**TABLE OF CONTENTS**

vii
Preface

AT&T UNIX System V/386 Release 3.2 successfully merges the functionality of the AT&T UNIX System V/386 and Microsoft XENIX System V/386 operating systems into a single UNIX operating system for the Intel 80386 based computer. It provides an environment capable of running current application executables developed for earlier releases of AT&T UNIX System V/386 as well as Microsoft XENIX System V/386. The product provides support for application executables developed for AT&T UNIX System V/286 Release 2 and Microsoft XENIX System V/286.

These Release Notes describe how AT&T UNIX System V/386 Release 3.2 compares to both AT&T UNIX System V/386 and Microsoft XENIX System V/386, focusing on new or modified features and functionality. In addition, these Release Notes contain a list of known software problems and workarounds.

Consult the Product Overview for a complete description of the functionality and components (software and documentation) of AT&T UNIX System V/386 Release 3.2.
Notational Conventions

The following notational conventions are used throughout these Release Notes:

**bold**  
User input, such as commands, options to commands, and names of directories and files, appear in **bold**.

**italic**  
Names of variables to which values must be assigned (such as *filename*) appear in **italic**.

**constant width**  
UNIX System output, such as prompt signs and responses to commands, appear in **constant width**.

<>  
Input that does not appear on the screen when typed, such as passwords, keys used as commands, or <RETURN> and other special keys, appear between angle brackets.

<`char`>  
Control characters are shown between angle brackets because they do not appear on the screen when typed. The circumflex (`^`) represents the control key (usually labeled CTRL). To type a control character, hold down the control key while you type the character specified by `char`. For example, the notation `<^D>` means to hold down the control key while pressing the d key; the letter d will not appear on the screen.

[ ]  
Command options and arguments that are optional, such as `[=-msCj]`, are enclosed in square brackets.

<p>| |</p>
<table>
<thead>
<tr>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>l</td>
</tr>
<tr>
<td>The vertical bar separates optional arguments from which you may choose one. For example, when a command line has the format</td>
</tr>
<tr>
<td>command [arg1</td>
</tr>
<tr>
<td>you may use either arg1 or arg2 when you issue command.</td>
</tr>
</tbody>
</table>
An ellipsis after an argument means that more than one argument may be used on a single command line.

A command name followed by a number in parentheses refers to the part of a UNIX System reference manual that documents that command. (There are two reference manuals: the User's/System Administrator's Reference Manual and the Programmer's Reference Manual.) For example, the notation `cat(1)` refers to the page in Section 1 of the User's/System Administrator's Reference Manual that documents the `cat` command.

In sample commands, the dollar sign ($) is used as the shell command prompt. This is not true for all systems. Whichever symbol your system uses, keep in mind that prompts are produced by the system. Although a prompt is sometimes shown at the beginning of a command line as it would appear on your screen, you are not meant to type it. In addition, some examples may use the default superuser prompt, the pound sign (#). As with the system prompt, you are not meant to type the superuser prompt.
Foundation Set Software Packages

The Foundation Set is the fundamental UNIX System software product supplied with your system. The Foundation Set provides you with the UNIX operating system kernel and a basic set of utilities. The Foundation Set consists of the following separately installable packages:

- Base System Package
- Editing Package
- Remote Terminal Package
- Security Administration Package
- 2 Kilobyte File System Utility Package
- Network Support Utility Package
- Remote File Sharing Package
- XENIX File System Utility Package

The Base System Package is the minimal required UNIX System. The other Foundation Set packages are optional, and you do not need to install them if you do not require the utilities they provide.
Features of AT&T UNIX System V/386 Release 3.2

AT&T UNIX System V/386 Release 3.2 provides the following new features. Consult the Product Overview for an overview of all the features.

XENIX System V Compatibility

AT&T UNIX System V/386 Release 3.2 provides full binary and source code compatibility with applications developed for Microsoft XENIX System V/386, Microsoft XENIX System V/286, AT&T UNIX System V/386, and AT&T UNIX System V/286. The following list describes the level of XENIX System V support:

- Source code written for Microsoft XENIX System V/386 programs and applications can be compiled and linked on AT&T UNIX System V/386 without having to modify the source code.

- Binary applications developed for Microsoft XENIX System V/386 (Release 2.2.0 and later) and Microsoft XENIX System V/286 (Release 2.0 and later) can be run on AT&T UNIX System V/386 without having to recompile the applications.

- The structure of the AT&T UNIX System V/386 file system allows both XENIX System V and UNIX System V binary applications to be executed. It also supports the mounting of a XENIX System removable file system (with the XENIX file system add-on installed).

- Support for XENIX System call extensions enables programs to run as they did under the XENIX System.

- All device driver support routines available under Microsoft XENIX System V/386 are available in AT&T UNIX System V/386.

In addition to the program interface, several XENIX System V commands have been added for ease of use and compatibility. Tools are provided that allow the installation of all existing UNIX System and XENIX System packages.

The following sections describe the XENIX System calls that are not supported in Release 3.2 and those that are supported, but have slightly different functionality.
XENIX System Calls that Function Differently in Release 3.2

The following XENIX System calls are supported in AT&T UNIX System V/386 Release 3.2, but function differently in the XENIX System:

execseg()

The XENIX execseg() system call has been added to Release 3.2. This system call provides a means by which data can be executed. The execseg() system call returns a far pointer (selector and offset) to the start of the data segment. To execute the data, you must set the offset portion of the far pointer returned by execseg to the address of the data to be executed. Then, you must perform a far (intersegment) call through the far pointer. Because the AT&T compiler does not support the "near" or "far" keywords (which correspond to intra- and intersegment addressing, respectively), it is not possible to use the execseg() system call directly in C language. To use execseg(), you must use in-line assembly instructions, as shown in the following example.
typedef struct feall {
    int (*fc_offset)();
    short fc_selector;
} fcall_t;

fcall_t codeitem; /* far pointer */

*fcptr = &codeitem; /* pointer to far pointer */

extern char code_in_data[]; /* data to be executed */

extern void execseg(); /* void due to lack of far */

execseg(); /* execseg returns far pointer */

asm("pushl %edi"); /* in eax,edx. This assembly */
asm("movl fcptr,%edi"); /* code places this return val */
asm("movl %eax,(%edi)"); /* in *fcptr */
asm("movl %edx,4(%edi)");
asm("popl %edi");

asm("pushl %edi"); /* do a far call into the data */
asm("movl fcptr, %edi"); /* pointed to by fcptr */
asm("lcall *%edi");
asm("popl %edi");

fcptr->fc_offset = (int (*)(()))code_in_data;

Note that any data to be executed must return by means of an "lret" instruction.

In addition, only one call to execseg() is required for executing data. After the initial call, multiple execseg() calls have no effect.

To remove the ability to execute data, use the unexecseg() system call. This system call disables execseg() by invalidating the selector execseg() returns. As a result, any attempt to perform a far (intersegment) call through the pointer returned by an earlier execseg() call causes a segmentation violation. As with execseg(), multiple calls to unexecseg() have no effect after the initial call.

Neither execseg() nor unexecseg() accepts arguments or returns errors.
fcntl() and lockf()
In Release 3.2, file locks placed using the `fcntl()` or `lockf()` system calls are always enforced, if the source is compiled on *Microsoft XENIX System V/386*. However, these file locks are not always enforced when the source is compiled on Release 3.2. If the source is compiled on Release 3.2, you must use the `chmod(1)` command to guarantee enforcement of the file locks.

*Microsoft XENIX System V/386* binaries that call `fcntl()` with `cmd LK_GETLK` and `flock L_type F_UNLCK` can receive blocking information. This feature is not supported in Release 3.2.

*Microsoft XENIX System V/386* binaries that call `fcntl()` and/or `lockf()` always have their read and write access permissions checked. When compiled on Release 3.2, however, read and write permissions are checked only when trying to set a lock.

*Microsoft XENIX System V/386* binaries that call `fcntl()` to set a non-blocking lock will receive `EAGAIN` if the call would block. On Release 3.2, binaries receive `EACCES`.

locking()
In Release 3.2, file locks placed using the XENIX `locking()` system call are always enforced.

ptrace()
In Release 3.2, the `ptrace()` system call is not supported for XENIX System binaries. XENIX System binaries that rely on `ptrace` to work will not work on Release 3.2. To make their code run on Release 3.2, you will have to modify their XENIX System code to use the UNIX System version of `ptrace`.

ulimit()
*Microsoft XENIX System V/386* binaries that call `ulimit()` with the `cmd` argument set to 2, cannot increase their limit beyond the maximum number of blocks that are representable in a 512-byte block file system. This restriction is not enforced when the source is compiled on Release 3.2.

uname()
The `utsname` structure returned from `uname()` is a different size, depending on whether you compile on *Microsoft XENIX System V/386* or on Release 3.2. On *Microsoft XENIX System V/386*, there are extra fields at the end of the structure.
XENIX System Calls Not Supported in Release 3.2

The following XENIX System calls are not supported on AT&T UNIX System V/386 Release 3.2:

**brkctl()**

**nfs_sys0**

**proctl0**

**shutdown0**
In Release 3.2, use the **uadmin()** system call with its **A_SHUTDOWN** command.

**stkgrow()**
Users will probably not be affected by the fact that this system call is not supported in Release 3.2.

**swapadd()**
In Release 3.2, use the **sysi86(SI86SWPL)** system call.

**xlist()** and **fxlist()**
The XENIX **xlist()** and **fxlist()** C-library functions are not supported by Release 3.2. Users must rewrite programs that use these two subroutines, using the 3.2 **nlist()** subroutine, as described in the *Programmer's Guide* and *Programmer's Reference Manual*.

Installing XENIX System Devices

XENIX System users should note that XENIX System device names (such as floppy drive devices) have been linked to their equivalent device names on AT&T UNIX System V/386 Release 3.2.

XENIX-286 Application Execution

This release of the UNIX System contains a *Microsoft XENIX System V/286* utility that allows *Microsoft XENIX System V/286* (*Microsoft Release 2.3* and *SCO*™ Release 2.3.2) programs to run on the *Intel 80386* processor under AT&T UNIX System V/386 Release 3.2.
For more information about the XENIX-286 feature, see the x286emul(1) manual page in the Programmer's Reference Manual.

