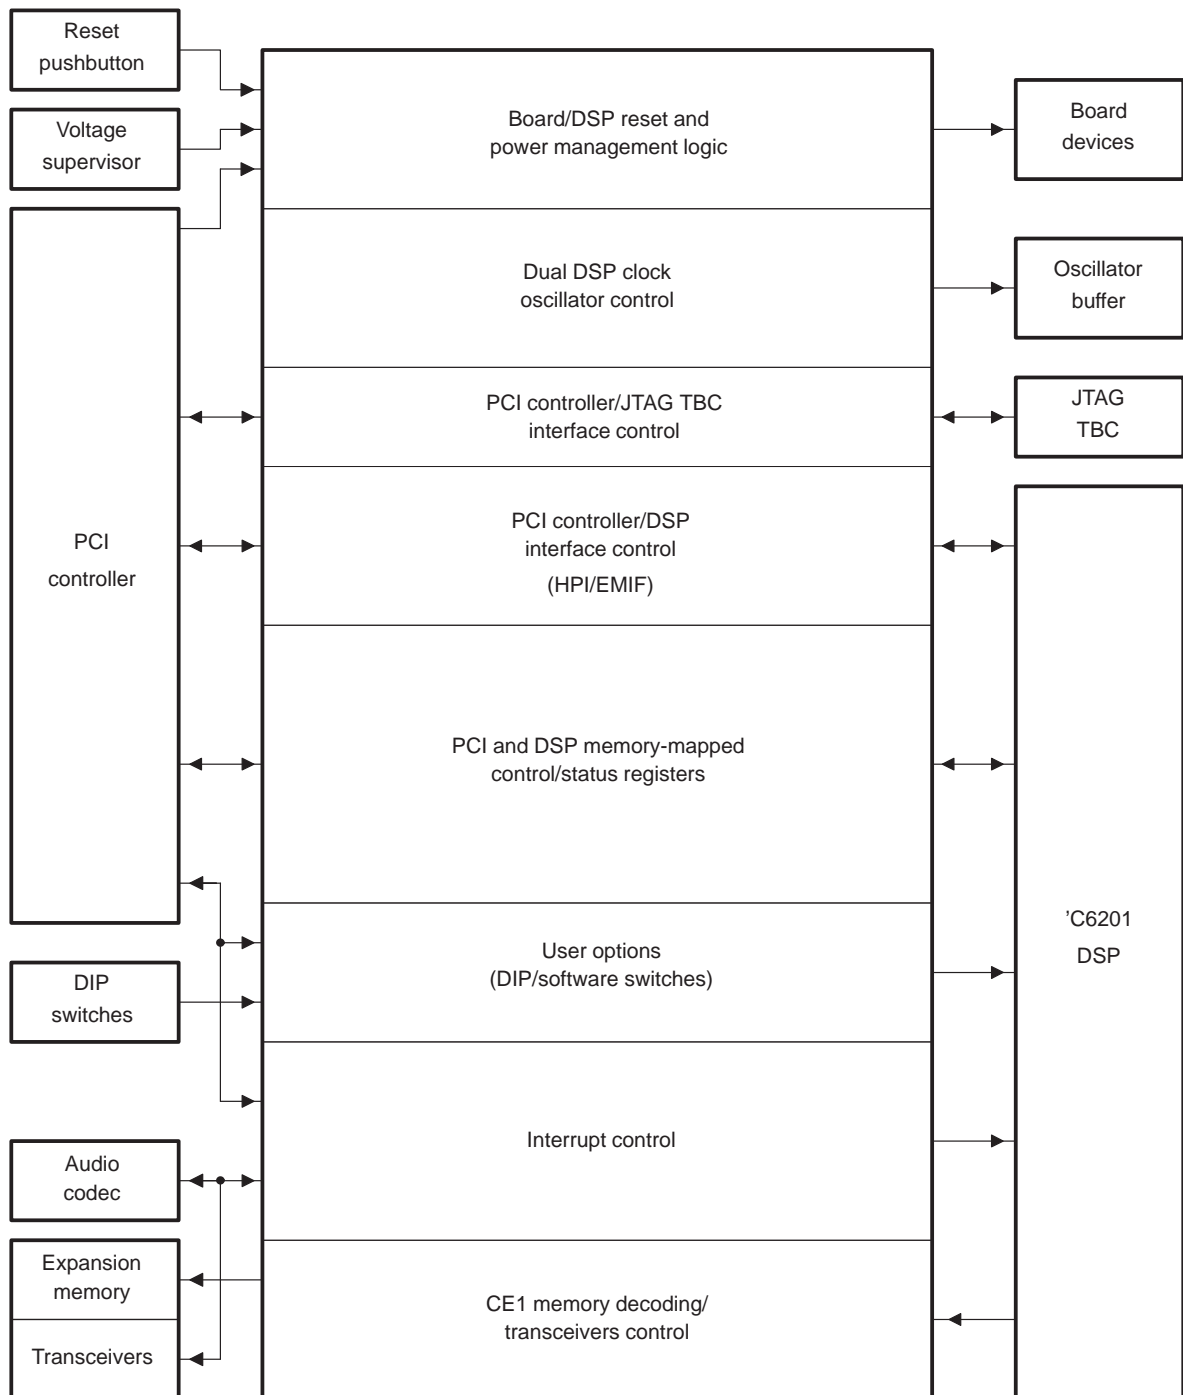

- ☐ Reset control
- ☐ Power management
- ☐ Dual DSP clock oscillator control
- ☐ PCI controller/DSP interface control
- ☐ PCI memory-mapped board control/status registers
- ☐ DSP memory-mapped control/status registers
- ☐ PCI and DSP interrupt control
- ☐ CE1 memory decoding
- ☐ Data transceivers control
- ☐ User options control

The EPM7256S CPLD is a 208-pin plastic quad flat pack (PQFP) device that provides 5000 usable gates, 160 user I/O pins, and a 10-ns pin-to-pin delay. The device is EEPROM-based and is in-system programmable via a dedicated JTAG interface presented as a 10-pin header on the EVM. This header is a factory option that is not installed.

The EPM7256S uses 5 V for internal operation and input buffers and 3.3 V for output drivers. This provides an optimal design with fast internal speed and the ability to interface with both 3.3- and 5-V devices on the EVM.

Figure 4–8 provides an overview of the CPLD's functions and their associated interfaces.

Figure 4–8. CPLD Interfaces and Functions

4.8.1 Reset Control

The CPLD works in tandem with a Maxim MAX708S voltage supervisor to provide several types of reset signals on the 'C6x EVM.

The EVM supports several methods to reset the board, DSP, JTAG TBC, and daughterboard. There are five reset sources:

- ☐ Power-up and undervoltage resets from the voltage supervisor
- ☐ Manual pushbutton reset
- ☐ PCI system reset from the PCI controller
- ☐ Daughterboard reset under DSP software control
- ☐ DSP and TBC resets under host software control

The MAX708S voltage supervisor asserts an active low reset to the CPLD whenever the 3.3-V supply is below 3.0 V, such as during power up and brown-out conditions. Additionally, the voltage supervisor supports an external reset control signal generated by the CPLD that forces a board reset whenever the reset pushbutton is pressed or a PCI system or software reset is received. The MAX708S provides an output signal that indicates when the 1.8-V/2.5-V supply has an undervoltage condition that the CPLD uses to control the DSP reset. The DSP is held in reset whenever either its core or I/O voltage is below a defined threshold.

The S5933 PCI controller provides a SYSRST# output that causes a reset whenever the PCI bus is reset, such as when a system is rebooted with Ctrl-Alt-Del or when the host software sets a bit in its MCSR register. The SYSRST# signal provides an automatic reset signal as well as a software-controlled reset control, similar to the voltage supervisor's support for automatic and manual reset.

The DSP software has access to a memory-mapped CPLD register bit that directly controls the reset to the daughterboard. This daughterboard reset (XRESET#) is asserted low during reset but defaults to an inactive high upon release of reset. This provides a reset to the daughterboard whenever the EVM is in reset, but it does not hold the daughterboard in reset. Subsequent control over the daughterboard reset is exclusively under DSP software control.

Both the DSP and JTAG TBC can be individually reset under host software control. PCI memory-mapped CPLD register bits allow the host software to directly control the reset signals to both the 'C6201 DSP and JTAG TBC. This is useful when doing controlled booting such as an HPI boot, performing a simple DSP reset operation, or putting the TBC in a known state. During board reset, the DSP and JTAG TBC are also held in reset. The DSP is also forced into reset whenever the board is in reset or its core voltage is not within

specification. When the board reset is released, the two register bits default to not active so that the DSP and TBC are not held in reset in the external environment. The host software-controlled DSP and TBC resets are only available with internal PCI operation.

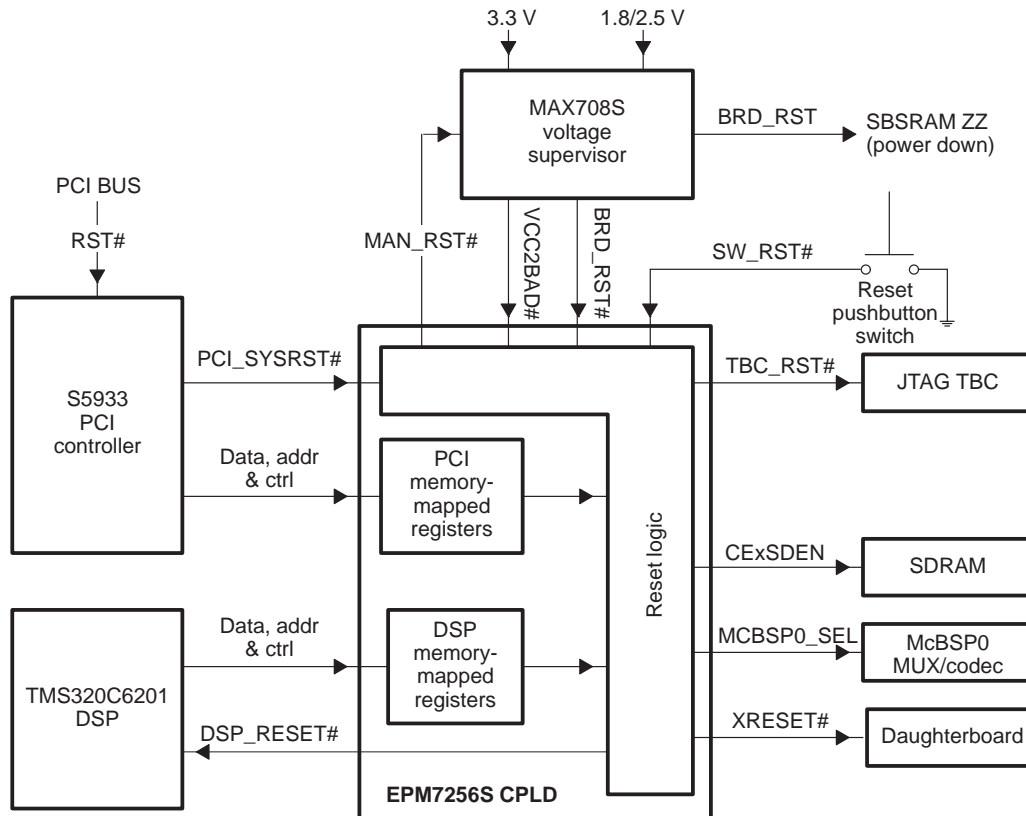

The board reset is produced when either the MAX708S indicates a reset (power up, undervoltage condition, or manual switch reset) or the PCI controller indicates a reset (PCI reset or manual software reset). The MAX708S provides two board reset signals: one active low and the other active high. The active-low board reset is routed to the CPLD, which directly controls the reset to the DSP, JTAG TBC, and daughterboard. The CPLD also indirectly controls the reset or power down of the audio codec via the McBSP0 multiplexer and the SDRAM via the clock enable control signals. The active-high board reset from the MAX708 is routed directly to the SBSRAM snooze (ZZ) input to put the device in an inactive, low-power state. When the EVM board is held in reset, it cannot respond to host PCI accesses.

The PCI bus can only reset the PCI controller at power up and whenever the system is reset. The BIOS only assigns the memory region addresses and the host interrupt upon reset of the host PC.

In the PCI environment, the EVM software drivers can put several board devices in a low-power state by holding the board in reset. The PCI specification recommends that PCI boards that dissipate more than 10 watts implement a default power reduction mode. This can be supported under driver control.

Figure 4–9 summarizes the 'C6x EVM's reset configuration.

Figure 4–9. Reset Configuration

4.8.2 Power Management

The *PCI Local Bus Specification Revision 2.1* recommends that PCI boards that can dissipate more than 10 watts under full operation have a power-saving state. The 'C6x EVM CPLD includes logic that provides a power management capability that does not require additional devices. Various devices on the EVM can be placed in a low-power state to reduce power consumption.

The EVM's power management feature is activated when the board is held in reset by the host software. This is achieved when the host software asserts the PCI controller's SYSRST# signal (setting bit 24 of the S5933 PCI controller's MCSR register).

When the EVM board is held in reset, CPLD logic directly controls devices to power them down or put them into a low-power state. The 'C6201 DSP is held in reset, which forces it to power down. The SBSRAM is powered down by asserting its ZZ sleep input signal. The SDRAM is disabled and put into a low-power mode by deasserting its CKE clock enable input signal. The McBSP0 multiplexer is configured to power down the audio codec by asserting the codec's $\overline{\text{PWDN}}$ input signal. Both an external reset and the DSP's power-down indication are provided to the expansion peripheral interface to enable power-down support on a daughterboard. Other devices on the board, such as the buffers, are indirectly placed into a low-power mode, since their inputs are static when the other devices are inactive. Table 4–11 lists the EVM devices that are directly controlled by CPLD logic and the control signals that are used to implement the power management feature of each device.

Table 4–11. Power Management Device Control Summary

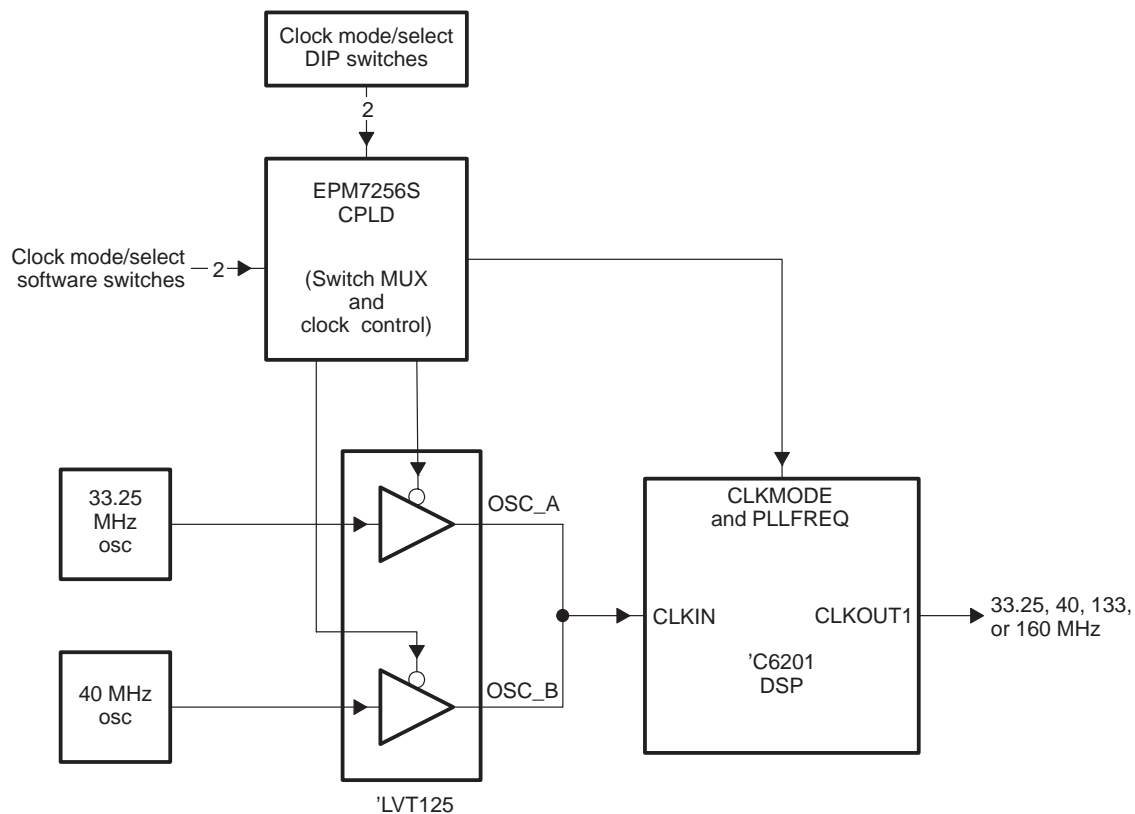

Device	Power Management Control Signals
DSP	$\overline{\text{RESET}} = 0$
SBSRAM	ZZ = 1
SDRAM	CKE = 0
Audio codec	$\overline{\text{PDWN}} = 0$
Daughterboard	XRESET = 0, DSP_PD = 1

4.8.3 Dual DSP Clock Oscillator Control

The 'C6x EVM includes dual DSP clock oscillator support to enable operation at the 160-MHz core clock rate with one-half-rate SBSRAM timing or at the full 133-MHz SBSRAM clock rate. You have the flexibility to select the clock rate that provides the best performance for your application. This clock selection can be made with the EVM DIP switches or from host software using the support software switches. For external operation, only the DIP switches are used to select the clock. For internal (PCI) operation, the DIP switches are selected for control by default unless overridden by host software using the software switches.

The user clock selection is used by CPLD logic to control two clock buffer enables. Each clock oscillator's output is connected to an 'LVT125 buffer that has independent output enables. The two clock buffer outputs are connected together to drive the DSP's CLKIN input. To provide the 2:1 clock selection function and ensure that there is no contention between the oscillators, the CPLD logic performs a "break-before-make" function that ensures that only one clock oscillator is driving the DSP's CLKIN input. Figure 4–10 summarizes the DSP clock selection configuration.

Figure 4–10. DSP Clock Selection Configuration

4.8.4 PCI Controller/JTAG TBC Interface Control

The CPLD includes a PCI add-on bus state machine that monitors and controls the interfaces between the S5933 PCI controller and the PCI memory-mapped devices on the EVM, including the JTAG TBC.

Whenever the S5933 indicates either a PCI read or write TBC access, the state machine acknowledges it by asserting S5933 and TBC control signals required to complete the data transfer. The lower 16 bits of the S5933 add-on data bus are connected to the TBC data bus interface. The CPLD latches the TBC register address during the PCI address phase and the state machine asserts the TBC read and write strobes to enable data transfers.

4.8.5 PCI Controller/DSP Interface Control

The CPLD's add-on bus state machine supports PCI transfers with the DSP's HPI, as well as DSP EMIF transfers with the S5933 PCI controller. These capabilities allow the host and DSP software to communicate with one another. The host software has read/write access to the DSP's memory space and can exchange messages with the DSP software using the S5933's mailboxes. The DSP software has read/write access to the host PC's memory space and can also exchange messages with the host software using S5933's mailboxes. The S5933's bidirectional FIFOs can also be used to pass data between the host and DSP software, although they are typically only used for bus master transfers.

The DSP HPI can be accessed by the host software with BAR3 and BAR4 PCI accesses. Whenever the S5933 indicates either a PCI read or write HPI access, the state machine acknowledges it by asserting S5933 and HPI control signals required to complete the data transfer. The lower 16 bits of the S5933 add-on data bus are connected to the HPI data bus interface, with TI 'CBT devices used to translate from 5- to 3.3-V signals. The internal byte-lane switching feature of the S5933 allows the low and high words of the 32-bit PCI data transfers to be output on the lower 16 bits of the add-on bus during the low and high word data transfer times to the HPI. The CPLD latches the HPI register address during the PCI address phase, and the state machine asserts the HPI control signals to enable data transfers.

CPLD output pins are shared to support both the TBC address and HPI control signals. Because an access can only be directed to one of the two at any one time, the outputs can be used for both interfaces and controlled as required for the different accesses. This is possible since the TBC address signals are don't cares unless the TBC read/write strobes are asserted, and the HPI control signals are don't cares unless the HPI chip and data select signals are asserted.

HPI data transfers are 16 bits wide, so a 32-bit data transfer between the host and DSP requires two HPI data transfers. The CPLD state machine manages each 16-bit data transfer by controlling the appropriate byte enable and other control signals. The state machine includes monitoring of the HPI ready output signal to determine when the next write can proceed and when read data is available.

Because the state machine is synchronous to the 33-MHz PCI clock, there is a minimum of 30 ns between control signal transitions. Therefore, the maximum transfer rate between the host and DSP is defined by the required HPI transfer protocol to transfer two 16-bit words and the 30-ns state machine clock period.

CPLD arbitration logic allows both PCI and DSP EMIF transfers to share the common PCI add-on bus. The add-on state machine controls DSP EMIF accesses to the S5933 controller's registers and FIFOs. Because the state machine may be in the process of transferring data between the S5933 and another device when the DSP attempts to access the S5933, the state machine provides arbitration logic that holds off the EMIF access via the DSP's ARDY input until the current add-on transfer is finished. Burst transfers are finished as soon as possible to allow EMIF accesses to have priority over the add-on bus. Logic is also included that disables the EMIF data bus connection to the add-on bus while the add-on bus is being used for other transfers to prevent data bus contention. When an EMIF access to the S5933 is taking place, PCI transfers are held until the add-on bus is released.

The CPLD add-on bus state machine controls the add-on bus control signals during EMIF accesses to the S5933 registers and FIFOs. When the EMIF is granted the add-on bus, the state machine latches the register address from the DSP's address lines and presents them on the add-on address bus. The other add-on bus control signals are also asserted by the state machine to provide data to the DSP EMIF data bus or to latch the data into the selected S5933 register or FIFO.

There is a 32-bit data interface between the DSP EMIF and the S5933 PCI controller. The DSP's EMIF 32-bit data bus is buffered with 'LVTH162245 and 'CBTD3384 devices to isolate it from the PCI add-on bus and to provide voltage translation between 5 V and 3.3 V.

4.8.6 PCI Memory-Mapped Board Control/Status Registers

The CPLD's add-on bus state machine supports PCI transfers with nine memory-mapped board control and status registers that are also implemented in the CPLD. These registers provide the host with the following capabilities:

- ☐ Interrupt the DSP (nonmaskable interrupt)
- ☐ Enable interrupts from the DSP and TBC
- ☐ Reset the DSP and TBC
- ☐ Monitor status of EVM devices
- ☐ Read the user-option DIP switches
- ☐ Select the user options via software switches
- ☐ Read the selected DSP options
- ☐ Read the CPLD revision number

Table 4–12 summarizes the PCI memory-mapped CPLD registers.

Table 4–12. PCI Memory-Mapped CPLD Registers

Address	Name	Description	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0

The following subsections describe each of the PCI memory-mapped CPLD registers.

Note:

All register bits are active high (1) for consistency and ease of use. For example, to reset the DSP, bit 0 of the CNTL register must be set to a 1. Highlighted register values denote the power-up default values.

4.8.6.1 PCI CNTL Register (BAR2 + 0x00)

The CNTL register enables the host software to interrupt and reset the DSP, enable interrupts from the DSP, and monitor TBC and DSP status. The host can be interrupted whenever the TBC or DSP host interrupts are asserted, or it can poll the status of these interrupt signals directly. The nonmaskable interrupt (NMI) and reset bits must be manually toggled to assert and deassert the respective signals. Table 4–13 summarizes the function of each bit in the CNTL register. Highlighted register values denote the power-up default values.

Table 4–13. PCI CNTL Register Bit Definitions

Bit	Name	Access	Description
7	DSPNMI	RW	Controls DSP's NMI (0 = no NMI , 1 = assert NMI)
6	TBCINTEN	RW	TBC interrupt enable (0 = disable TBC interrupt , 1 = enable TBC interrupt)
5	HINTEN	RW	DSP host interrupt enable (0 = disable host interrupt , 1 = enable host interrupt)
4	TBCRDY	R	TBC ready status (0 = TBC not ready, 1 = TBC ready)
3	TBCINT	R	TBC interrupt status (0 = no TBC interrupt, 1 = TBC interrupt)
2	DSPHINT	R	DSP host interrupt status (0 = no host interrupt, 1 = host interrupt)
1	TBCRST	RW	TBC hardware reset (0 = no TBC reset , 1 = TBC reset)
0	DSPRST	RW	DSP hardware reset (0 = no DSP Reset , 1 = DSP reset)

4.8.6.2 PCI STAT Register (BAR2 + 0x04)

The STAT register enables the host software to monitor the DSP core voltage, codec, DSP power down, daughterboard control, and user-defined LED status. Table 4–14 summarizes the function of each bit in the STAT register.

Table 4–14. PCI STAT Register Bit Definitions

Bit	Name	Access	Description
7	–	–	–
6	VCC2BAD	R	DSP core voltage status (0 = core voltage OK, 1 = core voltage bad)
5	CODECPD	R	Codec power-down status (0 = codec not in power down, 1 = codec in power down)
4	DSPPD	R	DSP power-down status (0 = DSP not in power down, 1 = DSP in power down)
3	XCNTL1	R	Control signal from DSP to daughterboard (0 = TTL low, 1 = TTL high)
2	XCNTL0	R	Control signal from DSP to daughterboard (0 = TTL low, 1 = TTL high)
1	USERLED1	R	User LED 1 status (0 = LED extinguished, 1 = LED illuminated)
0	USERLED0	R	User LED 0 status (0 = LED extinguished, 1 = LED illuminated)

4.8.6.3 PCI SWOPT Register (BAR2 + 0x08)

The SWOPT register enables the host software to override the EVM's onboard user option DIP switches. This capability provides software switches, which allow the DSP options to be controlled without having to remove the PC's cover. The values in this register are not used unless the SWSEL bit in the SWBOOT register is set to 1. Table 4–15 summarizes the function of each bit in the SWOPT register. Highlighted register values denote the power-up default values.

Table 4–15. PCI SWOPT Register Bit Definitions

Bit	Name	Access	Description
7	–	–	–
6	H_CLKMODE	RW	Host clock mode (0 = ×4 mode , 1 = ×1 mode)
5	H_CLKSEL	RW	Host clock select (0 = OSC_A = 33.25 MHz , 1 = OSC_B = 40 MHz)
4	H_ENDIAN	RW	Host endian control (0 = little endian , 1 = big endian)
3	H_JTAGSEL	RW	Host JTAG selection (0 = external XDS510 , 1 = onboard JTAG TBC)
2	H_USER2	RW	Host user-defined option 0 (0 = on , 1 = off)
1	H_USER1	RW	Host user-defined option 1 (0 = on , 1 = off)
0	H_USER0	RW	Host user-defined option 2 (0 = on , 1 = off)

4.8.6.4 PCI SWBOOT Register (BAR2 + 0x0C)

The SWBOOT register enables the host software to override the EVM's boot mode DIP switches. This capability provides software switches, which allow the DSP boot mode to be controlled without having to remove the PC's cover. The values in this register do not get used unless the SWSEL bit is set to 1. Table 4–16 summarizes the function of each bit in the SWBOOT register. Highlighted register values denote the power-up default values.

Table 4–16. PCI SWBOOT Register Bit Definitions

Bit	Name	Access	Description
7	SWSEL	RW	Software switch select (0 = DIP switches , 1 = software switches)
6	–	–	–
5	–	–	–
4	H_BMODE4	RW	Host boot mode 4 (0)
3	H_BMODE3	RW	Host boot mode 3 (0)
2	H_BMODE2	RW	Host boot mode 2 (1)
1	H_BMODE1	RW	Host boot mode 1 (0)
0	H_BMODE0	RW	Host boot mode 0 (1)

4.8.6.5 PCI DIPOPT Register (BAR2 + 0x10)

The DIPOPT register enables the host software to read the EVM's onboard user option DIP switches. Table 4–17 summarizes the function of each bit in the DIPOPT register.

Table 4–17. PCI DIPOPT Register Bit Definitions

Bit	Name	Access	Description
7	–	–	–
6	S_CLKMODE	R	Switch clock mode (0 = ×4 mode, 1 = ×1 mode)
5	S_CLKSEL	R	Switch clock select (0 = OSC_A = 33.25 MHz, 1 = OSC_B = 40 MHz)
4	S_ENDIAN	R	Switch endian control (0 = little endian, 1 = big endian)
3	S_JTAGSEL	R	Switch JTAG selection (0 = external XDS510, 1 = onboard JTAG TBC)
2	S_USER2	R	Switch user-defined option 0 (0 = on, 1 = off)
1	S_USER1	R	Switch user-defined option 1 (0 = on, 1 = off)
0	S_USER0	R	Switch user-defined option 2 (0 = on, 1 = off)

4.8.6.6 PCI DIPBOOT Register (BAR2 + 0x14)

The DIPBOOT register enables the host software to read the EVM's onboard boot mode DIP switches. Table 4–18 summarizes the function of each bit in the DIPBOOT register.

Table 4–18. PCI DIPBOOT Register Bit Definitions

Bit	Name	Access	Description
7	–	–	–
6	–	–	–
5	–	–	–
4	S_BMODE4	R	Switch boot mode 4
3	S_BMODE3	R	Switch boot mode 3
2	S_BMODE2	R	Switch boot mode 2
1	S_BMODE4	R	Switch boot mode 1
0	S_BMODE4	R	Switch boot mode 0

4.8.6.7 PCI DSPOPT Register (BAR2 + 0x18)

The DSPOPT register enables the host software to read the DSP options, which may either be from the DIP switches or the software switches, depending on which is selected. Table 5–14 summarizes the function of each bit in the DIPOPT register.

Table 4–19. PCI DSPOPT Register Bit Definitions

Bit	Name	Access	Description
7	–	–	–
6	CLKMODE	R	Clock mode (0 = ×1 mode, 1 = ×4 mode)
5	CLKSEL	R	Clock select (0 = OSC_A = 33.25 MHz, 1 = OSC_B = 40 MHz)
4	LENDIAN	R	Endian control (0 = big endian, 1 = little endian)
3	JTAGSEL	R	JTAG selection (0 = external XDS510, 1 = onboard JTAG TBC)
2	USER2	R	User-defined option 0 (0 = on, 1 = off)
1	USER1	R	User-defined option 1 (0 = on, 1 = off)
0	USER0	R	User-defined option 2 (0 = on, 1 = off)

4.8.6.8 PCI DSPBOOT Register (BAR2 + 0x1C)

The DSPBOOT register enables the host software to read the DSP's boot, which can either be from the DIP switches or the software switches, depending on which is selected. Table 4–20 summarizes the function of each bit in the DSPBOOT register.

Table 4–20. PCI DSPBOOT Register Bit Definitions

Bit	Name	Access	Description
7	–	–	–
6	–	–	–
5	–	–	–
4	BMODE4	R	Boot mode 4
3	BMODE3	R	Boot mode 3
2	BMODE2	R	Boot mode 2
1	BMODE1	R	Boot mode 1
0	BMODE0	R	Boot mode 0

4.8.6.9 PCI CPLDREV Register (BAR2 + 0x20)

The CPLDREV register provides the revision of the EVM's CPLD. This information may be useful in assisting technical support. The revision number can be up to eight bits in length. Table 4–21 summarizes the function of each bit in the CPLDREV register.

Table 4–21. PCI CPLDREV Register Bit Definitions

Bit	Name	Access	Description
7	CREV7	R	CPLD revision bit 7
6	CREV6	R	CPLD revision bit 6
5	CREV5	R	CPLD revision bit 5
4	CREV4	R	CPLD revision bit 4
3	CREV3	R	CPLD revision bit 3
2	CREV2	R	CPLD revision bit 2
1	CREV1	R	CPLD revision bit 1
0	CREV0	R	CPLD revision bit 0

4.8.7 DSP Memory-Mapped Control/Status Registers

The 'C6x EVM's CPLD provides eight control and status registers that are memory-mapped into the DSP's CE1 memory space. All registers are eight bits wide and are mapped into the least-significant byte of the EMIF data bus (ED[7:0]). The registers are mapped on DWORD address boundaries for little-endian mode, but, for big-endian mode, the registers are offset by 3 to access ED[7:0]. The memory-mapped DSP registers provide the DSP software to perform the following functions:

- ☐ Control the two user-defined LEDs
- ☐ Control and monitor the daughterboard
- ☐ Select NMI source and enable
- ☐ Select McBSP0 connection/power-down codec
- ☐ Determine the interrupt status
- ☐ Determine the operating environment
- ☐ Read the user options DIP switches
- ☐ Read the selected DSP options
- ☐ Monitor and control the PCI controller FIFO
- ☐ Control the two SDRAM banks

Address decoding generates the clock and output enable controls for the registers. Register clock enables are generated whenever the specific register is being addressed. The rising edge of the EMIF \overline{AWE} output is used to clock the lower eight bits of the EMIF data bus into the registers. Data is output on the lower eight bits of the EMIF data bus when the CPLD register space is read. This register space is allocated 64K bytes in the CE1 memory space, as shown in Table 4–2 and Table 4–3. The eight registers are addressed sequentially on DWORD address boundaries.

The lower eight bits of the EMIF data bus are buffered by an 'LVTH162245 transceiver to provide the peripheral data bus (PDB[7:0]) that is connected to the CPLD.

Table 4–22 summarizes the eight DSP memory-mapped control and status registers implemented in the CPLD.

Table 4–22. DSP Memory-Mapped Control/Status CPLD Registers

Address MAP 1 (MAP 0)	Name	Description	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
01780000 (01380000)	CNTL	Control	XCNTL1 RW 0 (inactive)	XCNTL0 RW 0 (inactive)	XRESET RW 0 (no reset)	NMIEN RW 0 (disabled)	NMISEL RW 0 (host)	SP0SEL RW 0 (DB)	LED1 RW 0 (off)	LED0 RW 0 (off)

The following subsections describe each of the eight DSP memory-mapped CPLD registers.

Note:

All register bits are active high (1) for consistency and ease of use. For example, to illuminate LED0, bit 0 of the CNTL register must be set to a 1. Highlighted register values denote the power-up default values.

4.8.7.1 DSP CNTL Register (0x01380000/0x01780000)

The CNTL register enables the DSP software to control the daughterboard, enable and select the NMI interrupt source, select the McBSP0 connection, and control the user-defined LEDs. Table 4–23 summarizes the function of each bit in the CNTL register. Highlighted register values denote the power-up default values.

Table 4–23. DSP CNTL Register Bit Definitions

Bit	Name	Access	Description
7	XCNTL1	RW	Control signal to daughterboard (0 = TTL low , 1 = TTL high)
6	XCNTL0	RW	Control signal to daughterboard (0 = TTL low , 1 = TTL high)
5	XRESET	RW	Daughterboard reset signal (0 = no reset , 1 = asserts active low reset)
4	NMIEN	RW	NMI interrupt enable (0 = disable NMI to DSP , 1 = enable NMI to DSP)
3	NMISEL	RW	NMI interrupt select (0 = PCI NMI register bit , 1 = codec interrupt)
2	SP0SEL	RW	McBSP0 selection (0 = daughterboard , 1 = audio codec)
1	LED1	RW	User-defined LED #1 on top of board (0 = extinguished , 1 = illuminated)
0	LED0	RW	User-defined LED #0 on bracket (0 = extinguished , 1 = illuminated)

4.8.7.2 DSP STAT Register (0x1380004/0x1780004)

The STAT register enables the DSP software to monitor the daughterboard, interrupts, audio codec status, and PCI detection indicator. Table 5–19 summarizes the function of each bit in the STAT register.

Table 4–24. DSP STAT Register Bit Definitions

Bit	Name	Access	Description
7	XSTAT1	R	Status signal from daughterboard (0 = TTL low, 1 = TTL high)
6	XSTAT0	R	Status signal from daughterboard (0 = TTL low, 1 = TTL high)
5	DBINT	R	Daughterboard interrupt status (0 = no interrupt, 1 = interrupt)
4	DSPNMI	R	DSP NMI interrupt (0 = no NMI, 1 = NMI)
3	CODECPD	R	Codec power-down status (0 = codec active, 1 = codec power down)
2	CODECIRQ	R	Codec interrupt status (0 = no interrupt, 1 = codec interrupt asserted)
1	PCIINT	R	PCI interrupt status (0 = no PCI interrupt, 1 = PCI interrupt asserted)
0	PCIDET	R	PCI detection indicator (0 = external operation, 1 = PCI operation)

4.8.7.3 DSP DIPOPT Register (0x1380008/0x1780008)

The DIPOPT register enables the DSP software to read the DIP switch user options. Table 4–25 summarizes the function of each bit in the DIPOPT register.

Table 4–25. DSP DIPOPT Register Bit Definitions

Bit	Name	Access	Description
7	–	–	–
6	S_CLKMODE	R	Switch clock mode (0 = ×4 mode, 1 = ×1 mode)
5	S_CLKSEL	R	Switch clock select (0 = OSC_A = 33.25 MHz, 1 = OSC_B = 40 MHz)
4	S_ENDIAN	R	Switch endian control (0 = little endian, 1 = big endian)
3	S_JTAGSEL	R	Switch JTAG selection (0 = external XDS510, 1 = onboard JTAG TBC)
2	S_USER2	R	User-defined switch 0 (0 = on, 1 = off)
1	S_USER1	R	User-defined switch 1 (0 = on, 1 = off)
0	S_USER0	R	User-defined switch 2 (0 = on, 1 = off)

4.8.7.4 DSP DIPBOOT Register (0x138000C/0x178000C)

The DIPBOOT register enables the DSP software to read the DIP switch boot mode selection. Table 4–26 summarizes the function of each bit in the DIPBOOT register.

Table 4–26. DSP DIPBOOT Register Bit Definitions

Bit	Name	Access	Description
7	–	–	–
6	–	–	–
5	–	–	–
4	S_BMODE4	R	Switch boot mode 4 (see Table 4–36 on page 4-78 for valid values)
3	S_BMODE3	R	Switch boot mode 3
2	S_BMODE2	R	Switch boot mode 2
1	S_BMODE1	R	Switch boot mode 1
0	S_BMODE0	R	Switch boot mode 0

4.8.7.5 DSP DSPOPT Register (0x1380010/0x1780010)

The DSPOPT register enables the DSP software to read the actual DSP options. Table 4–27 summarizes the function of each bit in the DSPOPT register.

Table 4–27. DSP DSPOPT Register Bit Definitions

Bit	Name	Access	Description
7	–	–	–
6	CLKMODE	R	Switch clock mode (0 = ×1 mode, 1 = ×4 mode)
5	CLKSEL	–	Switch clock select (0 = OSC_A = 33.25 MHz, 1 = OSC_B = 40 MHz)
4	LENDIAN	R	Switch endian control (0 = big endian, 1 = little endian)
3	JTAGSEL	R	Switch JTAG selection (0 = external XDS510, 1 = onboard JTAG TBC) [†]
2	USER2	R	User-defined switch 2 (0 = on, 1 = off)
1	USER1	R	User-defined switch 1 (0 = on, 1 = off)
0	USER0	R	User-defined switch 0 (0 = on, 1 = off)

[†] Bit 3 (JTAGSEL) is always 0 when the EVM is not installed in a PCI slot.

4.8.7.6 DSP DSPBOOT Register (0x1380014/0x1780014)

The DSPBOOT register enables the DSP software to read the DSP boot mode selection. Table 4–28 summarizes the function of each bit in the DSPBOOT register.

Table 4–28. DSP DSPBOOT Register Bit Definitions

Bit	Name	Access	Description
7	SWSEL	R	Software switch select (0 = DIP switches, 1 = software switches)
6	–	–	–
5	–	–	–
4	BMODE4	R	Boot mode 4 (see Table 4–36 on page 4-78 for valid values)
3	BMODE3	R	Boot mode 3
2	BMODE2	R	Boot mode 2
1	BMODE1	R	Boot mode 1
0	BMODE0	R	Boot mode 0

4.8.7.7 DSP FIFOSTAT Register (0x1380018/0x1780018)

The FIFOSTAT register enables the DSP software to determine the FIFOs' empty/full status and enable PCI bus master external interrupts based on the FIFOs' status. Table 4–29 summarizes the function of each bit in the FIFOSTAT register. Highlighted register values denote the power-up default values.

Table 4–29. DSP FIFOSTAT Register Bit Definitions

Bit	Name	Access	Description
7	–	–	–
6	–	–	–
5	PCIMRINT	R	PCI master read interrupt (0 = inactive, 1 = active)
4	PCIMWINT	R	PCI master write interrupt (0 = inactive, 1 = active)
3	RDEEMPTY	R	PCI controller read FIFO empty (0 = not empty, 1 = empty)
2	WRFULL	R	PCI controller write FIFO full (0 = not full, 1 = full)
1	PCIMREN	RW	PCI master read enable (0 = disable , 1 = enable)
0	PCIMWEN	RW	PCI master write enable (0 = disable , 1 = enable)

4.8.7.8 DSP SDCNTL Register (0x138001C/0x178001C)

The SDCNTL register enables the DSP software to enable and disable the two banks of SDRAM individually. When an SDRAM bank is disabled, the two associated devices are put into a power-down mode, and the CE memory space is available for asynchronous expansion memory use. Table 4–30 summarizes the function of each bit in the SDCNTL register. Highlighted register values denote the power-up default values.