Features from Microsoft XENIX System V/386

This section describes XENIX System utilities that have been added and Release 3.1 utilities that have been modified to support Microsoft XENIX System in Release 3.2.

New Utilities from XENIX System

The following utilities from Microsoft XENIX System V/386 are included in Release 3.2:

- clear(1) -- clears the terminal screen
- copy(1) -- copies multiple files, including directories
- csh(1) -- invokes a shell command interpreter with a C-like syntax
- ctags(1) -- creates a tags file for the vi(1) editor
- custom(1M) -- installs specific portions of XENIX System packages
- fixperm(1M) -- corrects or initializes XENIX System file permissions and ownership
- gethz(3C) -- returns the frequency of the system clock in ticks per second
- hd(1) -- displays files in hexadecimal format
- more(1) -- views a file one full screen at a time
- random(1) -- generates a random number
- settime(1) -- changes the access and modification dates of files
- strings(1) -- finds the printable strings in an object file
- sulogin(1M) -- allows access to single-user mode
- tset(1) -- provides information for setting terminal modes
- x286emul(1) -- emulates XENIX 80286
Features of AT&T UNIX System V/386 Release 3.2

- xinstall(1M) -- XENIX System installation shell script
- xrestore(1M) -- invokes XENIX incremental file system restorer
- yes(1) -- repeats "yes" string to prompts

Release 3.2 Utilities with New XENIX System Support

The following utilities from Release 3.1 have been modified to include XENIX System support in Release 3.2:

- ascii(5) -- reflects addition of decimal table
- asy(7) -- supports XENIX System "exclusive open" capability
- cc(1) -- supports new -Zp option for packing structure members into memory
- console(1) -- supports XENIX System compatibility
- convert(1) -- supports conversion of XENIX System archives
- core(4) -- usize parameter has been changed to USIZE
- cpp(1) -- supports new #pragma pack [1|2|4] option
- crash(1M) -- supports XENIX System IFNAM files
- cron(1M) -- supports XENIX System /etc/default/cron
- df(1M) -- supports -v option from XENIX System
- display(7) -- supports XENIX System functionality, including ANSI escape sequences
- echo(1) -- supports -n option from XENIX System
- egrep(1) -- supports -h and -y options from XENIX System
- fd(7) -- supports XENIX System device names
- fgrep(1) -- supports -h and -y options from XENIX System
- file(1) -- supports XENIX System IFNAM binaries, archives, and other files
- fsck(1M) -- recognizes files of type IFNAM and allows their recovery
Features of AT&T UNIX System V/386 Release 3.2

- grep(1) -- supports -h and -y options from XENIX System
- hd(7) -- supports XENIX System device names
- init(1) -- supports sulogin utility
- ipcs(1) -- supports new -X option for XENIX System compatibility
- keyboard(7) -- supports XENIX System ioctls
- limits(4) -- supports XENIX System-specific constants
- login(1) -- reflects changes in password aging and how the tty type is set in the environment
- ls (1) -- supports lc command from XENIX System, and lists XENIX System shared data and semaphores
- mdevice(4) -- supports ability to specify halt and poll routines in the functional field; also supports ability to share interrupts and DMA channels
- mount(1M) -- supports XENIX file system
- mountall(1M) -- supports XENIX file system
- passwd(1) -- supports three options (MINWEEK, MAXWEEK, and PASSLENGTH) read from /etc/default/passwd
- pwck(1M) -- supports XENIX System password information
- sdb(1) -- recognizes IFNAM type files
- sdevice(4) -- supports ability to share interrupt vectors
- sh(1) -- supports the -n option to echo
- stty(1) -- supports XENIX System console mode
- su(1M) -- supports the /etc/default/su file
- sysi86(2) -- supports 286 x.out emulation
- tar(1) -- supports XENIX System archives
- termio(7) -- supports XENIX System IOCTLs
- touch(1) -- merged with the XENIX System settime command
### AT&T UNIX System V/386 Release 3.2 Base System Devices

The following list defines the contents of the master device file (/etc/conf/cf.d/mdevice) before any add-on packages are installed.

</tbody>
</table>
Notes:

1. Nodes are not required for this device driver. See Note 4.

2. These devices are required to support add-on packages, or are stubs (place holders) for add-on device driver packages. The add-on packages may install nodes in the /dev directory.

3. The base system does not have nodes for this device. Nodes can be added later via the /etc/mknod command.

4. Several device drivers are software only drivers. That is, they provide a kernel software function packaged as a device that can be added to or removed from the system.
Differences Between XENIX System and Release 3.2

This section points out some important differences between XENIX System V and AT&T UNIX System V/386 Release 3.2 that XENIX System users should know and keep in mind.

Using the ftime() System Call

Users should stop using the XENIX ftime() system call, and begin using the time() call provided in Release 3.2.

Using Shared Data and Semaphore Facilities

For 286 processes, there are significant differences between the XENIX operating system and the UNIX operating system in the positioning of shared data and its effect on future memory allocation. For this reason, it is recommended that XENIX System users discontinue using XENIX System-specific shared data and semaphore facilities and begin using the equivalent UNIX System facilities.

Understanding Terminal Types

XENIX System users should note that Release 3.2 supports terminal types that were not supported in the XENIX System. For example, terminal type AT386-M is the default terminal type for AT&T UNIX System V/386. Use this terminal type instead of ansi for all console virtual terminals. The terminal type at386 should be used with color consoles.

UNIX System users should be aware that the $TERM environment variable can be set automatically, along with the capabilities and attributes associated with the terminal type, by using the tset(1) command in the user's .profile and by administration of the /etc/ttytype file. For additional information on using the tset(1) command and the /etc/ttytype file, see tset(1) in the User's/System Administrator's Reference Manual.
Differences Between XENIX System and Release 3.2

Shutting Down the System

Release 3.2 does not support the XENIX System haltsys utility. In Release 3.2, administrators must use the /etc/shutdown utility to shut the system down.

Using the curses Utility

The XENIX System curses is "termcap" curses, whereas the Release 3.2 curses is "terminfo" curses. The terminfo and termcap facilities co-exist in Release 3.2. For this reason, the XENIX System (termcap) curses libraries and header files have been renamed in AT&T UNIX System V/386 Release 3.2. For example, libxcurses is the XENIX System termcap based curses library. The corresponding header file is xcurses.h.

UNIX System to XENIX System Floppy Diskette Sharing

By default, the UNIX System can read data from raw devices in multiples of variable size, whereas the XENIX System reads data from raw devices in multiples of 512-byte blocks. Therefore, when writing UNIX System media that will be read from a XENIX System raw device (such as rfd0, the XENIX System primary floppy disk drive), you must specifically set the UNIX System write blocking factor to be a multiple of 512 bytes, so the XENIX System raw device will recognize the blocksize.

One way to avoid this problem is to always read from the non-raw forms of XENIX System devices, instead of using the raw devices. For example, to read a UNIX System tar diskette from a XENIX System primary floppy disk drive, specify /dev/fd0 on the tar command line, rather than /dev/rfd0.
Installation Notes

Overview

These installation notes provide information concerning the installation of an AT&T UNIX System V/386 Release 3.2 base system on your computer. Instructions are provided for the following conditions:

- New Installation
  - How to install AT&T UNIX System V/386 Release 3.2 over an AT&T 386 UNIX System V Release 3.1 or 3.1 Update system.
  - How to install AT&T UNIX System V/386 Release 3.2 over an already installed AT&T UNIX System V/386 Release 3.2.
  - How to install AT&T UNIX System V/386 Release 3.2 over a Non-AT&T UNIX System. (For example, a system with XENIX System or MS-DOS installed.)
  - How to install AT&T UNIX System V/386 Release 3.2 on a computer that has never had an operating system installed.

- Non-destructive installation
  - How to upgrade your AT&T 386 UNIX System V Release 3.1 or 3.1 Update base system software to AT&T UNIX System V/386 Release 3.2 without destroying any user files or non-Foundation Set packages. This is called a non-destructive upgrade installation.
  - How to overlay an AT&T UNIX System V/386 Release 3.2 over a previously installed AT&T UNIX System V/386 Release 3.2 without destroying any user files or non-Foundation Set packages. This is called a non-destructive overlay installation.
New Installation Notes

There are two ways you may be installing a new AT&T UNIX System V/386 Release 3.2.

- The AT&T UNIX System V/386 Release 3.2 base system is installed as "new" over any previous installed UNIX system. This includes AT&T 386 UNIX System V Release 3.1, Release 3.1 Update, or AT&T UNIX System V/386 Release 3.2. In this case you should begin with the section entitled "Initial Procedure".

- The AT&T UNIX System V/386 Release 3.2 base system is installed as the first system installed on your computer or Release 3.2 is installed over a non-AT&T UNIX System. In this case you may skip "Initial Procedure" and begin with the section entitled "Procedure for New Installation".

A new installation will destroy all files on the existing system. The Procedure For New Installation contains references to the installation procedures found in Chapter 2 of the Operations/System Administration Guide.

Installation of any new add-on packages, is covered in the "Install Optional Add-on Packages" section in the Operations/System Administration Guide.

Special Instructions for Upgrade and Overlay Installations

NOTE If a new installation of AT&T UNIX System V/386 Release 3.2 is to be performed, this section may be skipped.

This section contains precautions and notes relating to a non-destructive upgrade or overlay installation. It is divided into three categories:

- Non-Destructive installation functionality
Installation Notes

- Pre-installation procedures
- Post-installation procedures.

Non-Destructive Installation Functionality

The non-destructive installation performs the following high-level functions:

- Non-destructive upgrade installation
  - Upgrades from AT&T 386 UNIX System V Release 3.1 (or 3.1 Update) to AT&T UNIX System V/386 Release 3.2.
  - Does not destroy user data or non-Foundation Set add-on packages.
  - Preserves the current disk partitions and file systems.
  - Preserves the current user groups, logins, and passwords.
  - Removes the source files and data files associated with the adm command.
  - Requires removal of Foundation Set add-on packages.
  - Requires removal of existing line printer system, existing printers and classes, and any jobs in the printer queue.
  - Resets tunable parameters to default values.

- Non-destructive overlay installation
  - Overlays an AT&T UNIX System V/386 Release 3.2 over a previously installed AT&T UNIX System V/386 Release 3.2.
  - Does not destroy user data or non-Foundation Set add-on packages.
  - Preserves the current disk partitions and file systems.
  - Preserves the current user groups, logins, and passwords.
  - Does not require removal of Foundation Set add-on packages.
  - Does not require removal of existing line printer system, existing printers and classes, and any jobs in the printer queue.
Installation Notes

- Resets tunable parameters to default values.

Pre-Installation Procedures

Before beginning a non-destructive installation, you should perform the following procedures:

- You will be asked in the procedure if you wish to do a system backup. It is recommended that a system backup be done prior to starting the installation in case anything goes wrong. Backups of the required files can be made from the command line. Chapter 4 of the Operations/System Administration Guide provides the details.

- Record the current system configuration. This includes the add-on software device drivers installed on the system, serial port configurations, line printer configurations, etc. This information will be used in the post-installation procedures.

- If you are performing a system upgrade (not an overlay), you will be required to remove all Foundation Set add-on packages. It is recommended to remove these packages prior to starting the installation. This will make the installation flow more smoothly. The "Remove Add-on Software Package" section in the Operations/System Administration Guide may be used to remove these packages.

- To ensure that the system will be properly configured in the post-installation procedures, it is recommended that all currently installed add-on driver packages be removed before performing a non-destructive installation. This is recommended since the installation procedure does not rebuild the UNIX System kernel to incorporate currently installed software device drivers. Also, the files containing the tunable parameters and other system configuration information are overwritten with default information. The "Remove Add-on Software Package" section in the Operations/System Administration Guide may be used to remove these packages.

Post-Installation Procedures

After the installation is completed, you will want to return the system to its previous configuration. The following procedures should be followed using the system configuration that was recorded in the pre-installation procedures.

20 AT&T UNIX SYSTEM V/386 RELEASE 3.2
Installation Notes

- The software device drivers that were removed prior to installation must be installed. The "Install Optional Add-on Packages" section in the Operations/System Administration Guide may be used to install these packages.

- The AT&T UNIX System V/386 Release 3.2 equivalents of the Foundation Set add-on packages that were removed prior to an upgrade installation should be installed. The "Install Optional Add-on Packages" section in the Operations/System Administration Guide may be used to install these packages.

- Configure the line printer subsystem, second serial ports, etc. Configuration changes can be made to the required files from the command line. Chapter 4 of the Operations/System Administration Guide provides the details.
Installation Procedure

Initial Procedure

1. If you have either AT&T 386 UNIX System V Release 3.1 (or 3.1 Update) or AT&T UNIX System V/386 Release 3.2, perform the procedures starting at the beginning of Chapter 2 of the Operations/System Administration Guide through Step 5 in the section "Boot System to Single User Mode".

2. You will receive the following message:

   Is this a new installation or a release upgrade to your existing system? (Strike "n" (new) or "u" (upgrade) followed by ENTER).

3. If you enter n, use the "Procedure for New Installation" in this document.

4. If you enter u, use the "Procedure For Installing Upgrade" in this document.
Procedure for New Installation

NOTE This procedure assumes you have made the n response to Step 2 in the Initial Procedure.

or

The AT&T UNIX System V/386 Release 3.2 base system is installed as the first system installed on your computer or Release 3.2 is installed over a non-AT&T UNIX System. In this case, perform the procedures starting at the beginning of Chapter 2 of the Operations/System Administration Guide through Step 5 in the section "Boot System to Single User Mode" and return to Step 1 of this procedure.

or

You struck ENTER in Step 2 of the Procedure for Installing Upgrade.

1. You will receive the following message:

WARNING: A new installation of the UNIX System will destroy all files currently on the system. Do you wish to continue (y or n)?

To continue type y and proceed to Chapter 2 of the Operations/System Administration Guide. Perform the "Partition the Hard Disk" procedure.

If you type n, you will be placed at the single-user shell prompt.

If you wish to start this procedure over and not reboot the system, type:

INSTALL

If you wish to start the procedure again and reboot the system:

a. Type:

uadmin 2 0

RELEASE NOTES 23
Installation Procedure

b. Boot the system off the floppy by striking \texttt{CTRL}, \texttt{ALT}, and \texttt{DEL} simultaneously.

c. Start the installation process again by returning to the "Initial Procedure" section in this document.

2. If you type \texttt{y}, you will then receive the following message:

\begin{quote}
A surface analysis will now be done.  
This will destroy all data on the hard disk.  
Strike \texttt{ENTER} to continue or \texttt{DEL} to abort.
\end{quote}

If you wish to continue, strike \texttt{ENTER}.
If you type \texttt{DEL}, you will be placed at the single-user shell prompt.
If you wish to start this procedure over and not reboot the system, type:

\texttt{INSTALL}

If you wish to start the procedure again and reboot the system:

a. Type:

\texttt{uadmin 2 0}

b. Boot the system off the floppy by striking \texttt{CTRL}, \texttt{ALT}, and \texttt{DEL} simultaneously.

c. Start the installation process again by returning to the "Initial Procedure" section in this document.

3. If you strike \texttt{ENTER}, you will see the following message:

\begin{quote}
UNIX System file system(s) will now be created on the hard disk ...
\end{quote}

4. Go to Step 10 in the section "Create UNIX System File Systems" in Chapter 2 of the \textit{Operations/System Administration Guide} and complete the procedure for installing a base system on your computer.
Procedure for Installing Upgrade

NOTE This procedure assumes you have made the u response to Step 2 in the initial procedure.

1. A sanity check of the file systems will be done to determine if there is any uncorrectable file system damage that cannot be upgraded. If there is, an upgrade installation cannot be performed.

NOTE The following screen may be ignored if a system backup was performed prior to starting this installation. You may continue by striking ENTER.

If the sanity check determines that there is no file systems damage, you will receive the following message:

WARNING: A system backup is suggested prior to doing a system upgrade. To ensure a correctly functioning system, various add-on packages supplied with the foundation set will need to be removed. Also, if any packages are installed that reconfigure the UNIX System kernel, they should be removed before proceeding with the new installation. To proceed with the installation strike ENTER, otherwise, strike DEL to abort.

To continue with an upgrade installation, strike ENTER.

To abort the installation procedure, strike DEL. You will then be given the single-user shell prompt. Do the following:

a. Type:

uadmin 2 0
Installation Procedure

b. Remove the floppy from the disk drive.

c. Boot the system off the hard disk by striking \texttt{CTRL}, \texttt{ALT}, and \texttt{DEL} simultaneously.

d. Back up your files [use face menus or use the command level (refer to Chapter 4 in the \textit{Operations/System Administration Guide})].

e. Shutdown the system.

f. Reinsert the floppy and boot off the floppy by striking \texttt{CTRL}, \texttt{ALT}, and \texttt{DEL} simultaneously.

g. Start the installation process again by returning to the "Initial Procedure" section in this document.

2. If the sanity check determines that there is file system damage, you will receive the following message:

You will be unable to do an upgrade because your system
does not contain a valid UNIX System. Please consult your
"Release Notes" for further information.
Strike ENTER to continue with a new installation
or DEL to abort the installation procedure.

To continue strike \texttt{ENTER}. You will perform a new installation procedure. Go to the Procedure for New Installation.

To abort the installation procedure, strike \texttt{DEL}. You will then be given the single-user shell prompt. You may not be able to reboot the system. If you wish to start this procedure over without a reboot, type:

\texttt{INSTALL}

3. If you strike \texttt{ENTER} in Step 1, the root (/) file system will be checked to make sure that there is enough space for the files to be saved. Ten free blocks are needed. If there is not enough space, you will receive the following message:
There is not enough space in the root filesystem on your hard disk to back up files for a system upgrade. Please remove some files and try again. Consult your "Release Notes" for further information.

If there is not enough space, you will be given the single-user shell prompt. Do the following:

a. Type:

    uadmin 2 0

b. Remove the floppy from the disk drive.

c. Boot the system off the hard disk by striking $\text{CTRL}$, $\text{ALT}$, and $\text{DEL}$ simultaneously.

d. When the system comes up, remove enough root files to free 10 blocks. If you have created any files under $\text{/}$, consider these for removal.

e. Shut down the system.

f. Reinsert the floppy and boot off the floppy by striking $\text{CTRL}$, $\text{ALT}$, and $\text{DEL}$ simultaneously.

g. Start the installation process again by returning to the "Initial Procedure" section in this document.

4. If you are upgrading from Release 3.1 or 3.1 Update and if any Foundation Set add-on packages are installed, you will receive a message similar to the following:

   If your Foundation Set add-on packages were removed prior to starting this procedure, the following screen will not be seen.
Installation Procedure

NOTE You may have different packages installed from those shown in the following screen.

To ensure full UNIX System V/386 Release 3.2 functionality, the following operating system packages must be removed, and the Release 3.2 equivalents installed after the upgrade:

Editing Package Version 1.0
2 Kilobyte File System Utility Package Version 1.0
Security Administration Package

If not removed prior to the start of installation, you must remove all installed Foundation Set add-on packages before proceeding to ensure full Release 3.2 functionality. If you do not remove these packages all at once, the next time you select u to upgrade your system, you will receive the same message with the current packages to be removed.

If you are running Release 3.2, and doing the overlay upgrade, you will not be required to remove the Foundation Set add-on packages.