Table 4–30. DSP SDCNTL Register Bit Definitions

Bit	Name	Access	Description
7	–	–	–
6	–	–	–
5	–	–	–
4	–	–	–
3	–	–	–
2	–	–	–
1	CE3SDEN	RW	CE3 (bank 1) SDRAM enable (0 = disable, 1 = enable)
0	CE2SDEN	RW	CE2 (bank 0) SDRAM enable (0 = disable, 1 = enable)

4.8.8 PCI and DSP Interrupt Control

The CPLD provides interrupt control that allows the host and DSP to interrupt each other and supports various EVM interrupts related to the daughterboard, PCI controller, audio codec, and JTAG TBC. The CPLD also controls DSP interrupts that are used to drive PCI bus master transfers.

The host can interrupt the DSP with three different interrupts using the following methods:

- ☐ Setting the HPI control (HPIC) register DSPINT bit (DSPINT)
- ☐ Setting the PCI memory-mapped control register DSPNMI bit (NMI)
- ☐ Accessing a PCI controller mailbox (EXT_INT4)

The HPIC register can be accessed from the host by addressing offset 0 of PCI BAR3. A host write to this address, with the DSPINT bit set to 1, causes a DSPINT interrupt to the DSP. The CPLD provides a state machine that manages the data transfers between the PCI controller and the DSP HPI.

The CPLD provides a PCI memory-mapped board control register (CNTL) that can be accessed by the host at offset 0 of PCI BAR2. When the DSPNMI bit of this register is set to 1, it causes an NMI interrupt to the DSP if the host is selected by the DSP software as the NMI interrupt source. The DSP software can select whether the host or the audio codec sources NMI by setting the NMIEN and NMISEL bits in the DSP memory-mapped CNTL register provided by the CPLD.

The host can also interrupt the DSP by writing or reading a PCI controller mailbox register mapped into PCI BAR0. The incoming and outgoing mailbox registers can generate interrupts when they become full or empty. When the selected mailbox register conditions occur, the DSP's EXT_INT4 interrupt is asserted. The CPLD logic inverts the S5933's IRQ# active low output signal to generate a rising-edge EXT_INT4 signal because the DSP defaults to rising-edge interrupts.

The DSP can interrupt the host by setting the HPIC register's HINT bit to 1. This action forces the DSP's $\overline{\text{HINT}}$ output signal to be asserted low. The CPLD includes a falling-edge detector that generates a pulse on the S5933's external mailbox clock (EMBCLK) input, which causes an interrupt on INTA# to the host. A second falling-edge detector is used to generate an interrupt to the host when the TBC interrupt is asserted. The host software can enable HPI and TBC interrupts via the PCI memory-mapped CNTL register.

Both the host and DSP software can poll interrupt signals by reading PCI and DSP memory-mapped registers in the CPLD. The host can poll the DSP host and TBC interrupts. The DSP can poll the daughterboard, host NMI, codec, and PCI interrupts. The ability to poll interrupt signals from the software, as well as using them to interrupt execution flow, provides flexibility to the programmer that may be useful in various applications.

The CPLD includes two state machines that drive PCI bus master read and write operations based on the status of the PCI controller's read and write FIFO flags. The PCI bus master state machines are individually enabled by the DSP software by setting bits in the DSP memory-mapped FIFOSTAT register implemented in the CPLD. When the PCIMREN bit is set, the master read state machine generates EXT_INT5 interrupts to the DSP when the PCI controller's read FIFO flag (RDEMPTY) indicates that the read FIFO is not empty. The DSP can respond to the external interrupt with background DMA transfers or an interrupt service routine to read data from the PCI controller. The state machine waits for a DSP EMIF read of the FIFO before repeating the process. The state machine must be disabled at the end of each PCI bus master read block transfer. The CPLD provides a similar state machine for PCI bus master writes. When the PCIMWEN bit is set, the master write state machine generates EXT_INT6 interrupts to the DSP when the PCI controller's write FIFO

flag (WRFULL) indicates that the write FIFO is not full. Similar to read transfers, the DSP can use background DMA or an interrupt handler to write data to the PCI controller.

The DSP can be interrupted with four external maskable interrupts and one nonmaskable interrupt (NMI). All DSP interrupts on the 'C6x EVM are asserted on rising edges. Table 4–31 summarizes the DSP interrupts on the EVM.

Table 4–31. DSP Interrupts Usage

DSP Interrupt	Description of Use
EXT_INT4	PCI controller interrupts
EXT_INT5	PCI bus master reads DMA synchronization
EXT_INT6	PCI bus master writes DMA synchronization
EXT_INT7	Expansion peripheral interface (XEXT_INT7)
NMI	Host (PCI register) and audio codec (shared via CPLD logic)

EXT_INT4 indicates to the DSP that a significant event has occurred as a result of activity within the PCI controller. This activity may include mailbox full/empty conditions, end of bus master transfers, a self-test request from the PCI bus, and transfer errors.

EXT_INT5 and EXT_INT6 are used to synchronize PCI bus master reads and writes, respectively. They are generated by the CPLD in response to the PCI controller's FIFO status. These interrupts are used to trigger the DSP's DMA controllers or a CPU interrupt service routine.

EXT_INT7 is provided on the expansion peripheral interface (as XEXT_INT7) so that a daughterboard can interrupt the DSP to indicate significant events.

The NMI can be asserted by the stereo audio codec's timer or by the host software via a memory-mapped control register on the PCI bus. The DSP software can select the NMI source by writing to the memory-mapped control register in the CPLD. The NMI is handled and driven by the CPLD. The codec's timer can be disabled if it is not used. If enabled by the DSP's software, it could be used as an additional timer or even a watchdog timer, providing flexibility.

4.8.9 CE1 Memory Decoding/Data Transceivers Control

The CPLD decodes DSP EMIF CE1 memory accesses to control various EVM hardware and other logic within the CPLD itself.

The EVM uses 'LVTH162245 data transceivers to provide data bus isolation and voltage translation. These transceivers are enabled by CPLD memory decode logic based on the CE1 memory accesses. DSP EMIF accesses to the PCI controller's registers and FIFOs enable the PCI add-on bus transceiver. DSP EMIF accesses to the audio codec and the CPLD registers enable the peripheral bus transceiver. DSP EMIF accesses to the 3M-byte expansion memory space enable the expansion bus transceiver. The direction of these transceivers is controlled by the DSP's output enable ($\overline{\text{AOE}}$) signal, which defines the direction of the data access.

The CPLD provides audio codec chip select and read/write strobes when the audio codec memory space in CE1 is accessed.

A CPLD state machine, along with combinatorial logic, is used to generate the asynchronous ready (ARDY) signal to the DSP. Because the EVM includes different types of devices in the CE1 space, there are different timing requirements for each. The CPLD generates the ARDY signal based on the type of CE1 memory access. For PCI controller accesses, the ARDY signal is not asserted until the add-on bus is available, unless the board is operated stand-alone. In stand-alone operation, the ARDY signal is always asserted for PCI controller accesses so that the EMIF does not lock up waiting for ARDY. A state machine is used to generate the ready indication when the audio codec and DSP memory-mapped registers in the CPLD are accessed based on a defined number of CLKOUT2 clock cycles. The external ready from the daughterboard is presented to the DSP when expansion memory is accessed. The CPLD provides the ready logic that extends the asynchronous strobe time as needed for each particular access.

The CE2 and CE3 DSP memory spaces default to two banks of $1\text{M} \times 32\text{-bit}$ SDRAM. However, if one or both of these banks of SDRAM are not required for an application, and more or faster asynchronous memory or memory-mapped devices are required, CE2 and CE3 can support expansion memory on a daughterboard. The CE3SDEN and CE2SDEN bits in the CPLD's SDCNRL register determine whether the SDRAM banks are enabled or disabled. If a bank is disabled, it is put into a low-power mode and does not respond to accesses. Additionally, CPLD logic enables external accesses to asynchronous memory in these spaces by activating the expansion memory data transceivers.

4.8.10 User Options Control

The EVM provides users options to select the DSP's input clock source, endian and boot modes, and the JTAG emulation method. The CPLD includes user options control logic that selects between hardware DIP switch and software switch user options. Table 4–32 summarizes the EVM user options.

Table 4–32. User Options Summary

User Option	Description	Number of Signals
Boot mode	Selects no-boot, HPI-boot, or ROM-boot	5
Clock mode	Selects multiply-by-1 (no PLL) or multiply-by-4 (PLL) clock mode	1
Clock select	Selects 33.25 MHz or 40 MHz for CLKIN	1
Endian select	Selects big- or little-endian memory addressing	1
JTAG select	Selects internal or external JTAG emulation	1
User-defined	User-defined options	3

The boot mode option selects how the DSP boots upon the release of its reset input signal. It can begin execution immediately with no boot, or it can be booted from ROM in the CE1 space or from the host port interface (HPI). The five control signals select the type of boot, the type of memory located at address 0, and the memory map (MAP 0 or MAP 1) that is to be used.

The clock mode selects whether the CPU clock (CLKOUT1) is the same as CLKIN (multiply-by-1) or four times CLKIN (multiply-by-4). The 'C6201 provides two pins to select the clock mode. However, both pins have the same value in each of these modes, so only one control signal needs to be used. The clock mode pins are both set to 0 for multiply-by-1 mode and 1 for multiply-by-4 mode.

The clock selection determines which of two onboard clock sources is used. The EVM provides both 33.25- and 40-MHz clocks. If multiply-by-4 clock mode is selected, this results in a CPU clock rates of 133 MHz and 160 MHz, respectively.

The endian selection determines whether the DSP uses little- or big-endian byte/halfword addressing.

The JTAG selection determines whether the onboard JTAG controller or an external XDS510 emulator is to be used for debugging. When the 'C6x EVM operates outside the PC in stand-alone mode, the JTAG selection is forced by the CPLD to external XDS510 use.

Three user-defined options are provided for application use. These user options can be read by both the host and the DSP software via CPLD registers.

Because the EVM can operate in both PCI and stand-alone environments, it must support the selection of user options in both situations. When the EVM is operated outside the PC, DIP switches are used to configure the board. When the EVM is in the PC, configuration is done via software switches under software control to eliminate the need to remove the PC's cover. This dual-use option support is transparent because it defaults to the standard DIP switch control but allows for software switch override, if desired. If software does not control the configuration from the host side, the EVM uses its default switch settings. Therefore, in external operation, the DIP switches are used exclusively for user option selections.

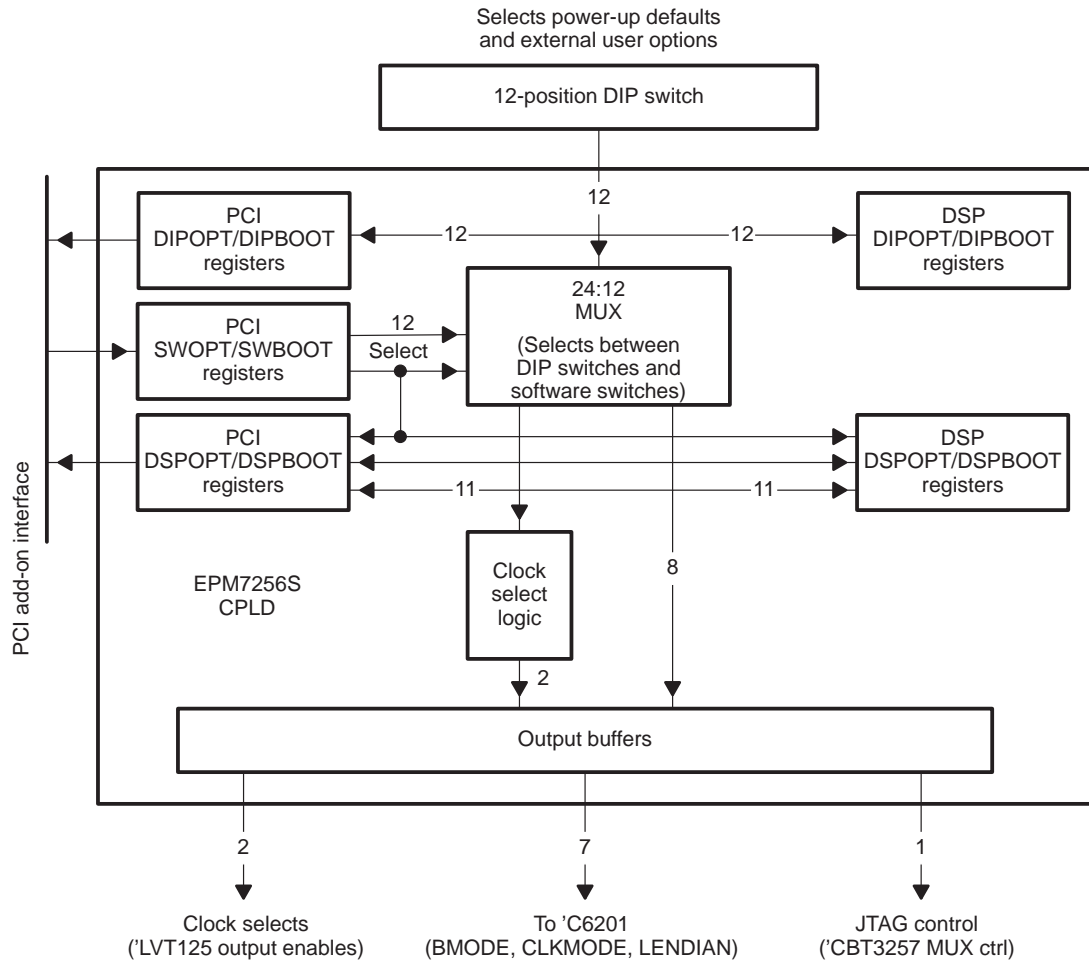

Figure 4–11 shows how this dual-use option support is implemented in the EVM's CPLD.

The EVM's CPLD includes a multiplexer that selects between the hardware DIP switches and PCI-controlled software switches. Upon power up, the CPLD defaults the configuration to the DIP switch settings, providing transparent operation. Memory-mapped registers on the PCI bus allow the host EVM driver to configure the board and DSP directly to override the hardware DIP switch settings, if desired.

Memory-mapped registers in the CPLD allow both the host and DSP software to observe DIP switches and the current DSP option selections. When the EVM is under software switch control, the 12 DIP switches can be used by the DSP software for other purposes.

Based on the selected configuration, the CPLD provides control signals to the DSP and external hardware for clock and JTAG selection. Transparent DIP switch configuration is provided upon power up, providing power-up defaults without the need for software control.

Figure 4–11. Dual-Use Option Support

4.9 Stereo Audio Interface

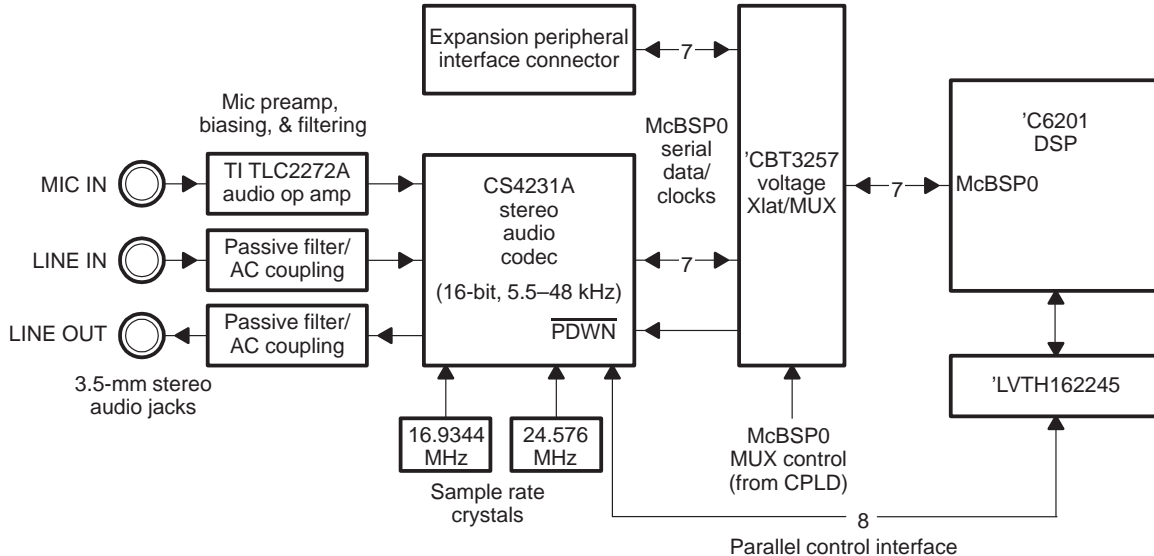

The 'C6x EVM includes a stereo audio interface that has the following characteristics:

- ☐ 16-bit stereo audio codec with sample rates from 5.5 kHz–48 kHz
- ☐ Linear (8- and 16-bit) and companded (μ -law and A-law) data formats
- ☐ Support for stereo electret microphones with voltage bias
- ☐ Stereo line-level input
- ☐ Stereo line-level output
- ☐ Input gain and output attenuation control
- ☐ Three 3.5-mm (1/8-inch) stereo audio jacks

Figure 4–12 shows the configuration of the 'C6x EVM's stereo audio interface.

The CS4231A multimedia codec provides a flexible, general-purpose audio front-end for the EVM. The CS4231A is a 16-bit stereo device. It includes complete on-chip filtering plus analog mixing and programmable gain and attenuation. The device supports 16-bit linear, 8-bit linear, and 8-bit companded (μ -law and A-law) data formats.

Figure 4–12. TMS320C6x EVM Stereo Audio Interface

The CS4231A supports the following popular sample rates (in kHz):

5.5125	22.0500
6.6150	27.4286
8.0000	32.0000
9.6000	33.0750
11.025	37.8000
16.0000	44.1000
18.9000	48.0000

This wide range of sample rates is compatible with applications ranging from telecom to pro-audio. The codec uses two crystals with frequencies of 16.9344 MHz and 24.576 MHz as sample clock master sources.

The CS4231A includes a byte-wide parallel control/status interface, which is compatible with the 'C6201 asynchronous timing that is independent from its serial data interface to the DSP's McBSP0. This independent parallel interface, which is memory-mapped into the 'C6201 asynchronous CE1 space, allows the DSP to configure and monitor the codec without impacting the serial data stream handler. This parallel interface can also be used for capture and playback data transfers from the DSP or even the host (via the HPI).

The CS4231A audio codec presents four control/status registers mapped into the DSP's CE1 memory space starting at address 0x01320000 (MAP 0) or 0x01720000 (MAP 1). These four registers are all eight bits wide. They are addressed by the DSP on 32-bit word boundaries, and only the lower eight bits are valid. Table 4–33 summarizes the four audio codec registers.

Table 4–33. CS4231A Audio Codec Registers

DSP Address MAP 1 (MAP 0)	Audio Codec Register	Description	Access
01720000 (01320000)	R0	Index address register	Read/write
01720004 (01320004)	R1	Indexed data register	Read/write
01720008 (01320008)	R2	Status register	Read/write
0172000C (01320008)	R3	PIO data register	Read/write

The CS4231A has 32 other registers (I0–I32) that are indirectly accessed by using the index address register mapped at 0x1320000 or 0x01720000. The address of the indexed register is written to this register before writing or reading the data register at offset 1.

A benefit of the codec's control interface being memory-mapped in the DSP's CE1 memory space is that the codec can be directly controlled from the PC host software via the PCI-mapped HPI. This is useful in some user applications that want to control the codec. For example, a visual control panel application could present switches and knobs that directly control the operation of the codec in real time, including input gain, output attenuation, input selection, test loopbacks, and more.

The CS4231A presents a 5-V TTL-compatible interface that is connected to the DSP through low-cost, TI 'CBT3257 multiplexers on its serial interface, and a TI 'LVTH162245 transceiver that provides the EVM's peripheral data bus on its parallel interface, for voltage translation.

The CS4231A includes multiple inputs that support line and microphone levels. The line input and line output jacks can be used for connecting to a stereo source such as a compact disc or cassette tape player. The software has independent control over the left and right input selections and their gains. It also includes a line-level output with DSP software-controllable attenuation.

Three industry-standard 3.5-mm audio jacks are located on the board's mounting bracket. The tip of each jack is the left audio channel, and the ring is the right audio channel. Mono connections only use the left channel.

TI op amps are used for the microphone preamplifier and filtering. A voltage bias is provided to support the use of battery-powered and electret microphones. Passive filtering is included on the EVM between the codec and the audio jacks for increased performance. Ferrite beads and bypass capacitors are used on all audio interfaces to reduce noise coupling. A separate 5-V analog supply is provided by a TI voltage regulator to reduce noise on the audio signals.

The microphone input is designed for electret microphones that require a bias voltage. A dynamic microphone can be used if capacitors are used to block the bias voltage. The maximum allowable signal level to the microphone is 300 mV. The microphone interface provides an external gain of 10 dB and an additional user-selectable codec gain of 0 dB or 20 dB.

The line input signal level can be a maximum of $6 V_{pp}$ ($2 V_{rms}$). The line input signal is attenuated 6 dB before it is presented to the codec. Internal codec gain from 0 dB–22.5 dB can be selected. The line output signal level can be a maximum of $3 V_{pp}$ ($1 V_{rms}$). The line output signal can be muted and attenuated from 0 dB–94.5 dB. The line output cannot drive low-impedance headphones or speakers (i.e. 8 or 32 ohm) directly. The line output must be connected to 10K or greater loads. Table 4–34 summarizes the signal levels of the input and output audio interfaces.

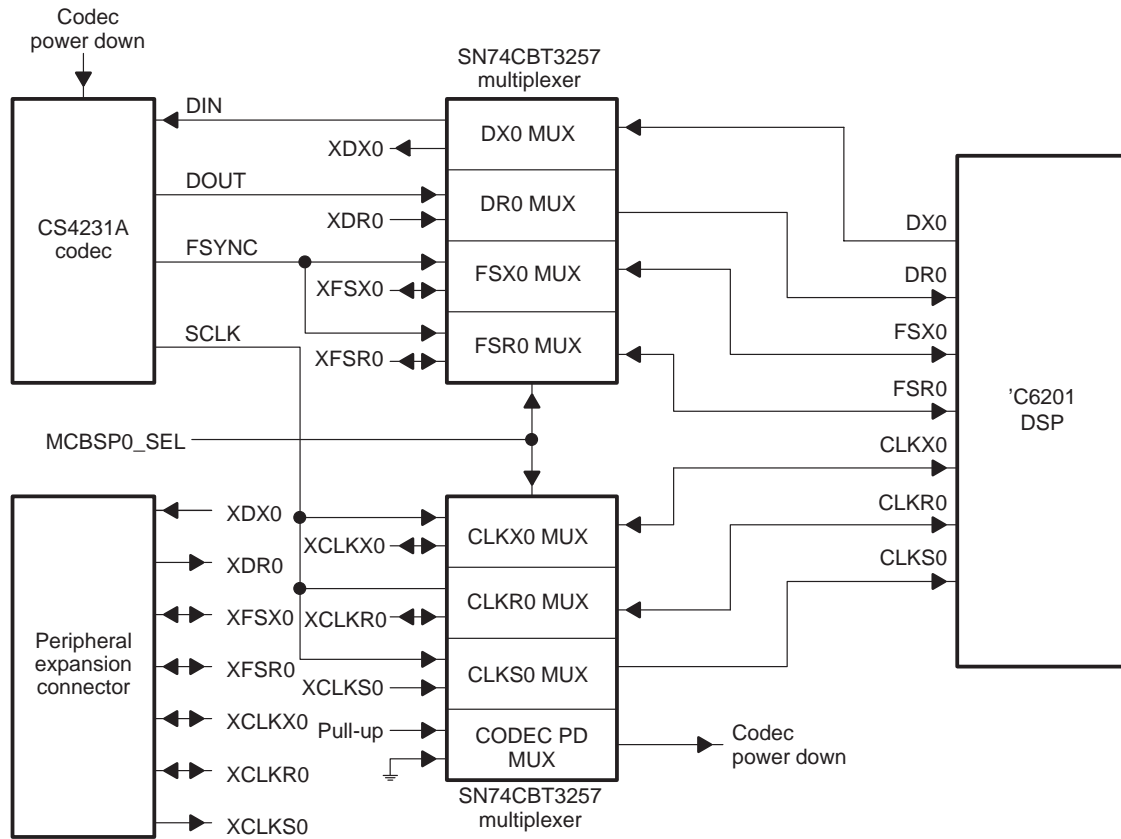

Table 4–34. Stereo Audio Interface Signal Levels

Audio Interface	Maximum Signal Level
Mic in with codec mic gain enabled (MGE = 1)	100 mV _{pp} (35 mV _{rms})
Mic in with codec mic gain disabled (MGE = 0)	1 V _{pp} (350 mV _{rms})
Line in	6 V _{pp} (2.1 V _{rms})
Line out	2.8 V _{pp} (1 V _{rms})

The CS4231A includes an on-chip 16-bit timer that can be useful to the DSP to supplement its two timers. The DSP can program a timer interval and the codec can interrupt the DSP, or the DSP can poll the timers counter register. The codec can be used as a watchdog timer because it is routed to the CPLD and can generate the DSP's nonmaskable interrupt (NMI).

The CS4231A serial interface is connected to the 'C6201 McBSP0 interface through a pair of TI 'CBT3257 quad 2:1 multiplexers as shown in Figure 4–13. This configuration allows the McBSP0 serial port to be connected to either the onboard audio codec or a daughterboard at any one time depending on your application. This allows daughterboards to use both of the DSP's serial ports, which is useful for many applications that do not require the audio codec. In addition to providing McBSP0 interface selection, one of the multiplexer outputs directly controls the codec's power-down input signal that reduces the codec's current from about 60 mA to 1 mA when the expansion interface is selected. The EVM defaults to the power-down state, and the audio codec's initialization library function controls a memory-mapped register bit in the CPLD's CNTL register to connect the codec to the DSP's McBSP0 interface. The CPLD CNTL register's SP0SEL bit must be set to 1 to activate the audio codec and allow it to accept configuration information. If the SP0SEL bit is 0, all accesses to the audio codec are ignored, and it always returns a value of 0x80.

Figure 4–13. McBSP0 Selection

4.10 Power Supplies

The EVM requires 1.8- or 2.5-V, 3.3-V, and 5-V supplies for its digital circuitry, as well as 5-V and 12-V supplies for its analog circuitry. An optional daughter-board –12-V supply is brought to the peripheral expansion interface from both the PCI bus and the external power connector. The digital 5 V and analog 12 V are obtained from the PCI bus during internal operation or an external power connector during external operation. The EVM's PCI connector's PRSNT1# and PRSNT2# pins are configured to indicate a maximum of 25 watts power dissipation. The EVM's other voltages are provided by onboard switching and linear voltage regulators that use the PCI or external 5-V and 12-V supplies as their inputs.

The PCI controller, JTAG TBC, serial EEPROM, oscillators, CPLD core, and 'CBT buffers/multiplexers require the digital 5 V from the PCI bus or external power connector. The audio codec and op amps require the analog 5 V, which is derived from the 12 V with a TI TL750L05 5-V regulator. The analog 5 V also has appropriate filtering and a separate, isolated analog ground plane to ensure a clean supply for the analog circuitry.

4.10.1 3.3-V Voltage Regulator

The DSP's I/O buffers, SBSRAM, SDRAM, low-voltage buffers/transceivers, and CPLD I/O buffers require 3.3 V. The 3.3-V supply is provided by an integrated switching regulator (ISR) (part number PT6405B). The PT6405B provides 3.3 V at up to 3 amps. The device's output voltage defaults to 3.3 V, but it can be adjusted in the range of 2.8 V–3.8 V by changing external resistors. The EVM layout supports the ability to adjust the voltage with resistors, but these are not installed during manufacturing. This surface-mount device is an efficient (85%) switching regulator that is mounted flat on the board with a 0.38-inch height that is compatible with a PCI slot. This regulator is positioned on the board so that it does not interfere with the daughterboard interface.

The PT6405B only requires a couple of external capacitors, so its external interface is similar to a linear regulator because it is a module. It therefore provides the advantages of a switching regulator (efficient and runs cool) in a package that is easy to use, requiring no specialized layout or multiple devices that are required by a custom switcher design. It has already been carefully designed for minimal emissions and has been tested.

4.10.2 1.8-V/2.5-V Voltage Regulator

The current revision 2.x DSP core requires 2.5 V for its core, and the future 0.18 micron version will require 1.8 V. The PT6502B ISR provides up to 8 A and is adjustable within a range of 1.3 V–2.6 V with external resistors. When a change is made to 0.18 micron silicon, the EVM can support the 1.8-V requirement with a simple resistor value change using the PT6502B, or a smaller, PT6407B 3A device can be used since the EVM provides a dual layout for both device packages. To support the large dynamic current requirements of the DSP, a 680- μ F external capacitor is used at the voltage regulator's output, along with a carefully-designed bulk and decoupling capacitor arrangement.

4.10.3 5-V Voltage Regulator

The audio codec and the analog circuitry on the EVM require a clean, 5-V analog power supply for optimal performance. A TI TL750L05 low-dropout, linear voltage regulator that can provide up to 150 mA is used to provide the analog 5 V.

The TL750L05 requires an input voltage in the range of 6 V–26 V, so the PCI or external 12 V is used. The audio codec requires a maximum of 60 mA on the analog 5 V and the filter/buffer op-amps only require a few milliamps.

4.10.4 External Power Connector

The 'C6x EVM's external power connector is an industry-standard Molex 4-pin connector that is commonly used in PCs for disk-drive power. The external power connector is located at the bottom of the board with its pins oriented downward to prevent connection while the board is installed in the PC. When the EVM operates outside the PC, the power connection is easily made at the edge of the board.

The four pins on the connector are used for 5 V, –12 V, GND, and 12 V. The standard disk-drive power cables do not supply –12 V, so if this is required by a daughterboard, an appropriate power supply should be used. If –12 V is not used on the daughterboard, then a standard disk-driver power cable can be used.

The user-supplied, external power supply should provide the following voltages and currents:

- ☐ 5 V_{DC} at 4A
- ☐ 12 V_{DC} at 500 mA
- ☐ –12 V_{DC} at 100 mA (if required by a daughterboard)

These are the voltages and their respective currents available to the 'C6x EVM in a PCI slot.

Figure 4–14 shows the orientation of the external power connector pins.

Figure 4–14. External Power Connector

Note: Drawing is not to scale.

4.10.5 Fan Power Connector

The 'C6x EVM includes a small, 2-pin connector to supply 5 V (at 100 mA) to a low-profile, integrated heat sink/fan that attaches on top of the 'C6201 DSP. A passive heat sink is unable to dissipate enough heat in a worst case PC environment (50° C, 0 airflow) within the 0.57-inch height constraint of a PCI card. The integrated heat sink and fan reduces the DSP's case temperature by 50–80%.

4.11 Voltage Supervision

The EVM's dual-voltage supervision and reset generation are provided by a single voltage supervisor device. The voltage supervisor monitors the 3.3-V and 1.8- or 2.5-V power supplies, provides manual reset switch debounce, and generates a clean, 140-ms minimum reset pulse.

Because the 1.8- or 2.5-V and 3.3-V power supplies are derived from the 5-V power supply, they reach their values after the 5 V, and their status inherently indicates the status of the 5 V. The board is held in reset until the two voltages are within specification. Whenever the 3.3-V supply is below 3 V, including during power up, the device forces a reset until the threshold is met. The voltage supervisor supports the monitoring of a secondary voltage on its power failure input. A threshold can be set via two external resistors configured as a voltage divider. Internally, the device triggers at 1.25 V. The resistor divider can set the external voltage trigger accordingly to support either 1.8 V or 2.5 V during manufacturing. The EVM is configured for a 2.3-V reset threshold for the 2.5-V voltage supply. An external resistor is also used to ensure a valid reset output down to 0 V.

The device also has a manual switch reset input that allows you to manually reset the DSP. This is important, particularly for the external EVM operation. The EVM's CPLD asserts this manual reset input whenever you press the manual reset pushbutton or a software reset is asserted by the PCI controller.

The voltage supervisor has two reset outputs, with one being active low and the other being active high. The active low reset is used for CPLD initialization and board reset control. The active high reset is used directly to control the SBSRAM ZZ (snooze) input, which puts the SBSRAM in a power-down mode during reset. This capability is part of the power management features that are included on the 'C6x EVM.

4.12 User Options

The 'C6x EVM includes a 12-position DIP switch (SW2-1 through SW2-12) that allow selection of user options. The user options include the DSP's boot and clock modes, clock oscillator selection, endian mode, JTAG selection, and three user-defined options.

Table 4–35 summarizes the 12 switches and their functions in both the ON and OFF settings. Table 4–36 lists the valid boot mode selections for the EVM. Highlighted table entries indicate the default switch settings. If a daughter-board is used that provides boot memory, you must select the appropriate ROM boot mode from the *TMS320C6201/C6701 Peripherals Reference Guide*. An ON setting translates to a logic 0, and an OFF setting translates to a logic 1.

Table 4–35. User Option DIP Switches

Switch Number	Name	OFF Selection	ON Selection
SW2-1–SW2-5	BOOTMODE4–BOOTMODE0	See Table 4–36	See Table 4–36
SW2-6	CLKMODE	Multiply-by-1 mode (PLL bypassed)	Multiply-by-4 mode
SW2-7	CLKSEL	OSC B (40 MHz)	OSC A (33.25 MHz)
SW2-8	ENDIAN	Big endian	Little endian
SW2-9	JTAGSEL†	Internal (TBC)	External (XDS510)
SW2-10	USER2	1	0
SW2-11	USER1	1	0
SW2-12	USER0	1	0

† The JTAGSEL selection is ignored in stand-alone mode where external operation is forced.

Table 4–36. Valid Boot Mode Selections

Boot Mode	Map	Memory at Address 0	BM4 (SW2-1)	BM3 (SW2-2)	BM2 (SW2-3)	BM1 (SW2-4)	BM0 (SW2-5)
None	MAP 0	1/2-rate SBSRAM	ON	ON	ON	OFF	OFF
None	MAP 0	1x-rate SBSRAM	ON	ON	OFF	ON	ON
None	MAP 1	Internal	ON	ON	OFF	ON	OFF
HPI	MAP 0	External	ON	ON	OFF	OFF	ON
HPI	MAP 1	Internal	ON	ON	OFF	OFF	OFF

4.13 Indicators

The EVM has three LEDs that provide a power-on indication and two user-defined status indications.

A green LED is hardwired on the 5-V supply, which can originate from the PCI bus during internal operation or the power connector during external operation. When the green LED is illuminated, it indicates that power is applied to the board.

Two red LEDs are controlled by CPLD register bits that are memory mapped in the DSP's CE1 memory space. One LED is located on the mounting bracket to allow you to see it when the PC cover is on. The other LED is located on top of the board to allow you to see it when the cover is off, without having to look at the back of the machine. Both LEDs are under user DSP control and are application dependent.

Because the LEDs are memory mapped in the DSP memory space, the host software can also control them from the HPI via the PCI bus.

TMS320C6x EVM Debugger

The TMS320C6x EVM source debugger is an advanced programmer's interface that helps you develop, test, and refine your programs in the language in which they were written. You can choose to debug your programs for the 'C6x in C, assembly language, or both. Unlike many other debuggers, the 'C6x EVM debugger's high-level features are available even when you are debugging assembly language.

The debugger is easy to learn and to use. Its friendly, window-oriented interface reduces learning time and eliminates the need to memorize complex commands. The debugger is capable of loading and executing code with single-step, breakpoint, and runtime halt capabilities.

This chapter only identifies key features of the 'C6x EVM debugger and EVM-specific debugger configuration information related to the PCI bus. For detailed information about the source debugger, see the *TMS320C6x C Source Debugger User's Guide*.

Notes:

- 1) The 'C6x EVM debugger is compatible only with the 'C6x EVM and cannot be used to debug code on other platforms.
- 2) The 'C6x EVM debugger can only be used when the EVM is operated in a PCI slot. If the EVM is operated in stand-alone mode, you must use the standard XDS510 debugger software for the 'C6x (not the 'C6x EVM C source debugger included in the kit).

Topic	Page
5.1 Key EVM Debugger Features	5-2
5.2 EVM-Specific Debugger Configuration	5-4

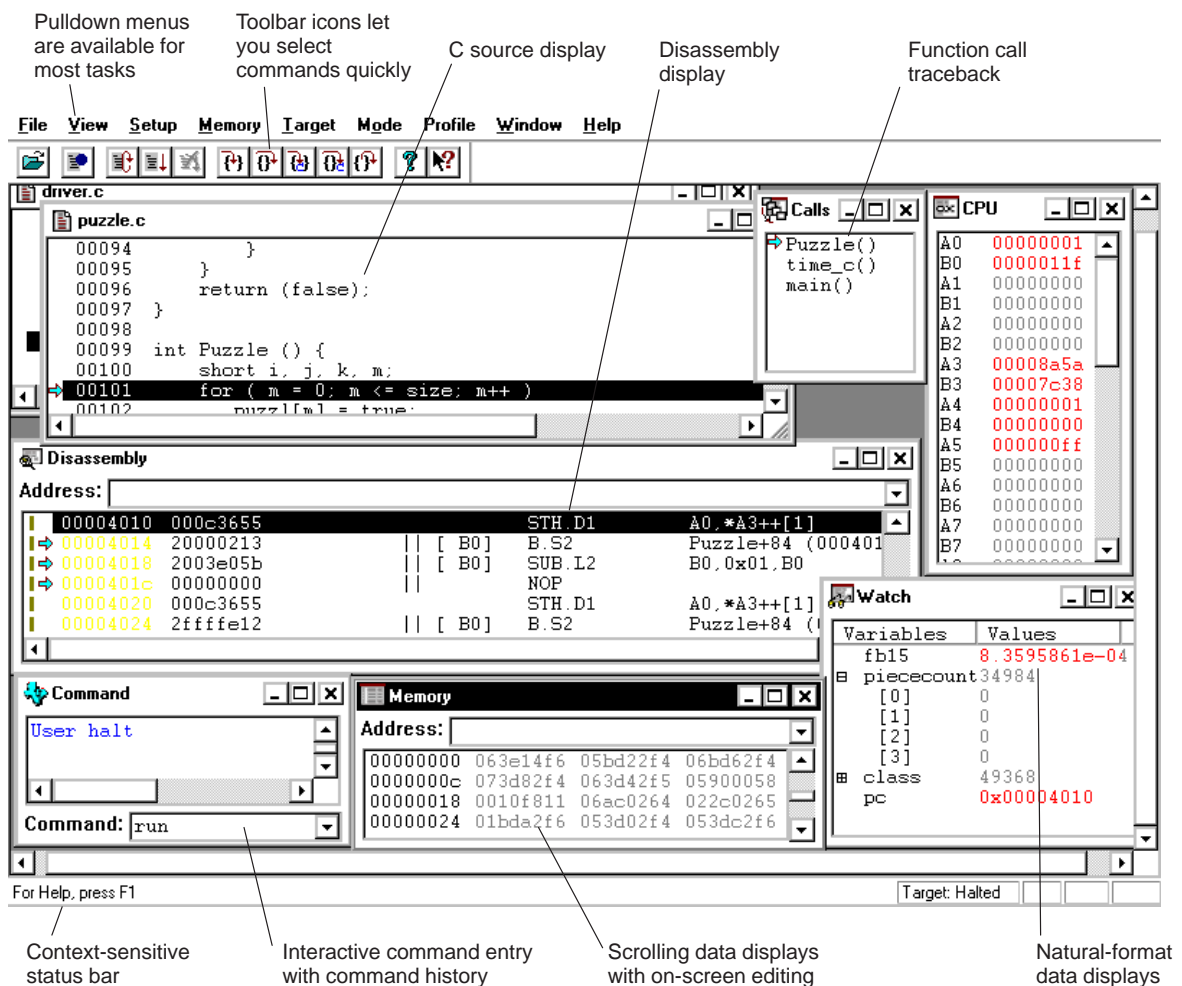

5.1 Key EVM Debugger Features

The key features of the 'C6x EVM debugger are as follows. Figure 5–1 depicts the C source debugger interface and identifies several of its features.

- ☐ **Powerful command set.** Unlike many other debugging systems, the debugger does not force you to learn a large, intricate command set. The debugger supports a small, but powerful, command set.
- ☐ **Multilevel debugging.** The debugger allows you to debug both C and assembly code. If you are debugging a C program, you can choose to view only the C source code, the disassembly of the object code created from the C source, or both. You can also use the debugger as an assembly language debugger and view the original assembly source code.
- ☐ **Fully configurable graphical user interface.** The C source debugger separates code, data, and commands into manageable portions. The graphical user interface is intuitive and follows the conventions used by Windows.
- ☐ **Comprehensive data displays.** You can easily create windows for displaying and editing the values of variables, arrays, structures, pointers, or other data in their natural form (float, int, char, enum, or pointer). You can even display entire linked lists.
- ☐ **On-screen editing.** You can change any data value displayed in any window—just click and type.
- ☐ **Automatic update.** The debugger automatically updates information on the screen, highlighting changed values.
- ☐ **Flexible command entry.** There are various ways to enter commands. You can use the menu options and dialog boxes, click toolbar icons or use function keys as shortcuts to often-used commands, or use a command line.
- ☐ **Dynamic profiling.** In addition to the basic debugging environment, a second environment—the *profiling environment*—is available. The profiling environment provides a method for collecting execution statistics about specific areas in your code. This gives you immediate feedback on your application's performance and helps you identify bottlenecks within the code.