If any of these packages are installed, you will be put in single-user shell prompt.

a. Type:

        uadmin 2 0

b. Remove the floppy from the disk drive.

c. Boot the system off the hard disk by striking [CTRL], [ALT], and [DEL] simultaneously.

d. When the system comes up, execute "removepkg" as covered in "Remove Add-on Software Package" in Chapter 2 of the Operations/System Administration Guide to remove the listed packages.
Installation Procedure

e. Shutdown the system.

f. Reinsert the floppy and boot off the floppy by striking \texttt{CTRL}, \texttt{ALT}, and \texttt{DEL} simultaneously.

g. Start the installation process again by returning to the "Initial Procedure" section in this document.

\begin{note}
The packages that are discussed below should have been backed up as discussed in the pre-installation procedures.
\end{note}

5. If all the Foundation Set add-on packages are removed, but there are still some other packages installed (e.g., \texttt{Crystal-Writer} and STARLAN Network), you will receive the following message:

\begin{warning}
If any of the packages currently on the system fail to work after the upgrade, remove the package and then re-install it.
\end{warning}

6. If the Release 3.1 Line Printer (LP) System is on your machine, you will receive the following message:

\begin{quote}
The 3.1 LP system exists on this machine.
This installation will remove the following:

Existing LP System
Existing Printers and Classes
Any Jobs in the Printer queues

Strike ENTER to continue or DEL to abort
\end{quote}

If you wish to preserve your LP files, strike \texttt{DEL}. You will then be put in single-user shell prompt.
Installation Procedure

- Type:
  `uadmin 2 0`

- Remove the floppy from the disk drive.

- Boot the system off the hard disk by striking `CTRL`, `ALT`, and `DEL` simultaneously.

- Backup or save the LP files required.

- Reinsert the floppy and boot off the floppy by striking `CTRL`, `ALT`, and `DEL` simultaneously.

- Start the installation process again by returning to the "Initial Procedure" section in this document.

7. A UNIX System will be installed on the hard disk. You will see the following message:

```
A UNIX System will now be installed on your hard disk ...
```

8. After a delay you will see the following message:

```
Please standby

When you are prompted to reboot your system, remove the floppy disk from the diskette drive, and strike CTRL-ALT-DEL.
Please wait for the prompt.
```

9. Your prompt to reboot will appear as follows:
10. To install the remainder of the base system, perform the procedures in the section "Install the Remainder of the Base System" in Chapter 2 of the *Operations/System Administration Guide*.

11. Configure your system as instructed in the sections "Pre-Installation Procedures" and "Post-Installation Procedures".
Overview of Basic Procedures

The following sections provide brief descriptions of some basic UNIX System procedures.

Booting the System

The following list of instructions will boot an AT&T UNIX System V/386 Release 3.2 system after the Base System has been installed. Apply power to the system and wait 1 or 2 minutes; the second-stage boot should be loaded automatically by the PROMs.

The boot program will load and give you the following message:

Booting UNIX System . . .

If you immediately press ANY key, the boot process will be interrupted and the following message will be displayed:

Enter name of a kernel to boot:

If you enter the name of a kernel to boot, the boot process will continue. If you do not enter anything, after 1 minute /unix will boot automatically; if you want to boot /unix immediately, press the (Enter) key.

Shutting Down the System

The following steps are necessary to shut down an AT&T UNIX System V/386 Release 3.2 computer properly:

1. Log in as root and change your directory to ./.. Note that you must be on the console (/dev/console).
2. Run the shutdown program with the following options:

   shutdown -y -gTIME

   where TIME is the number of seconds to be allotted before the system is actually halted. A time factor of at least 120 seconds (2 minutes) is recommended for your systems that are being used as multi-user sites. The time factor allows you to exit editors and save programs before the system goes down.
The system will proceed to shut itself down after the allotted time, and when the message

Reboot the system now

appears, the system can be turned off. The Ctrl Alt Delete key combination can be pressed, or the system can be turned off and then turned on again in order to reboot at this point.

Instructions for Updating Selected Files from the Release

If necessary, selected files may be extracted from the installation diskettes. Appendix A contains a list of all the files on the Foundation Set diskettes. All the installation diskettes, with the exception of diskette 1 of 7 of the Base System and diskette 1 of 1 of the Remote Terminal Package, are cpio diskettes. Diskette 1 of 7 of the Base System and diskette 1 of 1 of the Remote Terminal Package are mountable file systems. If the file that you want to extract is on a cpio diskette, you should insert the diskette into the floppy diskette drive and use the following command to extract the selected file:

    cpio -icBvd filename < /dev/dsk/f0

If the file you want to extract is on a mountable file system diskette, you should insert the diskette into the floppy diskette drive and use the following commands to extract the selected file:

    /etc/mount -r /dev/dsk/f0 /mnt
    cp /mnt/<filename> <newfile>
    /etc/umount /dev/dsk/f0
The following sections provide reminders and general system troubleshooting information.

Converting to getopt by Hand

getoptcvt [see getopt(1)] adds about 30 lines of code to a shell script, so you may want to convert scripts by hand instead. Converting by hand probably will make the code cleaner and easier to understand. Also, you do not have to worry about parsing option-arguments that are also options.

Follow these guidelines to convert most scripts that currently use the getopt(1) command.

Step 1 Delete the old invocation line and the if statement that checks the exit code.

Step 2 Change the for loop to a while loop that invokes getopt(1).

Step 3 Change the patterns in the case statement from -option to single option letters.

Step 4 Delete the case for --.

Step 5 Add a case for '?'. This case may be used to print the usage message and to exit with a non-zero exit code. Note that the ? is quoted since it is interpreted for filename expansion.

Step 6 Remove all shift commands within the case statement.

Step 7 Change $2 to $OPTARG for cases that require an option argument.

Step 8 Add the statement shift 'expr $OPTIND - 1' after the while loop so the remaining arguments can be referenced as before. Following is an example of a script before and after conversion.
Miscellaneous UNIX System Reminders

# before conversion
set -- 'getopt abo: $*
if [ $? != 0 ]
then
echo $USAGE
exit 2
fi
for i in $*
do
case $i in
   -a | -b) FLAG=$i; shift;;
   -o) OARG=$2; shift 2;;
   --) shift; break;;
esac
done

# after conversion
while getopt abo: i
do
case $i in
   a | b) FLAG=$i;;
   o) OARG=$OPTARG;;
   ?) echo $USAGE
      exit 2;;
esac
done
shift 'expr $OPTIND - 1'
If you want your script to be compatible with earlier UNIX systems (that is, use either `getopts` or `getopt`), convert it as the following example shows:

```bash
if [ "$OPTIND" = 1 ]
then
  while getopts abo: i
do
    case $i in
      a | b) FLAG=$i;;
      o) OARG=$OPTARG;;
      ?) echo $USAGE
        exit 2;;
    esac
done
  shift 'expr $OPTIND - 1'
echo $*
else
  set -- 'getopt abo: $*
  if [ $? != 0 ]
  then
    echo $USAGE
    exit 2
fi
for i in $*
do
  case $i in
    -a | -b) FLAG=$i; shift;;
    -o) OARG=$2; shift 2;;
    --) shift; break;;
  esac
done
  echo $*
fi
```
**edit, ex, vedit, vi, view**

The *edit, ex, vedit, vi, and view* commands allow separate `.exrc` files in any directory. In addition, if you change directory to another user’s directory and use any of these editors to edit a file in that other user’s directory, the editor will execute the `.exrc` file if it exists in the second user’s directory. This functionality has security implications depending on the contents of the `.exrc` file, because the commands are executed as the user invoking the editor and not as the person who owns the `.exrc` file.

In this release a new option has been added to the *vi/ex* commands to allow you the option of reading the `.exrc` file in the current directory. Initially, the flag is NOT set. That is, the *vi/ex* command will NOT read the `.exrc` file if it exists in the current working directory. You can modify this option by inserting the line

```
set exrc
```

or the abbreviation

```
set ex
```

in the `$HOME/.exrc` file which is read when one of these editors is executed if the `EXINIT` variable is not set in the `.profile`. If you want to set the `EXINIT` variable, add the following lines to your `.profile`:

```
EXINIT="set exrc"
export EXINIT
```

However, you should note that executing *vi/ex* as another user with `su` could result in your files being compromised, since certain variables in the environment are passed when `su` is executed without the "-".

For more information, see the `ex(1)` manual page in the *User’s/System Administrator’s Reference Manual*. 

---

**RELEASE NOTES** 37
Floating Point Emulation

Two floating point emulators are provided in the product. The default emulator, called /etc/emulator.dflt, is linked to /etc/emulator and provides better performance than the second emulator, kept in /etc/emulator.rel1. However, /etc/emulator.dflt does NOT emulate all the instructions of the 80387 processor, specifically the following:

- FCOS: cosine function (80387 only)
- FDECSTP: decrement stack pointer
- FINCSTP: increment stack pointer
- FPREM1: partial remainder (80387 only)
- FRSTOR: restore saved state
- FSAVE: save state
- FSETPM: set protected mode
- FSIN: only sine function (80387 only)
- FSINCOS: sine & cosine function (80387 only)
- FUCOM: unordered comparison (80387 only)
- FUCOMP: unordered comparison and pop (80387 only)
- FUCOMPP: unordered comparison and double pop (80387 only)

The second emulator, /etc/emulator.rel1, provides complete emulation of the 80387 instruction set. However, this emulator has less performance than the default emulator. This second emulator should be used if problems occur with UNIX System 286 applications. The problems will manifest themselves by the application core dumping with a floating point exception.

If you need to change from the /etc/emulator.dflt emulator to the /etc/emulator.rel1 emulator, log in as root and type the following command:

```
ln /etc/emulator.rel1 /etc/emulator
```

Similarly, if you need to change from the /etc/emulator.rel1 floating point emulator to /etc/emulator.dflt, log in as root and type the following command:

```
ln /etc/emulator.dflt /etc/emulator
```

After you relink the proper emulator, the machine must be rebooted for the system to start using the other emulator.
Floppy Disk Operations

The following enhancements have been made to the floppy disk subsystem for AT&T UNIX System V/386 Release 3.2:

- Enhanced 3.5 inch floppy disk support now allows the operating system to access a 3.5 inch diskette drive as either diskette 0 or diskette 1. In the previous release, the 3.5 inch floppy drive could be accessed only as diskette 1.

- Automatic format detection of floppy diskettes allows access to floppies using generic device names regardless of the format of the diskette inserted into the drive. The following nodes have been added to the system to support this enhancement:

  `/dev/(r)dsk/f0`
  `/dev/(r)dsk/f0t`
  `/dev/(r)dsk/f1`
  `/dev/(r)dsk/f1t`

For example, if drive 0 is a 5.25 inch floppy drive and you want to create a cpio file on a 1.2Mb diskette, you would insert a formatted 1.2Mb floppy diskette into the drive and type the following command:

```
find . -print | cpio -ocv > /dev/rdsk/f0t
```

Similarly, you can insert a formatted 360 Kb diskette into the drive and issue the same command. The system will automatically detect that a formatted 360 Kb diskette is in the drive and process the command appropriately.

The following list describes important reminders and troubleshooting information for floppy disk operations:

- Some error messages from floppy operations appear only at the console, regardless of which terminal invoked the floppy command from which the error originated. This is true for all errors detected and displayed by the device drivers.

- Sometimes reading from a 360 Kb disk drive may fail and it will appear as though the floppy disk drive door is not closed. If this should occur, reinsert the floppy disk and close the drive door.
On some 80386 computers, the system will not recognize that the floppy disk drive door is open if the floppy disk is completely inserted into the disk drive and the door is left open. To correct this, make sure that the floppy drive door is always closed when a floppy disk is completely inserted.

**Kernel Operations**

The following list describes important reminders and troubleshooting information for performing kernel procedures:

- The process accounting computation of a process's memory usage is incorrectly maintained. The value calculated for process memory usage is slightly less than the real result.

- When a program executes integer division by zero, the following error message is displayed:

  ```plaintext
  floating exception - core dumped
  ```

  This message does not accurately describe the error.

- Processes spawned by the kernel at boot time (`sched`, `/etc/init`, `vhand`, `bdflush`) have start times (`STIME`), that is the time the system was last brought down, not the time they were spawned.

- Some core dumps may have possible file size errors reported by `fsck`, but these are only warnings and can be ignored. To determine whether the possible file size errors reported are resulting from core dumps, execute: `ncheck -i i-number` where `i-number` is given in the `fsck` message:

  ```plaintext
  POSSIBLE FILE SIZE ERROR I=i-number
  ```

  `ncheck` will generate the path name of a file from its inode number, `i-number`.

- If the operating system runs out of free `clists`, all input/output activity from/to terminal ports and the console will cease. No warning message is printed by the system to show that it is out of `clists`.

- The value of the `SHMALL` tunable parameter specifies the maximum number of in-use shared memory segments allowable systemwide. This parameter is not checked by the system [that is, `shmget(2)` does not check this limit].
login

To discourage intruders, the encrypted password and password aging information formerly found in /etc/passwd has been moved to /etc/shadow. This file can be read only by the superuser. You will still be able to change their passwords using the passwd(1) command. Password and aging information is added to /etc/shadow by running a new program, pwconv(1M). This program can be executed only by the superuser.

If you have an application or program that writes password and/or aging information into /etc/passwd, the program will have to be modified so that pwconv(1M) is executed after the information is appended to /etc/passwd. Until the modification can be made, the administrator with superuser privilege will have to run the program before the user who has been added or whose password information has been modified can log in.

To set a variable in an /etc/default file, the name of the variable is followed by an "=" and the value of the variable, with no embedded spaces or tabs. In /etc/default/login, the following variables may be set:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONSOLE</td>
<td>If set, only the superuser may login on the terminal defined as the console. For example, CONSOLE=/dev/console</td>
</tr>
<tr>
<td>ALTSHELL</td>
<td>If set to YES, the SHELL environment variable will be set to the users shell, if that shell is not /bin/sh. If set to NO, the names of nonstandard shells will not be put in the SHELL environment variable. The default value for this variable is NO.</td>
</tr>
<tr>
<td>PASSREQ</td>
<td>If set to YES, all users must have have a password. Any user without a password will be asked for one at the first opportunity permitted by the password aging set for that user (i.e., users without passwords may not change their NULL passwords if password aging is enabled for them, and</td>
</tr>
</tbody>
</table>

RELEASE NOTES 41
the minimum time before a password can be changed has not elapsed).

**TIMEZONE**
This variable sets the TZ variable in the environment of the user. It must match the timezone set in `/etc/TIMEZONE`.

**HZ**
This variable sets the environment HZ, the rate of the system clock, for the user logging in.

**PATH**
This variable sets a default path for a user who does not have uid 0.

**SUPATH**
This variable sets the default path for the superuser logging in. Another default path for the superuser is in `/etc/default/su`, which is set for superusers who did not login as such.

**ULIMIT**
This variable sets the maximum file size for a user. It is in units of 512-byte blocks.

**TIMEOUT**
This variable is the length of time which "login" will wait for a password after receiving a user name. It is in units of seconds.

**UMASK**
This variable is the default umask for users.

**IDLEWEEKS**
This variable is the number of weeks which an account may remain idle before its login is disabled.

### passwd

The `/etc/default/passwd` file has the following variables which may be set:

**PASSLENGTH**
This variable is the minimum length of a password. Any password shorter than this length will be disallowed. The default length, if the variable is not set in the defaults file, is 6.

**MINWEEKS**
This variable is the number of weeks, after changing a password, during which the password may not be changed again.
MAXWEEKS  This variable is the number of weeks, after changing a pass-
word, after which you will be requested to change your
password when you next log on.

The MINWEEKS and MAXWEEKS variables may be overridden with the
passwd program, by explicitly setting password aging for a particular user.

Changing the ULIMIT Parameter

In AT&T 386 UNIX System V Release 3.1, the default ulimit is a tunable
parameter settable via ID/TP in the operating system. If an administrator
wanted larger values for the users of the system, the ID/TP ulimit value
would be changed by the administrator to reflect the new value. The system
would then need to be rebooted before the new default value went into effect.

In AT&T UNIX System V/386 Release 3.2, it is possible to override the
ulimit set in the operating system by setting the ULIMIT parameter in
/etc/default/login. The current /etc/default/login sets the ULIMIT parameter
to 4096. If an administrator wishes to change the default ulimit, both the
ID/TP value and the /etc/default/login value would need to be changed to
reflect the new value.

Longest Allowed Path Names

The longest path name is restricted to 1024 bytes. System calls that
require path names as arguments will now fail, setting errno to ENOENT, if a
longer path name is given.

Previously, the path name was not restricted by the UNIX operating sys-
tem; however, most programs gave an ad hoc limit to the length. Generally,
these limits were well below 1024 bytes, so most programs should not be
affected by this change.

The limits.h file defines a macro PATH_MAX to be the longest length of
a path name. In Release 3.1 this file incorrectly sets the macro to 256, but it
will probably be changed in a future release to 1024. Local system adminis-
trators can safely change the value for PATH_MAX to 1024 without harm,
since the Release 3.1 system internally uses the longer limit.
You are encouraged to include the `limits.h` file with a statement like

```c
#include <limits.h>
```

and to refer to the `PATH_MAX` macro for the longest path name allowed.

**Saving Device Files When Backing Up root File System**

When you back up the `root (/)` file system using the `backup(1M)` command, the device files (`/dev` directory) are not saved as part of the backup. To save the device files, become the superuser, mount a blank formatted floppy that has a file system on it, and enter the following commands:

```bash
# mount /dev/* /mnt
# find /dev -print | cpio -pd } /mnt
```

where `/mnt` is the directory on which the floppy disk file system is mounted. The `cpio` options are lowercase letters `p`, `d`, and `l`.

To restore the files, insert the floppy on which the files were saved, and enter the following commands:

```bash
# /etc/mount /dev/dsk/f0 /mnt

dir

dir

# cd /mnt
# find . -print | cpio -pd } /dev

dir

dir

# /etc/umount /dev/dsk/f0q15d
```
Shell Scripts

It is strongly recommended that all applications convert any shell scripts into binary programs if specific user (group) permissions are required in the shell script command lines. To pass permissions, the binary program must have the setuid (gid) mode bit on and the owner (group) of the binary program set to the ID required. Then the exec(2) system call can be invoked with the binary program as the argument and the correct permissions will be passed.

If it is not possible to convert the shell scripts into binary programs, then a binary interface program must be written that would have the setuid mode bit on and the owner of the file set to root. Next, the process would have to do a setuid (gid) system call internally with the uid (gid) that must be passed to a sub-shell. This is only possible because the setuid (setgid) system call sets both the real and effective uid (gid) when called by a process with the effective uid of root. Finally, the binary interface would then call the shell script. This is a potentially dangerous procedure unless the programmer is aware of all the implications.

Invoking Bourne Shell Scripts from CSH

A single line comprised of a colon (:) should be added as the first line of Bourne Shell scripts when these scripts are to be invoked from csh(1). This will cause csh(1) to recognize the script as a Bourne Shell Script and execute it appropriately.
Software Notes

This section describes problems that may occur with Release 3.2, and in some cases, workarounds to those problems.

mknod(1M)

The usage message for the mknod(1M) command is incorrect. It does not agree with the documentation since it does not display the p option for creating named pipes. The User's/System Administrator's Reference Manual manual page for mknod(1M) correctly documents the usage. mknod(1M).

layers(1)

XENIX termcap-based applications, such as SCO Professional, does not work properly under the UNIX System xt-layers. The problem is when TERM=630 or 5620 is declared, the size of the screen is defined at 70 lines. When xt-layers is invoked, and windows of a smaller size are created, SCO Professional still thinks that is dealing with a full screen. Since the screen is not 80 characters wide, double lines are created.

Workaround: The problem is that SCO Professional applications look in /etc/termcap directly for the value of the lines and columns. Therefore, it does not paint the screen correctly when a window with fewer lines and columns is created.

In order to have a /etc/termcap entry work on a terminal that has layers invoked, you will have to create a new entry in the /etc/termcap file. To create the new termcap description, edit the /etc/termcap file and search for the terminal name that you want to use with layers. The first line of a termcap entry begins in column one, the actual terminal description follows. The lines that describe that terminal start with a <TAB> and end with a backslash (\). Copy that termcap definition up to the beginning of the next terminal description. The following procedure will accomplish this goal.

1. Change the name that you would set your TERM to.

   EXAMPLE:
   for 5620/dmd terminal, change the following line from:

   att5620|ATT5620|dmd|tty5620|ttydmd|5620|5620
terminal 88 columns @(#)5620.ti 1.1:
to:

```
att5620-s|ATT5620-s|dmd-s|tty5620-s|ttydmd-
s|5620-s|5620 terminal < 88 columns @(#)5620.ti 1.1:
```

This allows you to set your TERM to "dmd-l" which is used in this example to specify a dmd invoked with layers.