- **All the standard features you expect in a world-class debugger.** The debugger provides you with complete control over program execution with features like conditional execution and single-stepping (including single-stepping into or over function calls). You can set or clear a breakpoint with a click of the mouse. You can define a memory map that identifies the portions of target memory that the debugger can access. The debugger can execute commands from a batch file, providing you with an easy method for entering often-used command sequences.

Figure 5–1. The Basic Debugger Display

5.2 EVM-Specific Debugger Configuration

The EVM 'C6x debugger and associated parallel debug manager (PDM) behave like the standard (emulator-based) 'C6x debugger and PDM with these exceptions:

- ☐ When a debugger instance is started, a particular EVM board is selected by its relative board index, rather than an I/O port address.
- ☐ The debugger accesses the JTAG interface through a dedicated test bus controller (TBC) on each EVM board. As a result, PDM parallel commands (PHALT, PRUN, PRUNF, and PSTEP) are unavailable.
- ☐ Application names are different from the ones used with the standard 'C6x debugger.

5.2.1 Identification of Boards by Relative Index

The EVM 'C6x debugger takes advantage of the PCI architecture by accessing the EVM board via standard memory operations, rather than by using slower, less flexible I/O port operations. Also, because the memory locations and other board-specific interface parameters are dynamically assigned, the debugger identifies each board merely by a simple relative index, rather than by an explicitly configured port address.

The PCI architecture provides an automatic mechanism for uniquely identifying the board type and bus slot location of each installed board. EVM boards are selected by using an index that starts at 0 for the first EVM board installed and increments to the total number of EVM boards installed, minus 1. In other words, a single board would be indexed as 0, two boards as 0 and 1, and n boards as 0, 1, 2, ... $n-1$.

The index is not determined by absolute slot location. A single EVM board is always board 0, no matter which slot it occupies. Inserting or removing one EVM board from a system can change the index value used to access other EVM boards. For example, consider a system with two EVM boards installed, indexed as 0 and 1. In this system, if board 1 were removed, the other would remain board 0. However, if board 0 were removed, the other board, previously identified as board 1, would then become board 0.

To select the desired board, invoke the debugger with the `-p` option. The format for the `-p` option is:

`-p` *port*

The *port* parameter is the zero-based relative board index. The default is 0.

5.2.2 Dedicated Test Bus Controller

The provision of a TBC on each EVM board means that the EVM 'C6x debugger can be used to develop and debug software on one or more 'C6x EVM boards without needing to use a separate emulator board. (A separate emulator board, i.e., an XDS510, and a standard 'C6x debugger can of course be used with the EVM, but they are not required.) On the other hand, the use of a dedicated TBC for each EVM board means that the DSPs residing on multiple EVM boards do not share a single test bus; for this reason, they cannot respond synchronously to debugger commands issued to multiple boards in parallel. Therefore, PDM parallel commands (PHALT, PRUN, PRUNF, and PSTEP) are unavailable when using the 'C6x EVM debugger and PDM.

5.2.3 Application Name Differences

Table 5–1 shows the 'C6x EVM support software application names and the corresponding application names used with the standard 'C6x debugger.

Table 5–1. Mapping of 'C6x EVM Applications to the Standard 'C6x Applications

'C6x EVM Application	Standard 'C6x Application
evm6xrst	emurst
evm6x	emu6x
evm6xpdm	pdm

TMS320C6x EVM Host Utilities

This chapter describes and tells you how to use the following TMS320C6x EVM host command-line utilities:

- ☐ EVM COFF loader utility
- ☐ EVM confidence test utility
- ☐ EVM board configuration utility

Topic	Page
6.1 EVM COFF Loader	6-2
6.2 EVM Confidence Test	6-4
6.3 EVM Board Configuration	6-6

6.1 EVM COFF Loader

The EVM COFF loader command-line utility provides a means of displaying and/or loading and executing a 'C6x application program image stored in a preexisting COFF file. These functions are accomplished via the PCI bus and the 'C6x host port interface (HPI), without the need for an emulator and without the use of the JTAG port.

To invoke the EVM COFF loader utility, use this syntax:

evm6xldr *filename* [*options*]

evm6xldr	Command that invokes the EVM COFF loader utility
<i>filename</i>	Name of the COFF file to be processed and loaded on the EVM board. You must supply a filename.
<i>options</i>	Options that affect the way the EVM COFF loader utility behaves. Options are not case sensitive and can appear anywhere on the command line following the command. The options are listed and described in Table 6–1. Each option is disabled by default.

Table 6–1. EVM COFF Loader Options

Option	Effect
–?	Displays command-line help information; all other options and parameters are ignored when you specify the –? option.
–c	Clears the bss section by setting all bss section variables to 0
–d	Displays all COFF section data in ASCII via the standard output stream. This can be a large amount of data. The –d option enables the –v (verbose) option.
–m <i>map</i>	Selects the DSP's memory map. If the <i>map</i> parameter is 0, memory map 0 (MAP 0) is selected. If the <i>map</i> parameter is 1, memory map 1 (MAP 1) is selected. The default value is 1 (MAP 1).
–p <i>port</i>	Selects a specific EVM target board; <i>port</i> is a zero-based relative board index, ranging from 0 (for 1 board) to n–1, where n EVM boards are installed. The default is 0.
–q	Suppresses output to the display (quiet option)
–r <i>reset</i>	Controls the EVM board reset. If the <i>reset</i> parameter is 0, the board is not reset. If the <i>reset</i> parameter is 1, the board is reset. The default is 1 (reset board).

Table 6–1. EVM COFF Loader Options (Continued)

Option	Effect
–s	Shows only; writes data to the standard output stream but does not write any data to DSP memory. The –s option enables the –v (verbose) option.
–v	Enables verbose mode, in which basic COFF section information is displayed via the standard output stream
–z	Displays loader status and waits for key press after each step

The loader generally performs the following steps:

- 1) If the –s (show) option is specified, the loader does not actually load an image but only reads the COFF file, sends output to stdout, and then stops. The information displayed depends on whether the –d (dump) option is selected:
 - If the –d option is not selected, the information sent to stdout consists of a descriptive line for each section, including name, size, and flags.
 - If the –d option is selected, all of the data in each section is displayed. This can be a very large amount of data and can take a long while to display.

If the –s option is not specified, the loader continues to step 2.
- 2) Opens a driver connection to a specific EVM target board
- 3) Performs a board reset (unless the –r0 option is selected)
- 4) Performs an HPI boot mode DSP reset, which permits HPI operation while holding the DSP in a halted state. The memory map mode is set by the –m0 or –m1 option.
- 5) Opens an HPI connection
- 6) Uses the HPI to load an executable image from a 'C6x COFF file. Optionally, clears the bss section (if the –c option is specified)
- 7) Closes the HPI connection
- 8) Releases the DSP from the halted reset state, thus starting program execution
- 9) Closes the driver connection to the EVM target board

An example load file, evm.out, is provided for rudimentary demonstration of loader operation. To load and execute it, simply enter the following command:

```
evm6xldr evm.out
```

6.2 EVM Confidence Test

The confidence test is a command-line utility that allows you to confirm the proper installation of the EVM board and drivers and performs several quick tests of the onboard hardware. A successful completion of this test assures you that the board is installed and working properly. If a hardware error is reported, see Appendix F, *Troubleshooting*.

This test must be executed from the directory into which it is installed. Several support files are required for the test operations. This directory is the `confest` directory within the EVM installation directory.

To invoke the EVM confidence test, use this syntax:

evm6xtst [*options*] [*log_filename*]

evm6xtst	Command that invokes the EVM confidence test
<i>options</i>	Options that affect the way the EVM confidence test utility behaves. Options are not case sensitive and can appear anywhere on the command line following the command. The options are listed and described in Table 6–2. Each option is disabled by default.
<i>log_filename</i>	Filename used for the log file. If no filename is supplied, a log file is not created.

Table 6–2. EVM Confidence Test Options

Option	Effect
–?	Displays command-line help information; all other options and parameters are ignored when you specify the –? option.
–p <i>port</i>	Specifies the board to be tested; <i>port</i> is the relative index of the board, ranging from 0 (for 1 board) to <i>n</i> –1, where <i>n</i> EVM boards are installed. The default is 0.
–i	Enables the information-only mode; in this mode, only the board configuration information is displayed, bypassing the board tests

The confidence test checks for proper installation of the Win32 DLL and low-level driver by opening a connection to the board. With successful access to the board, the board's configuration information is retrieved and displayed to the command window. If the information-only mode is requested (using the –i option), the program terminates at this time.

The configuration information includes:

- ☐ Board index
- ☐ Board type and revision
- ☐ Board clock
- ☐ Endian mode
- ☐ JTAG selection
- ☐ User-defined options
- ☐ CPLD revision

The target board being tested is reset and configured into SBSRAM clock mode and big-endian mode. While the board is configured in this manner, a 'C6x memory test module is loaded to the 'C6x and executed. This verifies proper operation of the host port interface (HPI), which is used to load the 'C6x executable code, and the onboard memory while in SBSRAM clock mode and big-endian mode.

The board is then reset and configured into the standard setup of NORMAL clock mode and little-endian mode. While the board is in the standard configuration, a sequence of tests are loaded to the 'C6x and executed. These tests include:

- ☐ Interrupt tests
- ☐ Device tests
- ☐ Timer tests
- ☐ LED tests
- ☐ DMA tests
- ☐ McBSP tests
- ☐ NVRAM checksum test

After these tests are finished, the board is reset and configured into SBSRAM clock mode and little-endian mode. While the board is in this configuration, a sequence of audio codec tests are performed. You can set up for these tests by connecting powered speakers to the LINE OUT connector, a microphone to the MIC IN connector, and a source such as the output from a CD-ROM drive playing an audio CD to the LINE IN connector. These connections, however, are not required for the successful completion of the following tests:

- ☐ Left channel tone test
- ☐ Right channel tone test
- ☐ Left/right channel tone test
- ☐ Line in loopback test
- ☐ Mic in loopback test

When the audio codec tests are finished, the board is reset and is allowed to remain in the configuration set by the onboard DIP switches.

All of the configuration and test information is written to stdout and optionally recorded to a file specified on the command line.

6.3 EVM Board Configuration

The EVM 'C6x board configuration utility resets the EVM board and, optionally, configures the board's clock speed, endian mode, memory map, JTAG selection, and user bits. If none of the configuration parameters are used, the board configuration is taken from the hardware DIP switches. With this utility, you can override the hardware DIP switch configuration of a board.

If you do not specify any of the clock speed, endian mode, memory map, JTAG selection, or user configuration parameters, the utility performs a board reset and the board configuration is determined by the EVM's hardware DIP switches.

If you specify any of the clock speed, endian mode, memory map, JTAG selection, or user configuration parameters, the utility modifies the board configuration and the EVM's hardware DIP switches are not used. All unspecified configuration parameters are set to the defaults described in Table 6–3.

To invoke the EVM 'C6x board configuration utility, use this syntax:

evm6xrst [*options*]

evm6xrst	Command that invokes the EVM 'C6x board configuration utility
<i>options</i>	Options that affect the way the EVM board configuration utility behaves. Options are not case sensitive and can appear anywhere on the command line following the command. The options are listed and described in Table 6–3. Each option is disabled by default.

Table 6–3. EVM Board Configuration Options

Option	Effect
–?	Displays command-line help information; all other options and parameters are ignored when you specify the –? option.
–e <i>endian</i>	Configures the DSP's endian mode. A value of 0 for the <i>endian</i> parameter selects little-endian mode; any other value selects big-endian mode. The default is 0.
–i <i>init</i>	Controls the initialization of the EVM's memory located at address 0 with simple loop code to ensure valid code execution upon the release of reset. If the DSP is executing invalid code when the debugger application is invoked, the debugger may not be able to communicate with the DSP. If the <i>init</i> parameter is 0, memory initialization is not performed. If the <i>init</i> parameter is 1, memory initialization is performed. The default value is 1 (initialize memory).

Table 6–3. EVM Board Configuration Options (Continued)

Option	Effect										
–je	Selects the external JTAG connection to the DSP for emulation. This configuration requires that an XDS510 or XDS510WS emulator, along with the TI C source debugger for the XDS510, be used. If this option is not used, the internal JTAG connection is selected by default.										
–ji	Selects the internal JTAG connection to the DSP. This configuration uses the EVM's JTAG test bus controller for embedded emulation and requires the use of the 'C6x EVM C source debugger. This is the default selection.										
–m <i>map</i>	Selects the DSP's memory map. If the <i>map</i> parameter is 0, memory map 0 (MAP 0) is selected. If the <i>map</i> parameter is 1, memory map 1 (MAP 1) is selected. The default value is 1 (MAP 1).										
–p <i>port</i>	Specifies the board to be reset and optionally configured; <i>port</i> is a zero-based relative board index, ranging from 0 (for 1 board) to n–1, where n EVM boards are installed. The default is 0.										
–q	Suppresses output to the display (quiet option)										
–r <i>reset</i>	Controls the EVM board reset. If the <i>reset</i> parameter is 0, the board is not reset. If the <i>reset</i> parameter is 1, the board is reset. The default value is 1 (reset board).										
–s <i>speed</i>	Configures the DSP clock speed based on the <i>speed</i> parameter as follows:										
	<table> <tr> <th><i>speed</i></th><th>Selected DSP Clock Speed</th></tr> <tr> <td>0</td><td>33.25 MHz</td></tr> <tr> <td>1</td><td>40 MHz</td></tr> <tr> <td>2</td><td>133 MHz</td></tr> <tr> <td>3</td><td>160 MHz</td></tr> </table>	<i>speed</i>	Selected DSP Clock Speed	0	33.25 MHz	1	40 MHz	2	133 MHz	3	160 MHz
<i>speed</i>	Selected DSP Clock Speed										
0	33.25 MHz										
1	40 MHz										
2	133 MHz										
3	160 MHz										
	The default is 2 (133 MHz).										
–u <i>user</i>	Configures the user bits; <i>user</i> is a value from 0 to 7 that is used to set the three user bits on the EVM board. If the <i>user</i> value is greater than 7 or if the user option is not used, the user bits default to the hardware DIP switch settings. (See Table 4–35 on page 4-78 for more information about the user bits.)										
–x	Ignores relative board index selected in the D_OPTIONS environment variable										
–z	Displays configuration status and waits for key press after each step										

TMS320C6x EVM Host Support Software

This chapter describes the support software for the host that is provided with the EVM board. This software works on Pentium-based PCs running either Windows 95 or Windows NT 4.0. The software is installed during the EVM board software installation operation.

With the provided low-level driver and user mode DLL, a user application on the host can:

- ☐ Reset and configure the 'C6x
- ☐ Load and execute code
- ☐ Send and receive messages
- ☐ Send and receive data streams
- ☐ Access board resources via the HPI

You can use the DLL functions described in section 7.3.2, *EVM Win32 DLL API Functions*, to perform all of these operations.

Topic	Page
7.1 Host Support Software Components	7-2
7.2 EVM Low-Level Windows Drivers	7-2
7.3 EVM Win32 DLL API	7-3
7.4 EVM Host Support Software Examples	7-42

7.1 Host Support Software Components

The host support software components consist of an operating-system-specific low-level driver and a user mode Win32 DLL. The Win32 DLL provides a consistent API for both Windows 95 and Windows NT 4.0 board access through the low-level driver. These components are used to create and execute user mode applications for the EVM board. By using the Win32 DLL, you can write user mode Win32 applications that execute under both operating systems.

These components, along with user mode host example code, are installed during the EVM software installation (see section 2.6, *EVM Software Installation*, for more information).

7.2 EVM Low-Level Windows Drivers

A low-level driver that is specific to the supported operating system handles all direct access to the one or more EVM boards in a system. For Windows 95, a Windows VxD, `evm6x.vxd`, is the low-level driver that provides access to the EVM hardware. For Windows NT 4.0, a kernel mode driver, `evm6x.sys`, provides the EVM hardware access.

All the functionality required for control and communication with the EVM hardware is provided by a Win32 DLL, `evm6x.dll`, which handles the details of the low-level driver access. This DLL presents a common Win32 API for both Windows 95 user applications and Windows NT 4.0 user applications. Thus, a Win32 user mode application using the Win32 DLL executes under either operating system.

7.3 EVM Win32 DLL API

This section describes the EVM Win32 DLL data types and provides summaries, in alphabetical order, of the EVM Win32 DLL API functions.

7.3.1 EVM Win32 DLL API Data Types

Example 7–1 provides definitions for the Win32 DLL API data types.

Example 7–1. Win32 DLL API Data Types

(a) Board types

```
typedef enum {
    TYPE_UNKNOWN = 0,
    TYPE_EVM,
    TYPE_MCEVM
} EVM6XDLL_BOARD_TYPE, *PEVM6XDLL_BOARD_TYPE;
```

The EVM6XDLL_BOARD_TYPE type definition defines the possible values returned by the evm6x_board_type() function. A properly functioning EVM board returns a board type of TYPE_EVM.

(b) Boot modes

```
typedef enum {
    NO_BOOT = 0,
    HPI_BOOT,
    ROM8_BOOT,
    ROM16_BOOT,
    ROM32_BOOT,
    NO_BOOT_MAP0,
    HPI_BOOT_MAP0,
    ROM8_BOOT_MAP0,
    ROM16_BOOT_MAP0,
    ROM32_BOOT_MAP0
} EVM6XDLL_BOOT_MODE, *PEVM6XDLL_BOOT_MODE;
```

The EVM6XDLL_BOOT_MODE type definition defines the valid values passed to the evm6x_reset_dsp() function. These values support all of the valid boot modes of the EVM board. The enumerations that do not explicitly describe a 'C6x memory map use the MAP 1 memory map.

*Example 7–1. Win32 DLL API Data Types (Continued)**(c) Clock modes*

```
typedef enum {  
    DSP_CLOCK_NORMAL = 0,  
    DSP_CLOCK_SBSRAM,  
    DSP_CLOCK_BX1,  
    DSP_CLOCK_AX1  
} EVM6XDLL_CLOCK_MODE, *PEVM6XDLL_CLOCK_MODE;
```

The EVM6XDLL_CLOCK_MODE type definition defines the valid values passed to the evm6x_set_board_config() function to set the board's clock configuration.

(d) Endian configuration

```
typedef enum {  
    LITTLE_ENDIAN_MODE = 0,  
    BIG_ENDIAN_MODE  
} EVM6XDLL_ENDIAN_MODE, *PEVM6XDLL_ENDIAN_MODE;
```

The EVM6XDLL_ENDIAN_MODE type definition defines the valid values passed to the evm6x_set_board_config() function to set the board's endian configuration.

(e) Send and retrieve messages

```
typedef ULONG EVM6XDLL_MESSAGE, *PEVM6XDLL_MESSAGE;
```

The EVM6XDLL_MESSAGE type definition defines the type used as the message value passed to and from the EVM board. This type is used in the evm6x_send_message() and the evm6x_retrieve_message() functions.

7.3.2 EVM Win32 DLL API Functions

The following alphabetical listing includes all of the Win32 DLL API functions. Use this listing as a table of contents to the Win32 DLL API functions.

Function	Description	Page
evm6x_abort_read	Terminate the current read request	7-6
evm6x_abort_write	Terminate the current write request	7-7
evm6x_board_type	Return EVM board type	7-8
evm6x_clear_message_event	Clear the incoming message event	7-9
evm6x_close	Close a driver connection to a board	7-10
evm6x_coff_display	Display COFF section information	7-11
evm6x_coff_load	Load a COFF image into DSP memory	7-12
evm6x_generate_nmi_int	Generate an NMI to a DSP	7-14
evm6x_hpi_close	Close the HPI for a DSP	7-15
evm6x_hpi_fill	Fill DSP memory using the HPI	7-16
evm6x_hpi_generate_int	Interrupt a DSP using the HPI	7-18
evm6x_hpi_open	Open the HPI for a DSP	7-19
evm6x_hpi_read	Read DSP memory using the HPI	7-20
evm6x_hpi_write	Write DSP memory using the HPI	7-22
evm6x_init_emif	Initialize the EMIF registers	7-23
evm6x_nvram_read	Read NVRAM memory on a board	7-25
evm6x_nvram_write	Write NVRAM memory on a board	7-27
evm6x_open	Open a driver connection to a board	7-28
evm6x_read	Read data from a boards PCI interface	7-29
evm6x_reset_board	Completely reset a board	7-31
evm6x_reset_dsp	Reset the DSP on a board and set boot mode	7-32
evm6x_retrieve_message	Get a message sent by a DSP	7-33
evm6x_send_message	Send a message to a DSP	7-35
evm6x_set_board_config	Set the board configuration settings	7-36
evm6x_set_timeout	Set the data transfer time out value	7-38
evm6x_unreset_dsp	Release the DSP from its reset state	7-39
evm6x_write	Write data to a boards PCI interface	7-40

evm6x_abort_read

evm6x_abort_read

Terminate a Pending Read Transfer

Syntax

```
#include <evm6xdll.h>
BOOL evm6x_abort_read(HANDLE h_device);
```

Description

The `evm6x_abort_read()` function terminates a pending read operation for a target board. This can be used by one thread to terminate the pending read operation of another thread.

- The `h_device` parameter is the handle returned from a successful `evm6x_open()` call.

Return Value

The function returns one of the following values:

TRUE Operation succeeded
FALSE Operation failed

Example

In the following example, the `evm6x_abort_read()` function is used to abort a read operation that has not finished. The `evm6x_read` call is pending in a separate thread.

```
#include <windows.h>
#include <evm6xdll.h>
. . .
HANDLE    h_board;

h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board */
    exit(-1);
}

/* Start thread to receive data */
. . .
/* Do something else, then check that receive is */
/* complete                                     */
. . .
/* Abort read operation that is not complete */
if ( !evm6x_abort_read( h_board ) )
{
    /* evm6x_abort_read() failed */
}
```

evm6x_abort_write*Terminate a Pending Write Transfer***Syntax**

```
#include <evm6xdll.h>
BOOL evm6x_abort_write(HANDLE h_device);
```

Description

The `evm6x_abort_write()` function terminates a pending write operation for a target board. This can be used by one thread to terminate the pending write operation of another thread.

- ❑ The *h_device* parameter is the handle returned from a successful `evm6x_open()` call.

Return Value

The function returns one of the following values:

TRUE Operation succeeded
FALSE Operation failed

Example

In the following example, the `evm6x_abort_write()` function is used to abort a write operation that has not finished. The `evm6x_write` call is pending in a separate thread.

```
#include <windows.h>
#include <evm6xdll.h>
. . .
HANDLE    h_board;

h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board */
    exit(-1);
}

/* Start thread to send data */
. . .
/* Do something else, then check that transfer is */
/* complete */
. . .
/* Abort write operation that is not complete */
if ( !evm6x_abort_write( h_board ) )
{
    /* evm6x_abort_write() failed */
}
```

evm6x_board_type

evm6x_board_type

Retrieve Board Type and Version Information

Syntax

```
#include <evm6xdll.h>
BOOL evm6x_board_type(
    HANDLE                h_device,
    PEVM6X_BOARD_TYPE     p_board_type,
    PULONG                p_rev_id);
```

Description

The `evm6x_board_type()` function retrieves the board type and revision ID information that is stored in the PCI configuration space of the board. The return value indicates the success of the function call.

- ☐ The `h_device` parameter is the handle returned from a successful `evm6x_open()` call.
- ☐ The `p_board_type` and `p_rev_id` parameters are pointers to the locations in which to place the requested information. After a successful `evm6x_board_type()` function call to an EVM board is made, the location pointed to by the `p_board_type` parameter contains the enumerated value `TYPE_EVM`. The location pointed to by the `p_rev_id` parameter contains the board's revision ID as retrieved from the board's PCI configuration space. The board revision ID is used to indicate EVM board hardware revisions.

Return Value

The function returns one of the following values:

TRUE Operation succeeded
FALSE Operation failed

Example

In the following example, the `evm6x_board_type()` function is used to retrieve information about the board type of the open board.

```
#include <windows.h>
#include <stdio.h>
#include <evm6xdll.h>
. . .
HANDLE                h_board;
EVM6XDLL_BOARD_TYPE   t_board_type;
ULONG                ul_rev_id;
h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    exit(-1);
}
if ( !evm6x_board_type( h_board, &t_board_type,
    &ul_rev_id) )
{
    printf( "ERROR: evm6x_board_type() failed.\n" );
}
```

```

else
{
    if ( t_board_type == TYPE_EVM )
    {
        printf( "EVM Board, Revision %d.\n", ul_rev_id );
    }
    else
    {
        printf( "Unknown board type.\n" );
    }
}

```

evm6x_clear_message_event

Clear the Message Event

Syntax

```

#include <evm6xdll.h>
BOOL evm6x_clear_message_event(HANDLE h_device);

```

Description

The evm6x_clear_message_event() function sets the message event to the nonsignaled state. Call this function to clear out any previous events before setting up to receive new events.

- ❑ The *h_device* parameter is the handle returned from a successful evm6x_open() call.

Return Value

The function returns one of the following values:

TRUE Operation succeeded
 FALSE Operation failed

Example

In the following example, the evm6x_clear_message_event() function is used to clear the message event for an EVM board to the nonsignaled state.

```

#include <windows.h>
#include <evm6xdll.h>
...
HANDLE    h_board;
h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board */
    exit(-1);
}
if ( !evm6x_clear_message_event( h_board ) )
{
    /* evm6x_clear_message_event failed */
    evm6x_close( h_board );
    exit(-1);
}
...

```

evm6x_close

evm6x_close

Close a Driver Connection to a Board

Syntax

```
#include <evm6xdll.h>
BOOL evm6x_close(HANDLE h_device);
```

Description

The evm6x_close() function closes a previously opened driver connection to a board. The returned value is TRUE for a successful operation.

- ❑ The *h_device* parameter is the handle returned from a successful evm6x_open() call.

Return Value

The function returns one of the following values:

TRUE Operation succeeded
FALSE Operation failed

Example

In the following example, the evm6x_close() function is used to close a previously opened driver connection to an EVM board.

```
#include <windows.h>
#include <evm6xdll.h>
. . .
HANDLE    h_board;
h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    exit(-1);
}
. . .
evm6x_close( h_board );
```

evm6x_coff_display*Display COFF Information***Syntax**

```
#include <evm6xdll.h>
BOOL evm6x_coff_display(
    char      *filename,
    BOOL      clear_bss_flag,
    BOOL      dump_flag);
```

Description

The evm6x_coff_display() function outputs COFF file information to stdout. This information includes details for each section, including name, size, and flags.

- ☐ The *filename* parameter is the filename of the COFF file to be processed.
- ☐ The *clear_bss_flag* parameter, if TRUE, causes the bss section to be set to 0. This is not the default behavior of the DSP debugger.
- ☐ The *dump_flag* parameter, if TRUE, causes all of the data being written to DSP memory to be displayed to stdout. This can be a very large amount of data.

Return Value

The function returns one of the following values:

TRUE Operation succeeded
FALSE Operation failed

Example

In the following example, the evm6x_coff_display() function is used to display the section information of a COFF file to stdout.

```
#include <windows.h>
#include <evm6xdll.h>
...
if ( !evm6x_coff_display( "example.out", FALSE, FALSE ) )
{
    /* COFF display failed */
}
```

evm6x_coff_load

evm6x_coff_load

Load a COFF Image to a Board Using the HPI

Syntax

```
#include <evm6xdll.h>
BOOL evm6x_coff_load(
    HANDLE      h_device,
    LPVOID      lp_hpi,
    char        *filename,
    BOOL        verbose_flag,
    BOOL        clear_bss_flag,
    BOOL        dump_flag);
```

Description

The `evm6x_coff_load()` function reads a COFF image and writes the data to DSP memory using the HPI. This function allows you to load data or executable images from a COFF file to DSP memory.

- ☐ The `h_device` parameter is the handle returned from a successful `evm6x_open()` call.
- ☐ The `lp_hpi` parameter is either NULL or the handle returned from a successful `evm6x_open_hpi()` call. If this parameter is NULL, the function calls `evm6x_open_hpi()` to get its own handle to the HPI then closes it before returning. If the parameter is not NULL, the function uses the provided handle to the HPI and does not close it before returning. If the HPI is currently open, it cannot be opened again because the HPI supports only one user at a time.
- ☐ The `filename` parameter is the filename of the COFF file to be processed.
- ☐ The `verbose_flag` parameter, if TRUE, causes COFF file information to be sent to stdout during COFF file processing.
- ☐ The `clear_bss_flag` parameter, if TRUE, causes the bss section to be set to 0. This is not the default behavior of the DSP debugger.
- ☐ The `dump_flag` parameter, if TRUE, causes all of the data being written to DSP memory to be displayed to stdout. This can be a very large amount of data.

Return Value

The function returns one of the following values:

TRUE Operation succeeded
FALSE Operation failed

Example

In the following example, the evm6x_coff_load() function is used to load a COFF executable to a DSP. The COFF executable is the file example.out, and the verbose flag is set, which causes COFF section information to be displayed to stdout during the load operation.

```
#include <windows.h>
#include <evm6xdll.h>
. . .
HANDLE    h_board;

h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board */
    exit(-1);
}

/*-----*
reset DSP into HPI boot mode
configure emif registers
load COFF executable
unreset DSP
*-----*/
evm6x_reset_dsp( h_board, HPI_BOOT );
evm6x_init_emif( h_board, NULL );
if ( !evm6x_coff_load( h_board, NULL, "example.out",
                      TRUE, FALSE, FALSE ) )
{
    /* COFF load failed */
}

evm6x_unreset_dsp( h_board );
```

evm6x_generate_nmi_int

evm6x_generate_nmi_int

Generate an NMI to a DSP

Syntax

```
#include <evm6xdll.h>
BOOL evm6x_generate_nmi_int(HANDLE h_device);
```

Description

The evm6x_generate_nmi_int() function causes an NMI interrupt to be generated to the DSP. This interrupt can be disabled by the DSP.

- ☐ The *h_device* parameter is the handle returned from a successful evm6x_open() call.

Return Value

The function returns one of the following values:

TRUE Operation succeeded
FALSE Operation failed

Example

In the following example, the evm6x_generate_nmi_int() function is used to generate an NMI to the DSP on an EVM board.

```
#include <windows.h>
#include <evm6xdll.h>
...
HANDLE    h_board;

h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board */
    exit(-1);
}

/* send a NMI to the DSP */
if ( !evm6x_generate_nmi_int( h_board ) )
{
    /* evm6x_generate_nmi_int function failed */
}
```

evm6x_hpi_close*Close the HPI for a Board***Syntax**

```
#include <evm6xdll.h>
BOOL evm6x_hpi_close(LPVOID h_hpi_map);
```

Description

The evm6x_hpi_close() function closes an open HPI session that was started with a successful evm6x_hpi_open() call.

- ❑ The *h_hpi_map* parameter is the handle returned from a successful evm6x_hpi_open() call.

Return Value

The function returns one of the following values:

TRUE Operation succeeded
 FALSE Operation failed

Example

In the following example, the evm6x_hpi_close() function is used to close the HPI after reading from DSP memory.

```
#include <windows.h>
#include <evm6xdll.h>
. . .
HANDLE      h_board;
LPVOID      h_hpi;
ULONG       ul_ret_len;
ULONG       ul_buffer[2];

h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board */
    exit(-1);
}

h_hpi = evm6x_hpi_open( h_board );
if ( h_hpi == NULL )
{
    /* evm6x_hpi_open() failed */
    evm6x_close( h_board );
    exit(-1);
}

/* read DSP memory (2 words, 32bits each) */
ul_ret_len = 8;
evm6x_hpi_read( h_hpi, ul_buffer, &ul_ret_len,
                0x1f0 );

if ( !evm6x_hpi_close( h_hpi ) )
{
    /* evm6x_hpi_close failed */
}
```

evm6x_hpi_fill

evm6x_hpi_fill

Fill DSP Memory Using the HPI

Syntax

```
#include <evm6xdll.h>
BOOL evm6x_hpi_fill(
    LPVOID    h_hpi_map,
    ULONG     fill_value,
    PULONG    p_length,
    ULONG     dest_addr);
```

Description

The evm6x_hpi_fill() function fills target DSP memory space with a fixed data value. The HPI is used to access DSP memory from the host.

- ☐ The *h_hpi_map* parameter is the handle returned from a successful evm6x_hpi_open() call.
- ☐ The *fill_value* parameter is the 32-bit data value to be written to DSP memory space.
- ☐ The *p_length* parameter is the address of the write length. The length is updated with the actual transfer length. The length is the number of bytes to be transferred but must be a multiple of 4 because all transfers are 32-bit words.
- ☐ The *dest_addr* parameter is the fill starting address in the DSP's memory space. The address must be 32-bit word aligned. This address is from the DSP's point of view.

Return Value

The function returns one of the following values:

TRUE Operation succeeded

FALSE Operation failed

Example

In the following example, the evm6x_hpi_fill() function is used to fill 31 words (32 bits each) of DSP memory starting with address 0x1f84 with the data pattern 0x1234cdef.

```
#include <windows.h>
#include <evm6xdll.h>
. . .
HANDLE    h_board;
LPVOID    h_hpi;
ULONG     ul_ret_len;

h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board */
    exit(-1);
}
```

```
h_hpi = evm6x_hpi_open( h_board );
if ( h_hpi == NULL )
{
    /* evm6x_hpi_open() failed */
    evm6x_close( h_board );
    exit(-1);
}

/* fill 31 words of DSP memory (32bits each) */
ul_ret_len = 0x7c;
if ( !evm6x_hpi_fill( h_hpi, 0x1234cdef, &ul_ret_len,
    0x1f84 ) || (ul_ret_len != 0x7c) )
{
    /* evm6x_hpi_fill() failed */
}

evm6x_hpi_close( h_hpi );
```

evm6x_hpi_generate_int

evm6x_hpi_generate_int

Generate an Interrupt to a DSP Using the HPI

Syntax	<pre>#include <evm6xdll.h> BOOL evm6x_hpi_generate_int(LPVOID h_hpi_map);</pre>
Description	<p>The evm6x_hpi_generate_int() function causes an HPI interrupt on the target DSP.</p> <p>□ The <i>h_hpi_map</i> parameter is the handle returned from a successful evm6x_hpi_open() call.</p>
Return Value	<p>The function returns one of the following values:</p> <p>TRUE Operation succeeded</p> <p>FALSE Operation failed</p>
Example	<p>In the following example, the evm6x_hpi_generate_int() function is used to generate an interrupt to a DSP using the HPI.</p>

```
#include <windows.h>
#include <evm6xdll.h>
. . .
HANDLE    h_board;
LPVOID    h_hpi;

h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board */
    exit(-1);
}

h_hpi = evm6x_hpi_open( h_board );
if ( h_hpi == NULL )
{
    /* evm6x_hpi_open() failed */
    evm6x_close( h_board );
    exit(-1);
}

/* generate an HPI interrupt */
if ( !evm6x_hpi_generate_int( h_hpi ) )
{
    /* evm6x_hpi_generate_int() failed */
}
. . .
```

evm6x_hpi_open

Open the HPI for a Board

Syntax

```
#include <evm6xdll.h>
LPVOID evm6x_hpi_open(HANDLE h_device);
```

Description

The `evm6x_hpi_open()` function establishes a single connection per target board to the HPI of a target board. After the HPI has been successfully opened, read and write operations can be performed to DSP memory.

- ❑ The *h_device* parameter is the handle returned from a successful `evm6x_open()` call.

Note:

The various HPI accesses performed to a board's HPI are protected by a MUTEX. This prevents multiple operations from interfering with each other. But, this also means that an operation may not begin immediately if another HPI operation is in progress. This could cause an HPI interrupt to the DSP to be delayed.

Return Value

The function returns one of the following values:

Handle	Handle to be used for HPI access
NULL	Attempt to open the HPI failed

Example

In the following example, the `evm6x_hpi_open()` function is used to open a handle to the HPI on an EVM board. This handle is required for access to DSP memory through the HPI using the `evm6x_hpi_read()`, `evm6x_hpi_write()`, and `evm6x_hpi_fill()` functions.

```
#include <windows.h>
#include <evm6xdll.h>
. . .
HANDLE      h_board;
LPVOID      h_hpi;
ULONG       ul_ret_len;
ULONG       ul_buffer[2];

h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board */
    exit(-1);
}
```

evm6x_hpi_read

```
h_hpi = evm6x_hpi_open( h_board );
if ( h_hpi == NULL )
{
    /* evm6x_hpi_open() failed */
    evm6x_close( h_board );
    exit(-1);
}

/* read DSP memory (2 words, 32bits each) */
ul_ret_len = 8;
if ( !evm6x_hpi_read( h_hpi, ul_buffer, &ul_ret_len,
    0x1f0 ) ||
    (ul_ret_len != 8) )
{
    /* evm6x_hpi_read() failed */
}
evm6x_hpi_close( h_hpi );
```

evm6x_hpi_read

Read DSP Memory Using the HPI

Syntax

```
#include <evm6xdll.h>
BOOL evm6x_hpi_read(
    LPVOID      h_hpi_map,
    PULONG      p_buffer,
    PULONG      p_length,
    ULONG       src_addr);
```

Description

The evm6x_hpi_read() function transfers data from the target DSP memory space to host memory. The HPI is used to access DSP memory from the host.

- ☐ The *h_hpi_map* parameter is the handle returned from a successful evm6x_hpi_open() call.
- ☐ The *p_buffer* parameter is the address of the buffer to be filled by the read operation. This address must be 32-bit word aligned.
- ☐ The *p_length* parameter is the address of the read length. The length is updated with the actual transfer length. The length is the number of bytes to be transferred but must be a multiple of 4 because all transfers are 32-bit words.
- ☐ The *src_addr* parameter is the transfer starting address in the DSP's memory space. The address must be 32-bit word aligned. This address is from the DSP's point of view.

Return Value

The function returns one of the following values:

TRUE Operation succeeded
FALSE Operation failed

Example

In the following example, the evm6x_hpi_read() function is used to read two words (32 bits each) from DSP memory at address 0x1f0.

```
#include <windows.h>
#include <evm6xdll.h>
. . .
HANDLE      h_board;
LPVOID      h_hpi;
ULONG       ul_ret_len;
ULONG       ul_buffer[2];

h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board */
    exit(-1);
}

h_hpi = evm6x_hpi_open( h_board );
if ( h_hpi == NULL )
{
    /* evm6x_hpi_open() failed */
    evm6x_close( h_board );
    exit(-1);
}

/* read DSP memory (2 words, 32bits each) */
ul_ret_len = 8;
if ( !evm6x_hpi_read( h_hpi, ul_buffer, &ul_ret_len,
                     0x1f0 ) ||
      (ul_ret_len != 8) )
{
    /* evm6x_hpi_read() failed */
}

evm6x_hpi_close( h_hpi );
```

evm6x_hpi_write

evm6x_hpi_write

Write to DSP Memory Using the HPI

Syntax

```
#include <evm6xdll.h>
BOOL evm6x_hpi_write(
    LPVOID    h_hpi_map,
    PULONG    p_buffer,
    PULONG    p_length,
    ULONG     dest_addr);
```

Description

The evm6x_hpi_write() function transfers data from host memory to the target DSP memory space. The HPI is used to access DSP memory from the host.

- ☐ The *h_hpi_map* parameter is the handle returned from a successful evm6x_hpi_open() call.
- ☐ The *p_buffer* parameter is the address of the buffer to be transferred by the write operation. This address must be 32-bit word aligned.
- ☐ The *p_length* parameter is the address of the write length. The length is updated with the actual transfer length. The length is the number of bytes to be transferred but must be a multiple of 4 because all transfers are 32-bit words.
- ☐ The *dest_addr* parameter is the transfer starting address in the DSP's memory space. The address must be 32-bit word aligned. This address is from the DSP's point of view.

Return Value

The function returns one of the following values:

TRUE Operation succeeded

FALSE Operation failed

Example

In the following example, the evm6x_hpi_write() function is used to write two words (32 bits each) to DSP memory at address 0x1f0.

```
#include <windows.h>
#include <evm6xdll.h>
. . .
HANDLE    h_board;
LPVOID    h_hpi;
ULONG     ul_ret_len;
ULONG     ul_buffer[2];

h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board */
    exit(-1);
}
```

```

h_hpi = evm6x_hpi_open( h_board );
if ( h_hpi == NULL )
{
    /* evm6x_hpi_open() failed */
    evm6x_close( h_board );
    exit(-1);
}

/* write 2 words to DSP memory (32bits each) */
ul_ret_len = 8;
ul_buffer[0] = 0x12345678;
ul_buffer[1] = 0xfedcba98;
if ( !evm6x_hpi_write( h_hpi, ul_buffer, &ul_ret_len,
                      0x1f0 ) ||
      (ul_ret_len != 8) )
{
    /* evm6x_hpi_write() failed */
}

evm6x_hpi_close( h_hpi );

```

evm6x_init_emif*Initialize the EMIF Registers***Syntax**

```

#include <evm6xdll.h>
BOOL evm6x_init_emif(
    HANDLE      h_device,
    LPVOID      lp_hpi);

```

Description

The `evm6x_init_emif()` function sets the EMIF registers using HPI accesses to the DSP memory space. This operation is used in conjunction with HPI boot mode. Call the `evm6x_reset_dsp()` function to reset the DSP and put it into HPI boot mode (see page 7-32). Then, before loading code to memory, call the `evm6x_init_emif()` function to initialize the EMIF registers so that external memory on the board is accessible via the HPI.