2. Modify the variables for lines "li" and columns "co". Search for the line that has the lines and columns defined. It will look similar to:

```
:co#88:li#70:kn#4:
```

In this example, change the "88" to the number of columns you predict will be in your average size window. Also, change the number of lines from "70" to what you would expect them to be.

3. Using "dmd-s" as an example, set your TERM to the name you gave your new termcap definition before invoking the SCO application. However, this TERM name is not recognized by curses applications (i.e., vi, ed, etc). You will be able to set your TERM to one type if you link /usr/lib/terminfo/d/dmd to /usr/lib/terminfo/d/dmd-s.

**ps(1)**

In AT&T 386 UNIX System V Release 3.1, the usage of ps changed. The ps command now checks and sets the user's effective UID to the real UID and the effective GID to the real GID. Therefore, only users with a real user id of root or a real group id of sys will be able to use the -I options to ps.

**/etc/sulogin(1M)**

/etc/sulogin(1M) is intended to be invoked by init when the root user invokes init to enter single user mode. This command should never be invoked directly from the command line.

When invoked by the root from the command line, /etc/sulogin will invoke a second shell for the root user but will not place the system in maintenance mode.
When `/etc/sulogin` is run by a normal user from the command line, the following error message is printed:

```plaintext
••• * 
NO ENTRY FOR root IN SHADOW FILE! ••••
Entering system maintenance mode".
```

This command does nothing except display the error message which should be ignored.

**System Startup**

If `/tmp` is a separate mount point, then `/tmp` is never cleaned up when a reboot occurs. This may lead to wasted disk space. This change is only necessary if the machine is configured with the `tmp` file systems (`/tmp` and `/usr/tmp`) on separate file systems.

**Workaround:** The following modification should be made to the `/etc/init.d/RMTMPFILES` file by root.

- If `/tmp` is a separate file system, add the following two lines after the `chown sys /tmp` line:
  ```bash
  else
      rm -rf /tmp/*
  ```
- If `/usr/tmp` is a separate file system, add the following two lines after the `chown sys /usr/tmp` line:
  ```bash
  else
      rm -rf /usr/tmp/*
  ```

**kernel**

The kernel will not rebuild properly if "weitek" is turned off in `/etc/conf/cf.d/sdevice`. If you try to rebuild the kernel using the `idbuild(1M)` command, the build will fail with the following symbols undefined:

```plaintext
get87
weitek_intr
weitek_reg
```
Workaround: Edit /etc/conf/cf.d/sdevice and search for "weitek". Change the second field on the line from "N" to "Y". Write the file and quit the editor. Then rebuild the kernel using the /etc/conf/bin/idbuild(1M) command. This will turn Weitek back on.

If it is absolutely necessary to turn off Weitek, these lines must be added to the /etc/conf/pack.d/weitek/stubs.c file. Immediately after the line

/* Weitek stubs */

add the following lines:

```c
int get87() {}
weitek_intr() {};
char *weitek_reg = (char *)0;
```

Installation and backup(1M)

A complete or partial system backup(1M) will back up Foundation Set add-on packages in addition to the user files. This is not a serious problem, but may result in a new package being overwritten by an older version if a complete restore is done. The new package would then have to be reinstalled. It also causes the backup to take more time and to use more media than simply backing up user files.

Workaround: If a complete restore is to be done, it should be done immediately after the Base System is installed, and before any of the Foundation Set add-on packages are installed. It may be necessary to use removepkg(1M) to remove an old package before the new version can be installed.

If a selective restore is done, and if only user files are to be restored, the order of installation is not important. However, it is still advisable that the restore be done before add-on packages are installed.
Software Notes

backup(1M) and restore(1M)

If you are doing a complete restore of a backup, it is not advisable to use the overwrite option since old versions of files may overwrite new versions. If you want to overwrite, do a selective restore so that you know exactly which files are to be overwritten.

If, when doing a complete or partial backup, the number of floppies needed appear to be unnecessarily large, press "delete" and remove the files /etc/.lastbackup and /etc/.lastpartial. A complete backup should be started.

Enhanced EGA Support

Some video boards do not work correctly. The Zenith/Heath "Enhanced" EGA is an example of such a board not supported by the operating system.

Application Installation

The normal XENIX SGS is not present. Installation procedures that call the XENIX System language tools directly must be modified to use the UNIX System tools. Application installation procedures that must use the XENIX System linkage editor to link pre-existing object modules will not work.

System Startup (/etc/rc files)

There is no longer a single /etc/rc file. Installation procedures that attempt to modify /etc/rc or /etc/rc.local must be modified to alter the appropriate rc file for the appropriate run level.

Uid for bin

The numeric uid for the user bin, and the numeric gid for the group bin, have changed. Installation scripts which depend on the old values must be changed to accept the new values. The values for the XENIX System were 3 and 3; the values are now 2 and 2.
**ls(1)**

The UNIX System command `ls` and the XENIX System command `ls` differ in the meaning of the size of a file in blocks (as provided by the `-s` option). The XENIX System understands that all filesystems have a block size of 1024 bytes, and thus correctly calculates the number of direct and indirect blocks. The UNIX System assumes a 512-byte block size when making the calculation.

**passwd(1)**

For enhanced security, encrypted passwords have been moved out of the file `/etc/passwd`. Installation procedures that examine or modify the password file directly must be modified to use the new scheme. Under the new scheme, user passwords and aging information are stored in `/etc/shadow`. Refer to Chapter 5 of the *Operations/System Administrator's Guide* for more information.

**uname(1)**

The default settings for the fields of the `uname` structure are different. This will result in different output for the `-m` and `-s` options of the `uname` command. Installation procedures that use the output of the `uname` command to determine machine type or system type must be modified to handle the new output correctly. Under the XENIX System, the "sys" entry defaults to "XENIX", and the "cpu" field defaults to "iAPX386". Under the UNIX System, the respective entries default to "unix" and "i386". Under both XENIX System and UNIX System, the remaining entries have release-dependent defaults.
Differences in Support of XENIX-286 Execution

XENIX-286 Emulation

Support of XENIX-286 executables is now handled by a user-level emulator, rather than by the kernel. As a result, attempts to execute a text file that is open for writing (which fail with the error ETXTBSY under the XENIX System) will succeed, and the emulator will then refuse to run the executable.

init(1M)

The shell that is provided when the user puts the system in single-user mode (via "init" s) has a useless path. Immediately after entering single-user mode, the shell search path should be set to whatever the user wants.

mountall(1M)

The documentation for the mountall command states that the command can take a list of files (or "-" for stdin) as command line arguments. This is not true. The mountall command ignores its arguments, and always reads the file /etc/fstab.

tlssadmin(1M)

In the Operations/Systems Administration Guide, the RFS chapter states that to start the Starlan listener, the command is:

    nlsadmin -S starlan

The correct command is:

    nlsadmin -s starlan

uname(1)

In the Operations/Systems Administration Guide, the RFS chapter states that typing the command

    uname -S nodename

will result in the user being prompted for the new name. In fact, the system’s name is set to nodename.
Future Directions

awk, nawk, oawk

With Release 3.1 there is a new awk (nawk). For this release awk is linked to oawk and is the default when you type awk. In the next major release of UNIX System V, nawk will be the default and will be linked to awk, but oawk will still be available.

NOTE nawk must be used with the international version of the software.

getdents(2)

The implementation of getdents(2) does not match the description in the dirent(4) manual page. The field d_off in struct dirent does not contain the file offset of the current directory entry, but rather the file offset of the following entry. This will be corrected in the next major UNIX System V release. The correction may require the re-compilation or re-linking of programs using the directory-management library routines described in directory(3X) (opendir, closedir, readdir, telldir, seekdir, rewinddir) and may require source changes to programs using the getdents(2) system call directly.

Regular Expressions

In Release 3.1 the implementation of regular expressions (for example in ex, egrep, regexp.h, and sh) has been extended to support 8-bit characters. The semantics for the range notation, which currently uses ordinal values for the character, are the same as in previous releases. This permits ranges to include: 7-bit characters, 8-bit characters, and 7- and 8-bit characters.
Remote File Sharing Notes

Software Description

Remote File Sharing (RFS) Release 1.2 is a software package that allows computers running AT&T 386 UNIX System V Release 3.1 or later releases to share resources (directories containing files, subdirectories, devices, and named pipes) selectively across a network. Administrators for computers on an RFS network can choose directories on their systems they want to share and add them to a list of available resources on the network. From this list, they can choose resources from remote computers that they would like to use on their computers.

Each computer on a Remote File Sharing system can be grouped with others in a "domain" or can operate as an independent domain. The domain can provide a central point for administering a group of computers. Unlike other distributed file systems used with the UNIX operating system, Remote File Sharing is built into the operating system. This approach has several advantages:

Compatibility  Once you mount a remote resource on your system, it will look to your users as though it is part of the local system. You will be able to use most standard UNIX System features on the resource. Standard commands and system calls, as well as features such as File and Record Locking, work the same on remote resources as they do locally. Applications should be able to work on remote resources without modification.

Security       Standard UNIX System file security measures will be available to protect your resources. Special means for verifying computers and restricting remote user permissions have been added for Remote File Sharing.

Flexibility    Since you can mount a remote resource on any directory on your system, you have a lot of freedom to set up your computer's view of the world. You do not have to open up all your files to every host on the network. Likewise, you do not have to make all files on the network available to users of your computer.
New Features

Two major features have been added to Remote File Sharing Release 1.2: client caching and loop-back.

Client Caching

The client caching feature of RFS provides substantial performance improvements over non-caching systems by reducing the number of times data must be read across the network. Client refers to the computer that is using a remote resource, while caching refers to the client's ability to store data in local buffer pools.

The first time a client process reads a block of data from a remote resource, it is placed in local buffer pools. Subsequent client processes reading a server file can avoid network access by finding the data already present in local buffers. This generally causes a large reduction in network messages, resulting in improved performance.