- ☐ The `h_device` parameter is the handle returned from a successful `evm6x_open()` call.
- ☐ The `lp_hpi` parameter is the handle returned from a successful `evm6x_hpi_open()` call or NULL if the HPI is not already open. If this parameter is NULL, the HPI is opened for this operation then closed at the completion of the function. If this parameter is not NULL, the value is used as the handle for HPI accesses and is not closed at the completion of the function.

Return Value

The function returns one of the following values:

```

TRUE   Operation succeeded
FALSE  Operation failed

```

evm6x_init_emif

Example

In the following example, the `evm6x_init_emif()` function is used to properly configure the EMIF registers of the DSP for the EVM board. This step must be done after resetting the DSP and before the DSP tries to access memory on the EVM board.

```
#include <windows.h>
#include <evm6xdll.h>
. . .
HANDLE    h_board;

h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board */
    exit(-1);
}

/*-----*
reset DSP into HPI boot mode
configure emif registers
load COFF executable
unreset DSP
*-----*/
evm6x_reset_dsp( h_board, HPI_BOOT );
if ( !evm6x_init_emif( h_board, NULL ) )
{
    /* evm6x_init_emif call failed */
}

evm6x_coff_load( h_board, NULL, "example.out",
                FALSE, FALSE, FALSE );
evm6x_unreset_dsp( h_board );
```

evm6x_nvram_read*Read a Byte of NVRAM***Syntax**

```
#include <evm6xdll.h>
BOOL evm6x_nvram_read(
    HANDLE    h_device,
    USHORT    offset,
    PCHAR     p_data);
```

Description

The evm6x_nvram_read() function reads a byte from a target board's NVRAM.

Avoiding Simultaneous NVRAM Accesses

Make sure that NVRAM read and/or write operations do not happen at the same time from both the host and the DSP. Simultaneous accesses to NVRAM will result in invalid operations and will possibly corrupt data stored in NVRAM.

- ☐ The *h_device* parameter is the handle returned from a successful evm6x_open() call.
- ☐ The *offset* parameter is the NVRAM byte offset to be read.
- ☐ The *p_data* parameter is a pointer to the location in which to place the byte read from NVRAM.

Return Value

The function returns one of the following values:

TRUE Operation succeeded
FALSE Operation failed

Example

In the following example, the evm6x_nvram_read() function is used to read the byte value stored in NVRAM at offset 0x83.

```
#include <windows.h>
#include <evm6xdll.h>
. . .
HANDLE    h_board;
UCHAR     c_data;

h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board */
    exit(-1);
}
```

evm6x_nvram_read

```
if ( !evm6x_nvram_read( h_board, 0x83, &c_data ) )
{
    /* evm6x_nvram_read failed */
}
else
{
    /* byte read from offset 0x83 is in c_data */
}
```

evm6x_nvram_write*Write a Byte to NVRAM***Syntax**

```
#include <evm6xdll.h>
BOOL evm6x_nvram_write(
    HANDLE    h_device,
    USHORT    offset,
    UCHAR     data);
```

Description

The evm6x_nvram_write() function writes a byte to a target board's NVRAM. This write operation is not allowed to the lower 0x80 bytes of NVRAM. This space is used for PCI configuration settings and should not be modified.

Avoiding Simultaneous NVRAM Accesses

Make sure that NVRAM read and/or write operations do not happen at the same time from both the host and the DSP. Simultaneous accesses to NVRAM will result in invalid operations and will possibly corrupt data stored in NVRAM.

- ☐ The *h_device* parameter is the handle returned from a successful evm6x_open() call.
- ☐ The *offset* parameter is the NVRAM byte offset to be written.
- ☐ The *data* parameter is the byte data value to be written to NVRAM.

Return Value

The function returns one of the following values:

TRUE Operation succeeded
FALSE Operation failed

Example

In the following example, the evm6x_nvram_write() function is used to write the byte value 0x3f to NVRAM at offset 0xc3.

```
#include <windows.h>
#include <evm6xdll.h>
...
HANDLE    h_board;
UCHAR     c_data;
h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board */
    exit(-1);
}
c_data = 0x3f;
if ( !evm6x_nvram_write( h_board, 0xc3, c_data ) )
{
    /* evm6x_nvram_write failed */
}
```

evm6x_open

evm6x_open

Open a Driver Connection to a Board

Syntax

```
#include <evm6xdll.h>
HANDLE evm6x_open(
    int      board_index,
    BOOL     exclusive_flag);
```

Description

The `evm6x_open()` function opens a driver connection to a specific EVM or McEVM board. The returned handle is used for all further accesses to the target board.

- ❑ The `board_index` parameter is a zero-based relative index. Valid index values depend on the number of EVM and McEVM boards in a system and range from 0 to $n-1$, where n is the number of boards.
- ❑ The `exclusive_flag` parameter indicates an exclusive open request of the target board. An exclusive open will fail if the target board is currently open, and additional open requests will fail for a target board that has been opened exclusively.

Return Value

The function returns one of the following values:

HANDLE	Handle to be used for all further accesses to the target board
INVALID_HANDLE_VALUE	Operation failed

Example

In the following example, the `evm6x_open()` function is used to perform a non-exclusive open of the first EVM board in a system.

```
#include <windows.h>
#include <evm6xdll.h>
. . .
int      board_index;
HANDLE   h_board;

board_index = 0; /* select the first (or only) EVM */
                /* board */
                */

h_board = evm6x_open( board_index, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* board open failed */
    exit(-1);
}
. . .
evm6x_close( h_board );
```

evm6x_read*Read Data from a Board***Syntax**

```
#include <evm6xdll.h>
BOOL evm6x_read(
    HANDLE        h_device,
    PULONG        p_buffer,
    PULONG        p_length);
```

Description

The evm6x_read() function transfers data from the DSP to the host using the PCI bus mastering capability of the board. This transfer can take an indeterminate amount of time, depending on the DSP making data available for the transfer. To prevent the host from waiting too long for a transfer, a time-out feature is available. Use the evm6x_set_timeout() function to set the time-out value (see page 7-38).

Also, a transfer can be terminated at any time using the evm6x_abort_read() function (see page 7-6). A transfer that has been timed out or terminated still returns a success indication, but the length value returned is not the same as the originally requested transfer length.

- ☐ The *h_device* parameter is the handle returned from a successful evm6x_open() call.
- ☐ The *p_buffer* parameter is the address of the buffer to be filled by the read operation. This address must be 32-bit word aligned.
- ☐ The *p_length* parameter is the address of the read length. The length is updated with the actual transfer length. The length is the number of bytes to be transferred, but must be a multiple of 4 because all transfers are 32-bit words.

Return Value

The function returns one of the following values:

```
TRUE   Operation succeeded
FALSE  Operation failed
```

Example

In the following example, the `evm6x_read()` function is used to transfer 292 bytes (73 words, 32 bits each) from the DSP into host memory using the PCI FIFO interface provided on the EVM board. The transfer may succeed, but be incomplete if the transfer timed out or a transfer abort request was initiated from a separate thread. For additional information, see the `evm6x_set_timeout()` function description on page 7-38 and the `evm6x_abort_read()` function description on page 7-6.

```
#include <windows.h>
#include <evm6xdll.h>
. . .
HANDLE    h_board;
ULONG     ul_length;           /* requested transfer */
                                   /* length in bytes    */
ULONG     ul_ret_len;          /* returned transfer */
                                   /* length in bytes    */
ULONG     ul_buffer[1024];     /* data buffer, must */
                                   /* be 32bit aligned   */

h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board */
    exit(-1);
}

ul_length = 292;
ul_ret_len = ul_length;
if ( !evm6x_read( h_board, ul_buffer, &ul_ret_len ) )
{
    /* evm6x_read failed. */
}
else
{
    if ( ul_ret_len != ul_length )
    {
        /* evm6x_read incomplete */
        /* this can be the result of a time out or */
        /* an abort */
    }
}
```

evm6x_reset_board*Reset a Board***Syntax**

```
#include <evm6xdll.h>
BOOL evm6x_reset_board(HANDLE h_device);
```

Description

The evm6x_reset_board() function causes a hardware reset pulse on the target board. The target board must be opened exclusively using the evm6x_open() function (see page 7-28) or this function will fail. The return value indicates the success of the function call.

- ❑ The *h_device* parameter is the handle returned from a successful exclusive evm6x_open() call.

Return Value

The function returns one of the following values:

TRUE Operation succeeded
FALSE Operation failed

Example

In the following example, the evm6x_reset_board() function is used to reset the second EVM board in the system. This board was previously opened exclusively.

```
#include <windows.h>
#include <evm6xdll.h>
. . .
HANDLE    h_board;

/* open the second EVM board exclusively */
h_board = evm6x_open( 1, TRUE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board exclusively */
    exit(-1);
}

if ( !evm6x_reset_board( h_board ) )
{
    /* reset call failed */
}
else
{
    /* reset call succeeded */
}
```

evm6x_reset_dsp

evm6x_reset_dsp

Reset a DSP

Syntax

```
#include <evm6xdll.h>
BOOL evm6x_reset_dsp(
    HANDLE                h_device,
    EVM6XDLL_BOOT_MODE    mode);
```

Description

The `evm6x_reset_dsp()` function sets the boot mode and causes a reset pulse to only the DSP. If the boot mode is set to HPI boot, the DSP is left in a halted state. To allow the DSP to begin executing, use the `evm6x_unreset_dsp()` function (see page 7-39). The return value indicates the success of the function call.

- ☐ The *h_device* parameter is the handle returned from a successful `evm6x_open()` call.
- ☐ The enumerated *mode* parameter is the boot mode in which to reset the DSP.
 - HPI_BOOT resets the DSP into HPI boot mode with the MAP 1 memory map.
 - HPI_BOOT_MAP0 resets into HPI boot mode with MAP 0.
 - NO_BOOT selects no boot mode with MAP 1.
 - NO_BOOT_MAP0 selects no boot mode with MAP 0.
 - The various ROMX_BOOT boot modes require that an executable boot image is present on a daughterboard.

The usual procedure for loading and starting a DSP is:

- 1) Reset the DSP in HPI boot mode using the `evm6x_reset_dsp()` function.
- 2) Configure the DSP memory interface with HPI write calls to access the EMIF registers. This can be accomplished with the `evm6x_init_emif()` function (see page 7-23).
- 3) Load the DSP program with HPI write calls using the `evm6x_coff_load()` function (see page 7-12).
- 4) Unreset the DSP from its halted state using the `evm6x_unreset_dsp()` function (see page 7-39).

Return Value

The function returns one of the following values:

TRUE Operation succeeded
FALSE Operation failed

Example

In the following example, the the evm6x_reset_dsp() function is used to place the DSP into HPI boot mode. While in this state, the DSP accepts HPI accesses. The evm6x_unreset_dsp() function is used to release the DSP from this state and to begin execution of DSP code. See the evm6x_unreset_dsp() function example on page 7-39 for more information.

```
#include <windows.h>
#include <evm6xdll.h>
. . .
HANDLE h_board;
h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board */
    exit(-1);
}
if ( !evm6x_reset_dsp(h_board, HPI_BOOT) )
{
    /* DSP reset call failed */
}
else
{
    /* DSP reset call succeeded */
}
```

evm6x_retrieve_message

Retrieve a Message from a DSP

Syntax

```
#include <evm6xdll.h>
BOOL evm6x_retrieve_message(
    HANDLE h_device,
    PEVM6X_MESSAGE p_message);
```

Description

The evm6x_retrieve_message() function retrieves a mailbox message from the target DSP. This function returns FALSE if the mailbox to the host from the DSP is not full.

This is a completely independent mailbox from that used by the evm6x_send_message() function. Also, the receipt of a message from the DSP can be detected by a Win32 event. The interrupt caused by an incoming message signals an event. The name of the event signaled is the string defined in EVM6X_GLOBAL_MESSAGE_EVENT_BASE_NAME with the board index value appended as a decimal number.

- ☐ The *h_device* parameter is the handle returned from a successful evm6x_open() call.
- ☐ The *p_message* parameter is a pointer to the location to place the message from the DSP.

evm6x_retrieve_message

Return Value

The function returns one of the following values:

TRUE Operation succeeded

FALSE Operation failed

Example

In the following example, the `evm6x_retrieve_message()` function is used to check for and retrieve a 32-bit word sent by the DSP after waiting for the Win32 event signaling a message arrival. If the `evm6x_retrieve_message()` function fails, then a message has not been sent by the DSP. However, this should not happen in this example because the routine waits for the event signaling a new message before retrieving the message.

```
#include <windows.h>
#include <stdio.h>
#include <evm6xdll.h>
. . .
HANDLE          h_board;
HANDLE          h_event;
EVM6XDLL_MESSAGE t_message;
int             n_board_index;
char            s_buffer[80];

n_board_index = 1;
h_board = evm6x_open( n_board_index, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board */
    exit(-1);
}

/* create event name and open handle to the event */
sprintf( s_buffer, "%s%d",
        EVM6X_GLOBAL_MESSAGE_EVENT_BASE_NAME,
        n_board_index );
h_event = OpenEvent( SYNCHRONIZE, FALSE, s_buffer );
/* wait for event signaling a message from the DSP */
if ( WaitForSingleObject( h_event, INFINITE )
    != WAIT_OBJECT_0 )
{
    /* wait for event failed */
}

/* retrieve message sent by DSP */
if ( !evm6x_retrieve_message( h_board, &t_message ) )
{
    /* evm6x_retrieve_message() failed */
    /* this means that no message is available */
}
else
{
    /* the 32bit value sent by the DSP is in t_message */
}
. . .
```

evm6x_send_message

Send a Message to a DSP

Syntax

```
#include <evm6xdll.h>
BOOL evm6x_send_message(
    HANDLE          h_device,
    PEVM6X_MESSAGE  p_message);
```

Description

The evm6x_send_message() function sends a mailbox message to the target DSP. This function returns FALSE if the mailbox from the host to the DSP is not empty.

- ☐ The *h_device* parameter is the handle returned from a successful evm6x_open() call.
- ☐ The *p_message* parameter is a pointer to the message to be sent to the DSP.

Return Value

The function returns one of the following values:

TRUE Operation succeeded
FALSE Operation failed

Example

In the following example, the evm6x_send_message() function is used to send a 32-bit value, 0xfeed002f, to a DSP using the mailbox capability of the EVM board.

```
#include <windows.h>
#include <evm6xdll.h>
. . .
    HANDLE          h_board;
    EVM6XDLL_MESSAGE t_message;

    h_board = evm6x_open( 0, FALSE );
    if ( h_board == INVALID_HANDLE_VALUE )
    {
        /* unable to open board */
        exit(-1);
    }

    /* send message to DSP */
    t_message = 0xfeed002f;
    if ( !evm6x_send_message( h_board, &t_message ) )
    {
        /* evm6x_send_message() failed */
    }
. . .
```

evm6x_set_board_config

Set the User Board Options

Syntax

```
#include <evm6xdll.h>
BOOL evm6x_set_board_config(
    HANDLE                h_device,
    EVM6XDLL_CLOCK_MODE   e_clock_mode,
    EVM6XDLL_ENDIAN_MODE  e_endian_mode,
    ULONG                 user_bits );
```

Description

The `evm6x_set_board_config()` function sets the software configuration for the board. This includes the clock mode, the endian mode, and the user bits. This operation is not required if the hardware DIP switch settings are to be used. If software settings are to be used, this operation must be done before the DSP is reset using the `evm6x_reset_dsp()` function (see page 7-32).

- ☐ The *h_device* parameter is the handle returned from a successful `evm6x_open()` call.
- ☐ The *e_clock_mode* enumerated parameter is one of these values:
 - `DSP_CLOCK_SBSRAM` configures the DSP to run at the maximum speed for SBSRAM accesses
 - `DSP_CLOCK_NORMAL` configures the DSP to run at the normal clock speed.
 - `DSP_CLOCK_AX1` configures the DSP to run at the oscillator A multiply-by-1 clock speed.
 - `DSP_CLOCK_BX1` configures the DSP to run at the oscillator B multiply-by-1 clock speed.
- ☐ The *e_endian_mode* enumerated parameter is one of these values:
 - `LITTLE_ENDIAN_MODE` configures the DSP to run in little-endian mode.
 - `BIG_ENDIAN_MODE` configures the DSP to run in big-endian mode.
- ☐ The *user_bits* parameter is the value to be used for the three user bits. If the value is greater than 7, the value is not used. In this case, the hardware DIP switch setting for the user bits is used.

Return Value

The function returns one of the following values:

TRUE Operation succeeded
FALSE Operation failed

Example

In the following example, the `evm6x_set_board_config()` function sets the EVM board configuration, overriding the hardware DIP switch settings. This must be done before resetting the DSP. In this example, the clock mode is set to `DSP_CLOCK_SBSRAM` mode, which configures the DSP clock to the speed of the SBSRAM. This allows the DSP to access SBSRAM at one clock per access. The endian mode is set to `BIG_ENDIAN_MODE`, which allows the DSP to execute software compiled and linked to run on a big-endian DSP. The user bits are set to `0xff`. The user bits set on the hardware DIP switch are used because the user bits value is greater than 7.

```
#include <windows.h>
#include <evm6xdll.h>
. . .
HANDLE    h_board;

h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board */
    exit(-1);
}

/*-----*
set board configuration
reset DSP into HPI boot mode
configure emif registers
load COFF executable
unreset DSP
*-----*/
if ( !evm6x_set_board_config( h_board,
                             DSP_CLOCK_SBSRAM,
                             BIG_ENDIAN_MODE, 0xff ) )
{
    /* evm6x_set_board_config call failed */
}

evm6x_reset_dsp( h_board, HPI_BOOT );
evm6x_init_emif( h_board, NULL );
evm6x_coff_load( h_board, NULL, "example.out",
                FALSE, FALSE, FALSE );
evm6x_unreset_dsp( h_board);
```

evm6x_set_timeout

evm6x_set_timeout

Set the Transfer Time-Out

Syntax

```
#include <evm6xdll.h>
BOOL evm6x_set_timeout(
    HANDLE h_device,
    ULONG timeout);
```

Description

The `evm6x_set_timeout()` function sets the time-out value for the PCI bus mastering data transfers. If a transfer exceeds this time-out period, the transfer is terminated. The transfer return value indicates how much of the data was transferred.

- ☐ The `h_device` parameter is the handle returned from a successful `evm6x_open()` call.
- ☐ The `timeout` parameter is the number of milliseconds to wait before terminating a pending transfer. A value of 0 disables the time-out feature. The default value at driver startup is 0.

Return Value

The function returns one of the following values:

TRUE Operation succeeded
FALSE Operation failed

Example

In the following example, the `evm6x_set_timeout()` function is used to set the bus master transfer time-out value to 5000 milliseconds (or 5 seconds). This means that any transfer that takes longer than 5 seconds will terminate, returning the actual number of bytes transferred during the transfer. A transfer stalls when data to or from the DSP is not available.

```
#include <windows.h>
#include <evm6xdll.h>
. . .
HANDLE h_board;

h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board */
    exit(-1);
}

/* set the transfer timeout to 5 seconds */
if ( !evm6x_set_timeout( h_board, 5000 ) )
{
    /* evm6x_set_timeout failed */
}
```

evm6x_unreset_dsp*Unreset a DSP After Using HPI Boot Mode***Syntax**

```
#include <evm6xdll.h>
BOOL evm6x_unreset_dsp(HANDLE h_device);
```

Description

The evm6x_unreset_dsp() function releases the DSP from the halted state invoked by the evm6x_reset_dsp() function with the *mode* parameter set to HPI boot (see page 7-32). Use this function in conjunction with an evm6x_reset_dsp() call only. The return value indicates the success of the function call.

- ☐ The *h_device* parameter is the handle returned from a successful evm6x_open() call.

Return Value

The function returns one of the following values:

TRUE Operation succeeded
FALSE Operation failed

Example

In the following example, the evm6x_unreset_dsp() function is used to release the DSP from the halted state that results from resetting the DSP into HPI boot mode.

```
#include <windows.h>
#include <evm6xdll.h>
. . .
HANDLE     h_board;

h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board */
    exit(-1);
}

/*-----*
   reset DSP into HPI boot mode
   configure emif registers
   load COFF executable
   unreset DSP
*-----*/

evm6x_reset_dsp( h_board, HPI_BOOT );
evm6x_init_emif( h_board, NULL);
evm6x_coff_load( h_board, NULL, "example.out",
                FALSE, FALSE, FALSE );

if ( !evm6x_unreset_dsp( h_board ) )
{
    /* DSP unreset call failed */
}
```

evm6x_write

evm6x_write

Write Data to a Board

Syntax

```
#include <evm6xdll.h>
BOOL evm6x_write(
    HANDLE    h_device,
    PULONG    p_buffer,
    PULONG    p_length);
```

Description

The `evm6x_write()` function transfers data from host memory to the DSP using the PCI bus mastering capability of the board. This transfer can take an indeterminate amount of time, depending on the DSP accepting data for the transfer. To prevent the host from waiting too long for a transfer, a time-out feature is available. Use the `evm6x_set_timeout()` function to set the time-out value (see page 7-38).

Also, a transfer can be terminated at any time using the `evm6x_abort_write()` function (see page 7-7). A transfer that has been timed out or terminated still returns a success indication, but the length value returned is not the same as the originally requested transfer length.

- ☐ The *h_device* parameter is the handle returned from a successful `evm6x_open()` call.
- ☐ The *p_buffer* parameter is the address of the buffer to be transferred by the write operation. This address must be 32-bit word aligned.
- ☐ The *p_length* parameter is the address of the write length. The length is updated with the actual transfer length. The length is the number of bytes to be transferred but must be a multiple of 4 because all transfers are 32-bit words.

Return Value

The function returns one of the following values:

TRUE Operation succeeded
FALSE Operation failed

Example

In the following example, the `evm6x_write()` function is used to send 292 bytes (73 words, 32 bits each) from host memory to the DSP using the PCI FIFO interface provided on the EVM board. The transfer may succeed, but be incomplete if the transfer timed out or a transfer abort request was initiated from a separate thread. For additional information, see the `evm6x_set_timeout()` function description on page 7-38 and the `evm6x_abort_write()` function description on page 7-7.

```
#include <windows.h>
#include <evm6xdll.h>
. . .
HANDLE    h_board;
ULONG     ul_length;          /* requested transfer */
                                /* length in bytes      */
ULONG     ul_ret_len;         /* returned transfer */
                                /* length in bytes    */
ULONG     ul_buffer[1024];    /* data buffer, must */
                                /* be 32bit aligned   */

h_board = evm6x_open( 0, FALSE );
if ( h_board == INVALID_HANDLE_VALUE )
{
    /* unable to open board */
    exit(-1);
}
. . .
ul_length = 292;
ul_ret_len = ul_length;
if ( !evm6x_write( h_board, ul_buffer, &ul_ret_len ) )
{
    /* evm6x_write failed. */
}
else
{
    if ( ul_ret_len != ul_length )
    {
        /* evm6x_write incomplete */
        /* this can be the result of a time out or */
        /* an abort                               */
    }
}
```

7.4 EVM Host Support Software Example

The following is a simple program that loads and runs a COFF file in the EVM. The program illustrates the use of a number of the most basic EVM Win32 DLL calls.

Example 7–2. EVM Win32 DLL Sample Code

```

/*-----*/
/* FILENAME: HostApp.c -- Host Support Software Example */
/*-----*/

#include <windows.h>
#include "evm6xdll.h"

void WriteWord2Mem( LPVOID, ULONG, ULONG );

/*-----*/
/* main() */
/*-----*/

void main(int argc1, char *argv1[])
{
    HANDLE hBd      = NULL; /* Board device handle */
    short  iBd      = 0;    /* Board index */
    BOOL   bExcl    = 1;    /* Exclusive open = TRUE */
    short  iMp      = 0;    /* Map selector = MAP0 */
    EVM6XDLL_BOOT_MODE mode = HPI_BOOT_MAP0;
                          /* DSP boot mode */
    LPVOID hHpi     = NULL; /* HPI interface handle */
    char  coffNam[] = "blink.out";
                          /* COFF file name */
    BOOL  bVerbose  = 0;    /* COFF load verbose mode = FALSE */
    BOOL  bClr      = 0;    /* Clear bss mode = FALSE */
    BOOL  bDump     = 0;    /* Dump mode = FALSE */

    /*-----*/
    /* Open a driver connection to a specific [Mc]EVM6x board. */
    /*-----*/

    hBd = evm6x_open( iBd, bExcl );

TMS320C6x EVM DSP Support Software

This chapter describes the EVM DSP support software by providing application programming interfaces (APIs) and example code for the multichannel buffered serial port (McBSP) driver, audio codec library, and board support library. All of these modules use the TMS320C6x peripheral support library to access and control internal peripheral registers. See the *TMS320C6x Peripheral Support Library Programmer's Reference* for a description of this library.

Topic	Page
8.1 DSP Support Software Components	8-2
8.2 Using the DSP Support Software Components	8-3
8.3 McBSP Driver API	8-4
8.4 Codec Library API	8-22
8.5 Board Support Library API	8-39
8.6 DSP Support Software Examples	8-45

8.1 DSP Support Software Components

The DSP support software consists of the McBSP driver, the codec library, and the board support library. The example code provided operates the CS4231A audio codec in serial data mode, and all audio data is communicated to and from the 'C6x via the McBSP port 0. Configuration and control of the codec is achieved via the parallel data interface. These two modules are totally independent of one another in that the codec library makes no calls to the McBSP driver and vice-versa. It is your responsibility to configure both peripherals for use and to control them independently. The board support library, on the other hand, is used by both the McBSP driver and the codec library.

The McBSP provides two types of routines for sending and receiving data. The *synchronous routines* `mcbasp_sync_send()` and `mcbasp_sync_receive()` transfer data by polling the data transmit ready (DXR) and data receive ready (DRR) bits, respectively, to determine when the next word can be written or read. These routines are referred to as blocking because the CPU is blocked waiting for the transfer to complete before returning control to the caller. The *asynchronous routines* `mcbasp_async_send()` and `mcbasp_async_receive()` use the direct memory access (DMA) engine of the 'C6x to transfer the data in the background. User-supplied callback functions are invoked upon completion of the data transfers to signal the caller. These callback functions are invoked from an interrupt service routine and may set a global flag, for instance, which would indicate data is ready to be processed.

The codec library is a collection of routines that configure and control the operation of the CS4231A audio codec. The API functions correspond closely to the functional organization of the chip. Numerous macros are defined for this library in the file `codec.h`. These macros may be used as arguments to the API functions.

The board support library provides routines for configuring and controlling the EVM and returning status information to the caller. The module also includes utility functions such as delay routines.

8.2 Using the DSP Support Software Components

The DSP support software, which consists of the McBSP driver, audio codec library, and board support library, is installed from the accompanying CD-ROM to the \evm6x\dsp\lib directory. These components are in object format and are supplied in the archived object library file drv6x.lib. Another file, drv6xe.lib, is the big-endian version of the archived object library. The source for the DSP support software is contained in the source library file drv6x.src. To extract the source files, assuming that you have installed the 'C6x code generation tools, enter:

```
ar6x -x drv6x.src
```

This command extracts the two makefiles in the drv6x.src file. The files makefile and makefile.big are the little- and big-endian makefile versions, respectively. The first two lines of these files must be modified to point to your c6xtools directory and to your 'C6x peripheral support library files. See the *TMS320C6x Peripheral Support Library Programmer's Reference* for more information about building this library in the desired mode.

To build the object files from the extracted source (*.c) files, enter one of these commands:

```
nmake                                For little-endian object modules
nmake -fmakefile.big                For big-endian object modules
```

To rebuild the object library, enter one of these commands:

```
nmake drv6x.lib                    For little-endian object library
nmake -fmakefile.big drv6xe.lib    For big-endian object library
```

It is possible to build the file drv6xe.lib with little-endian object files and vice-versa, so use caution when building these libraries. Any attempt to use a library of one endian version with code of another will produce a linker error.

Example code that uses the McBSP driver, audio codec library, and board support library exists in the .\dsp\examples directory. Again, the files makefile and makefile.big refer to the little- and big-endian makefiles, respectively. The first two lines of these makefiles must also be modified to point to your c6xtools and 'C6x peripheral support library files. These makefiles also provide an example of how to include the drv6x.lib file on the linker command line for user-developed code. See the *TMS320C6x Assembly Language Tools User's Guide* for more information about using object libraries.

The provided example code configures and uses the audio codec and McBSP in numerous configurations, such as loopback, block capture and playback, continuous capture and playback using ping-pong buffering, and continuous tone generation. You can run the example code via the 'C6x EVM debugger, or you can load the code and allow it to run using the EVM COFF loader utility (evm6xldr). The print statements that are visible in the debugger command window are not visible on the DOS screen when you use the COFF loader.

8.3 McBSP Driver API

This section discusses the multichannel buffered serial port (McBSP) driver API. Included in this discussion are the macros, data types, and defined functions that comprise the McBSP driver for the 'C6x EVM board.

8.3.1 McBSP Driver Macros

Table 8–1 lists the macros defined, their values, and a description of each. The API functions that use each macro are also listed. These macros are defined within the public header file `mcbspdrv.h`. The majority of the macros used by the McBSP driver are defined within the 'C6x device library header file `mcbsp.h`. These macros are used as bit and bit field values within registers and correspondingly within elements of the driver data types. See the *TMS320C6x Peripheral Support Library Programmer's Reference* and the following section for further information.

Table 8–1. McBSP Driver API State Macros

Macro	Value	Description
CLOSED	1	Flags McBSP as closed
OPEN	2	Flags McBSP as open and waiting for control
BUSY	3	Flags McBSP as busy

Note: These macros are used by all McBSP driver functions.

8.3.2 McBSP Driver Data Types

This section lists the public data types defined by the McBSP driver that are required for accessing McBSP driver functions.

Example 8–1. McBSP Driver API Data Types

(a) McBSP device handle

```
typedef   Mcbbsp_handle * Mcbbsp_dev;
```

An initialized Mcbbsp_handle is required for all subsequent McBSP driver calls. The data structure Mcbbsp_dev is used as a private (global static) structure that records state information for each port.

(b) McBSP callback function

```
typedef void Callback(Mcbbsp_dev dev, int status);
```

Callback functions are used by mcbbsp_async_send() and mcbbsp_async_receive() to indicate completion of the requested action.

(c) McBSP configuration structure

```
typedef struct Mcbbsp_config_struct
{
    int                loopback;
    Mcbbsp_tx_config   tx;
    Mcbbsp_rx_config   rx;
    Mcbbsp_srg_config   srg;
}
Mcbbsp_config;
```

The Mcbbsp_config structure is used when calling the mcbbsp_config() function. The element loopback is TRUE or FALSE and is used to control the data loopback mode. The transmitter, receiver, and sample rate generator configuration values are contained in the three structure elements listed in Example 8–1(d), Example 8–1(e), and Example 8–1(f), respectively.

Example 8–1. McBSP Driver API Data Types (Continued)**(d) McBSP transmitter configuration structure**

```
typedef struct Mcbsp_tx_config_struct
{
    unsigned char    update;           /* Update Tx Parameters? T/F          */
    unsigned char    interrupt_mode;   /* SPCR(2): XRDY,Blk,Frame,SyncErr   */
    unsigned char    clock_polarity;   /* PCR(1): Rise or Fall of CLKX       */
    unsigned char    frame_sync_polarity; /* PCR(1): Active High or Low        */
    unsigned char    clock_mode;       /* PCR(1): External or Internal        */
    unsigned char    frame_sync_mode;  /* PCR(1): External or Internal        */
    unsigned char    phase_mode;       /* XCR(1): Single or Dual              */
    unsigned char    frame_length1;    /* XCR(7): 1 to 128 wpf for phase 1   */
    unsigned char    frame_length2;    /* XCR(7):      "      "      phase 2 */
    unsigned char    word_length1;     /* XCR(3): bits per phase 1 word       */
    unsigned char    word_length2;     /* XCR(3): bits per phase 2 word       */
    unsigned char    companding;       /* XCR(2): ALAW ULAW or MSB or LSB     */
    unsigned char    frame_ignore;     /* XCR(1): T/F                         */
    unsigned char    data_delay;       /* XCR(3): 0-2 Tx data delay           */
    unsigned char    dummy[2];        /* pad bytes to 32 bit align           */
}
Mcbsp_tx_config;
```

The `Mcbsp_tx_config` structure is a substructure of `Mcbsp_config` and is used to assign register values for the transmitter. The corresponding bits and bit field values are shown to the right of each structure element. See the *TMS320C6201/C6701 Peripherals Reference Guide* for a detailed discussion of each value.

Example 8–1. McBSP Driver API Data Types (Continued)**(e) McBSP receiver configuration structure**

```
typedef struct Mcbsp_rx_config_struct
{
    unsigned char    update;           /* Update Rx Parameters? T/F          */
    unsigned char    interrupt_mode;   /* SPCR(2): RRDY,Blk,Frame,Syncerr   */
    unsigned char    justification;    /* SPCR(2): RJZF, RJSE or LJZF        */
    unsigned char    clock_polarity;   /* PCR(1): Rise or Fall of CLKX       */
    unsigned char    frame_sync_polarity; /* PCR(1): Active High or Low        */
    unsigned char    clock_mode;       /* PCR(1): External or Internal        */
    unsigned char    frame_sync_mode;  /* PCR(1): External or Internal        */
    unsigned char    phase_mode;       /* XCR(1): Single or Dual              */
    unsigned char    frame_length1;    /* XCR(7):1 to 128 wpf for phase 1    */
    unsigned char    frame_length2;    /* XCR(7): " " " phase 2              */
    unsigned char    word_length1;     /* XCR(3): bits per phase 1 word       */
    unsigned char    word_length2;     /* XCR(3): bits per phase 2 word       */
    unsigned char    companding;       /* XCR(2): ALAW ULAW or MSB or LSB     */
    unsigned char    frame_ignore;     /* XCR(1): T/F                         */
    unsigned char    data_delay;       /* XCR(3): 0-2 Rx data delay           */
    unsigned char    dummy;            /* pad bytes                           */
}
Mcbsp_rx_config;
```

The `Mcbsp_rx_config` structure is a substructure of `Mcbsp_config` and is used to assign register values for the receiver. The corresponding bits and bit field values are shown to the right of each structure element. See the *TMS320C6201/C6701 Peripherals Reference Guide* for a detailed discussion of each value.

(f) McBSP sample rate generator configuration structure

```
typedef struct Mcbsp_srg_config_struct
{
    unsigned char    update;           /* Update SRGR Parameters? T/F          */
    unsigned char    clock_sync;       /* SRGR(1): GSYNC_OFF or GSYNC_ON      */
    unsigned char    clks_polarity;    /* SRGR(1): rising or falling edge      */
    unsigned char    clks_mode;        /* SRGR(1): external or internal        */
    unsigned char    frame_sync_mode;  /* SRGR(1): FSX due to DXR-XSR, FSG    */
    unsigned short   frame_period;     /* SRGR(12): Frame period 1-4096       */
    unsigned char    frame_width;      /* SRGR(8): 1 to 256 CLKG periods      */
    unsigned char    clock_divider;    /* SRGR(8): SRGR clock dvdr: 1-256     */
}
Mcbsp_srg_config;
```

The `Mcbsp_srg_config` structure is a substructure of `Mcbsp_config` and is used to assign register values for the receiver. The corresponding bits and bit field values are shown to the right of each structure element. See the *TMS320C6201/C6701 Peripherals Reference Guide* for a detailed discussion of each value.

8.3.3 McBSP Driver Functions

The following alphabetical listing includes all of the McBSP driver API functions. Use this listing as a table of contents to the McBSP driver API functions.

Function	Description	Page
mcbasp_async_receive	Receive a buffer of data on the selected McBSP asynchronously	8-9
mcbasp_async_send	Send a buffer of data on the selected McBSP asynchronously	8-11
mcbasp_close	Close the selected McBSP/release the device handle	8-12
mcbasp_config	Configure the selected McBSP	8-13
mcbasp_cont_async_send	Continuously send a buffer of data on the selected McBSP	8-14
mcbasp_drv_init	Initialize the McBSP driver	8-16
mcbasp_open	Open the selected McBSP/obtain a device handle	8-17
mcbasp_reset	Reset the selected McBSP	8-18
mcbasp_stop	Stop operation of the selected McBSP	8-18
mcbasp_sync_receive	Receive a buffer of data on the selected McBSP synchronously	8-19
mcbasp_sync_send	Send a buffer of data on the selected McBSP synchronously	8-20

mcbasp_async_receive*Receive a Buffer of Data on the Selected McBSP Asynchronously***Syntax**

```
#include <mcbaspdrv.h>
int mcbasp_async_receive(
    Mcbsp_dev    dev,
    unsigned char *p_buffer,
    unsigned int  num_bytes,
    unsigned int  frame_sync_enable,
    Mcbsp_dev    frame_sync_dev,
    Callback      *p_ract);
```

Defined in

mcbaspdrv.c as a callable C routine

Description

The `mcbasp_async_receive()` function is used to receive a buffer of data from the indicated McBSP in an asynchronous (also known as nonblocking) manner. This routine transfers data in the background using an available direct memory access (DMA) engine. An interrupt service routine is set up by this routine; once the indicated number of bytes have been transferred, the BLOCK COND bit in the DMA secondary control register triggers the enabled DMA interrupt. This interrupt service routine can call a user-supplied callback function, which could, for example, be used to set a global transfer flag indicating that reception is finished. You do not have access to the interrupt service routine, only the callback function to which you provide a pointer.

- ☐ Parameter *dev* refers to the initialized device handle returned by the `mcbasp_open()` call.
- ☐ The *p_buffer* parameter is a pointer to the buffer used to hold received data.
- ☐ The *num_bytes* parameter refers to the number of bytes to receive. Typically, the McBSP is configured for 32-bit transfers. In this case, *num_bytes* is four times the number of 32-bit elements to receive. You must ensure that the buffer pointed to by *p_buffer* is at least as large as *num_bytes*.
- ☐ The *frame_sync_enable* parameter is used to enable the internal frame sync generator. Valid values are TRUE or FALSE.
- ☐ The *frame_sync_dev* parameter indicates which port's frame sync generator to enable. If *frame_sync_enable* is FALSE, set *frame_sync_dev* to NULL. In most cases, *frame_sync_dev* is the same as *dev*.
- ☐ The *p_ract* parameter is a pointer to the user-supplied callback function. See section 8.3.2, *McBSP Driver Data Types*, for the typedef `Callback`, which defines the structure of the callback function.

mcbasp_async_receive

Return Value

The function returns one of the following values:

OK	Transfer setup succeeded
ERROR	Transfer setup failed

Example

The following code provides an example invocation assuming that the driver has been initialized and the device has been opened and configured for an external frame sync and 32-bit transfers.

```
#define NUM_WORDS      128

Callback callback_function(Mcbasp_dev dev, int status)
{
    printf("Data transfer for mcbasp_async_receive() completed
           with status = %d\n",status);
    return;
}

int      status;
unsigned int buffer[NUM_WORDS];

status= mcbasp_async_receive(dev0,
                             buffer,
                             NUM_WORDS * sizeof(int),
                             FALSE,
                             NULL,
                             callback_function
                             );

if (status == ERROR)
{
    printf("Error setting up data transfer with
           mcbasp_sync_receive()\n");
    return(ERROR);
}
```

mcbasp_async_send*Send a Buffer of Data on the Selected McBSP Asynchronously***Syntax**

```
#include <mcbaspdrv.h>
int mcbasp_async_send(
    Mcbsp_dev      dev,
    unsigned char   *p_buffer,
    unsigned int    num_bytes,
    unsigned int    frame_sync_enable,
    Mcbsp_dev      frame_sync_dev,
    Callback        *p_wact);
```

Defined in

mcbaspdrv.c as a callable C routine

Description

The `mcbasp_async_send()` function is used to send a buffer of data from the indicated McBSP in an asynchronous (also known as nonblocking) manner. This routine transfers data in the background using an available DMA engine. An interrupt service routine is set up by this routine; once the indicated number of bytes have been transferred, the BLOCK COND bit in the DMA secondary control register triggers the enabled DMA interrupt. This interrupt service routine can call a user-supplied callback function, which could, for example, be used to set a global transfer flag indicating that transmission is finished. You do not have access to the interrupt service routine, only the callback function to which you provide a pointer.

- ☐ The *dev* parameter refers to the initialized device handle returned by the `mcbasp_open()` call.
- ☐ The *p_buffer* parameter is a pointer to the buffer used to hold data to be transmitted.
- ☐ The *num_bytes* parameter refers to the number of bytes to send. Typically, the McBSP is configured for 32-bit transfers. In this case, *num_bytes* is four times the number of 32-bit elements to receive.
- ☐ The *frame_sync_enable* parameter is used to enable the internal frame sync generator. Valid values are TRUE or FALSE.
- ☐ The *frame_sync_dev* parameter indicates which port's frame sync generator to enable. If *frame_sync_enable* is FALSE, set *frame_sync_dev* to NULL. In most cases, *frame_sync_dev* is the same as *dev*.
- ☐ The *p_wact* parameter is a pointer to the user-supplied callback function. See section 8.3.2, *McBSP Driver Data Types*, for the typedef `Callback`, which defines the structure of the callback function.

mcbasp_close

Return Value

The function returns one of the following values:

OK Transfer setup succeeded
ERROR Transfer setup failed

Example

The following code provides an example invocation assuming that the driver has been initialized and the device has been opened and configured for an internal frame sync and 32-bit transfers.

```
#define NUM_WORDS        128
Callback    callback_function(Mcbasp_dev dev, int status)
{
    printf("Data transfer for mcbasp_async_send() completed
           with status = %d\n",status);
    return;
}

int            status;
unsigned int   buffer[NUM_WORDS];
status= mcbasp_async_send(dev0,
                          buffer,
                          NUM_WORDS * sizeof(int),
                          TRUE,
                          dev0,
                          callback_function
                          );

if (status == ERROR)
{
    printf("Error setting up data transfer with \
          mcbasp_sync_send()\n");
    return(ERROR);
}
```

mcbasp_close

Close the Selected McBSP/Release the Device Handle

Syntax

```
#include <mcbaspdrv.h>
void mcbasp_close(Mcbasp_dev dev);
```

Defined in

mcbaspdrv.c as a callable C routine

Description

The mcbasp_close() function closes the selected McBSP and releases its associated device handle structure.

- ❑ The *dev* parameter is the device handle that was initialized by the mcbasp_open() call.

Return Value

None

Example

The code in this example closes the McBSP associated with *dev*, allowing another routine or thread to control its operation.

```
mcbasp_close(dev);
```

mcbbsp_config*Configure the Selected McBSP***Syntax**

```
#include <mcbbspdrv.h>
int mcbbsp_config(
    Mcbsp_dev      dev,
    Mcbsp_config    *p_mcbbsp_config);
```

Defined in

mcbbspdrv.c as a callable C routine

Description

The mcbbsp_config() function configures the selected McBSP. Configuration values are passed to this routine via the Mcbsp_config structure (see section 8.3.2, *McBSP Driver Data Types*, for the definition of this structure). The macro defines for the configuration structure elements are defined in the file mcbbsp.h, which is part of the 'C6x device library.

- ☐ The *dev* parameter refers to the initialized device handle returned by the mcbbsp_open() call.
- ☐ The *p_mcbbsp_config* parameter is a pointer to a user-initialized McBSP configuration structure.

Return Value

The function returns one of the following values:

- | | |
|-------|--|
| OK | Configuration values are within range of their respective min/max values. |
| ERROR | Configuration values were greater than or less than their respective min/max values. |

Example

The code in this example configures the transmitter, receiver, and sample rate generator for the McBSP associated with the initialized device handle *dev* for use in internal loopback mode. Defines shown in this example are part of the 'C6x peripheral control library.

```
config.loopback           = TRUE;
config.tx.update          = TRUE;
config.tx.clock_polarity  = CLKX_POL_RISING;
config.tx.frame_sync_polarity= FSYNC_POL_HIGH;
config.tx.clock_mode       = CLK_MODE_INT;
config.tx.frame_sync_mode  = FSYNC_MODE_INT;
config.tx.phase_mode       = SINGLE_PHASE;
config.tx.frame_length1    = 0;

config.srg.clock_divider       = 0xff;
if (mcbbsp_config(dev0,&config))
{
    printf("Error returned from mcbbsp_config() for dev0");
    mcbbsp_close(dev0);
    return(ERROR);
}
```

mcbbsp_cont_async_send

Continuously Send a Buffer of Data on the Selected McBSP

Syntax

```
#include <mcbbspdrv.h>
int mcbbsp_cont_async_send(
    Mcbsp_dev      dev,
    unsigned char   *p_ping_buff,
    unsigned char   *p_pong_buff,
    unsigned int    num_bytes,
    unsigned int    frame_sync_enable,
    int             frame_sync_dev,
    Callback        *p_wactf);
```

Defined in

mcbbspdrv.c as a callable C routine

Description

The `mcbbsp_cont_async_send()` function is used to repeatedly send either a single buffer or a ping-pong type buffer in an asynchronous (also known as nonblocking) manner. This routine transfers data in the background using an available DMA engine. An interrupt service routine is set up by this routine; once the indicated number of bytes have been transferred, the BLOCK COND bit in the DMA secondary control register triggers the enabled DMA interrupt. This interrupt service routine can call a user-supplied callback function, which could, for example, be used to set a global transfer flag indicating another transmission is finished. You do not have access to the interrupt service routine, only the callback function to which you provide a pointer.

- ☐ The `dev` parameter refers to the initialized device handle returned by the `mcbbsp_open()` call.
- ☐ The `p_ping_buffer` parameter is a pointer to the buffer used to hold data to be transmitted.

- ❑ The *p_pong_buffer* parameter is a pointer to the secondary transmit buffer. If this parameter is NULL, the data in *p_ping_buffer* is continuously sent. If this parameter is valid, then data transmission ping-pongs between these two buffers.
- ❑ The *num_bytes* parameter refers to the number of bytes to send (same for each buffer). Typically, the McBSP is configured for 32-bit transfers. In this case, *num_bytes* is four times the number of 32-bit elements to receive.
- ❑ The *frame_sync_enable* parameter is used to enable the internal frame sync generator. Valid values are TRUE or FALSE.
- ❑ The *frame_sync_dev* parameter indicates which port's frame sync generator to enable. If *frame_sync_enable* is FALSE, set *frame_sync_dev* to NULL. In most cases, *frame_sync_dev* is the same as *dev*.
- ❑ The *p_wact* parameter is a pointer to the user-supplied callback function. See section 8.3.2, *McBSP Driver Data Types*, for the typedef *Callback*, which defines the structure of the callback function.

Return Value

The function returns one of the following values:

OK	Transfer setup succeeded
ERROR	Transfer setup failed

Example

The following code provides an example invocation assuming that the driver has been initialized and the device has been opened and configured for an internal frame sync and 32-bit transfers. This code continuously sends 16 buffers of data, eight from the *ping_buff[]* and eight from the *pong_buff[]*. To turn off continuous operation, the callback function must set *dev->tx_dma.continuous* to FALSE one block before transmission should stop.

```
#define NUM_WORDS      128
#define NUM_BUFFS      16

int      num_buffs_sent= 0;
Callback callback_function(
            Mcbsp_dev dev,
            int      status)
{
    printf("Data transfer for mcbasp_async_send() completed
           with\ status = %d\n",status);
    num_buffs_sent++;
    if (num_buffs_sent == NUM_BUFFS)
        mcbasp_stop(dev);
    return;
}

int      status;
unsigned int ping_buff[NUM_WORDS];
unsigned int pong_buff[NUM_WORDS];
```

mcbbsp_drv_init

```
for (i=0;i<NUM_WORDS;i++) /* create a ramp */
    ping_buff[i] = i;
for (i=0;i<NUM_WORDS;i++) /* create a ramp */
    pong_buff[i] = i;
status= mcbbsp_cont_async_send( dev0,
                                ping_buff,
                                pong_buff,
                                NUM_WORDS * sizeof(int),
                                TRUE,
                                dev0,
                                callback_function
                                );

if (status == ERROR)
{
    printf("Error setting up data transfer with \
          mcbbsp_sync_send() \n");
    return(ERROR);
}
```

mcbbsp_drv_init

Initialize the McBSP Driver

Syntax

```
#include <mcbbspdrv.h>
int mcbbsp_drv_init(void);
```

Defined in

mcbbspdrv.c as a callable C routine

Description

The mcbbsp_drv_init() function initializes the McBSP driver for use and must be called before any other driver calls. This function allocates memory for the port 0 and port 1 device handles and initializes structure elements to their default values.

Return Value

The function returns one of the following values:

OK Memory allocation succeeded
ERROR Memory allocation failed

Subsequent calls to this function simply return OK.

Example

The code in this example initializes the McBSP driver for use and is called before any other McBSP routines.

```
int status;
status = mcbbsp_drv_init();
if (status == ERROR)
{
    printf("Error initializing the McBSP driver\n");
    return(ERROR);
}
```

mcbasp_open*Open the Selected McBSP/Obtain a Device Handle***Syntax**

```
#include <mcbaspdrv.h>
Mcbasp_dev mcbasp_open(int port);
```

Defined in

mcbaspdrv.c as a callable C routine

Description

The mcbasp_open() function opens the selected McBSP for use. All subsequent driver calls require an initialized *Mcbasp_dev* argument.

- ☐ The *port* parameter indicates which serial port to open, with valid values of 0 or 1.

Return Value

The function returns one of the following values:

Mcbasp_dev A valid device handle value is returned if the indicated *port* is not already in use.

NULL The indicated *port* is already in use.

Example

The code in this example obtains a device handle for the McBSP port 0. This device handle is required in subsequent McBSP calls, such as mcbasp_config() and mcbasp_async_receive().

```
Mcbasp_dev dev0;
dev0 = mcbasp_open(0);
if (dev0 == NULL)
{
    printf("Unable to obtain a device handle for McBSP 0.");
    return(ERROR);
}
```

mcbbsp_reset

mcbbsp_reset

Reset the Selected McBSP

Syntax	<pre>#include <mcbbspdrv.h> void mcbbsp_reset(Mcbbsp_dev dev);</pre>				
Defined in	mcbbspdrv.c as a callable C routine				
Description	<p>The <code>mcbbsp_reset()</code> function simply resets the selected McBSP associated with <i>dev</i> to its default state.</p> <p><input type="checkbox"/> The <i>dev</i> parameter refers to the initialized device handle returned by the <code>mcbbsp_open()</code> call.</p>				
Return Value	<p>The function returns one of the following values:</p> <table><tr><td>OK</td><td>The <i>dev</i> parameter was supplied as a valid device handle.</td></tr><tr><td>ERROR</td><td>The <i>dev</i> parameter was not supplied as a valid device handle.</td></tr></table>	OK	The <i>dev</i> parameter was supplied as a valid device handle.	ERROR	The <i>dev</i> parameter was not supplied as a valid device handle.
OK	The <i>dev</i> parameter was supplied as a valid device handle.				
ERROR	The <i>dev</i> parameter was not supplied as a valid device handle.				
Example	<p>The code in this example resets the associated McBSP to its default state.</p> <pre>if (mcbbsp_reset(dev)) { printf("Invalid device handle passed to mcbbsp_reset\n"); return(ERROR); }</pre>				

mcbbsp_stop

Stop Operation of the Selected McBSP

Syntax	<pre>#include <mcbbspdrv.h> void mcbbsp_stop(Mcbbsp_dev dev);</pre>
Defined in	mcbbspdrv.c as a callable C routine
Description	<p>The <code>mcbbsp_stop()</code> function completely disables the selected McBSP. Both the transmit and receive sections are disabled, as well as the sample rate and frame sync generators.</p> <p><input type="checkbox"/> The <i>dev</i> parameter refers to the initialized device handle returned by the <code>mcbbsp_open()</code> call.</p>
Return Value	None
Example	<p>The code in this example disables the selected McBSP.</p> <pre>mcbbsp_stop(dev);</pre>

mcbbsp_sync_receive*Receive a Buffer of Data on the Selected McBSP Synchronously***Syntax**

```
#include <mcbbspdrv.h>
int mcbbsp_sync_receive(
    Mcbsp_dev      dev,
    unsigned char   *p_buffer,
    unsigned int     num_bytes,
    unsigned int     frame_sync_enable,
    Mcbsp_dev      frame_sync_dev,
    int             pack_data);
```

Defined in

mcbbspdrv.c as a callable C routine

Description

The `mcbbsp_sync_receive()` function is used to receive a buffer of data from the indicated McBSP in a synchronous (also known as blocking) manner. During data reception, the CPU is busy polling the data receive ready (DRR) flag in the serial port control register to determine when the next data word is available. Once the indicated number of bytes have been transferred to the buffer, this routine returns to the caller.

- ☐ The *dev* parameter refers to the initialized device handle returned by the `mcbbsp_open()` call.
- ☐ The *p_buffer* parameter is a pointer to the buffer used to hold received data.
- ☐ The *num_bytes* parameter refers to the number of bytes to receive. Typically, the McBSP is configured for 32-bit transfers. In this case, *num_bytes* is four times the number of 32-bit elements to receive. You must ensure that the buffer pointed to by *p_buffer* is at least as large as *num_bytes*.
- ☐ The *frame_sync_enable* parameter is used to enable the internal frame sync generator. Valid values are TRUE or FALSE.
- ☐ The *frame_sync_dev* parameter indicates which port's frame sync generator to enable. If *frame_sync_enable* is FALSE, set *frame_sync_dev* to NULL. In most cases, *frame_sync_dev* is the same as *dev*.
- ☐ Parameter *pack_data* can be used to pack received elements that are less than 32 bits into *p_buffer*. Valid values for *pack_data* are TRUE or FALSE. The *pack_data* feature can only be used when the serial port is configured for single-phase transfers.

Return Value

The function returns one of the following values:

OK	Transfer succeeded
ERROR	Transfer failed

mcbbsp_sync_send

Example

The following code provides an example invocation assuming that the driver has been initialized and the device has been opened and configured for an external frame sync and 32-bit transfers.

```
#define NUM_WORDS      128

int          status;
unsigned int buffer[NUM_WORDS];

status= mcbbsp_sync_receive(    dev0,
                                buffer,
                                NUM_WORDS * sizeof(int),
                                FALSE,
                                NULL,
                                FALSE);

if (status == ERROR)
{
    printf("Error receiving data with mcbbsp_sync_receive()\n");
    return(ERROR);
}
```

mcbbsp_sync_send

Send a Buffer of Data on the Selected McBSP Synchronously

Syntax

```
#include <mcbbspdrv.h>
int mcbbsp_sync_send(
    Mcbsp_dev    dev,
    unsigned char *p_buffer,
    unsigned int  num_bytes,
    unsigned int  frame_sync_enable,
    Mcbsp_dev    frame_sync_dev,
    int           packed_data);
```

Defined in

mcbbspdrv.c as a callable C routine

Description

The `mcbbsp_sync_send()` function sends a buffer of data across the indicated McBSP in a synchronous (also known as blocking) manner. During data transmission, the CPU is busy polling the data transmit ready (DXR) flag in the serial port control register to determine when the next element can be written. Once the indicated number of bytes have been transferred from the buffer, this routine returns to the caller.

- ☐ The *dev* parameter refers to the initialized device handle returned by the `mcbbsp_open()` call.
- ☐ The *p_buffer* parameter is a pointer to the buffer initialized with the data to send.

- ❑ The *num_bytes* parameter refers to the number of bytes to send. Typically, the McBSP is configured for 32-bit transfers. In this case, *num_bytes* is four times the number of 32-bit elements to send.
- ❑ The *frame_sync_enable* parameter is used to enable the internal frame sync generator. Valid values are TRUE or FALSE.
- ❑ The *frame_sync_dev* parameter indicates which port's frame sync generator to enable. If *frame_sync_enable* is FALSE, set *frame_sync_dev* to NULL. In most cases, *frame_sync_dev* is the same as *dev*.
- ❑ The *packed_data* parameter, if TRUE, indicates that the data in *p_buffer* is packed. For element transfers of less than 32 bits, this routine sends only the significant bits for each transfer, sign extended and justified as indicated in the *mcbbsp_config()* call (see page 8-13).

Return Value

The function returns one of the following values:

OK	Transfer succeeded
ERROR	Transfer failed

Example

The following code provides an example invocation assuming that the driver has been initialized and the device has been opened and configured for an internal frame sync (FSG) and 32-bit transfers.

```
#define NUM_WORDS      128

int      status;
unsigned int buffer[NUM_WORDS];

for (i=0;i<NUM_WORDS;i++)      /* generate ramp */
    buffer[i]= i;

status= mcbbsp_sync_send( dev0,
                          buffer,
                          NUM_WORDS * sizeof(int),
                          TRUE,
                          dev0,
                          FALSE);

if (status == ERROR)
{
    printf("Error sending data with mcbbsp_sync_send()\n");
    return(ERROR);
}
```

8.4 Codec Library API

This section discusses the audio codec library API. Included in this discussion are the macros and defined functions that comprise the audio codec library for the 'C6x EVM board.

8.4.1 Codec Library Macros

Table 9–2 lists the macros defined, their values, and a description of each. The API functions that use each set of macros are also listed. These macros are defined within the public header file `codec.h`.

Table 8–2. Codec Library API Macros

(a) Mode selection macros

Macro	Value	Description
CAPTURE	1	Selects capture mode for control
PLAYBACK	2	Selects playback mode for control
BOTH	3	Applies arguments to both capture and playback modes

Note: These macros are used by the function `codec_audio_data_format()`.

(b) Left/right channel selection macros

Macro	Value	Description
LEFT	1	Selects left channel for control
RIGHT	2	Selects right channel for control

Note: These macros are used by the following functions:

```

codec_adc_control()
codec_line_in_control()
codec_aux_control()
codec_dac_control()

```

(c) Auxiliary port selection macros

Macro	Value	Description
CHAN1	1	Selects auxiliary port 1 for control
CHAN2	2	Selects auxiliary port 2 for control

Note: These macros are used by the function `codec_aux_control()`.

Table 8–2. Codec Library API Macros (Continued)

(d) Analog-to-digital converter (ADC) input gain macros

Macro	Value	Description
MIN_ADC_INPUT_GAIN	0.0	Minimum gain setting in dB for left and right input ADCs
MAX_ADC_INPUT_GAIN	22.5	Maximum gain setting in dB for left and right input ADCs
ADC_INPUT_GAIN_STEP	1.5	Gain setting resolution for left and right input ADCs

Note: These macros are used by the function `codec_adc_control()`.

(e) Auxiliary and line mixer gain macros

Macro	Value	Description
MIN_AUX_LINE_GAIN	–34.5	Minimum gain setting in dB for AUX1, AUX2, and LINE mixer gain
MAX_AUX_LINE_GAIN	12.0	Maximum gain setting in dB for AUX1, AUX2, and LINE mixer gain
AUX_LINE_GAIN_STEP	1.5	Gain setting resolution for AUX1, AUX2, and LINE mixers

Note: These macros are used by the following functions:
`codec_line_in_control()`
`codec_aux_control()`

(f) Digital-to-analog converter (DAC) and loopback attenuation macros

Macro	Value	Description
MIN_DAC_LBACK_ATTEN	0.0	Minimum attenuation setting in dB for left and right DACs and left and right loopback attenuators
MAX_DAC_LBACK_ATTEN	94.5	Maximum attenuation setting in dB for left and right DACs and left and right loopback attenuators
DAC_LBACK_ATTEN_STEP	1.5	Attenuation setting resolution for DACs and loopback attenuators

Note: These macros are used by the following functions:
`codec_dac_control()`
`codec_loopback_enable()`

Table 8–2. Codec Library API Macros (Continued)

(g) ADC input selector macros

Macro	Value	Description
LINE_SEL	0	Selects LINE input as source for left or right ADC
AUX1_SEL	1	Selects AUX1 input as source for left or right ADC
MIC_SEL	2	Selects MIC input as source for left or right ADC
LINE_OUT_LBACK_SEL	3	Selects LINE OUT as source for left or right ADC

Note: These macros are used by the function `codec_adc_control()`.

(h) Capture and playback audio data format macros

Macro	Value	Description
LINEAR_8BIT_UNSIGNED	0	Selects linear, 8-bit unsigned data format
ULAW_8BIT_COMPANDED	1	Selects μ -Law, 8-bit companded format
LINEAR_16BIT_SIGNED_LE	2	Selects linear, 16-bit signed little-endian data format
ALAW_8BIT_COMPANDED	3	Selects A-Law, 8-bit companded format
RSVD_FORMAT	4	Reserved data format designator
ADPCM_4BIT_IMA	5	Selects ADPCM, 4-bit, IMA-compatible data format
LINEAR_16BIT_SIGNED_BE	6	Selects linear, 16-bit signed big-endian data format

Note: These macros are used by the function `codec_audio_data_format()`

Table 8–2. Codec Library API Macros (Continued)

(i) Calibration mode macros

Macro	Value	Description
NO_CAL	0	No calibration is performed after resetting the MCE bit
CONVERTER_CAL	1	Calibrates only ADCs and DACs
DAC_CAL	2	Calibrates only the DAC interpolation filters
FULL_CAL	3	Calibrates all offsets, ADCs, DACs, and analog mixers

Note: These macros are used by the function `codec_calibrate()`.

(j) Serial data format macros

Macro	Value	Description
SERIAL_64BIT_ENHANCED	0	Selects 64-bit enhanced serial audio data format; contains status information
SERIAL_64BIT	1	Selects 64-bit serial audio data format; does not contain status information
SERIAL_32BIT	2	Selects 32-bit serial audio data format; does not contain status information

Note: These macros are used by the function `codec_serial_port_enable()`.

8.4.2 Codec Library API Functions

The following alphabetical listing includes all of the codec library API functions. Use this listing as a table of contents to the codec library API functions.

Function	Description	Page
codec_adc_control	Control input analog-to-digital converters	8-27
codec_audio_data_format	Assign the audio data format for both capture and playback	8-28
codec_aux_control	Control the two pairs of auxiliary inputs	8-29
codec_calibrate	Calibrate the CS4231A codec	8-30
codec_capture_disable	Disable capture mode	8-30
codec_capture_enable	Enable capture mode	8-31
codec_change_sample_rate	Set capture and playback sample rates on the CS4231A codec	8-31
codec_dac_control	Control the output digital-to-analog converters	8-32
codec_id	Return codec ID, codec version, and chip ID	8-33
codec_init	Perform required codec initialization and default configuration	8-33
codec_interrupt_disable	Disable interrupt mode	8-34
codec_interrupt_enable	Enable interrupts from CS4231A codec	8-34
codec_line_in_control	Control left and right line inputs	8-34
codec_loopback_disable	Disable loopback mode	8-35
codec_loopback_enable	Enable loopback mode	8-35
codec_playback_disable	Disable playback mode	8-35
codec_playback_enable	Enable playback mode	8-36
codec_reset	Reset codec	8-36
codec_serial_port_disable	Disable serial port transfers on CS4231A codec	8-36
codec_serial_port_enable	Enable serial port transfers on CS4231A codec	8-37
codec_set_base	Set base address for codec based on memory map and endian mode	8-37
codec_timer	Use internal timer of codec	8-38

codec_adc_control

Control Input ADCs

Syntax

```
#include <codec.h>
int codec_adc_control(
    int    leftRightSel,
    float  adcGain,
    int    micGain,
    int    sourceSel);
```

Defined in

codec.c as a callable C routine

Description

The `codec_adc_control()` function controls the left and right input analog-to-digital converters (ADCs) in the CS4231A codec.

- ☐ The *leftRightSel* parameter selects between the left and right converters. Valid defined values are LEFT and RIGHT.
- ☐ The *adcGain* parameter specifies the ADC gain. Valid values are 0.0 dB–22.5 dB in .5-dB increments.
- ☐ The *micGain* parameter indicates whether or not to enable the 20-dB microphone input gains. Valid values are either TRUE (nonzero) or FALSE (zero).
- ☐ The *sourceSel* parameter selects the input source for the specified ADC. It can be one of these values:
 - LINE_SEL selects LINE input as the source.
 - AUX1_SEL selects AUX1 input as the source.
 - MIC_SEL selects MIC input as the source.
 - LINE_OUT_LBACK_SEL selects LINE OUT as the source.

Note:

The AUX1 input selection is provided for library completeness; however, the auxiliary inputs are not used on the EVM.

Return Value

The function returns one of the following values:

OK	Operation succeeded
ERROR	Operation failed

Example

This example sets the left ADC gain to 0 dB and disables the 20-dB microphone input gain. LINE is selected as the input source.

```
int status;
status= codec_adc_control( LEFT, 0.0, FALSE, LINE_SEL );
if (status == ERROR)
    return(ERROR);
```

codec_audio_data_format

codec_audio_data_format

Assign the Audio Data Format for Both Capture and Playback

Syntax

```
#include <codec.h>
int codec_audio_data_format(
    unsigned char format,
    int stereo,
    int selection );
```

Defined in

codec.c as a callable C routine

Description

The `codec_audio_data_format()` function assigns the audio data format on the CS4231A codec.

- ☐ The *format* parameter selects the data format, which can be one of the following defined values:
 - `ULAW_8BIT_COMPANDED` selects μ -Law, 8-bit companded format.
 - `LINEAR_16BIT_SIGNED_LE` selects linear, 16-bit signed little-endian data format.
 - `ALAW_8BIT_COMPANDED` selects A-Law, 8-bit companded format.
 - `ADPCM_4BIT_IMA` selects ADPCM, 4-bit IMA-compatible format.
 - `LINEAR_16BIT_SIGNED_BE` selects linear, 16-bit signed big-endian data format.
 - `LINEAR_8BIT_UNSIGNED` selects linear, 8-bit unsigned data format.
- ☐ The *stereo* parameter selects the stereo format.
 - A value of `TRUE` (nonzero) selects stereo format, in which alternating samples represent left and right channels.
 - A value of `FALSE` (zero) selects mono format, in which the left channel sample occurs twice.
- ☐ The *selection* parameter selects the operating mode, which can be one of the following defined values:
 - `CAPTURE` selects capture mode.
 - `PLAYBACK` selects playback mode.
 - `BOTH` applies arguments to both the capture and the playback mode.

Return Value

The function returns one of the following values:

OK	Operation succeeded
ERROR	Operation failed

Example

This example selects the linear 16-bit signed little-endian data format operating in stereo mode for both capture and playback.

```
int status;
status = codec_audio_data_format( LINEAR_16BIT_SIGNED_LE,
                                TRUE, BOTH);
if (status == ERROR)
    return(ERROR);
```

codec_aux_control

Control the Two Pairs of Auxiliary Inputs

Syntax

```
#include <codec.h>
int codec_aux_control(
    int    leftRightSel,
    int    channelSel,
    float  mixGain,
    int    mute );
```

Defined in

codec.c as a callable C routine

Description

This codec_aux_control() function controls the two pairs of auxiliary inputs on the CS4231A codec.

- ☐ The *leftRightSel* parameter selects between the left and right side inputs. Valid defined values are LEFT and RIGHT.
- ☐ The *channelSel* parameter selects between auxiliary port 1 and auxiliary port 2. Valid defined values are CHAN1 and CHAN2.
- ☐ The *mixGain* parameter specifies the auxiliary input mixer gain setting. Valid values are –34.5 dB–12.0 dB in 1.5-dB increments.
- ☐ The *mute* parameter, if TRUE (nonzero), mutes the selected line to the mixer.

Note:

This function is provided for library completeness; however, the auxiliary inputs are not used on the EVM.

Return Value

The function returns one of the following values:

OK	Operation succeeded
ERROR	Operation failed

Example

This example enables the left auxiliary 1 input mixer and sets its gain to 0 dB.

```
int status;
status = codec_aux_control( LEFT, CHAN1, 0.0, FALSE );
if (status == ERROR)
    return(ERROR);
```

codec_calibrate

codec_calibrate

Calibrate the CS4231A Codec

Syntax

```
#include <codec.h>
int codec_calibrate( int calVal );
```

Defined in

codec.c as a callable C routine

Description

The `codec_calibrate()` function calibrates the CS4231A codec.

The *calVal* parameter determines the calibration mode, which can be one of the following defined values:

- ☐ `CONVERTER_CAL` calibrates only the ADCs and DACs.
- ☐ `DAC_CAL` calibrates only the DAC interpolation filters.
- ☐ `FULL_CAL` calibrates all offsets, ADCs, DACs, and analog mixers.
- ☐ `NO_CAL` specifies that no calibration is performed after resetting the MCE bit.

Return Value

The function returns one of the following values:

OK	Operation succeeded
ERROR	Operation failed

Example

This example performs a full calibration on the CS4231A codec, which means the function calibrates all offsets, ADCs, DACs, and analog mixers.

```
int status;

status = codec_calibrate( FULL_CAL );
if (status == ERROR)
    return(ERROR);
```

codec_capture_disable

Disable Capture Mode

Syntax

```
#include <codec.h>
void codec_capture_disable( void );
```

Defined in

codec.c as a callable C routine

Description

The `codec_capture_disable()` function disables capture mode on the CS4231A codec.

Return Value

None

codec_capture_enable

Enable Capture Mode

Syntax	<pre>#include <codec.h> void codec_capture_enable(void);</pre>
Defined in	codec.c as a callable C routine
Description	The codec_capture_enable() function enables capture mode on the CS4231A codec.
Return Value	None

codec_change_sample_rate

Set Capture and Playback Sample Rates on the CS4231A Codec

Syntax	<pre>#include <codec.h> int codec_change_sample_rate(int <i>sampleRate</i>, int <i>returnFromMce</i>);</pre>
Defined in	codec.c as a callable C routine
Description	<p>The codec_change_sample_rate() function changes the capture and playback sample rates on the CS4231A codec.</p> <ul style="list-style-type: none"> <input type="checkbox"/> The <i>sampleRate</i> parameter sets the sample rate in Hz. The given <i>sampleRate</i> is matched to a table of valid values, and the actual sample rate is set to the closest value found. <input type="checkbox"/> The <i>returnFromMce</i> parameter, if TRUE, causes this function to clear the MCE bit before returning to the caller. If FALSE, the function returns to the caller with the codec in MCE mode.
Return Value	The function returns the actual sample rate (in Hz).
Example	<p>This example sets the codec sample rate to the value closest to 44 kHz.</p> <pre>int actualSampleRate; actualSampleRate= codec_change_sample_rate(44000,TRUE);</pre>

codec_dac_control

codec_dac_control

Control the Output DACs

Syntax

```
#include <codec.h>
int codec_dac_control(
    int    leftRightSel,
    float  dacAtten,
    int    mute );
```

Defined in

codec.c as a callable C routine

Description

The `codec_dac_control()` function controls the left and right output digital-to-analog converters (DACs) on the CS4231A codec.

- ☐ The *leftRightSel* parameter selects between the left and right DACs. Valid defined values are LEFT and RIGHT.
- ☐ The *dacAtten* parameter specifies the attenuation applied to the output of the selected DAC. Valid values are 0.0 dB–94.5 dB in 1.5-dB increments.
- ☐ The *mute* parameter, if TRUE (nonzero), mutes the selected line to the mixer.

Return Value

The function returns one of the following values:

OK	Operation succeeded
ERROR	Operation failed

Example

This example enables the right output DAC and sets its attenuation to 3 dB.

```
int status;

status = codec_dac_control( LEFT, 3.0, FALSE );
if (status == ERROR)
    return(ERROR);
```

codec_id

Return Codec ID, Codec Version, and Chip ID

Syntax

```
#include <codec.h>
int codec_id(
    int *pVersion,
    int *pChipId);
```

Defined in

codec.c as a callable C routine

Description

The `codec_id()` function returns the codec ID, codec version, and chip ID.

- ☐ The *pVersion* parameter is a pointer to the caller-declared integer in which to place the chip version.
- ☐ The *pChipId* parameter is a pointer to the caller-declared integer in which to place the chip ID.

Return Value

The function returns the codec ID.

Example

The following example returns the codec ID.

```
int version;
int chipId;
int codec_id;

codec_id = codec_id( &version, &chipId);
```

codec_init

Perform Required Codec Initialization and Default Configuration

Syntax

```
#include <codec.h>
int codec_init( void );
```

Defined in

codec.c as a callable C routine

Description

The `codec_init()` function initializes the CS4231A codec, sets default parameters for the codec, and calibrates it.

Return Value

The function returns one of the following values:

OK	Operation succeeded
ERROR	Operation failed

Example

The following example initializes the codec for use.

```
int status;

status= codec_init( );
if (status == ERROR)
    return(ERROR);
```

codec_interrupt_disable

codec_interrupt_disable

Disable Interrupt Mode

Syntax	<pre>#include <codec.h> int codec_interrupt_disable(void);</pre>
Defined in	codec.c as a callable C routine
Description	The codec_interrupt_disable() function disables interrupts from the CS4231A codec.
Return Value	None

codec_interrupt_enable

Enable Interrupts from CS4231A Codec

Syntax	<pre>#include <codec.h> void codec_interrupt_enable(void);</pre>
Defined in	codec.c as a callable C routine
Description	The codec_interrupt_enable() function enables interrupts from the CS4231A codec.
Return Value	None

codec_line_in_control

Control Left and Right Line Inputs

Syntax	<pre>#include <codec.h> int codec_line_in_control(int <i>leftRightSel</i>, float <i>mixGain</i>, int <i>mute</i>);</pre>
Defined in	codec.c as a callable C routine
Description	<p>The codec_line_in_control() function controls the left and right line inputs on the CS4231A codec.</p> <ul style="list-style-type: none"><input type="checkbox"/> The <i>leftRightSel</i> parameter selects between the left and right line inputs. Valid defined values are LEFT and RIGHT.<input type="checkbox"/> The <i>mixGain</i> parameter specifies the line input mixer gain setting. Valid values are –34.5 dB–12.0 dB in 1.5-dB increments.<input type="checkbox"/> The <i>mute</i> parameter, if TRUE (nonzero), mutes the selected line to the mixer.

Return Value The function returns one of the following values:

OK Operation succeeded
 ERROR Operation failed

Example This example enables the right line input mixer and sets its gain to 0 dB.

```
int status;
status = codec_line_in_control( RIGHT, 0.0, FALSE);
if (status == ERROR)
    return(ERROR);
```

codec_loopback_disable

Disable Loopback Mode

Syntax

```
#include <codec.h>
void codec_loopback_disable( void );
```

Defined in

codec.c as a callable C routine

Description

The codec_loopback_disable() function disables loopback mode on the CS4231A codec.

Return Value

None

codec_loopback_enable

Enable Loopback Mode

Syntax

```
#include <codec.h>
int codec_loopback_enable( void );
```

Defined in

codec.c as a callable C routine

Description

The codec_loopback_enable() function enables loopback mode on the CS4231A codec.

Return Value

None

codec_playback_disable

Disable Playback Mode

Syntax

```
#include <codec.h>
void codec_playback_disable( void );
```

Defined in

codec.c as a callable C routine

Description

The codec_playback_disable() function disables playback mode on the CS4231A codec.

Return Value

None

codec_playback_enable

codec_playback_enable

Enable Playback Mode

Syntax	<pre>#include <codec.h> void codec_playback_enable(void);</pre>
Defined in	codec.c as a callable C routine
Description	The codec_playback_enable() function enables playback mode on the CS4231A codec.
Return Value	None

codec_reset

Reset Codec

Syntax	<pre>#include <codec.h> void codec_reset(void);</pre>
Defined in	codec.c as a callable C routine
Description	The codec_reset() function resets the CS4231A codec by asserting then de-asserting the PWDN pin. All registers are configured to their POR values.
Return Value	The function returns one of the following values: OK Operation succeeded ERROR Operation failed

codec_serial_port_disable

Disable Serial Port Transfers on CS4231A Codec

Syntax	<pre>#include <codec.h> void codec_serial_port_disable(void);</pre>
Defined in	codec.c as a callable C routine
Description	The codec_serial_port_disable() function disables the serial port on the CS4231A codec.
Return Value	None

codec_serial_port_enable

Enable Serial Port Transfers on CS4231A Codec

Syntax	<pre>#include <codec.h> int CodecSerialPortEnable(void);</pre>
Defined in	codec.c as a callable C routine
Description	The codec_serial_port_enable() function enables the serial port on the CS4231A codec.
Return Value	None

codec_set_base

Set Base Codec Address Based on Memory Map and Endian Mode

Syntax	<pre>#include <codec.h> int codec_set_base(int mapMode, int littleEndian);</pre>				
Defined in	codec.c as a callable C routine				
Description	<p>The codec_set_base() function configures the codec library for use based on the map and endian mode selected. This function is called from evm_init() and therefore does not need to be called directly (see page 8-42 for a description of the evm_init() function).</p> <ul style="list-style-type: none"> <input type="checkbox"/> The <i>mapMode</i> parameter indicates the current 'C6x memory map, with valid values of 0 or 1. <input type="checkbox"/> The <i>littleEndian</i> parameter is TRUE if the 'C6x is in little-endian mode; otherwise, it is FALSE. 				
Return Value	<p>The function returns one of the following values:</p> <table> <tr> <td>OK</td><td>Operation succeeded</td></tr> <tr> <td>ERROR</td><td>Operation failed</td></tr> </table>	OK	Operation succeeded	ERROR	Operation failed
OK	Operation succeeded				
ERROR	Operation failed				

codec_timer

codec_timer

Use Internal Codec Timer

Syntax

```
#include <codec.h>
int codec_timer(
    int usec,
    void (*fp)(void) );
```

Defined in

codec.c as a callable C routine

Description

The `codec_timer()` function controls the internal CS4231A timer in either a polled (blocking) or interrupt driven (nonblocking) fashion.

- ☐ The *usec* parameter specifies the number of microseconds to wait.
- ☐ If *fp* is NULL, this function returns after the specified number of microseconds. If *fp* is not NULL, this function returns immediately and the interrupt service routine pointed to by *fp* is called after the specified number of microseconds.

Note:

The maximum time supported by this routine is 650 000 μ s (0.650 s). This is a limitation of the codec timer's 10- μ s clock period and 16-bit counter register.

Return Value

The function returns one of the following values:

OK	Operation succeeded
ERROR	Operation failed

Example

This example demonstrates using the codec timer in interrupt-driven mode. Global variable `timerExpired` indicates to the main program that the codec timer has expired and has generated an interrupt.

```
interrupt void codec_timerISR( void )
{
    timerExpired = TRUE;
    return;
}

int timerExpired;
int status;

timerExpired = FALSE;
status= codec_timer( 100, codec_timerISR );
if (status == ERROR)
    return(ERROR);
```

8.5 Board Support Library API

This section discusses the EVM board support library API. Included in this discussion are the functions defined that comprise the board library for the 'C6x EVM board. No public macros are defined for this module.

The following alphabetical listing includes all of the board support library API functions. Use this listing as a table of contents to the board support library API functions.

Function	Description	Page
cpu_freq	Return current CPU frequency in MHz	8-40
delay_msec	Delay CPU for specified number of milliseconds	8-40
delay_usec	Delay CPU for specified number of microseconds	8-40
evm_codec_disable	Disconnect codec from 'C6x McBSP	8-41
evm_codec_enable	Connect codec to 'C6x McBSP	8-41
evm_default_emif_init	Initialize EMIF for EVM board to default parameters	8-41
evm_emif_int	Initialize EMIF for EVM board to clock rate-tailored values	8-42
evm_init	Initialize EVM board	8-42
evm_led_disable	Disable selected EVM LED	8-43
evm_led_enable	Enable selected EVM LED	8-43
evm_nmi_disable	Externally disable NMI	8-43
evm_nmi_enable	Externally enable NMI	8-44
evm_nmi_sel	Select the host or codec as source for NMI	8-44

cpu_freq

cpu_freq

Return Current CPU Frequency in MHz

Syntax	<pre>#include <board.h> int cpu_freq(void);</pre>
Defined in	board.c as a callable C routine
Description	The <code>cpu_freq()</code> function determines the internal CPU clock frequency by reading the CLKMODE and CLKSEL bits in the DSPOPT register of the onboard complex programmable logic device (CPLD).
Return Value	CPU frequency in Mhz

delay_msec

Delay CPU for Indicated Number of Milliseconds

Syntax	<pre>#include <board.h> int delay_msec(unsigned short <i>numMsec</i>);</pre>				
Defined in	board.c as a callable C routine				
Description	<p>The <code>delay_msec()</code> function uses an available timer to delay the specified number of milliseconds before returning to the caller.</p> <p><input type="checkbox"/> The <i>numMsec</i> parameter is a value between 0 and 65 535. For delay values less than 1 ms, use the <code>delay_usec()</code> function.</p>				
Return Value	<p>The function returns one of the following values:</p> <table><tr><td>OK</td><td>Operation succeeded</td></tr><tr><td>ERROR</td><td>Operation failed</td></tr></table>	OK	Operation succeeded	ERROR	Operation failed
OK	Operation succeeded				
ERROR	Operation failed				

delay_usec

Delay CPU for Indicated Number of Microseconds

Syntax	<pre>#include <board.h> int delay_usec(unsigned short <i>numUsec</i>);</pre>				
Defined in	board.c as a callable C routine				
Description	<p>The <code>delay_usec()</code> function uses an available timer to delay the specified number of microseconds before returning to the caller.</p> <p><input type="checkbox"/> The <i>numUsec</i> parameter is a value between 0 and 65 535. For delay intervals greater than 65.5 milliseconds, use the <code>delay_msec()</code> function.</p>				
Return Value	<p>The function returns one of the following values:</p> <table><tr><td>OK</td><td>Operation succeeded</td></tr><tr><td>ERROR</td><td>Operation failed</td></tr></table>	OK	Operation succeeded	ERROR	Operation failed
OK	Operation succeeded				
ERROR	Operation failed				

evm_codec_disable

Disconnect Codec from 'C6x McBSP

Syntax

```
#include <board.h>
int evm_codec_disable( void );
```

Defined in

board.c as a callable C routine

Description

The evm_codec_disable() function disconnects the CS4231A codec from the 'C6x McBSP port 0, placing it in power-down mode. This function connects McBSP port 0 to the daughterboard expansion connector.

Return Value

The function returns one of the following values:

OK	Operation succeeded
ERROR	Operation failed

evm_codec_enable

Connect Codec to 'C6x McBSP

Syntax

```
#include <board.h>
int evm_codec_enable( void );
```

Defined in

board.c as a callable C routine

Description

The evm_codec_enable() function connects the CS4231A codec to the 'C6x McBSP port 0, removing it from power-down mode. This function disconnects McBSP port 0 from the daughterboard expansion connector.

Return Value

The function returns one of the following values:

OK	Operation succeeded
ERROR	Operation failed

evm_default_emif_init

Initialize EMIF for EVM Board to Default Parameters

Syntax

```
#include <board.h>
void evm_default_emif_init( void );
```

Defined in

board.c as a callable C routine

Description

The evm_default_emif_init() function initializes the EMIF to default values that will work at any available CPU frequency.

Return Value

None

evm_emif_init

evm_emif_init

Initialize EMIF for EVM Board

Syntax	<pre>#include <board.h> void evm_emif_init(void);</pre>
Defined in	board.c as a callable C routine
Description	The evm_emif_init() function initializes the EMIF to clock rate-tailored values.
Return Value	None

evm_init

Initialize EVM Board

Syntax	<pre>#include <board.h> int evm_init(void);</pre>
Defined in	board.c as a callable C routine
Description	The evm_init() function initializes the EVM board for use by configuring base address variables based upon the 'C6x memory map (MAP 0 or MAP 1) and endian mode selected, initializing the EMIF and enabling the NMI bit in the interrupt enable register. This function must be called before any other DSP support software routines.
Return Value	The function returns one of the following values: OK Operation succeeded ERROR Operation failed

Example This example initializes the EVM board for use.