In order for client caching to work simply and reliably, the following features were built into it.

- **Cache consistency.** Checking mechanisms are used to ensure that the cache buffers accurately reflect the contents of the remote file the user is accessing.

- **Transparency.** The only difference users should see between caching and non-caching systems is improved response time. RFS-based applications do not have to be changed to run on a Remote File Sharing system that caches remote data.

- **Administration.** By default, client caching is on. However, options are available to turn off caching for an entire system or for a particular resource. (You would probably only do this if you have an application that does its own network buffering.) There are also some tunable parameters available to fine tune your system to the way you use RFS.

Loop-Back

The loop-back feature allows you to simulate the higher levels of RFS within one computer. For example, you could advertise a resource and mount it in a different location on the same machine.
Remote File Sharing Notes

The main use of the loop-back feature is to test application programs and give RFS demonstrations with only one computer. For information describing how to use this feature, see the -o option on the radmin(1M) manual page in the User's/System Administrator's Reference Manual.

Software Notes

This section describes problems that may occur with Remote File Sharing and, in some cases, workarounds to those problems.

acct

The accounting file passed to the acct(2) system call cannot be remote. This restriction applies to user software that uses the system call directly and to the process accounting software. RFS does not allow the acct system call; if passed a remote path name, acct will return an errno of EINVVAL.

chroot

If you use the chroot command to change to the root directory of a remote machine, the ps command will not work properly.

Client Caching

Reads and writes of block special files are not cached because they could duplicate other data in the cache (for example, data from a regular file residing on the block device defined by the special file). However, if you write to a block device special file on a server machine, the contents of regular files on the block device may be changed. Client-cache buffers associated with these files may be out of date. (Local disk accesses do not suffer from this problem, since block-device writes go through the local buffer pool).

Users who write to block special files on file systems that are advertised remotely in a way that affects the contents of regular files should turn off caching when the resource containing the device is first mounted. (See the -c option of mount(1M).)
df

If df is used without options, it will list each occurrence of a remote resource that is mounted on a system and place an asterisk next to the word blocks for the second and each subsequent resource that was advertised under the same remote file system (for example, /usr/mail and /usr/bin). This signifies that the identical block counts for the resources reside under the same file system.

The problem is that if df is used with multiple remote resources passed as arguments, the asterisk never appears. In this example, the two resources are on the same remote file system, though the asterisk does not appear:

```
$df USRMAIL USRBin
/mnt/(USRMAIL) 30402 blocks
/mnt/(USRBIN) 30402 blocks
```

fumount

The -w option to the fumount command allows you to specify a grace period between warning clients that a resource is to be removed and actually removing the resource. The atoi subroutine [strtol(3C)] calculates the number of seconds. This routine looks for an initial numeric string and converts it to an integer. Any non-numeric character in the argument terminates the argument. For example, the argument -w 123abc gives a grace period of 123 seconds. Missing arguments and arguments without an initial numeric string produce an error message.

fuser

The fuser command does not find remote users with open local files. For example, mount a 1.2 Mbyte floppy file system as /tmp/a. Advertise the /tmp directory as resource TMP. Mount the TMP resource on a remote system and open a file residing in the TMP/a directory you just mounted. On the local system, run fuser /dev/dsk/f0 (the floppy). The remote user will not be found.

fuser

fuser may miss a process if that process gets a reference to the resource after fuser has begun its search. In this case, the offending process can be killed explicitly with the kill command. When all processes using the resource are gone, the resource can be unmounted.
Remote File Sharing Notes

idload

Many ID mapping features do not function properly with the loop-back function. Only use global blocks of information in mapping files (uid.rules and gid.rules). Within global blocks only default transparent works as intended. Specific mapping (map lines) or attempts to use host blocks will result in users and groups being mapped to 60002.

labelit

labelit performs a check to ensure that the destination device path begins with /dev/r?? for tape devices. However, remote tape devices on an RFS network are typically mounted under a local directory or in /dev. As a result, labelit cannot be used over RFS for remote tape devices.

Logs

These log files may contain information relating to RFS activities:

/usr/adm/rfuadmin.log
/usr/adm/log/rfuadmin.log
/usr/net/servers/rfs/rfs.log
/usr/net/nls/netspec/log

These files are for internal use only! Customers should not rely on the contents of these files because the information may change or the file may be deleted in future releases. Any tool written that takes advantage of the information contained in these files is not guaranteed to work in the future. (In the list above, netspec is replaced by the transport provider used by RFS. For the STARLAN NETWORK, the netspec is starlan.) The rfuadmin.log files are NOT automatically truncated. You may want to monitor them to make sure they do not get too large.

Iseek

Using Iseek with a negative offset on a remote file behaves differently than on a local file. On a local file, the call fails and returns EINVAL, as it always has. However, on a remote file the call succeeds and returns the negative offset.

58 AT&T UNIX SYSTEM V/386 RELEASE 3.2
mount

When a mount fails because of a password mismatch, the error message can be confusing. The following error messages result from a remote mount failure due to mismatched passwords:

- **negotiate**: An event requires attention
- **mount**: negotiations failed
- **mount**: possible cause: machine password incorrect
- **mount**: could not connect to remote machine

mount

When a remote resource is disconnected by a `fumount(1M)` command or a broken link, the default action in the client `rfuadmin` script is to try to remount the resource as it was mounted before. Therefore, if a resource that was originally advertised by the server as read/write is readvertised read-only, the client’s automatic mount will never succeed.

An administrator can always enter `mount` directly using the latest advertised mode.

mount

The programs that automatically remount remote resources (/etc/rmount, /etc/rmountall, and /usr/nserve/rfuadmin) do not recognize the `-e` option of the `/etc/mount` command as valid. The result is that when they attempt to remount a resource that was disconnected and that was originally mounted with client caching turned off [mount(1M) with the `-e` option], the resource is remounted with client caching turned on (the default).

One possible workaround for this problem is for the administrator to wait until the program that does the remount completes successfully, then to unmount and to remount the resource manually using the `mount -c` command. The administrator might also consider killing the process that does the remount, but there is no assurance that other actions that the process must perform will complete successfully.
mount

The `mount` command returns a different `ERRNO` and error message than it did in UNIX System V Release 3.0. The error occurs when you try to mount a local device on a subdirectory of a Remote File Sharing resource you mounted from another machine. The previous error was `EMULTIHO`P and the error message was:

```
mount: Multihop attempted
mount: cannot mount device
```

The new `errno` is `EREMOTE` and the error message is:

```
mount: Object is remote
mount: cannot mount device
```

Name Server

When the primary and secondary name servers are under heavy load, the normal passing of name server information between these machines may cause them to hang because the 1K Streams buffers have been depleted. There is one long-term and one short-term solution to the problem.

For the long term, you can increase the number of 1K Streams buffers in `/etc/conf/cf.d/mntune`. The parameter is `NBLK1024`. Increasing 2K Streams buffers (`NBLK2048` parameter) may also help because the system will try to use 2K buffers when 1K buffers are depleted.

The short-term solution is that you can stop Remote File Sharing on any secondary name server that is hung and then bring it back up again; that will clear the `NBLK1024` buffers.

nsquery

The resource list printed by `nsquery` does not always reflect the current state of the domain. If a resource is advertised and the server goes down, a subsequent `nsquery` from a client may still list the resource as being available, even though it is not. An attempt to mount the resource will fail, because it is unable to contact the server. You will have to wait for the remote machine to make the resource available again.

Programs

If a program creating remote directories or files loses its link to the remote machine, and the remote resource is unmounted, the program may begin to create local directories and files. For example, if you are using the find command piped to cpio to a remote machine and the link to the remote machine goes down and the resource is then unmounted, cpio may begin writing on the local machine—the target directory now looks just like an ordinary local directory.

Recovery

Remote File Sharing limits the size of a resource name to 14 characters. This is intended to limit only the resource name and not the domain name (if addressing a resource from another domain).

When a resource is mounted, the stated length of domain and resource name combinations can be used. However, when a link is broken to a server machine, the client's recovery mechanism tries to unmount the server resources. In doing so, it calculates the size of the resource name including the domain and the "." that separates them. If this string exceeds 14 characters, recovery fails to unmount the resource and may not complete. The result is that users will not be able to access the resource, but the resources will still be listed when you print the names of locally mounted resources (mount command).

This problem can be solved in one of two ways. If the problem occurs, the administrator can manually unmount the resource that is posing the problem and then recovery will complete properly (umount -d resource). To avoid the problem altogether, the administrator should use domain names and resource names that, when concatenated together, will not exceed a total length of 14 characters.

Recovery

If a client loses its link to a server, any attempt to umount one of that server's file systems from the client tree will fail until recovery runs. Recovery from a link failure is handled by rfuadmin(1M) and rfudaemon(1M).

Recovery runs automatically when the link breaks, but not until someone tries to access the link or until a maximum of 11 minutes have passed. (The 11-minute time interval applies if you are using STARLAN network. The time may be different for other transport providers.)
If the `umount` fails because the link is gone, the `umount` will start recovery. After recovery runs, a second `umount` will succeed.

**rfadmin**

The `rfadmin -p` command should not be used to pass name server responsibilities back to the primary while the RFS domain is in an unstable state. After RFS is restarted on the primary, the administrator on the secondary machine that is the current domain name server should wait until all requests to mount resources from the primary are completed. (When the primary went down `rmount` requests were placed in the background on all client machines that had mounted resources from the primary.) The secondary administrator can safely use `rfadmin -p` when the mount requests are completed.

**rfadmin**

The `-p` option of the `rfadmin` command returns a value of 2 if the command fails because no computer is available to take over primary name server responsibility.

In earlier releases, the `-p` option of the `rfadmin` command returned a 0 upon success or a 1 upon failure. In RFS Release 1.1, the `-p` option returns a 0 upon success, a 2 if the command fails because there is no computer available to assume primary name server responsibilities, or a 1 if the command fails for some other reason. This change gives the `rfstop(1M)` command the ability to warn the administrator if the machine being stopped will cause the domain to be without a primary name server.