```
int status;

status = evm_init( );
if (status == ERROR)
    return(ERROR);
```

evm_led_disable

Disable Selected EVM LED

Syntax	#include <board.h> int evm_led_disable (int <i>ledNumber</i>);
Defined in	board.c as a callable C routine
Description	The evm_led_disable() function extinguishes the selected LED on the EVM board. <input type="checkbox"/> Parameter <i>ledNumber</i> selects the LED to extinguish. Valid values are 0 (for LED0) or 1 (for LED1).
Return Value	The function returns one of the following values: OK Operation succeeded ERROR Operation failed

evm_led_enable

Enable Selected EVM LED

Syntax	#include <board.h> int evm_led_enable (int <i>ledNumber</i>);
Defined in	board.c as a callable C routine
Description	The evm_led_enable() function illuminates the selected LED on the EVM board. <input type="checkbox"/> The <i>ledNumber</i> parameter selects the LED to illuminate. Valid values are 0 (for LED0) or 1 (for LED1).
Return Value	The function returns one of the following values: OK Operation succeeded ERROR Operation failed

evm_nmi_disable

Externally Disable NMI

Syntax	#include <board.h> void evm_nmi_disable (void);
Defined in	board.c as a callable C routine
Description	The evm_nmi_disable() function externally disables the NMI source to the 'C6x by clearing the NMIE bit in the CNTL register of the EVM CPLD.
Return Value	None

evm_nmi_enable

evm_nmi_enable

Externally Enable NMI

Syntax	<pre>#include <board.h> void evm_nmi_enable(void);</pre>
Defined in	board.c as a callable C routine
Description	The evm_nmi_enable() function externally enables the NMI source to the 'C6x by setting the NMIEN bit in the CNTL register of the EVM CPLD.
Return Value	None

evm_nmi_sel

Select Source for NMI

Syntax	<pre>#include <board.h> void evm_nmi_sel(int <i>sel</i>);</pre>
Defined in	board.c as a callable C routine
Description	<p>The evm_nmi_sel() function selects the source for the external NMI to the 'C6x on the EVM board.</p> <p><input type="checkbox"/> If <i>sel</i> is 0, the host is selected as the source for the NMI; otherwise, the codec is selected as the source for the NMI.</p>
Return Value	None

8.6 DSP Support Software Examples

The following module provides examples of configuring and controlling the McBSP and audio codec. The board support library is also used in the examples.

Example 8–2. McBSP, Audio Codec, and Board Support Sample Code

(a) codec_ex.c file

```

/*****
/*  <CODEC_EX.C> - Example code for CODEC and McBSP use.

TMS320C6x EVM Connector Pinouts

This appendix contains the pinout information for each connector on the TMS320C6x EVM.

Topic	Page
A.1 TMS320C6x EVM Connector Summary	A-2
A.2 Stereo Microphone Input Jack	A-2
A.3 Stereo Line Input Jack	A-3
A.4 Stereo Line Output Jack	A-3
A.5 CPLD ISP Header	A-4
A.6 TMS320C6x JTAG Emulation Header	A-5
A.7 Expansion Memory Interface Connector	A-6
A.8 Expansion Peripheral Interface Connector	A-7
A.9 External Power Connector	A-8
A.10 DSP Fan Power Connector	A-8
A.11 PCI Local Bus Connector	A-9

A.1 TMS320C6x EVM Connector Summary

There are ten connectors on the 'C6x EVM, as shown in Table A–1. The J4 CPLD ISP connector is for factory use and is not installed.

Table A–1. TMS320C6x EVM Connectors Summary

Connector	No. of Pins	Description	Type	See Page
J1	3	Stereo microphone input	3.5-mm audio jack	A-2
J2	3	Stereo line input	3.5-mm audio jack	A-3
J3	3	Stereo line output	3.5-mm audio jack	A-3
J4	10	CPLD ISP header	2 × 5 pin, 0.1 in.	A-4
J5	14	'C6x JTAG emulation header	2 × 7 pin, 0.1 in.	A-5
J6	80	Expansion memory interface	2 × 40 pos, 0.050-in. SMT	A-6
J7	80	Expansion peripheral interface	2 × 40 pos., 0.050-in. SMT	A-7
J8	4	External power	Molex disk drive, right-angle	A-8
J9	2	DSP fan power	Molex 1.25-mm, right-angle	A-8
P1	124	PCI local bus	Edge connector	A-9

A.2 Stereo Microphone Input Jack

Connector J1 supports a stereo microphone input. If a mono microphone is used, then the input left (tip) channel is only used. Both microphone input channels provide a voltage bias for electret microphones. The microphone input is the top 3.5-mm jack on the EVM's mounting bracket (adjacent to the status LED).

Table A–2. Stereo Microphone Input Connector J1 Pinout

J1 Pin	Signal Name	Description	Type
TIP	MIC_L	Microphone left input channel	I
RING	MIC_R	Microphone right input channel	I
SLEEVE	AGND	Audio ground	–

A.3 Stereo Line Input Jack

Connector J2 supports a stereo line input. The line input audio connector is the middle 3.5-mm jack on the EVM's mounting bracket.

Table A–3. Stereo Line Input Connector J2 Pinout

J2 Pin	Signal Name	Description	Type
TIP	LI_L	Line input left channel	I
RING	LI_R	Line input right channel	I
SLEEVE	AGND	Audio ground	–

A.4 Stereo Line Output Jack

Connector J3 supports a stereo line input. The line output audio connector is the bottom 3.5-mm jack on the EVM's mounting bracket.

Table A–4. Stereo Line Output Connector J3 Pinout

J3 Pin	Signal Name	Description	Type
TIP	LO_L	Line output left channel	O
RING	LO_R	Line output right channel	O
SLEEVE	AGND	Audio ground	–

A.5 CPLD ISP Header

Connector J4 provides the CPLD's JTAG in-system programming port that allows the EVM's onboard logic to be reprogrammed. This connector is a 10-pin header (two rows of five pins) with connections shown in Table A–5 to communicate with the Altera ByteBlaster™ parallel port cable. The 10-pin female connector on the cable is connected to the male header on the EVM. The pins have 0.025-inch square posts with 0.100-inch spacing.

The J4 CPLD ISP connector is for factory use and is not installed.

Table A–5. CPLD ISP J4 Pinout

J4 Pin No.	Signal Name	Description	Type
1	TCK	Test clock	I
2	GND	Ground	–
3	TDO	Test data output	O
4	VCC	5 V	O
5	TMS	Test mode select	I
6	NC	–	–
7	NC	–	–
8	NC	–	–
9	TDI	Test data input	I
10	GND	–	–

A.6 TMS320C6x JTAG Emulation Header

Connector J5 provides the 'C6201's emulation port based on the IEEE 1149.1 standard. This connector is a 14-pin header (two rows of seven pins) with connections shown in Table A–6 to communicate with an XDS510 emulator. Pin 6 is used for keying to ensure a proper connection.

Table A–6. TMS320C6x JTAG Emulation Header J5 Pinout

J5 Pin No.	Signal Name	Description	Type
1	TMS	Test mode select	I
2	$\overline{\text{TRST}}$	Test reset	I
3	TDI	Test data input	I
4	GND	Ground	–
5	PD (V _{CC})	Presence detect. Indicates that the emulation cable is connected and the target is powered up. PD is tied to 3.3 V on the EVM.	O
6	KEY	Not used. This pin is cut off on the J5 header. This pin is filled in on the XDS510 connector.	–
7	TDO	Test data out	O
8	GND	Ground	–
9	TCK_RET	Test clock return. Test clock input to the emulator.	O
10	GND	Ground	–
11	TCK	Test clock. TCK is a 10.368-MHz clock source from the emulation cable pod.	I
12	GND	Ground	–
13	EMU0	Emulation pin 0	I/O
14	EMU1	Emulation pin 1	I/O

A.7 Expansion Memory Interface Connector

Connector J6 provides the 'C6201 asynchronous expansion memory interface signals to a daughterboard that can provide additional memory and memory-mapped devices.

Table A–7. Expansion Memory Interface J6 Connector Pinout

J6 Pin No.	Signal Name	Type	J6 Pin No.	Signal Name	Type
1	5 V	O	2	5 V	O
3	XA21	O	4	XA20	O
5	XA19	O	6	XA18	O
7	XA17	O	8	XA16	O
9	XA15	O	10	XA14	O
11	GND	–	12	GND	–
13	XA13	O	14	XA12	O

A.9 External Power Connector

Connector J8 enables the 'C6x EVM to be connected to an external power supply during stand-alone operation.

Table A–9. External Power J8 Connector Pinout

J8 Pin No.	Signal Name	Description	Type
1	12	12 V _{DC} at 500 mA	I
2	–12	–12 V _{DC} at 100 mA	I
3	GND	Ground	–
4	5	5 V _{DC} at 4 A	I

A.10 DSP Fan Power Connector

Connector J9 provides power to the DSP cooling fan. This 2-pin connector provides 5 V at 100 mA to the fan.

Table A–10. DSP Fan Power J9 Connector Pinout

J9 Pin No.	Signal Name	Description	Type
1	GND	Ground	–
2	PWR	5 V _{DC} at 100 mA	O

A.11 PCI Local Bus Connector

Connector P1 provides the PCI local bus to the 'C6x EVM.

Table A–11. PCI Local Bus P1 Connector Pinout

TMS320C6x EVM DIP Switches

There are 12 dual in-line package (DIP) switches (SW2-1 through SW2-12) on the TMS320C6x EVM, as shown in Table B–1. Table B–2 lists the valid boot mode selections for the EVM. The highlighted (boldface) items in both tables denote the factory default switch settings.

Table B–1. TMS320C6x EVM User Options DIP Switches

Switch Number	Name	OFF Selection	ON Selection
SW2-1– SW2-5	BOOTMODE4– BOOTMODE0	See Table B–2	See Table B–2
SW2-6	CLKMODE	Multiply-by-1 mode (PLL bypassed)	Multiply-by-4 mode
SW2-7	CLKSEL	OSC B (40 MHz)	OSC A (33.25 MHz)
SW2-8	ENDIAN	Big endian	Little endian
SW2-9	JTAGSEL	Internal (TBC)	External (XDS510)
SW2-10	USER2	1	0
SW2-11	USER1	1	0
SW2-12	USER0	1	0

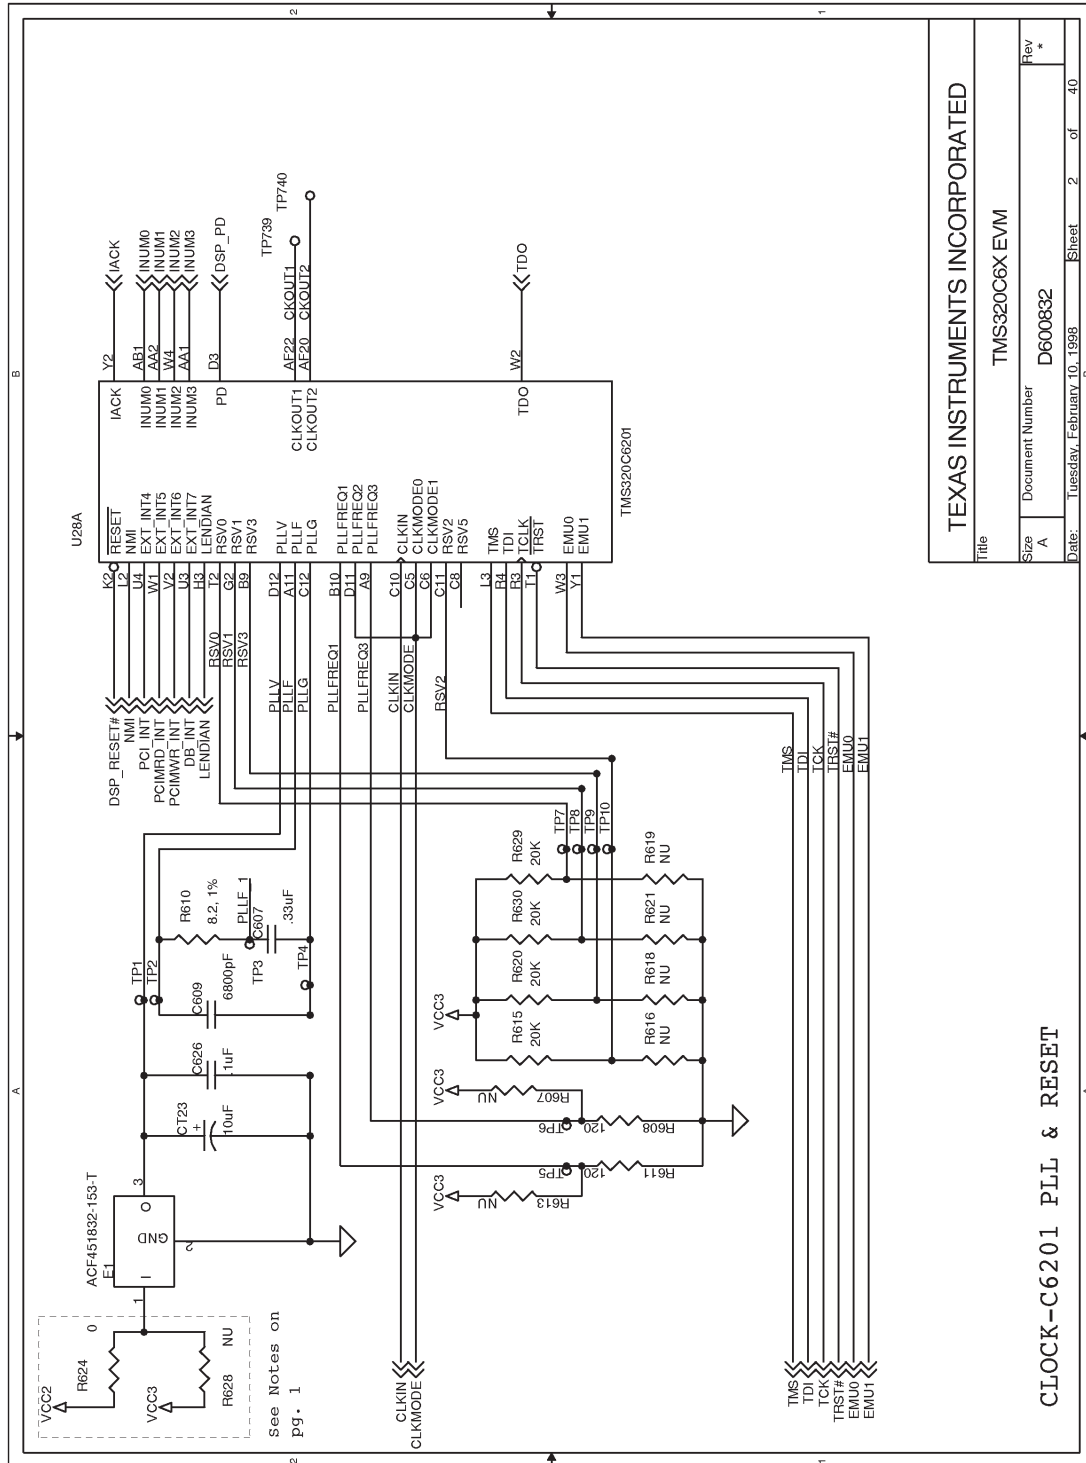

Table B–2. TMS320C6x EVM Boot Mode DIP Switches

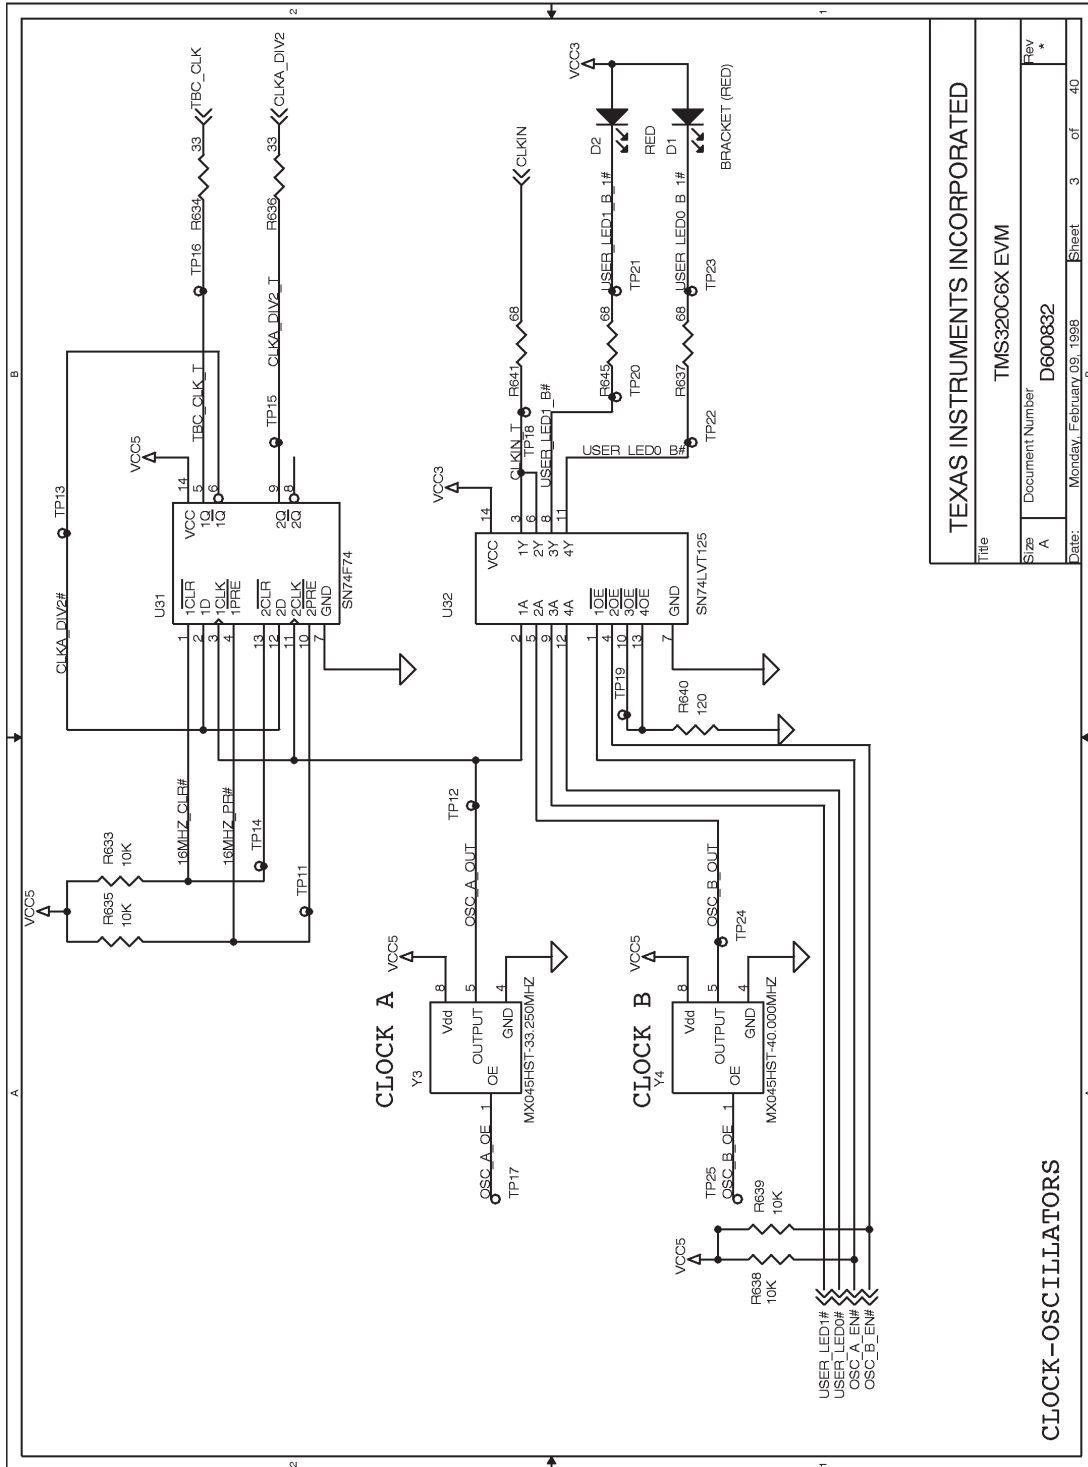

Boot Mode	Map	Memory at Address 0	BM4 (SW2-1)	BM3 (SW2-2)	BM2 (SW2-3)	BM1 (SW2-4)	BM0 (SW2-5)
None	MAP 0	1/2-rate SBSRAM	ON	ON	ON	OFF	OFF
None	MAP 0	1×-rate SBSRAM	ON	ON	OFF	ON	ON
None	MAP 1	Internal	ON	ON	OFF	ON	OFF
HPI	MAP 0	External	ON	ON	OFF	OFF	ON
HPI	MAP 1	Internal	ON	ON	OFF	OFF	OFF

TMS320C6x EVM Schematics

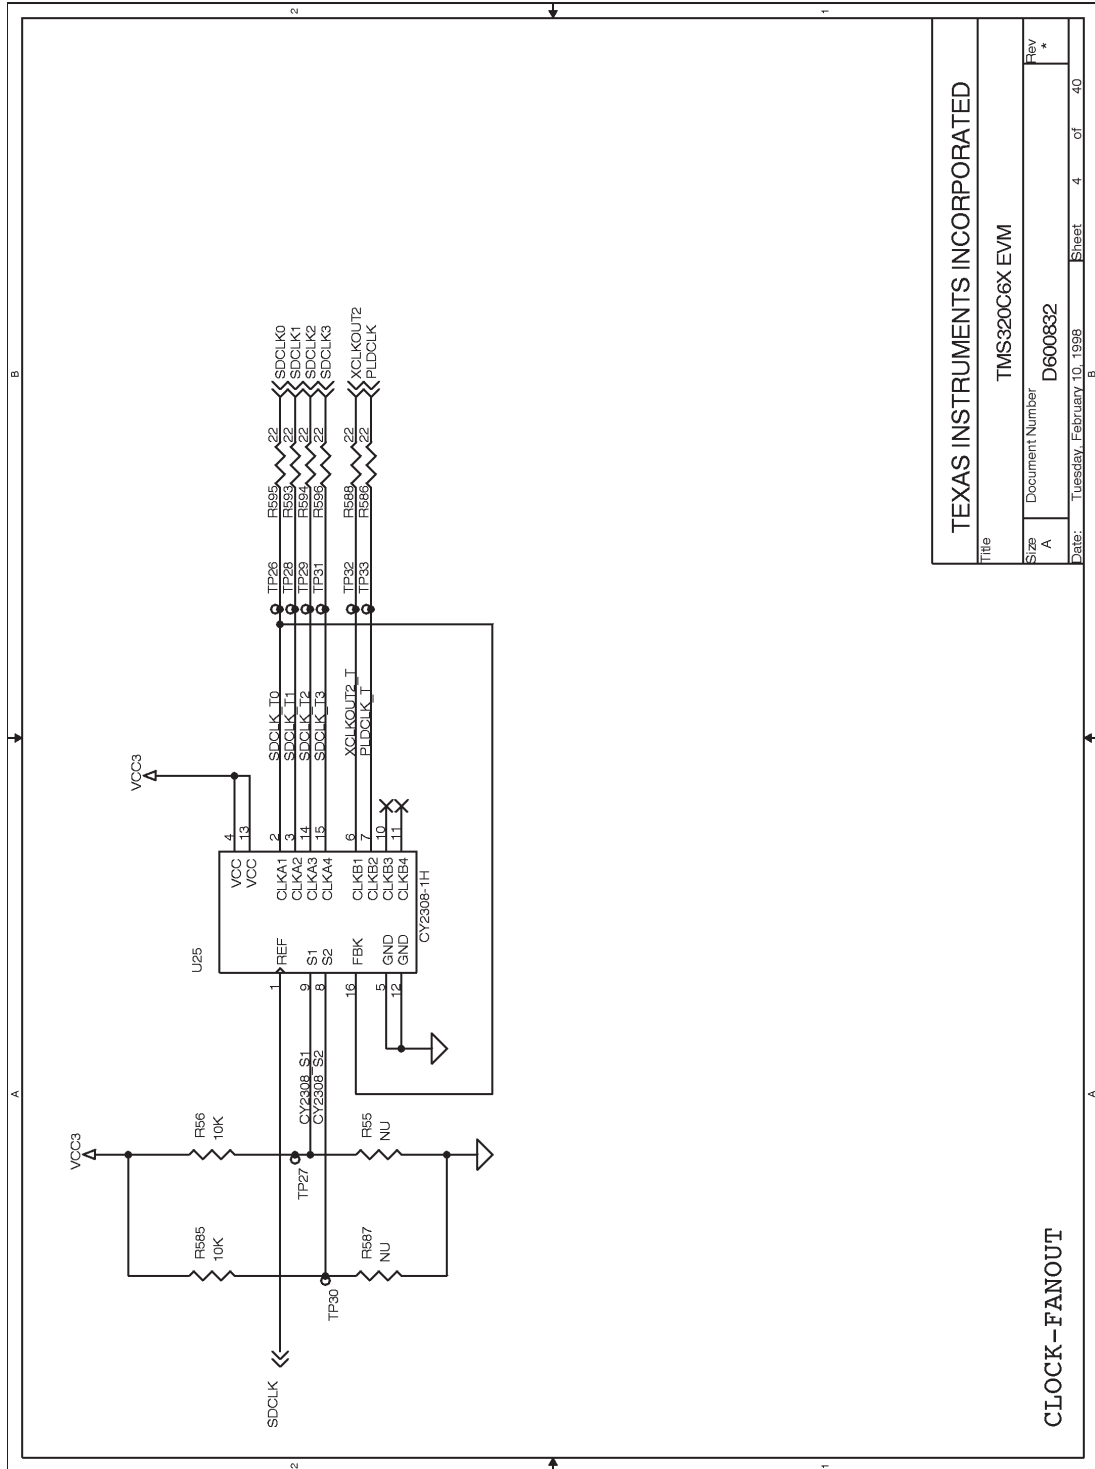

This appendix contains the schematics for the TMS320C6x EVM.

TMS320C6x EVM CPLD Equations

This appendix provides the complex programmable logic device (CPLD) equations. The CPLD, which is the only programmable logic device on the 'C6x EVM, is designated as U12 on the board.

Topic	Page
D.1 Overview of the EVM CPLD	D-2
D.2 EVM CPLD Equations	D-8

D.1 Overview of the EVM CPLD

The CPLD is an Altera EPM7256SQC208–10 device that has a 208-pin PQFP package. A summary of the pin allocation is shown in Table D–1.

Table D–1. TMS320C6x EVM CPLD Pin Summary

Pin Type	Number of Pins
Inputs	64
Bidirectional	16
Outputs	60
Unused	20
JTAG	4
5 V	4
3.3 V	10
GND	14
No connects	16
Total pins	208

The EPM7256SQC208–10 CPLD provides 5000 usable gates, of which approximately 75% are used in this design. The device contains 256 macro-cells arranged in 16 logic array blocks. The maximum pin-to-pin delay is 10.5 ns. The CPLD uses 5 V for internal operation and 3.3 V for its I/O buffers. It can interface to both 3.3- and 5-V devices.

The CPLD was designed using Synario™ ABEL™ version 6.5 and Altera MAX+ PLUS™ II version 8.1. Synario was used to enter the design in the ABEL hardware design language, and MAX+ PLUS II was used for design compilation, simulation, and programming file generation.

The CPLD's ABEL source files are modular with a top-level module and six low-level modules as shown in Figure D–1. These seven source files are provided in section D.2, *EVM CPLD Equations*.

Figure D–1. TMS320C6x EVM CPLD Source Files

Table D–2 provides the CPLD pin definitions in numerical pin order. Table D–3 provides the CPLD pin definitions in sequential alphabetical order.

TITLE 'TMS320C6x EVM Top-Level Programmable Logic'

"DWG NAME TMS320C6x Evaluation Module (EVM)

"ASSY# D600830-0001

"PAL # U12, 830*

"PAL TYPE Altera EPM7256SQC208-10 (256-Macrocells, 10-ns, 208-PQFP)

"COMPANY Texas Instruments Incorporated / DNA Enterprises, Inc.

"ENGR Brian G. Carlson

"DATE 02/04/98

"TOOLS Synario ABEL 6.5 / Altera Max Plus II 8.1

"DESCRIPTION

"This is the top-level module for the TMS320C6x EVM's CPLD. It
"defines the CPLD's pin names, the low-level modules that are used,
"and all inter-module connections. All CPLD registers that are
"memory-mapped into the PCI and DSP memory spaces are implemented
"in this top-level module. The ability to float all CPLD output
"pins to support in-circuit testing is also implemented in this module.

"REVISIONS

" 03/11/98 - Changed CPLD_REV to 2

"

" 03/05/98 - Changed CPLD_REV to 1

TITLE 'TMS320C62x EVM Reset Logic'

"DWG NAME   TMS320C6x Evaluation Module (EVM)
"ASSY#      D600830-0001
"PAL #      U12, 830*
"PAL TYPE   Altera EPM7256SQC208-10 (256-Macrocells, 10-ns, 208-PQFP)
"COMPANY    Texas Instruments Incorporated / DNA Enterprises, Inc.
"ENGR       Brian G. Carlson
"DATE       02/04/98
"TOOLS      Synario ABEL 6.5 / Altera Max Plus II 8.1

"DESCRIPTION
  "This module controls the various types of reset signals that
  "are used on the 'C6x EVM board.  Signals are generated that
  "reset the board, DSP, JTAG TBC and external daughterboard
  "independently.  All resets are asserted upon power-up, when
  "the manual reset pushbutton is pressed and when the board is
  "in a software board reset under control of the host.  The
  "host can reset the board, DSP and TBC.  The DSP can reset the
  "external daughterboard.

"INPUTS
  BRD_RST_   pin;    "Reset from voltage supervisor
  SW_RST_    pin;    "Reset from push button switch
  VCC2BAD_   pin;    "VCC bad from the voltage supervisor
  PCI_RST_   pin;    "Reset from PCI controller
  PCI_DET_   pin;    "PCI detection (when 0)
  xreset     pin;    "Ext. reset from DSP-mapped register
  dsprst     pin;    "DSP reset from PCI-mapped register
  tbcrst     pin;    "TBC reset from PCI-mapped register

"OUTPUTS
  MAN_RST_   pin;    "Manual reset to voltage supervisor
  DSP_RST_   pin;    "DSP reset
  TBC_RST_   pin;    "TBC reset
  EXT_RST_   pin;    "Daughter board reset

"Constants
  h,1,x = 1, 0, .X. ;

```

Equations

```

"-----
"Reset Control

"Manual Reset - Asserted when PCI or switch reset.
"NOTE: SW_RST_ will bounce during reset pushbutton use, but
"       the MAX708 voltage supervisor effectively provides a
"       debounce by holding the reset line active for about
"       140 ns after the last low value.
!MAN_RST_ = (!PCI_RST_ & !PCI_DET_) # !SW_RST_;

"DSP Reset - Asserted when DSP software reset is asserted,
"           DSP core voltage bad or board reset.
"           Allows host to control DSP reset for HPI booting.
!DSP_RST_ = dsprst # !VCC2BAD_ # !BRD_RST_;

"TBC Reset - Asserted upon host assertion or board reset.
!TBC_RST_ = tbcrst # !BRD_RST_;

"External (Daughter Board) Reset - Asserted upon DSP firmware
"           assertion or board reset.
!EXT_RST_ = xreset # !BRD_RST_;

END

```

```

"DESCRIPTION
  "This module provides multiplexing between hardware DIP switch
  "user options and software switches that are controlled by the
  "host software.  The CPLD defaults to the use of the DIP switch
  "settings at power-up and board reset.  The multiplexer is
  "controlled by the host software using the PCI memory-mapped
  "CPLD SWBOOT register's SWSEL bit.  When SWSEL is 0, the DIP
  "switches are used, and when SWSEL is 1, the software switches
  "are used.

TITLE 'TMS320C6x EVM Memory Decode Logic'

"DWG NAME TMS320C6x Evaluation Module (EVM)

"ASSY# D600830-0001

"PAL # U12, 830*

"PAL TYPE Altera EPM7256SQC208-10 (256-Macrocells, 10-ns, 208-PQFP)

"COMPANY Texas Instruments Incorporated / DNA Enterprises, Inc.

"ENGR Brian G. Carlson

"DATE 02/04/98

"TOOLS Synario ABEL 6.5 / Altera Max Plus II 8.1

"DESCRIPTION

"This module provides DSP EMIF memory decoding to control
 "asynchronous memory accesses to the CE1 memory space. The devices
 "in the CE1 memory space include CPLD registers, the PCI controller,
 "the audio codec and the expansion memory (daughterboard). Decode
 "logic controls data bus transceivers that connect the DSP's EMIF
 "data bus to the peripheral, PCI add-on and external daughterboard
 "data busses. The asynchronous ARE_ and AWE_ EMIF signals are
 "synchronized for use by the PCI controller state machine. Asynchronous
 "memory access ready (RDY) generation is implemented for each type
 "of device access in the CE1 space. Audio codec chip select and
 "read/write strobes are controlled with a state machine to ensure
 "proper single-cycle and back-to-back access timing.

"REVISIONS

" 03/05/98 - Modified DSP EMIF ready logic to provide ARDY for invalid
 " async accesses to non-CE1 memory spaces to prevent the
 " EMIF from locking-up at power-up when invalid code is
 " executed in the no-boot mode. Also, extended codec_rdy
 " flag assertion to maintain ARDY assertion until ARE- or
 " AWE- is deasserted to support any strobe period >= 3
 " CLKOUT1 clocks.

"DESCRIPTION
  "This module controls interrupts to the host (via the PCI controller) and the 'C6201 DSP.
  "The DSP host interrupt and the JTAG TBC interrupt can be used to interrupt the host.
  "This module implements falling edge detectors to determine when these source interrupts
  "occur to force a PCI mailbox interrupt in the S5933 PCI controller which causes an
  "INTA# host interrupt. Logic is included to implement a DSP NMI interrupt source
  "multiplexer that selects between the host and codec-controlled NMI interrupts. The
  "PCI controller add-on IRQ# interrupt is passed to the DSP via its EXT_INT4 input.
  "Additionally, PCI bus master read (EXT_INT5) and (EXT_INT6) interrupts are generated
  "by state machines implemented in this module that monitor the PCI controller's FIFO
  "RDEEMPTY and WRFULL flags to determine when data can be transferred between the
  "PCI controller and the DSP memory space. These interrupts can be used by the DSP to
  "trigger an interrupt service routine, or more typically, be used to trigger background DMA
  "data transfers. Optionally, DSP software could even poll the state of these interrupts, or the
  "FIFO flags themselves, to control the data transfers.

TITLE 'TMS320C6x EVM PCI Controller Logic'

"DWG NAME TMS320C6x Evaluation Module (EVM)

"ASSY# D600830-0001

"PAL # U12, 830*

"PAL TYPE Altera EPM7256SQC208-10 (256-Macrocells, 10-ns, 208-PQFP)

"COMPANY Texas Instruments Incorporated / DNA Enterprises, Inc.

"ENGR Brian G. Carlson

"DATE 02/04/98

"TOOLS Synario ABEL 6.5 / Altera Max Plus II 8.1

"DESCRIPTION

"This module controls the slave (target) interface between the
"PCI controller and the JTAG TBC, DSP HPI and CPLD PCI registers,
"as well as DSP EMIF accesses to the PCI controller which include
"PCI bus master read/write transfers. This module consists of a
"large state machine that monitors and controls all the signals
"that are required to transfer data between the PCI controller and
"the devices on the 'C6x EVM board. The PCI controller handles
"all the PCI bus transactions, so the CPLD is not involved at all
"on the actual PCI bus. The CPLD only manages the transfers with
"the PCI controller's add-on bus. The state machine in this module
"runs from the buffered PCI clock which has a maximum frequency of
"33 MHz.

```

"REVISIONS
" 03/11/98 - Modified HPI write timing to work with new 'C6201 data
"           sheet timing which samples HBE[1:0] on the rising edge of
"           HSTROBE-, instead of falling edge. This was not a problem
"           with Rev. 2.0 silicon. However, the BE2- and BE3- signals
"           do not get generated with Rev. 2.1 silicon without this
"           change.
"
" 03/05/98 - Modified DSP EMIF ready logic for PCI controller registers
"           and FIFO accesses to hold ARDY active until ARE- or AWE-
"           is deasserted. This allows the PCI controller to be
"           accessed with any strobe period >= 3 CLKOUT1 clocks.

TMS320C6x EVM PCI Configuration EEPROM

This appendix documents the EEPROM used on the 'C6x EVM to initialize the AMCC S5933 peripheral component interconnect (PCI) controller's configuration space registers.

The S5933 PCI controller provides the configuration registers required to support PCI's plug-and-play capability. The initialization of these registers is performed upon power up and system reset by the S5933, which clocks serial data in from the EEPROM using a two-wire, bidirectional data transfer. This automatic register initialization is performed since the S5933's SNV pin is pulled up on the EVM to indicate that a serial nonvolatile memory device is present.

Table E–1 summarizes the contents of the 1K-byte EEPROM. Multibyte default values are stored in least-significant-byte to most-significant-byte (little-endian) order. The 64-byte configuration information is stored in the EEPROM locations 0x40 to 0x7F. Locations 0x00 to 0x3F are reserved for future use by Texas Instruments. Locations 0x80 to 0x3FF are available for user-defined, nonvolatile storage that is accessible by both host and DSP software.

Table E–1. PCI Configuration EEPROM Summary

EEPROM Offset	Register Initialized	Description	Value	Selection
0x00–0x3F	–	Reserved for future use	All 0x00	–
0x40–0x41	VID	Vendor identification	0x104C	TI
0x42–0x043	DID	Device identification	0x1002	EVM
0x44	–	Reserved	0x00	–
0x45	–	FIFO configuration	0xE1	PCI, async
0x46–0x47	–	Reserved	0x0000	–
0x48	RID	Revision identification register	0x00	Rev. 0 board
0x49–0x4B	CLCD	Class code register	0x0B4000	Coprocessor
0x4C	–	Reserved	0x00	–
0x4D	LAT	Master latency timer	0xF8	248 clocks
0x4E	HDR	Header type	0x00	One function
0x4F	BIST	Built-in self test	0x00	No BIST
0x50–0x53	BAR0	Base address register 0	0x10E8FFC0	16 DWORDs
0x54–0x57	BAR1	Base address register 1	0xFFFFFFFF80	32 DWORDs
0x58–0x5B	BAR2	Base address register 2	0xFFFFFFFF80	32 DWORDs
0x5C–0x5F	BAR3	Base address register 3	0xBFFFFFFF0	4 DWORDs
0x60–0x63	BAR4	Base address register 4	0xBFFC0000	64K DWORDs
0x64–0x67	BAR5	Base address register 5	0x00000000	Not used
0x68–0x6F	–	Reserved	All 0x00	–
0x70–0x73	EXROM	Expansion ROM base address	0x00000000	No ROM
0x74–0x7B	–	Reserved	All 0x00	–
0x7C	INTLN	Interrupt line	0xFF	Autoassign IRQ
0x7D	INTPIN	Interrupt pin	0x01	INTA#
0x7E	MINGNT	Minimum grant	0x00	No min grant
0x7F	MAXLAT	Maximum latency	0x00	No max latency
0x80–0x3FF†	–	Not used (available)	All 0x00	–

† These address offsets are available for general-purpose use. This is a total of 896 bytes.

Troubleshooting

This chapter lists common error conditions and explains how to correct them.

If you experience difficulty when installing or using the TMS320C6x EVM board, follow these guidelines before seeking technical support:

- ☐ Read the topic in this chapter that relates to the problem.
- ☐ Read the portion of this manual that discusses the procedures you followed or tasks you performed before the problem occurred.

The following error conditions may occur during or after installation of the EVM and its software. To correct the problem, take the action specified here for that message or condition. If the problem persists, seek technical support.

At least one service driver failed during system startup

<i>Description</i>	<p>This message indicates one of the following problems:</p> <ul style="list-style-type: none"><input type="checkbox"/> The drivers were installed incorrectly.<input type="checkbox"/> The motherboard peripheral component interface (PCI) configuration is incorrect.
<i>Action</i>	<p>Make sure the EVM is fully seated in the PCI connector. If the EVM is not fully seated, power down the PC and correct the problem. Rerun the setup.exe program on the CD-ROM to reinstall the EVM support software.</p> <p>Make sure that the PCI BIOS autoconfiguration is enabled. (Ask your system administrator.) Enable the PCI BIOS autoconfiguration, if necessary, and rerun the setup.exe program on the CD-ROM to reinstall the EVM support software.</p>

Audio codec failure

<i>Description</i>	<p>If the DSP software does not configure the 'C6x EVM hardware as required or communicate with the audio codec properly, the audio codec may not operate. In this situation, no audio is output from the audio codec, and no audio samples are received by the DSP.</p> <p>This problem should not occur if the included audio codec library is used to control the audio codec, because it configures the hardware and communicates with the codec as required.</p>
<i>Action</i>	<p>First, verify that the McBSP0 multiplexer is configured for a serial connection between the DSP and the audio codec. By default, McBSP0 is connected to the expansion peripheral interface, not the audio codec. Therefore, the SP0SEL bit in the DSP's memory-mapped CPLD CNTL register must be set to 1 to connect the DSP's serial port to the audio codec. When the audio codec is not connected, all reads from the audio codec's parallel bus via the EMIF return 0x80. This is an indication that the audio codec is busy or in its power-down state.</p>

If the DSP's McBSP0 is connected to the audio codec and the audio codec still does not work, verify that the DSP's CE1 memory space control register mapped at address 0x01800004 is configured for a read and write strobe periods of 3 CLKOUT1 cycles. See Table 4–4 on page 4-16 for CE1 control register values for the four possible CLKOUT1 speeds.

If the audio codec still does not work, use the audio codec library functions provided with the EVM since they have been fully tested and work at all CPU clock rates.

Could not open handle

<i>Description</i>	<p>If an EVM application displays a message similar to:</p> <p>**Error: could not open handle to \\.\Evm6xDev0 (2)**</p> <p>then the EVM board or its Windows driver is not installed correctly.</p>
<i>Action</i>	<p>Make sure that the EVM is fully seated in the PCI connector. If the EVM is not fully seated, power down the PC and correct the problem.</p> <p>If the EVM is fully seated, reboot the PC and check if the problem is solved. If you move an EVM board from one PCI slot to another or install it into a PCI slot that previously held an EVM board, Windows 95 may not prompt you to reboot the PC, which is required for proper driver operation. By simply rebooting the machine, the driver may be configured properly, and the problem may be solved.</p> <p>If the problem persists, rerun the setup.exe program on the 'C6x EVM support software CD-ROM to reinstall the EVM support software.</p> <p>If you continue to receive the error message, make sure that the PCI BIOS autoconfiguration is enabled. Enable the PCI BIOS autoconfigure, if necessary, and rerun the setup program on the CD-ROM to reinstall the EVM support software.</p> <p>In some systems, it may be necessary to reboot the computer two times after the support software is installed.</p>

Driver not loaded

Description The most common reason the EVM device driver does not load once the drivers and software files are properly installed is that your PC has an improper motherboard BIOS configuration.

Action Ask your system administrator to verify the following items:

- ☐ PCI interrupts are enabled and one is allocated to the EVM.
- ☐ PCI autoconfiguration is enabled.
- ☐ The motherboard/chipset supports the *PCI Local Bus Specification Revision 2.1*. Motherboards with chipsets supporting earlier versions do not correctly configure the EVM, and, therefore, the device driver will not load.

If a correction is made, you must rerun the setup.exe program to reinstall the EVM support software.

Interrupt (IRQ) conflict

Description If an EVM application locks up the PC or causes a Windows exception screen to be displayed, there is potentially an interrupt conflict between the EVM and another board in the system. The EVM's plug-and-play functionality provides problem-free interrupt assignments in most cases, but conflicts can arise.

Action The PC's plug-and-play BIOS automatically determines the appropriate interrupt assignment for each board on the PCI bus. Sometimes this is a difficult task for a computer to do without human intervention. As boards are added and removed, the BIOS can get confused and may end up making inappropriate decisions that can result in an interrupt being shared between the EVM and another board. The EVM's support software handles shared PCI interrupts properly. However, other boards' drivers may not be able to share interrupts.

You can use several methods to resolve an interrupt conflict:

- ☐ The easiest method that works in most cases is to simply move the EVM to another PCI slot. The system's plug-and-play BIOS usually assigns a different interrupt to the board when you move it. If the new assignment does not conflict with any other boards, the problem is solved.

- ☐ If moving the EVM to another PCI slot does not solve the problem or there is not another full-size PCI slot available, either remove the other board or have its interrupt physically changed to an unused IRQ. It is recommended that any unused IDE and USB interfaces in the system be disabled in the system BIOS to free up interrupts. If your system BIOS allows you to assign interrupts to specific PCI slots, the problem can also be resolved in this manner by selecting an unused interrupt manually.
- ☐ If your system does not appear to have an interrupt conflict or its BIOS does not support user-configurable interrupts to resolve the conflict, remove and reinstall all of the PCI boards one at a time; reboot between each addition. This procedure allows the system BIOS to start from scratch and reallocate interrupts for each board.
- ☐ It may be helpful to check your system's current interrupt assignments to determine exactly what device is conflicting with the EVM's interrupt.

To observe the interrupt assignments, perform the following steps in the applicable operating system:

■ Windows 95

- 1) From the Windows 95 desktop, right click on the My Computer icon.
- 2) Select the Properties menu item.
- 3) Select the Device Manager tab.
- 4) Double click on the Computer menu item.
- 5) Select the Interrupt request (IRQ) radio button in the View Resources tab to display the interrupt assignments.

■ Windows NT

- 1) Select the Run... menu item from the Windows NT Start menu.
- 2) At the Open: prompt type **winmsd** and press Enter.
- 3) Select the Resources tab of the Windows NT Diagnostics window.
- 4) Click on the IRQ button to display the interrupt assignments.

PCI bus mastering failure

<i>Description</i>	To use the EVM's PCI bus mastering capability, the EVM must be installed in a PCI slot that supports bus mastering. Not all PCI slots allow bus mastering.
<i>Action</i>	Check your system's documentation or contact your computer's manufacturer to make sure that you are installing the EVM into a PCI slot that supports bus mastering.

Source debugger cannot be started successfully

<i>Description</i>	If a message similar to the following one displays in a pop-up error window, the C source debugger application cannot be started successfully:
--------------------	--

Function: fatal_msg()
<pre> Init error -1 CANNOT INITIALIZE THE EVM!! - Check I/O configuration [OK]</pre>

After you click on the [OK] button, the debugger command window displays a red error message as follows:

— Processor access timeout at 00000000

This condition occurs when the debugger is started when the DSP is running invalid code, which almost always is true the first time the debugger is invoked because the EVM does not have nonvolatile program memory storage. When the DSP executes invalid code, the debugger may not be able to communicate with the DSP via its JTAG interface. If this occurs, the debugger displays the identified error message and exits.

<i>Action</i>	<p>If you are using the 'C6x EVM debugger with the EVM board installed in a PCI slot, invoke the evm6xrst command with the -i1 option. This prevents the problem by initializing the DSP's memory at address 0 to known code. The evm6xrst command is described in section 6.3, <i>EVM Board Configuration</i>, on page 6-6.</p> <p>If you are using the 'C6x EVM in a stand-alone configuration with an external XDS510 or XDS510WS emulator and the standard TI 'C6x source debugger, press the EVM's manual reset pushbutton after the debugger displays the blue Texas Instruments banner in the command window and before the error message is displayed to successfully start the debugger.</p>
---------------	---

You have insufficient privilege to add or remove a driver

<i>Description</i>	If you did not log onto Windows NT as a user with administrative privileges, this message appears.
<i>Action</i>	Log onto Windows NT as a user with administrative privileges and then rerun the setup.exe program to reinstall the EVM support software.

Glossary

A

A/D: See *analog-to-digital*.

adaptive differential pulse code modulation (ADPCM): A speech coding method that calculates the difference between two consecutive speech samples and encodes it using an adaptive filter to transmit at a lower rate than the standard 64-kbps pulse code modulation technique.

ADC: See *analog-to-digital converter*.

address: The logical location of program code or data stored in memory.

administrative privileges: Authority to set software and hardware access; includes access and privileges to install, manage, and maintain system and application software and directories on a network server or individual computer systems.

ADPCM: See *adaptive differential pulse code modulation*.

A-Law companding: See *compress and expand (compand)*.

ALU: See *arithmetic logic unit*.

American National Standards Institute (ANSI): A standards-setting, non-government organization that develops and publishes standards for voluntary use in the United States.

American Standard Code for Information Interchange (ASCII): A standard computer code for representing and exchanging alphanumeric information.

analog-to-digital (A/D): Conversion of continuously variable electrical signals to discrete or discontinuous electrical signals.

analog-to-digital converter (ADC): A converter with internal sample-and-hold circuitry used to translate an analog signal to a digital signal.

ANSI C: A version of the C programming language that conforms to the C standards defined by the American National Standards Institute.

application programming interface (API): A set of standard software function calls and data formats that application programs use to interact with other applications, device-specific drivers, or the operating system.

application-specific integrated circuit (ASIC): A custom chip designed for a specific application. It is designed by integrating standard cells from a library.

arithmetic logic unit (ALU): The section of the computer that carries out all arithmetic operations (addition, subtraction, multiplication, division, or comparison) and logic functions.

ASCII: See *American Standard Code for Information Interchange*.

ASIC: See *application-specific integrated circuit*.

assembler: A software program that creates a machine language program from a source file that contains assembly language instructions, directives, and macros. The assembler substitutes absolute operation codes for symbolic operation codes, and absolute or relocatable addresses for symbolic addresses.

assert: To make a digital logic device pin active. If the pin is active low, then a low voltage on the pin asserts it. If the pin is active high, then a high voltage asserts it.

B

ball grid array (BGA): An integrated circuit package in which the input and output connections are solder balls arranged in a grid pattern.

base address register (BAR): A device configuration register that defines the start address, length, and type of memory space required by a peripheral component interconnect (PCI) device. The value written to this register during device configuration programs its memory decoder to detect accesses within the indicated range.

basic input/output system (BIOS): A firmware program that is responsible for power-on testing and initialization of a computer. In addition, it may provide runtime services for operating systems.

BBS: See *bulletin board service*.

benchmarking: A type of program execution that allows you to track the number of CPU cycles consumed by a specific section of code.

BGA: See *ball grid array*.

big endian: An addressing protocol in which bytes are numbered from left to right within a word. More significant bytes in a word have lower numbered addresses. Endian ordering is specific to hardware and is determined at reset. See also *little endian*.

BIOS: See *basic input/output system*.

bit: A binary digit, either 0 or 1.

boot: The process of loading a program into program memory.

boot mode: The method of loading a program into program memory. The 'C6x DSP supports booting from external ROM or the host port interface (HPI).

bulletin board service (BBS): An electronic bulletin board that allows users to post and read messages and download software.

bus master: A device capable of initiating a data transfer with another device.

byte: A sequence of eight adjacent bits operated upon as a unit.

C

CBT: See *crossbar technology*.

CD-ROM: See *compact disc read-only memory*.

central processing unit (CPU): The CPU is the portion of the processor involved in arithmetic, shifting, and Boolean logic operations, as well as the generation of data- and program-memory addresses. The CPU includes the central arithmetic logic unit (CALU), the multiplier, and the auxiliary register arithmetic unit (ARAU).

clock cycle: A cycle based on the input from the external clock.

clock mode (clock generator): One of the modes that sets the internal CPU clock frequency to a fraction or multiple of the frequency of the input clock signal CLKIN.

clock modes: Options used by the clock generator to change the internal CPU clock frequency to a fraction or multiple of the frequency of the input clock signal.

CMOS: See *complementary metal oxide semiconductor*.

coder-decoder or compression/decompression (codec): A device that codes in one direction of transmission and decodes in another direction of transmission.

common object file format (COFF): A system of object files configured according to a standard developed by AT&T. These files are relocatable in memory space. The 'C6x code generation tools generate COFF files.

compact disc read-only memory (CD-ROM): A 4.7-inch optical disk that can hold as much as 660M bytes of digital data. A CD-ROM can store digitized audio, image, video, text, and application data.

compiler: A translation program that converts a high-level language set of instructions into a target machine's assembly language.

complementary metal oxide semiconductor (CMOS): An integrated circuit technology that uses complementary transistors to efficiently charge and discharge capacitive loads in both the positive and negative directions and dissipates power only on transitions.

complex programmable logic device (CPLD): A digital, user-configurable integrated circuit used to implement custom logic functions.

compress and expand (compand): A quantization scheme for audio signals in which the input signal is compressed and then, after processing, is reconstructed at the output by expansion. There are two distinct companding schemes—A-law, used in Europe, and μ -law, used in the United States.

CPLD: See *complex programmable logic device*.

crossbar technology (CBT): High-speed bus-connect devices that are useful for bus isolation, multiplexing, and voltage translation. These devices have an on-state resistance of 5 ohms and a propagation delay of 250 ps.

CPU: See *central processing unit*.

D

D/A: See *digital-to-analog*.

DAC: See *digital-to-analog converter*.

daughterboard: A circuit board that connects to a motherboard to provide additional capabilities and/or interfaces. See also *motherboard*.

dB: See *decibels*.

debugger: A software interface used to identify and eliminate mistakes in a program.

decibels (dB): A unit for measuring the level of signal relative to a defined reference signal that follows it. For example, the notation dBm indicates a signal power level relative to a 1 milliwatt reference signal.

device driver: Software that enables computer hardware to communicate with a device. A device driver may also translate data and call other drivers to actually send data to a device.

device ID: Every peripheral component interconnect (PCI) device must have a device ID configuration register to identify itself.

digital signal processor (DSP): A semiconductor that turns analog signals—such as sound or light—into digital signals, which are discrete or discontinuous electrical impulses, so that they can be manipulated.

digital-to-analog (D/A): Conversion of discrete or discontinuous electrical signals to continuously variable signals. See also *digital-to-analog converter*.

digital-to-analog converter (DAC): A device that converts a signal represented by a series of numbers (digital) to a continuously varying signal (analog). See also *digital-to-analog*.

DIP: See *dual in-line package*.

direct memory access (DMA): A mechanism whereby a device other than the host processor contends for, and receives, mastery of the memory bus so that data transfers can take place independent of the host.

DLL: See *dynamic link library*.

DMA: See *direct memory access*.

doubleword (DWORD): The PCI (host) defines a doubleword as a 32-bit value. See also *word* and *halfword*.

driver: See *device driver*.

DSP: See *digital signal processor*.

dual in-line package (DIP): A common rectangular chip housing with leads (pins) on both long sides.

DWORD: See *doubleword*.

dynamic link library (DLL): A Windows software library that is linked dynamically at run time, rather than statically at compile time. DLLs can be shared among multiple applications and be replaced with newer versions without requiring the applications to be recompiled.

E

EEPROM: See *electrically-erasable programmable read-only memory*.

electret microphone: A condenser microphone that requires an external power source.

electrically-erasable programmable read-only memory (EEPROM): A nonvolatile memory device that can be programmed in-circuit and have its contents selectively changed. Although its name includes *read-only*, it supports both read and write accesses.

electrostatic discharge (ESD): Discharge of a static charge on a surface or body through a conductive path to ground, which can be damaging to integrated circuits.

EMIF: See *external memory interface*.

erasable programmable read-only memory (EPROM): A nonvolatile memory device that can be erased with exposure to ultraviolet light. The device can be randomly accessed, but it is read only.

ESD: See *electrostatic discharge*.

evaluation module (EVM): A board and software tools that allow the user to evaluate a specific device.

expansion interface: An interface that allows additional capabilities to be added to a base product.

external interrupt: A hardware interrupt triggered by a specific value on a pin.

external memory interface (EMIF): The boundary between the CPU and external memory through which information is conveyed.

F

first in, first out (FIFO): A queue; a data structure or hardware buffer from which items are taken out in the same order they were put in. A FIFO is useful for buffering a stream of data between a sender and receiver that are not synchronized; that is, the sender and receiver are not sending and receiving at exactly the same rate. If the rates differ by too much in one direction for too long, the FIFO becomes either full (blocking the sender) or empty (blocking the receiver).

flag: A binary status indicator whose state indicates whether a particular condition has occurred or is in effect.

Flash memory: Nonvolatile read-only memory that is electronically erasable and programmable.

H

halfword: The 'C6x DSP defines a halfword as a 16-bit data value. See also *doubleword* and *word*.

handle: An identifier used by software to reference a file or device.

high-level language (HLL): A general-purpose language that can be used to program a microprocessor rather than using a low-level, machine-dependent language.

host: A device to which other devices (peripherals) are connected and that generally controls those devices.

host port interface (HPI): A 16-bit parallel interface that the host uses to access the DSP's memory space.

I

identifier (ID): A field that contains a resource-table index, a sequence number, and a resource-type code; it identifies a kernel resource such as a port, semaphore, or task.

IEEE 1149.1 standard: "IEEE Standard Test Access Port and Boundary-Scan Architecture", first released in 1990. See also *JTAG*.

Industry Standard Architecture (ISA): An industry-standard 8/16-bit bus used in IBM™ compatible desktops. It provides a theoretical maximum data transfer rate of 8.33M bytes per second.

initiator: When a PCI bus master has arbitrated for and won access to the PCI bus, it becomes the initiator of a transaction.

Institute of Electrical and Electronic Engineers (IEEE): A publishing and standards-making body focused on advancing the theory and practice of electrical, electronics, computer engineering, and computer science.

in-system programmable (ISP): The ability to program and reprogram a device on a circuit board.

integrated switching regulator (ISR): A complete switch-mode power supply in a modular, board-mounted package.

internal interrupt: A hardware interrupt caused by an on-chip peripheral.

interrupt: A signal sent by hardware or software to a processor requesting attention. An interrupt tells the processor to suspend its current operation, save the current task status, and perform a particular set of instructions. Interrupts communicate with the operating system and prioritize tasks to be performed.

interrupt service routine: A module of code that is executed in response to a hardware or software interrupt.

ISP: See *in-system programmable*.

ISR: See *integrated switching regulator*.

J

Joint Test Action Group (JTAG): The Joint Test Action Group was formed in 1985 to develop economical test methodologies for systems designed around complex integrated circuits and assembled with surface-mount technologies. The group drafted a standard that was subsequently adopted by IEEE as IEEE Standard 1149.1-1990, "IEEE Standard Test Access Port and Boundary-Scan Architecture".

K

kilohertz (kHz): One thousand hertz, or cycles per second, used to indicate the frequency of a clock signal.

L

latch phase: The phase of a CPU cycle during which internal values are held constant.

light emitting diode (LED): A semiconductor chip that gives off visible or infrared light when activated.

linker: A software tool that combines object files to form an object module, which can be loaded into memory and executed.

little endian: An addressing protocol in which bytes are numbered from right to left within a word. More significant bytes in a word have higher numbered addresses. Endian ordering is specific to hardware and is determined at reset. See also *big endian*.

load: To enter data into storage or working registers.

loader: A device that places an executable module into system memory.

M

mA: See *milliamp*.

macro: A sequence of statements or instructions that is represented by a symbolic symbol.

μF: See *microfarad*.

μ-Law companding: See *compress and expand (compand)*.

mailbox: A 32-bit register that provides a simple communication method to pass messages between the host and DSP software. Multiple mailboxes are typically available to support bidirectional, multiword message transfers.

maskable interrupt: An interrupt that can be enabled or disabled through software.

master clock output signal (CLKOUT1): The output signal of the on-chip clock generator. The CLKOUT1 high pulse signifies the CPU's logic phrase (when internal values are changed), while the CLKOUT1 low pulse signifies the CPU's latch phase (when the values are held constant).

McBSP: See *multichannel buffered serial port*.

megahertz (MHz): One million hertz, or cycles per second, used to indicate the frequency of a clock signal.

memory map: A graphical representation of a computer system's memory, showing the locations of program space, data space, reserved space, and other memory-resident elements.

memory-mapped register: An on-chip register mapped to an address in memory. Some memory-mapped registers are mapped to data memory, and some are mapped to input/output memory.

MHz: See *megahertz*.

microfarad (μF): One-millionth of a farad, which is the basic unit of capacitance.

microsecond (μs): One-millionth of a second.

milliamp (mA): One-thousandth of an ampere, which is the basic unit of current.

millimeter (mm): One-thousandth of a meter.

million instructions per second (MIPS): A unit of instruction execution speed of a computer.

millisecond (ms): One-thousandth of a second.

millivolts root mean square (mV_{rms}): One-thousandth of a volt root mean square. See also *volts root mean square*.

MIPS: See *million instructions per second*.

mm: See *millimeter*.

most significant byte (MSbyte): The byte in a multibyte word that has the most influence on the value of a word.

motherboard: The main circuit board that contains the processor, main memory, circuitry, bus controller, connectors, and primary components of the computer. See also *daughterboard*.

μs : See *microsecond*.

ms: See *millisecond*.

MSbyte: See *most significant byte*.

multichannel buffered serial port (McBSP): A standard serial port interface found on 'C6x devices. It provides full-duplex communication, double-buffered data registers, independent transmit and receive framing and clocking, direct interface to industry-standard serial devices, internal and external clock support, and an autobuffering capability using a DMA controller.

multiplexing: A process of transmitting more than one set of signals at a time over a single wire or communications link. (Also known as muxing.)

mutex: A mutual exclusion semaphore used to restrict access to a resource.

mV_{rms}: See *millivolts root mean square*.

N

nanosecond (ns): One-billionth of a second, the basic unit of time.

nonmaskable interrupt (NMI): An interrupt that uses the same logic as the maskable interrupts, but can be neither masked nor disabled. It is often used as a soft reset.

nonvolatile random access memory (NVRAM): A type of random access memory that retains its data when its power source is turned off, providing nonvolatile storage.

O

object file: A file that has been assembled or linked and contains machine language object code.

off chip: A device external to the device.

on chip: An element or module internal to the device.

P

parallel debug manager (PDM): A program used for creating and controlling multiple debuggers for the purpose of debugging code in a parallel-processing environment.

PC: *Personal computer*.

PCI: See *peripheral component interconnect*.

PCM: See *pulse code modulation*.

PDM: See *parallel debug manager*.

peripheral component interconnect (PCI): A high-speed local bus that supports data-transfer speeds of up to 132M bytes per second at 33 MHz.

phase-locked loop (PLL): A unit within a system that uses phase to lock on to a signal to ensure synchronous clocking of digital signals.

pitch: The distance between successive centers of leads of a component package.

plastic quad flat pack (PQFP): A low-profile, surface-mount integrated circuit package that is plastic and has leads (pins) on all four sides.

PLL: See *phase-locked loop*.

poll: A continuous test used by the program until a desired condition is met.

PQFP: See *plastic quad flat pack*.

profiling environment: A special debugger environment that provides a method for collecting execution statistics about specific areas in application code.

pulse code modulation (PCM): The most common method of encoding an analog voice signal into digital data. Voice signals are encoded into 8-bit data samples at an 8-kHz sample rate, resulting in a 64-kbps digital data stream.

R

random-access memory (RAM): A memory element that can be written to as well as read from.

read-only memory (ROM): A semiconductor storage element containing permanent data that cannot be changed.

ready: A task state indicating that the task either is currently executing or is able to execute as soon as it acquires the processor.

real time: The actual time during which the physical process of computation transpires in order that results of the computation interact with a physical process.

reduced instruction set computer (RISC): A computer whose instruction set and related decode mechanism are much simpler than those of microprogrammed complex instruction set computers. The result is a higher instruction throughput and a faster real-time interrupt service response from a smaller, cost-effective chip.

register: A small area of high-speed memory, located within a processor or electronic device, that is used for temporarily storing data or instructions. Each register is given a name, contains a few bytes of information, and is referenced by programs.

reset: A means to bring processors to known states by setting registers and control bits to predetermined values and signaling execution to start at a specified address.

ring 0: Highest level of privilege available on an Intel processor that defines what data can be accessed, what code in memory can be executed, and what machine instructions can be executed by a program. Low-level device drivers run at ring 0. See also *ring 3*.

ring 3: Lowest level of privilege available on an Intel processor that defines what data can be accessed, what code in memory can be executed, and what machine instructions can be executed by a program. High-level user-mode applications and DLL run at ring 3. See also *ring 0*.

RISC: See *reduced instruction set computer*.

ROM: See *read-only memory*.

S

sample rate: The rate at which the audio codec samples audio data. Usually specified in hertz (samples per second).

SBSRAM: See *synchronous burst static random-access memory*.

SDRAM: See *synchronous dynamic random-access memory*.

slave: Another name for the target being addressed during a PCI transaction.

static random-access memory (SRAM): Fast memory that does not require refreshing, as DRAM does. It is more expensive than DRAM, though, and is not available in as high a density as DRAM.

structure: A collection of one or more variables grouped together under a single name.

surface-mount technology: A method of assembling printed wiring boards where components are mounted onto the surface rather than through holes.

synchronous burst static random-access memory (SBSRAM): High-performance SRAM device with accesses that are synchronized to a microprocessor clock and includes a burst address counter.

synchronous dynamic random-access memory (SDRAM): High-performance DRAM device with accesses that are synchronized to a microprocessor clock and support for page bursts.

syntax: The grammatical and structural rules of a language. All higher-level programming languages possess a formal syntax.

T

target: When related to PCI, it is the device that is the target of a PCI transaction initiated by a PCI bus master. When related to the debugger, the DSP is the target of an emulation access.

target memory: Physical memory in a device into which executable object code is loaded.

test bus controller (TBC): Application-specific integrated circuit that controls an IEEE 1149.1–1990 (JTAG) serial-test bus to support production testing and in-system microprocessor emulation. The TBC provides control of the DSP and access to all of its registers and memory.

thin quad flat pack (TQFP): A very low-profile, surface-mount integrated circuit package that is plastic and has leads (pins) on all four sides.

thread of execution: A schedulable unit of execution in a multitasking system. The term refers specifically to the progressive execution of a program element; it excludes other attributes, such as the system resources allocated to a task or process.

timer: A programmable peripheral used to generate pulses or to time events.

TQFP: See *thin quad flat pack*.

transistor-transistor logic (TTL): A family of logic devices that are made with bipolar junction transistors and resistors. A TTL low level is defined as a voltage level below 0.4 volts. A TTL high level is defined as a voltage level above 2.4 volts.

V

V: See *volt*.

V_{dc}: See *volts direct current*.

VelociTI: Architecture developed by Texas Instruments that features very long instruction words.

vendor ID: Every PCI device must have a vendor ID configuration register that identifies the vendor of the device.

very long instruction word (VLIW): Architecture using words between the sizes of 256 bits and 1024 bits.

virtual device driver (VxD): A 32-bit, ring-0 module that virtualizes hardware for ring-3 modules to provide a primary interface to hardware or specialized software services.

VLIW: See *very long instruction word*.

volt (V): The unit of voltage, or potential difference.

volts direct current (V_{dc}): The voltage measurement of a direct current signal.

volts peak-to-peak (V_{pp}): A measurement of a signal that indicates the difference between its maximum and minimum voltage values.

volts root mean square (V_{rms}): A measurement of a periodic signal that indicates the effective voltage at which a direct current voltage would deliver the same average power. This measurement provides a method for comparing the power delivered by different waveforms.

VxD: See *virtual device driver*.

W

Win32: The 32-bit application programming interface for both Windows 95 and Windows NT.

word: A character or bit string considered as an entity. The length of the word is machine-dependent. The 'C6x DSP defines a word as a 16-bit data value. The PCI (host) defines a word as a 16-bit data value. See also *doubleword* and *halfword*.

X

XDS510: A hardware emulator that provides a scan-path connection to a DSP for source code debugging.

Summary of Updates in This Document

This appendix provides a summary of the updates in this version of the document. Updates within paragraphs appear in a **bold typeface**.

Page:**Change or Add:**

iii

Replace the fourth paragraph with the following text:

This manual assumes that you are familiar with working in a Windows™ 95 or a Windows NT™ environment and understand general and technical PC terminology. This manual specifically addresses the 'C6x EVM and its support software. Detailed information about the 'C6x DSP and TI code development support tools is provided separately (see the *Related Documentation From Texas Instruments* section in this *Preface* for a list of documents and ordering information). For up-to-date information on the 'C6x EVM, as well as related products, visit the 'C6x EVM website at <http://www.ti.com/sc/c62xevm>.

1-2

Replace the second item in the list of key features with the following text:

- ☐ Quad clock support (33.25 MHz, **40** MHz, 133 MHz, and **160** MHz)

1-3

In section 1.1.1, *User Controls and Indicators*, replace the second and third items in the list with the following text:

- ☐ DSP oscillator clock selection (33.25 MHz or **40** MHz)
- ☐ Clock mode (multiply-by-1 or multiply-by-4 for 33.25-MHz, **40**-MHz, 133-MHz, or **160**-MHz DSP CLKOUT1)

Page: **Change or Add:**

1-5 In Figure 1–1, change the frequency in the label for OSC B to 40 MHz.

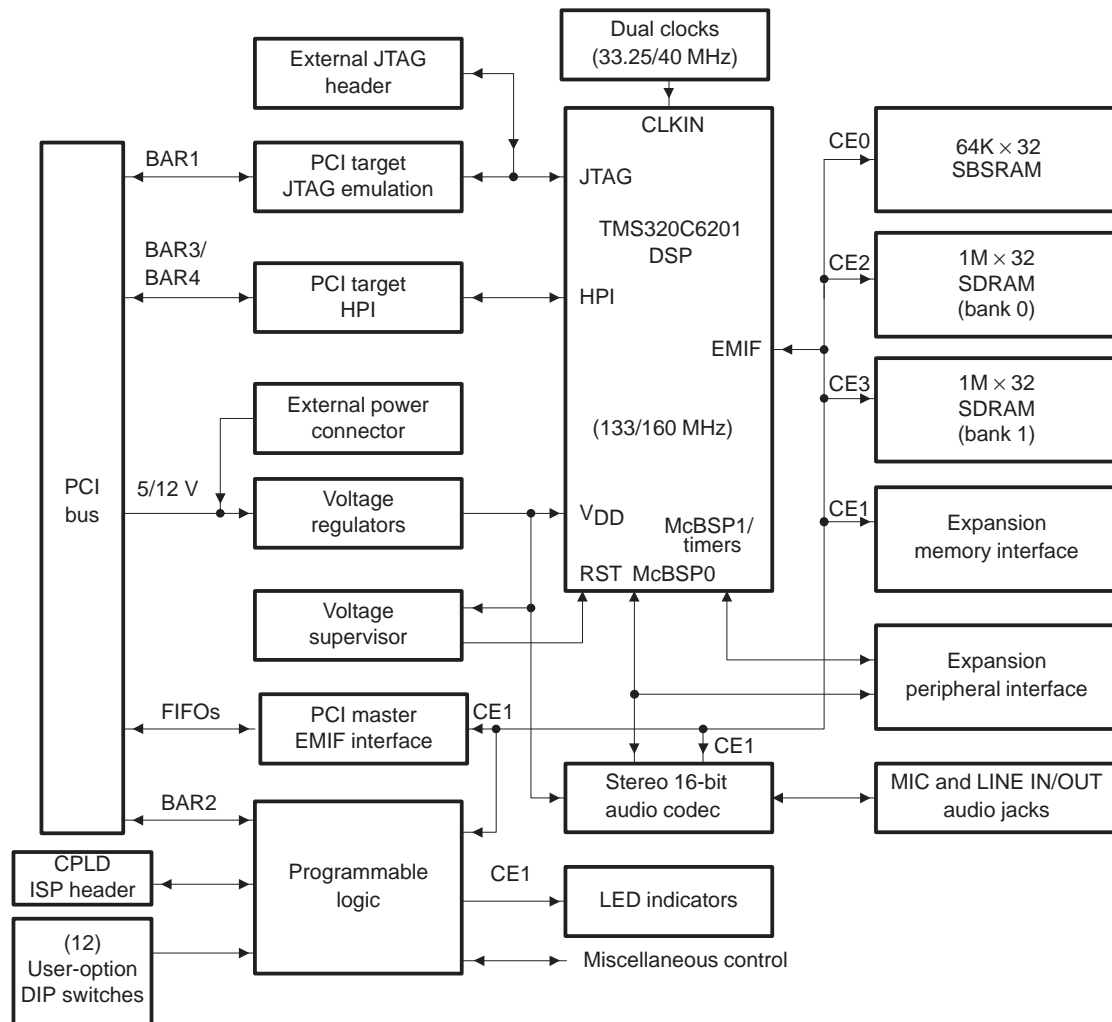

Figure 1–1. TMS320C6x EVM Layout (Top Side)

Page: Change or Add:

1-7 In Figure 1–3, change the frequencies for the dual clocks to 33.25/40 MHz and for the TMS320C6201 DSP to 133/160 MHz.

Figure 1–3. TMS320C6x EVM Block Diagram

1-8 Replace the second item in the list of hardware functional areas with the following text:

- ☐ **DSP clocks.** The 'C6x EVM supports operation with two different onboard clock sources (33.25 MHz and **40 MHz**) and two clock modes (multiply-by-1 and multiply-by-4). As a result, the DSP can operate at four different clock rates, including 33.25 MHz, **40 MHz**, 133 MHz, or **160 MHz**. For more information, see section 4.3, *DSP Clocks*.

Page: Change or Add:

2-2 Remove the following item from the kit checklist:

☐ **Other hardware** Six rubber feet for stand-alone operation

2-5 In the *Hardware checklist* section, replace the sixth item with the following text:

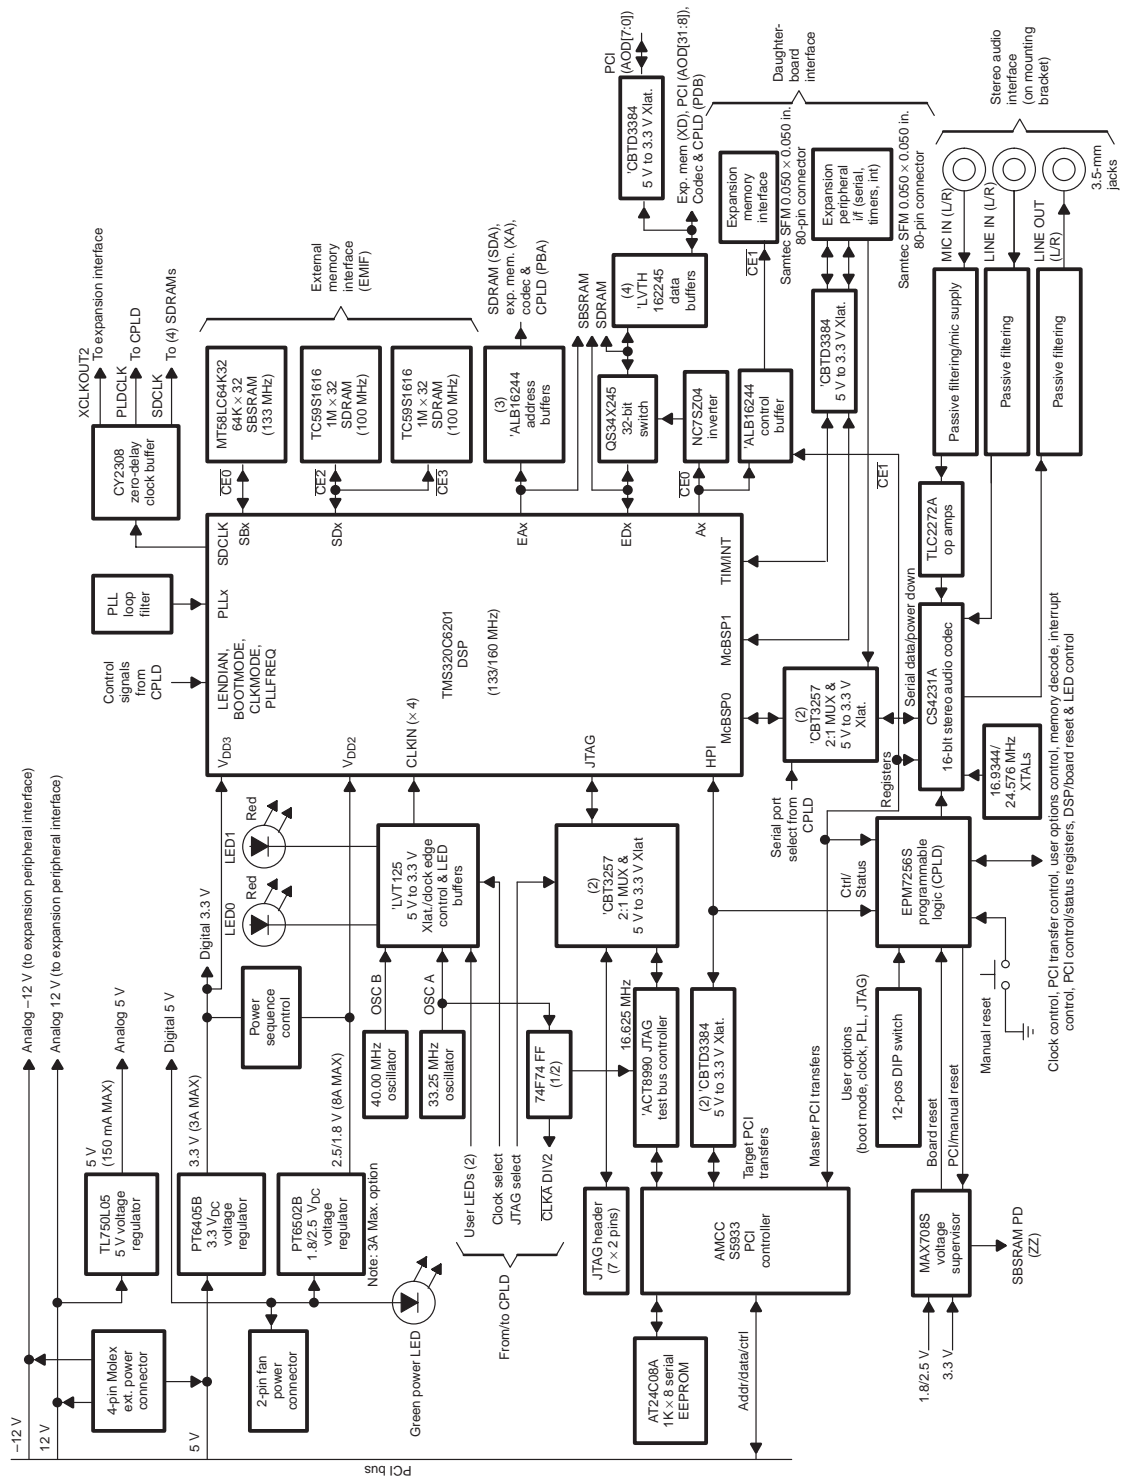

☐ **Other hardware** CD-ROM drive

3-2 In section 3.2, *Verifying the EVM Installation*, replace step 1 with the following text:

- 1) Install the 'C6x EVM board and supplied software as described in Chapter 2, *Getting Started With the TMS320C6x EVM*. **If you want to verify the stereo audio capabilities of the EVM board during the confidence test, you must connect input sources to the microphone and line inputs and an amplified speaker to the line output.**

4-3 In Figure 4–1, change the frequency for OSC B to 40 MHz; change the frequencies for the TMS320C6201 DSP to 133/160 MHz.

Figure 4-1. TMS320C6x EVM Detailed Block Diagram

Page: Change or Add:

4-5 Replace the second paragraph with the following text:

Because the 'C6x EVM is a hardware reference design intended to provide you with maximum flexibility, it supports all of the DSP's external interfaces. The 'C6x EVM uses the PLL clock generator interface to support multiply-by-1 and multiply-by-4 clock modes with CPU clock rates of 33.25 MHz, **40** MHz, 133 MHz, and **160** MHz. The JTAG test/emulation interface supports both embedded and external emulation for source code debugging. The control interface resets the DSP, provides external interrupts, chooses data endian mode, and selects the DSP's boot method. The external memory interface (EMIF) supports synchronous SBSRAM and SDRAM memories and asynchronous accesses to the CPLD registers, stereo audio codec, PCI controller, and expansion memory. The EMIF is also brought out to an expansion memory interface connector for daughterboard use. The host port interface (HPI) is used for bidirectional data transfers between the PC and the DSP. The timer interfaces are provided on the expansion peripheral interface connector for daughterboard use. The multichannel buffered serial ports provide interfaces to an onboard stereo audio codec and/or a daughterboard connected to the expansion peripheral interface.

4-7 Replace the list of DSP core rates with the following items:

- ☐ Full speed (**160** MHz)
- ☐ Speed of the SBSRAM (133 MHz)
- ☐ Multiply-by-1 clock modes (33.25 MHz and **40** MHz)

Replace the third paragraph with the following text:

The EVM uses two half-size oscillators, along with a TI SN74LVT125 quad bus buffer device, to provide 33.25- and **40**-MHz CLKIN signals to the 'C6201. The use of the 'LVT125 device provides multiple functions, including 5-V to 3.3-V signal level translation, clock selection, and clock edge control with fast rise and fall times required by the DSP.

Replace the fifth paragraph with the following text:

The EVM provides user options for selecting the CLKIN frequency (33.25 or **40** MHz) and the clock mode (multiply-by-1 or multiply-by-4), so the CLKOUT1 (CPU clock) frequency can be 33.25 MHz, **40** MHz, 133 MHz, or **160** MHz (see Table 4–1). The SBSRAM clock (SSCLK) can be configured by the DSP software to be one-half the CPU clock (CLKOUT1) or the same as CLKOUT1. The SDRAM clock (SDCLK) is always one-half of CLKOUT1. The CPLD also controls the DSP's CLKMODE and PLLFREQ control inputs based on the clock mode selection.

Page: Change or Add:

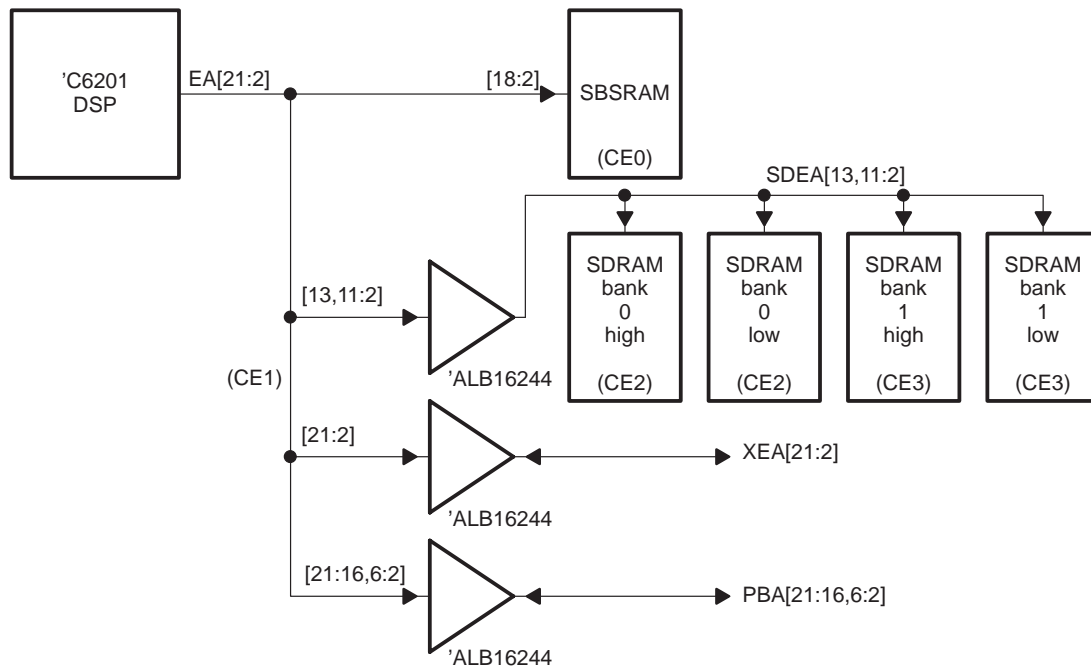

4-7 Replace Table 4–1 with the following table:

Table 4–1. DSP Clock Summary

Clock Source	Clock Mode	CLKOUT1	SSCLK (1/2 rate/1× rate)	SDCLK
33.25 MHz	Multiply-by-1	33.25 MHz	16.625/33.25 MHz	16.625 MHz
40.00 MHz	Multiply-by-1	40.00 MHz	20/40 MHz	20 MHz
33.25 MHz	Multiply-by-4	133 MHz	66.5/133 MHz	66.5 MHz
40.00 MHz	Multiply-by-4	160 MHz	80 MHz[†]	80 MHz

[†] 1× SSCLK rate is invalid when CLKOUT1 is 160 MHz.

4-10 In Figure 4–4, remove the arrow between the top 'ALB16244 buffer and the SDRAM bank 0 high box.

Figure 4–4. EMIF Address Bus Topology

Legend: EA DSP EMIF address
SDEA SDRAM access
XEA Expansion memory address
PBA Peripheral bus address

Note: The transceiver signal assignments provide a functional overview only. The actual signal assignments are optimized for layout.

Page: **Change or Add:**

4-10 Replace the second paragraph of section 4.4.1, *SBSRAM*, with the following text:

The SBSRAM device can be clocked by the 'C6201 at the CPU clock speed when operating at 133 MHz, one-half the clock speed when operating at **160** MHz, or at either the same as or one-half the clock speed when operating in the multiply-by-1 clock mode (33.25 MHz and **40** MHz). This selection is made based on the setting of the SSCRT bit in the EMIF global control register. Additionally, various boot modes inherently select the clock speed used for the SBSRAM interface. You must correctly select the SBSRAM clock rate for the selected CPU clock rate.

4-11 Replace the second paragraph of section 4.4.2, *SDRAM*, with the following text:

The SDRAM devices are always clocked at one-half the CPU clock rate. This means that when the DSP core runs at 133 MHz, the SDRAM runs at 66.5 MHz (15 ns), and when the DSP core runs at **160** MHz, the SDRAM runs at **80** MHz (**12.5** ns). The EVM's SDRAM devices are rated for 100-MHz operation.

Page: Change or Add:

4-15 Replace Table 4–3 with the following table:

Table 4–3. TMS320C6x EVM DSP Memory Map (MAP 1)

Start Address	End Address	External Memory Space	Size (Bytes)	Description
00000000	0000FFFF	N/A	64K	Internal program memory (IPM)
00010000	003FFFFF	N/A	4M–64K	Reserved (future IPM)
00400000	0043FFFF	CE0	256K	SBSRAM
00440000	013FFFFF	CE0	16M – 256K	Unused
01400000	016FFFFF	CE1	3M	Asynchronous expansion memory
01700000	0170003F	CE1	64	PCI add-on registers
01700040	0170FFFF	CE1	64K – 64	Unavailable
01710000	01710003	CE1	4	PCI FIFO
01710004	0171FFFF	CE1	64K – 4	Unavailable
01720000	0172000F	CE1	16	Audio codec registers
01720010	0172FFFF	CE1	64K – 16	Unavailable
01730000	0177FFFF	CE1	320K	Reserved
01780000	0178001F	CE1	32	DSP control/status registers
01780020	0178FFFF	CE1	64K – 32	Unavailable
01790000	017FFFFF	CE1	448K	Reserved
01800000	01BFFFFF	N/A	4M	Internal peripherals
01C00000	01FFFFFF	N/A	4M	Reserved
02000000	023FFFFF	CE2	4M	SDRAM (bank 0) or optional asynchronous expansion memory
02400000	02FFFFFF	CE2	12M	Reserved
03000000	033FFFFF	CE3	4M	SDRAM (bank 1) or optional asynchronous expansion memory
03400000	03FFFFFF	CE3	12M	Reserved

80400000	FFFFFFFF	N/A	2044M	Reserved

Page: Change or Add:

4-16 Replace the second paragraph with the following text:

The EMIF global control register must be initialized to enable the various DSP output clocks and select clock polarities, the SBSRAM clock rate (one-half the CPU clock or the same as the CPU clock), and the requester arbitration mode. The 'C6x EVM does not use the CLKOUT1 and CLKOUT2 outputs, so these clocks should be disabled to minimize EMI emissions. The SDCLK output (which is used to clock the EVM's four SDRAM devices, the CPLD, and the daughterboard circuitry) should have its polarity identical to the DSP's internal SDCLK. The SBSRAM clock rate (SSCLK) can be either one-half the CPU clock or the same as the CPU clock when the CPU clock rate is 33.25 MHz, **40** MHz, or 133 MHz. When the CPU clock rate is **160** MHz, only one-half the CPU clock rate is valid for SSCLK. The requester arbitration mode selection is application dependent. For a one-half-rate SSCLK operation, a value of 0x3060 is recommended. For a full-rate SSCLK operation, a value of 0x3064 is recommended.

Replace Table 4–4 with the following table:

Table 4–4. TMS320C6x EVM CE Memory Space Initialization Summary

CE Memory Space	Memory Type	Memory Characteristics	Control Register Address	Control Register Value
CE0	SBSRAM	133 MHz maximum	0x1800008	0x40
CE1	PCI controller, CPLD registers, audio codec, and expansion memory	32-bit async, strobe = 3	0x1800004	160 MHz: 0x30F30323 133 MHz: 0x20E20322 40 MHz: 0x10D10321 33.25 MHz: 0x10D10321
CE2	SDRAM (bank 0)	100 MHz maximum	0x1800010	0x30
CE3	SDRAM (bank1)	100 MHz maximum	0x1800014	0x30

Page: Change or Add:

4-17 Replace the first paragraph with the following text:

Because the 'C6x EVM includes SDRAM, the EMIF SDRAM control and timing registers must be initialized to select timing and device width, enable refresh, initialize the SDRAM devices, and control the SDRAM refresh period. The SDRAM timing selection is dependent on the CPU clock speed, so the host or DSP software must determine its clock speed to properly initialize the timing control bits. The host and DSP can each read CPLD registers to determine the CPU clock speed based on the clock selection (33.25 MHz or **40** MHz) and clock mode (multiply-by-1 or multiply-by-4). The SDRAM devices have a t_{RC} (refresh/active-to-refresh/active) period of 100 ns, a t_{RP} (precharge-to-active) period of 30 ns, and a t_{RCD} (active-to-read/write) period of 30 ns. Based on the determined CPU clock period, the TRC, TRP, and TRCD fields of the EMIF SDRAM control register can be initialized based on the CLKOUT2 period, as summarized in Table 4–5.

Replace Table 4–5 with the following table:

Table 4–5. EMIF SDRAM Control Register Timing Fields

CPU Clock (MHz)	CLKOUT2 Period (ns)	TRC Field	TRP Field	TRCD Field
33.25	60	1	0	0
40	50	1	0	0
133	15	6	1	1
160	12.5	7	2	2

Replace Table 4–6 with the following table:

Table 4–6. EMIF SDRAM Timing Register Values

CPU Clock (MHz)	CLKOUT2 Period (ns)	Maximum Register Value
33.25	60	0x103
40	50	0x138
133	15	0x410
160	12.5	0x4E1

Page: **Change or Add:**

4-43 Replace the first paragraph with the following text:

The board reset is produced when either the MAX708S indicates a reset (power up, undervoltage condition, or manual switch reset) or the PCI controller indicates a reset (PCI reset or manual software reset). The MAX708S provides two board reset signals: one active low and the other active high. The active-low board reset is routed to the CPLD, which directly controls the reset to the DSP, JTAG TBC, and daughterboard. The CPLD also indirectly controls the reset or power down of the audio codec via the McBSP0 multiplexer and the SDRAM via the clock enable control signals. The active-high board reset from the MAX708 is routed directly to the SBSRAM snooze (ZZ) input to put the device in an inactive, low-power state. **When the EVM board is held in reset, it cannot respond to host PCI accesses.**

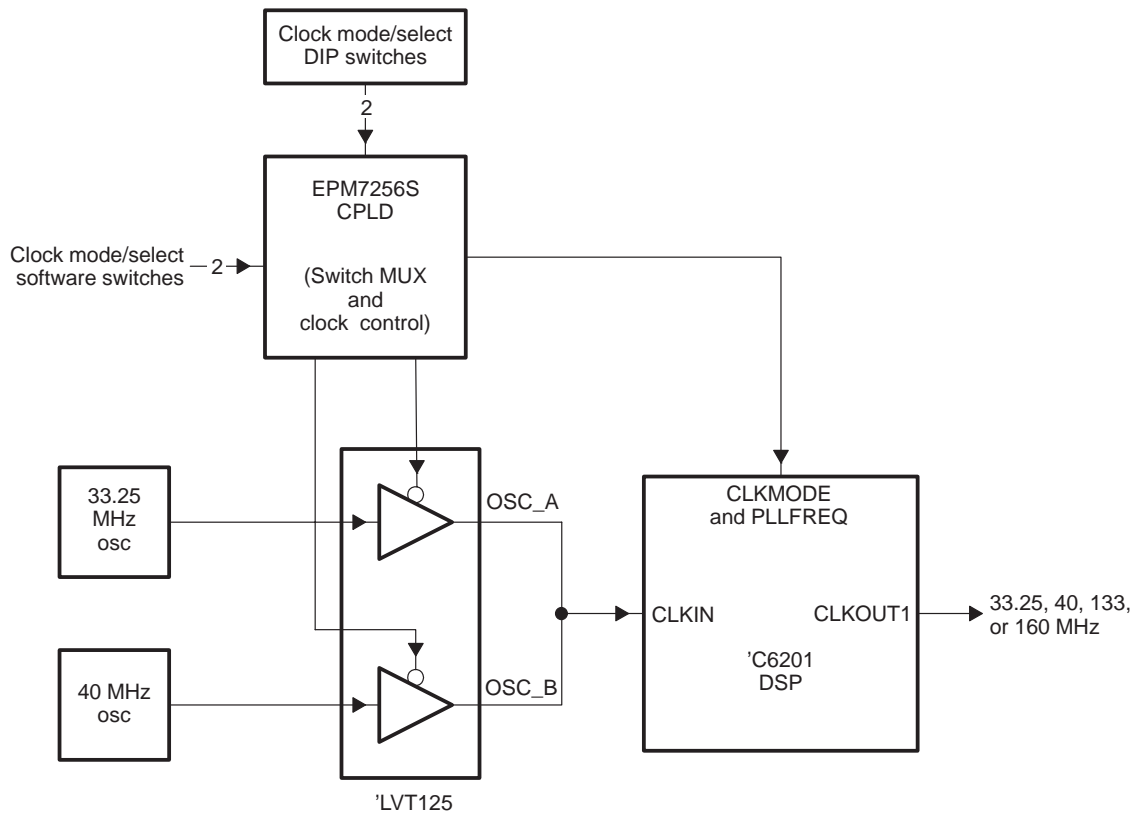

4-45 In section 4.8.3, *Dual DSP Clock Oscillator Control*, replace the first paragraph with the following text:

The 'C6x EVM includes dual DSP clock oscillator support to enable operation at the **160**-MHz core clock rate with one-half-rate SBSRAM timing or at the full 133-MHz SBSRAM clock rate. You have the flexibility to select the clock rate that provides the best performance for your application. This clock selection can be made with the EVM DIP switches or from host software using the support software switches. For external operation, only the DIP switches are used to select the clock. For internal (PCI) operation, the DIP switches are selected for control by default unless overridden by host software using the software switches.

Page: Change or Add:

4-46 In Figure 4–10, change the frequency for OSC B to 40 MHz; change the frequencies for CLKOUT1 to 33.25, 40, 133, or 160 MHz.

Figure 4–10. DSP Clock Selection Configuration

4-52 Replace Table 4–15 with the following table:

Table 4–15. PCI SWOPT Register Bit Definitions

Bit	Name	Access	Description
7	–	–	–
6	H_CLKMODE	RW	Host clock mode (0 = $\times 4$ mode, 1 = $\times 1$ mode)
5	H_CLKSEL	RW	Host clock select (0 = OSC_A = 33.25 MHz , 1 = OSC_B = 40 MHz)
4	H_ENDIAN	RW	Host endian control (0 = little endian , 1 = big endian)
3	H_JTAGSEL	RW	Host JTAG selection (0 = external XDS510 , 1 = onboard JTAG TBC)
2	H_USER2	RW	Host user-defined option 0 (0 = on , 1 = off)
1	H_USER1	RW	Host user-defined option 1 (0 = on , 1 = off)
0	H_USER0	RW	Host user-defined option 2 (0 = on , 1 = off)

Page: **Change or Add:**

4-53 Replace Table 4–17 with the following table:

Table 4–17. PCI DIPOPT Register Bit Definitions

Bit	Name	Access	Description
7	–	–	–
6	S_CLKMODE	R	Switch clock mode (0 = ×4 mode, 1 = ×1 mode)
5	S_CLKSEL	R	Switch clock select (0 = OSC_A = 33.25 MHz, 1 = OSC_B = 40 MHz)
4	S_ENDIAN	R	Switch endian control (0 = little endian, 1 = big endian)
3	S_JTAGSEL	R	Switch JTAG selection (0 = external XDS510, 1 = onboard JTAG TBC)
2	S_USER2	R	Switch user-defined option 0 (0 = on, 1 = off)
1	S_USER1	R	Switch user-defined option 1 (0 = on, 1 = off)
0	S_USER0	R	Switch user-defined option 2 (0 = on, 1 = off)

4-54 Replace Table 4–19 with the following table:

Table 4–19. PCI DSPOPT Register Bit Definitions

Bit	Name	Access	Description
7	–	–	–
6	CLKMODE	R	Clock mode (0 = ×1 mode, 1 = ×4 mode)
5	CLKSEL	R	Clock select (0 = OSC_A = 33.25 MHz, 1 = OSC_B = 40 MHz)
4	LENDIAN	R	Endian control (0 = big endian, 1 = little endian)
3	JTAGSEL	R	JTAG selection (0 = external XDS510, 1 = onboard JTAG TBC)
2	USER2	R	User-defined option 0 (0 = on , 1 = off)
1	USER1	R	User-defined option 1 (0 = on , 1 = off)
0	USER0	R	User-defined option 2 (0 = on , 1 = off)

Page: Change or Add:

4-59 Replace Table 4–25 with the following table:

Table 4–25. DSP DIPOPT Register Bit Definitions

Bit	Name	Access	Description
7	–	–	–
6	S_CLKMODE	R	Switch clock mode (0 = $\times 4$ mode, 1 = $\times 1$ mode)
5	S_CLKSEL	R	Switch clock select (0 = OSC_A = 33.25 MHz, 1 = OSC_B = 40 MHz)
4	S_ENDIAN	R	Switch endian control (0 = little endian, 1 = big endian)
3	S_JTAGSEL	R	Switch JTAG selection (0 = external XDS510, 1 = onboard JTAG TBC)
2	S_USER2	R	User-defined switch 0 (0 = on , 1 = off)
1	S_USER1	R	User-defined switch 1 (0 = on , 1 = off)
0	S_USER0	R	User-defined switch 2 (0 = on , 1 = off)

4-60 Replace Table 4–27 with the following table:

Table 4–27. DSP DSPOPT Register Bit Definitions

Bit	Name	Access	Description
7	–	–	–
6	CLKMODE	R	Switch clock mode (0 = $\times 1$ mode, 1 = $\times 4$ mode)
5	CLKSEL	–	Switch clock select (0 = OSC_A = 33.25 MHz, 1 = OSC_B = 40 MHz)
4	LENDIAN	R	Switch endian control (0 = big endian, 1 = little endian)
3	JTAGSEL	R	Switch JTAG selection (0 = external XDS510, 1 = onboard JTAG TBC) [†]
2	USER2	R	User-defined switch 2 (0 = on , 1 = off)
1	USER1	R	User-defined switch 1 (0 = on , 1 = off)
0	USER0	R	User-defined switch 0 (0 = on , 1 = off)

[†] Bit 3 (JTAGSEL) is always 0 when the EVM is not installed in a PCI slot.

Page: Change or Add:

4-66 Replace Table 4–32 with the following table:

Table 4–32. User Options Summary

User Option	Description	Number of Signals
Boot mode	Selects no-boot, HPI-boot, or ROM-boot	5
Clock mode	Selects multiply-by-1 (no PLL) or multiply-by-4 (PLL) clock mode	1
Clock select	Selects 33.25 MHz or 40 MHz for CLKIN	1
Endian select	Selects big- or little-endian memory addressing	1
JTAG select	Selects internal or external JTAG emulation	1
User-defined	User-defined options	3

Replace the fourth paragraph with the following text:

The clock selection determines which of two onboard clock sources is used. The EVM provides both 33.25- and **40**-MHz clocks. If multiply-by-4 clock mode is selected, this results in a CPU clock rates of 133 MHz and **160** MHz, respectively.

4-78 Replace Table 4–35 with the following table:

Table 4–35. User Option DIP Switches

Switch Number	Name	OFF Selection	ON Selection
SW2-1– SW2-5	BOOTMODE4– BOOTMODE0	See Table 4–36	See Table 4–36
SW2-6	CLKMODE	Multiply-by-1 mode (PLL bypassed)	Multiply-by-4 mode
SW2-7	CLKSEL	OSC B (40 MHz)	OSC A (33.25 MHz)
SW2-8	ENDIAN	Big endian	Little endian
SW2-9	JTAGSEL†	Internal (TBC)	External (XDS510)
SW2-10	USER2	1	0
SW2-11	USER1	1	0
SW2-12	USER0	1	0

† The JTAGSEL selection is ignored in stand-alone mode where external operation is forced.

Page: Change or Add:

6-5 Replace the fourth paragraph with the following text:

After these tests are finished, the **board** is reset and configured into SBSRAM clock mode and little-endian mode. While the board is in this configuration, a sequence of audio codec tests are performed. You can set up for these tests by connecting powered speakers to the LINE OUT connector, a microphone to the MIC IN connector, and a source such as the output from a CD-ROM drive playing an audio CD to the LINE IN connector. These connections, however, are not required for the successful completion of the following tests:

6-7 In Table 6–3, *EVM Board Configuration Options*, replace the table for the `–s speed` option with the following table:

<i>speed</i>	Selected DSP Clock Speed
0	33.25 MHz
1	40 MHz
2	133 MHz
3	160 MHz

7-30 In the Example section, replace the `evm6x_read()` call with the following text:

```
if ( !evm6x_read( h_board, ul_buffer, &ul_ret_len ) )
```

7-37 Replace the example description with the following text:

Example In the following example, the `evm6x_set_board_config()` function sets the EVM board configuration, overriding the hardware DIP switch settings. This must be done before resetting the DSP. In this example, the clock mode is set to `DSP_CLOCK_SBSRAM` mode, which configures the DSP clock to the speed of the SBSRAM. This allows the DSP to access SBSRAM at one clock per access. The endian mode is set to `BIG_ENDIAN_MODE`, which allows the DSP to execute software compiled and linked to run on a big-endian DSP. The user bits are set to `0xff`. The user bits set on the hardware DIP switch **are** used because the user bits value is greater than 7.

7-41 In the Example section, replace the `evm6x_write()` call with the following text:

```
if ( !evm6x_write( h_board, ul_buffer, &ul_ret_len ) )
```

8-31 In the Example section for the `codec_change_sample_rate` function, replace the second line of code with the following text:

```
actualSampleRate= codec_change_sample_rate(44000,TRUE);
```

Page: **Change or Add:**

8-38 Add the following note to the end of the Description section for the codec_timer function:

Note:

The maximum time supported by this routine is 650 000 μ s (0.650 s). This is a limitation of the codec timer's 10- μ s clock period and 16-bit counter register.

8-45 Replace the introductory comments section of Example 8–2(a) with the following block of comments:

Example 8–2. McBSP, Audio Codec, and Board Support Sample Code

(a) codec_ex.c file

```
/* **** */
/* <CODEC_EX.C> - Example code for CODEC and McBSP use. */
/* */

```

B-1 Replace Table B–1 with the following table:

Table B–1. TMS320C6x EVM User Options DIP Switches

Switch Number	Name	OFF Selection	ON Selection
SW2-1– SW2-5	BOOTMODE4– BOOTMODE0	See Table B–2	See Table B–2
SW2-6	CLKMODE	Multiply-by-1 mode (PLL bypassed)	Multiply-by-4 mode
SW2-7	CLKSEL	OSC B (40 MHz)	OSC A (33.25 MHz)
SW2-8	ENDIAN	Big endian	Little endian
SW2-9	JTAGSEL	Internal (TBC)	External (XDS510)
SW2-10	USER2	1	0
SW2-11	USER1	1	0
SW2-12	USER0	1	0

C-4 In the schematic (sheet 3), change the frequency for CLOCK B to 40.000MHZ.

D-9 Add the following text after the DESCRIPTION comment:

```

"REVISIONS
"   03/11/98 - Changed CPLD_REV to 2
"
"   03/05/98 - Changed CPLD_REV to 1

```

Page: Change or Add:

D-17 Replace the text under the Revision Control comment with the following text:

```
"Revision Control
CPLD_REV  = ^h02;
```

D-36 Replace the text under the DESCRIPTION heading with the following text:

```
"DESCRIPTION
"This module implements the DSP source clock selection.  The DSP
"source clock (CLKIN) can either be 33.25 or 40 MHz.  The two oscillator
"outputs are buffered using a SN74LVT125 quad buffer device which
"has independent output enable controls.  The two buffered clock outputs
"are tied together.  The state machine in this module ensures that only
"one clock output is enabled at any one time by implementing a
"break-before-make switch.  The source clock selection can be made
"using a DIP switch (SW2-7) or a software switch (DSPBOOT-SWSEL).
```

D-37 Replace the text under the Equations heading with the following text:

```
"clkssel = 0 selects oscillator A (33.25 MHz)
"clkssel = 1 selects oscillator B (40.00 MHz)
```

D-38 Add the following text after the DESCRIPTION comment:

```
"REVISIONS
" 03/05/98 - Modified DSP EMIF ready logic to provide ARDY for invalid
"           async accesses to non-CE1 memory spaces to prevent the
"           EMIF from locking-up at power-up when invalid code is
"           executed in the no-boot mode.  Also, extended codec_rdy
"           flag assertion to maintain ARDY assertion until ARE- or
"           AWE- is deasserted to support any strobe period >= 3
"           CLKOUT1 clocks.
```

D-43 Replace the text after the NOTE comment with the following text:

```
"NOTE: ARDY is defaulted to asserted for all other CE1
"       accesses to prevent the DSP from being locked up
"       on an invalid memory access.
"BGC-03/05/98-Rev. 1- Added non-CE1 async ARDY generation to prevent
"EMIF bus lock on invalid memory access during power-up
"when no valid program is in memory.
else ARDY = !CE1_ # (CE1_ & !ARE_) # (CE1_ & !AWE_);
```

Replace the first bordered comment with the following text:

```
"-----
"Generate DSPCLK2/2 for synchronization (33.25 / 40 MHz)
"-----
```

THC_HPI_BWR5= [1,1,0,1,hcntl1,hcntl0,1,0,0];
THC_HPI_BWR6= [1,1,0,0,hcntl1,hcntl0,1,0,0];

// BGC-03/11/98-Rev. 2 - Changed THC_HPI_BWR7 vector to
// hold HBE1_ and HBE0_ asserted for one extra clock cycle
// since they are sampled by the DSP on the rising edge
// of HDS1_. Previously, they were set to one in this state.
THC_HPI_BWR7= [1,1,0,1,1,1,1,0,0];
THC_HPI_BWR8= [1,1,1,1,1,1,1,1,1];
THC_HPI_BWR9= [1,1,1,1,1,1,1,1,1];
```

Page: Change or Add:

D-80 Replace the text under “state EMIF_WR3:” with the following text:

```
state EMIF_WR3:
  ao_cntl := AOC_EMIF_WR3;
  th_cntl := THC_EMIF_WR3;
  ao_bsy  := 0;
  // BGC-03/05/98-Rev. 1 - Changed emif_ack from 0 to 1 to support unknown strobe
  //                        period. This prevents the EMIF bus from locking up waiting for
  //                        an ARDY signal at end of strobe - 3 CPU clock periods.
  emif_ack:= 1;

  if (AWE_) then AO_IDLE1 with {
    ao_cntl := AOC_DONE;
    th_cntl := THC_DONE;
  //BGC--3/05/98-Rev. 1 - Added emif_ack assignment to clear acknowledgement flag
  //                        when AWE_ is deasserted.
    emif_ack:= 0;
  }
  else EMIF_WR3;
```

D-81 Replace the text under “state EMIF_RD2:” with the following text:

```
state EMIF_RD2:
  ao_cntl := AOC_EMIF_RD2;
  th_cntl := THC_EMIF_RD2;
  ao_bsy  := 0;
  emif_ack:= 1;

  if (ARE_) then AO_IDLE1 with {
    ao_cntl := AOC_DONE;
    th_cntl := THC_DONE;
  //BGC--3/05/98-Rev. 1 - Added emif_ack assignment to clear acknowledgement flag
  //                        when ARE_ is deasserted.
    emif_ack:= 0;
  }
  else EMIF_RD2;
```

D-82 Replace the text under “state FIFO_WR2:” with the following text:

```
state FIFO_WR2:
  ao_cntl := AOC_FIFO_WR2;
  th_cntl := THC_FIFO_WR2;
  ao_bsy  := 0;
  emif_ack:= 1;

  if (AWE_) then AO_IDLE1 with {
    ao_cntl := AOC_DONE;
    th_cntl := THC_DONE;
  //BGC--3/05/98-Rev. 1 - Added emif_ack assignment to clear acknowledgement flag
  //                        when AWE_ is deasserted.
    emif_ack:= 0;
  }
  else FIFO_WR2;
```

Page: Change or Add:

D-82 Replace the text under “state FIFO_RD2:” with the following text:

```
state FIFO_RD2:
  ao_cntl := AOC_FIFO_RD2;
  th_cntl := THC_FIFO_RD2;
  ao_bsy  := 0;
  emif_ack:= 1;

  if (ARE_) then FIFO_RD3 with {
    ao_cntl := AOC_FIFO_RD3;
    //BGC--3/05/98-Rev. 1 - Added emif_ack assignment to clear acknowledgement flag
    //                      when ARE_ is deasserted.
    emif_ack:= 0;
  }
else FIFO_RD2;
```

F-4 Replace the first Action paragraph for the Interrupt (IRQ) conflict condition with the following text:

Action

The PC's plug-and-play BIOS automatically determines the appropriate interrupt assignment for each board on the PCI bus. Sometimes this is a difficult task for a computer to do without human intervention. As boards are added and removed, the BIOS can get confused and may end up making inappropriate decisions that can result in an interrupt being shared between the EVM and another board. **The EVM's support software handles shared PCI interrupts properly. However, other boards' drivers may not be able to share interrupts.**

Page: Change or Add:

F-5 Add the following item to the list of methods for resolving an interrupt conflict:

- ☐ It may be helpful to check your system's current interrupt assignments to determine exactly what device is conflicting with the EVM's interrupt.

To observe the interrupt assignments, perform the following steps in the applicable operating system:

■ **Windows 95**

- 1) From the Windows 95 desktop, right click on the My Computer icon.
- 2) Select the Properties menu item.
- 3) Select the Device Manager tab.
- 4) Double click on the Computer menu item.
- 5) Select the Interrupt request (IRQ) radio button in the View Resources tab to display the interrupt assignments.

■ **Windows NT**

- 2) Select the Run... menu item from the Windows NT Start menu.
- 3) At the Open: prompt type **winmsd** and press Enter.
- 4) Select the Resources tab of the Windows NT Diagnostics window.
- 5) Click on the IRQ button to display the interrupt assignments.

API data types 8-5 to 8-7

API functions summary 8-8

API macros 8-4

asynchronous routines

description 8-2

mcbbsp_async_receive function 8-9

mcbbsp_async_send function 8-11

in DSP support software block diagram 1-12

synchronous routines

description 8-2

mcbbsp_sync_receive function 8-19

mcbbsp_sync_send function 8-20

McBSP receiver configuration structure

(Mcbbsp_rx_config) data type 8-7

McBSP sample rate generator configuration

structure (Mcbbsp_srg_config) data type 8-7

McBSP state macros 8-4

McBSP transmitter configuration structure

(Mcbbsp_tx_config) data type 8-6

mcbbsp.h header file 8-4

mcbbsp_async_receive function 8-9

mcbbsp_async_send 8-11

mcbbsp_close function 8-12

Mcbbsp_config data type 8-5

mcbbsp_config function 8-13

mcbbsp_cont_async_send function 8-14

Mcbbsp_dev data type 8-5

mcbbsp_drv_init function 8-16

mcbbsp_open function 8-17

mcbbsp_reset function 8-18

Mcbbsp_rx_config data type 8-7

Mcbbsp_srg_config data type 8-7

mcbbsp_stop function 8-18

mcbbsp_sync_receive function 8-19

mcbbsp_sync_send function 8-20

Mcbbsp_tx_config data type 8-6

McBSP0

in basic block diagram 1-7

selection 4-73

signals 4-19

McBSP1 1-7, 4-3, 4-19

mcbbspdrv.h header file 8-4

MCSR register 4-28

memory decoding 4-65

memory maps

definition G-10

MAP 0 4-14

MAP 1 4-15

message event, clearing 7-9

MIC_SEL macro 8-24

microphone input 4-71

MIN_ADC_INPUT_GAIN macro 8-23

MIN_AUX_LINE_GAIN macro 8-23

MIN_DAC_LBACK_ATTEN macro 8-23

mode selection macros 8-22

mounting bracket 2-9

MRAR register 4-28

MRTC register 4-28

multiplexers 4-72

MUTEX 7-19

MWAR register 4-28

MWTC register 4-28

N

NMI

- definition G-11
- externally disabling 8-43
- externally enabling 8-44
- generating to DSP 7-14
- selecting source for 8-44

NO_CAL macro 8-25

nonvolatile memory 4-13

notational conventions v to vi

NVRAM

- definition G-11
- reading byte of 7-25
- writing byte of 7-27

O

obtaining technical support ix

OMB1–OMB4 registers 4-28

op amps

- description 1-9, 4-71
- in board layout diagram 1-5
- in detailed block diagram 4-3

open driver connection function 7-28

open HPI for a board function 7-19

OPEN macro 8-4

open McBSP/obtain device handle function 8-17

operating scenarios 1-13

oscillators 1-5, 4-3, 4-7, 4-45 to 4-46

outgoing mailbox registers (OMB1–OMB4) 4-28

P

–p option 5-4, 6-2, 6-4, 6-7

parallel debug manager (PDM) commands 5-4, 5-5

PATH environment variable 2-13

PCI

- bus mastering support 4-33
- CNTL register 4-51
- CPLD control/status registers 4-49 to 4-55
- CPLDREV register 4-55
- definition G-11
- DIPBOOT register 4-54
- DIPOPT register 4-53

PCI (continued)

- DSPBOOT register 4-55
- DSPOPT register 4-54
- FIFO 4-14, 4-15
- interrupt control 4-62 to 4-64
- operating scenario 1-13
- slave support 4-30
- STAT register 4-52
- SWBOOT register 4-53
- SWOPT register 4-52

PCI add-on bus, operation registers

- AFIFO 4-29
- AGCSTS 4-29
- AIMB1–AIMB4 4-29
- AINTE 4-29
- AMBEF 4-29
- AOMB1–AOMB4 4-29
- description 4-29 to 4-30
- in MAP 0 memory map 4-14
- in MAP 1 memory map 4-15
- summary table 4-29

PCI bus

- description 4-23
- in basic block diagram 1-7
- in detailed block diagram 4-3

PCI controller

- base address registers (BARs) 4-24
- description 4-24
- in board layout diagram 1-5
- interfaces 4-25
- operation registers
 - FIFO 4-28
 - IMB1–IMB4 4-28
 - INTCSR 4-28
 - MBEF 4-28
 - MCSR 4-28
 - MRAR 4-28
 - MRTC 4-28
 - MWAR 4-28
 - MWTC 4-28
 - OMB1–OMB4 4-28
 - summary table 4-28

PCI interface

- description 1-8, 4-23
- implementation 4-24 to 4-27
- in basic block diagram 1-7
- in detailed block diagram 4-3
- plug-and-play feature 4-23
- perform codec initialization and default configuration function 8-33

- pin notation v
- pinouts, connector
 - CPLD ISP header A-4
 - DSP fan power A-8
 - expansion memory interface A-6
 - expansion peripheral interface A-7
 - external power A-8
 - JTAG emulation header A-5
 - PCI local bus A-9
 - stereo line input jack A-3
 - stereo line output jack A-3
 - stereo microphone input jack A-2
 - summary A-2
- PIO data register (R3) 4-70
- PLAYBACK macro 8-22
- plug-and-play feature 4-23
- power management 4-44 to 4-45, 4-77
- power sequence control 4-3
- power supplies 1-9, 4-74 to 4-76
- programmable logic
 - description 1-8, 4-40 to 4-41
 - in basic block diagram 1-7
 - in detailed block diagram 4-3

Q

- q option 6-2, 6-7

R

- r option 6-2, 6-7
- R0–R3 registers 4-70
- read byte of NVRAM function 7-25
- read data from board function 7-29
- read DSP memory using HPI function 7-20
- read operation, terminating 7-6
- receive buffer on McBSP asynchronously function 8-9
- receive buffer on McBSP synchronously function 8-19
- relative index 5-4
- requester arbitration mode 4-16
- reset board function 7-31
- reset codec function 8-36
- reset control 1-9, 4-42 to 4-44, 4-77
- reset DSP function 7-32

- reset McBSP function 8-18
- reset pushbutton 1-5, 4-77
- retrieve board type and version function 7-8
- retrieve message from DSP function 7-33
- return codec ID function 8-33
- return current CPU frequency function 8-40
- RIGHT macro 8-22
- ring 0 1-11, G-13
- ring 3 1-11, G-13
- RSVD_FORMAT macro 8-24

S

- s option 6-3 to 6-4, 6-7
- sample rate crystals, codec 1-5, 4-3
- SBSRAM
 - definition G-13
 - description 1-8, 4-10 to 4-11
 - in basic block diagram 1-7
 - in board layout diagram 1-5
 - in detailed block diagram 4-3
 - in MAP 0 memory map 4-14
 - in MAP 1 memory map 4-15
 - power management 4-11
 - selecting clock speed 4-10 to 4-11
- scenarios, EVM operation 1-13
- schematics C-1 to C-42
- SDCNTL register 4-62
- SDRAM
 - control register 4-17
 - definition G-13
 - description 1-8, 4-11
 - disabling 4-12
 - enabling 4-12
 - in basic block diagram 1-7
 - in board layout diagram 1-5, 1-6
 - in detailed block diagram 4-3
 - in MAP 0 memory map 4-14
 - in MAP 1 memory map 4-15
 - power management 4-12
 - refreshing 4-11
 - selecting refresh period 4-17
 - timing register 4-17
- select source for NMI function 8-44
- send buffer on McBSP asynchronously function 8-11
- send buffer on McBSP continuously function 8-14
- send buffer on McBSP synchronously function 8-20

- send message to DSP function 7-35
- serial data format macros 8-25
- SERIAL_32BIT macro 8-25
- SERIAL_64BIT macro 8-25
- SERIAL_64BIT_ENHANCED macro 8-25
- service driver failure error message F-2
- set base codec address function 8-37
- set capture and playback rates function 8-31
- set transfer time-out value function 7-38
- set user board options functions 7-36
- setting the boot mode 7-32
- setup.exe program 2-13
- signal levels, stereo audio interface 4-72
- software
 - See also* DSP support software; host support software
 - functional overview 1-10 to 1-12
- stand-alone operation scenario 1-13
- STAT register 4-52, 4-59
- status register (R2) 4-70
- stereo audio interface. *See* audio interface
- stop McBSP operation function 8-18
- support from TI ix, x
- SWBOOT register 4-53
- SWOPT register 4-52

T

- TBC. *See* test bus controller
- technical support ix, x
- terminate pending read transfer function 7-6
- terminate pending write transfer function 7-7
- test bus controller
 - and the EVM debugger 5-5
 - definition G-14
 - description 1-8, 4-30, 4-38
 - in board layout diagram 1-5
 - in detailed block diagram 4-3
- timer
 - audio codec 4-72
 - definition G-14
 - delaying CPU with 8-40
- timing fields, EMIF SDRAM control register 4-17

- transceivers 4-65
- transferring data
 - from DSP to host 7-29
 - from host to DSP 7-40
 - setting time-out value 7-38
- troubleshooting F-1 to F-8
- TTL, definition G-14

U

- u option 6-7
- ULAW_8BIT_COMPANDED macro 8-24
- unreset DSP function 7-39
- use internal codec timer function 8-38
- user applications
 - in DSP support software block diagram 1-12
 - in host support software block diagram 1-11
- user controls 1-3
- user options
 - control 4-66
 - description 1-3, 1-9, 4-78
 - DIP switches 4-78
 - dual-use option support diagram 4-68
 - in basic block diagram 1-7
 - in board layout diagram 1-5
 - in detailed block diagram 4-3
 - summary table 4-66
 - user defined 4-67, 4-78

V

- v option 6-3
- VelociTI 4-4, G-14
- very long instruction word (VLIW) 4-4, G-14
- voltage regulators
 - description 1-9, 4-74 to 4-75
 - in basic block diagram 1-7
 - in board layout diagram 1-5
 - in detailed block diagram 4-3
- voltage supervisor
 - description 1-9, 4-77
 - in basic block diagram 1-7
 - in board layout diagram 1-5
 - in detailed block diagram 4-3

W

warnings

- avoiding personal injury risk 2-8
- information about vi

Win32 DLL API

- data types 7-3
- functions summary 7-5
- in block diagram 1-11

Windows drivers 7-2

write a byte of NVRAM function 7-27

write data to board function 7-40

write DSP memory using HPI function 7-22

write operation, terminating 7-7

X

-x option 6-7

Z

-z option 6-3, 6-7