**rfmaster**

The acting domain name server is responsible for distributing important name service information to all other accessible (secondary) name servers that are serving the same domain, with no more than a 15-minute lag, so that if the acting name server should fail, another host could assume the name server role with a minimal loss of information. However, changes to the `rfmaster` file after `rfstart` has been run are not included in the information that is distributed in this way. Because the designation of hosts as primary and secondary name servers is made in the `rfmaster` file, this has the consequence of not allowing a change to the configuration of which hosts are the primary and secondary name servers for a domain without stopping and re-starting RFS on the affected hosts. For example, adding a new secondary name server to the
rfmaster file will not take effect until RFS is taken down on all of the existing (primary and secondary) name servers, as well as the newly designated secondary and then re-started.

This limitation should not be confused with the temporary transfer of name server responsibility to another one of the hosts already listed in the rfmaster file as a primary or secondary name server; this temporary transfer is performed with the rfadmin -p command.

rfmaster

When rfstart is executed, the name server process (nsserve) scans the rfmaster file and reports possible errors. However, if there is an entry in the rfmaster file that identifies a computer as a name server (either primary or secondary), but there is not a corresponding address entry in the rfmaster file for that computer, it is not reported as an error, even though it should be. In attempting to contact a name server (for example, during rfstart or rfadmin -p), name servers with no address listed will be silently skipped.

rfpasswd

The rfpasswd command is used to change the host password used for RFS, and it is intended to parallel the passwd command in the way it prompts for old and new passwords. However, if a host has no password (for example, it has a null password), the rfpasswd command will still prompt for the old password before asking for the new one, although it should ask only for the new one.

rfstart

This problem only happens when you are issuing an rfstart command from one terminal and some other RFS command from another terminal.

Sometimes when you run the rfstart command it will prompt for a password. RFS has actually started when the password prompt occurs, so an adv command from another terminal would be accepted. After the password is entered, rfstart completes, which includes clearing the advertise table. The result is that the domain advertise table would show the advertised resource as available, while the local advertise table would not.

This problem can be avoided by not issuing additional RFS commands until the rfstart completes and exits to the shell. If the problem does occur, use the adv -m or unadv commands to put the two advertise tables back in agreement.
Remote File Sharing Notes

rfudaemon

User-level recovery of resources that are disconnected gracefully (the remote system shuts down) may fail if the number of lost resources exceeds half of the value of the tunable parameter **MAXGDP** in */etc/conf/cf.d/mtune*. By default, **MAXGDP** is 24. The failure is accompanied by one or more of the following messages:

```
  rfs user-daemon queue overflow:
  make sure rfudaemon is running
```

STREAMS

The three system calls related to STREAMS—**getmsg**, **putmsg**, and **poll**—will not operate with a file descriptor associated with a remote file. If this is attempted, the system call will fail with **errno** equal to **ENOSTR**.

swap

Swap devices cannot be remote, including the swap device configured initially and any swap devices added using the **swap(1M)** command.

System Calls

When a Remote File Sharing server does not recognize an incoming request, it will return an **EREMOTE**. In Release 3.0, unrecognized system calls were ignored by the server.
Network Support Utilities Notes

Introduction

The Network Support Utilities (NSU) Release 1.2 package extends system capabilities to support networking applications. The package includes software support for STREAMS, the AT&T Transport Interface, and the Listener.

The Network Support Utilities package is required to take advantage of the following features of AT&T 386 UNIX System V Release 3.1 and later: the Remote File Sharing package, STREAMS mechanisms and tools, the AT&T Transport Interface, the enhanced Basic Networking Utilities, and the Listener.

STREAMS

STREAMS is a general, flexible facility for developing UNIX System communication services. By defining standard interfaces for character input/output within the kernel, STREAMS supports development ranging from complete networking protocol suites to individual device drivers. The standard interfaces and associated tools enable modular, portable development and easy integration of network services and their components—these were used to develop protocol modules and device drivers for Release 3. STREAMS provides a broad framework that does not impose any specific network architecture. It implements a user interface consistent and compatible with the character I/O mechanism that is also available in the UNIX System.

The power of STREAMS resides in its modularity. The design reflects the layering characteristics of contemporary networking architectures. Each basic component (called a module) in a STREAMS implementation represents a set of processing functions and communicates with other modules via a standard interface. From the user level, kernel resident modules can be dynamically selected and interconnected to implement any rational processing sequence. No additional kernel programming, assembly, or link editing is required. Modularity allows for the following advantages:

- User-level programs (commands such as uucp) can be independent of underlying protocols and communications media so the programs need not be changed when new media or protocols between systems become available.
Network Support Utilities Notes

- Network architectures and higher-level protocols are independent of underlying protocols, drivers, and media.

- Higher-level services can be created by selecting and connecting lower-level services and protocols.

In addition to the standard interfaces, STREAMS provides a set of software tools that help source customers build modules and drivers.

**AT&T Transport Interface**

With Release 3, UNIX System V supports a Transport Interface based on the Transport Service Definition (Level 4) of the International Organization for Standardization (ISO) Open Systems Interconnection (OSI) reference model. The transport service supports two modes of transfer: connection mode and connectionless mode. Connection mode is circuit-oriented and supports data transfer over an established connection in a reliable, sequenced manner. The connectionless mode is message-oriented (datagrams) and supports data transfer in self-contained units with no logical relationship required among units.

The AT&T Transport Interface defines how to access the services of a transport protocol, called a Transport Provider. An example of a Transport Provider is the ISO. Application programs access the Transport Provider by using the Transport Interface routines in the new Network Services Library. These routines support access to a Transport Provider in a media and protocol-independent manner. The Transport Provider uses kernel level programs to send the information to the desired physical device, such as the STARLAN Network Access Unit (NAU). By using the AT&T Transport Interface, application programs will be able to access other Transport Providers that may be available in the future.

For more information, see the *Network Programmer's Guide* and the *Programmer's Reference Manual*.

**Listener**

The "listener" is a program that can be used with Transport Providers on a system. The purpose of the listener is to receive requests for services from another system, interpret which service is needed, and start a process that has been named to provide the requested service. The listener then drops out of the communications path and continues to listen for new service requests.
For more information about the listener, see \texttt{nlsadmin(1M)} in the \textit{User's/System Administrator's Reference Manual}. Also, see the Basic Network Utilities and Remote File Sharing sections of the \textit{Operations/System Administration Guide} for information on how to set up the listener for these products.

\section*{Software Notes}

This section describes problems that may occur with the Network Support Utilities and, in some cases, workarounds for these problems.

\section*{Listener}

- In general, when the listener has trouble binding its listening addresses during its start sequence, the actual addresses bound will be chosen by the protocol and hence will differ from the ones requested. There are two cases where this can happen: when the address requested to be bound is either already bound for listening on that network, or when that address does not conform to whatever criteria the protocol is expecting for an address.

In both of these cases, the listener will output a message to the console stating the address returned by the protocol and

\begin{quote}
\texttt{TLI bound a different name than requested.}
\end{quote}

Additionally, the requested address appears in the listener's log file along with the messages sent to the console. The listener will then exit.

- The listener process can now parse quoted strings in the command line in the data base file.

  In the previous release, the listener did not understand quoted strings as arguments to servers. If quoted strings were required, it was necessary to specify a shell script as the server and embed the real server and the quoted string arguments there. This change eliminates the need for that indirection.

- The listener process now runs as \texttt{root} and sets both the user and group ID as specified by the user ID in the data base file.

  In the previous release, the listener ran as user ID \texttt{listen}. Because of this, servers that required special permissions needed to be owned by the appropriate user with the setuser or setgroup ID bits set.
accordingly. The proliferation of privileged servers was deemed to be a potential security hazard. This change allows the administrator to specify in the listener data base file the user ID under which the server should run:

```
nlsadmin -a svc -ccmd -wid -y comment netspec
```

The listener will perform `setuid` and `setgid` system calls based on this ID before exec'ing the server.

**STREAMS**

**open**

A race condition exists in clone opens from different inodes. This problem exists when two or more disk inodes with the major of the clone device and equal minors are being opened at the same time. If the window is hit, then another `open` after the first `open` may bypass the clone device entirely, thus failing. For example, if `/dev/node1` was major 63 and minor 57, and `/dev/node2` was also major 63 and minor 57, and if they were two different inodes, then simultaneous opens of the two devices may result in failure of the second open.

If two or more separate files are needed on disk, they should be created as links to one disk inode, thereby closing the window. In the previous example, `/dev/node2` should be linked to `/dev/node1` instead of being a separate inode.

**read**

For a STREAMS file, when a message containing 1 or more bytes is read and the first message block of the message contains 0 bytes, the message will be erroneously treated as a 0 byte message.

**write**

For a STREAMS file, if `write` is interrupted by a signal after some data have been written, it should return the number of bytes written. However, it returns -1 and sets `errno` to `EINTR`.

Even when there are no flow control restrictions, `write` will block if STREAMS internal resources are not available, regardless of the state of `O_NDELAY`. 
STREAMS Programmer's Guide

In Appendix C, the initial lines of qenable should read as follows:

```
qenable - enable a queue

int qenable(q)
queue_t *q;
qenable places the queue pointed at by q ...
```

Transport Interface Library

Network Programmer's Guide

The reference to tirdwr(7) in the caution note on Page 5-2 should reflect the change (in the manual page) that popping the module from a stream no longer causes a disconnect.

`t_accept`

The description of TBADDATA has been modified to clarify the condition under which it occurs.

[TBADDATA] The amount of user data specified exceeds the allowed amount as returned in the info.connect field by `t_open` or `t_getinfo`.

`t_connect`

The description of TBADDATA has been modified to clarify the condition under which it occurs.

[TBADDATA] The amount of user data specified exceeds the allowed amount as returned in the info.connect field by `t_open` or `t_getinfo`.

`t_getstate`

`t_getstate` will not work following an exec(2)/sync(3N) call sequence because there is insufficient information available to determine the state. The problem arises because the state is maintained in a user process data space, but an exec will overwrite that data space and the state information will be lost. If `t_getstate` is called in this case, it will fail with `t_error` set to TSTATECHNG.
Network Support Utilities Notes

The processing of expedited transport data units (ETSDU) by \_rcv has been modified. The function will now set the T\_EXPEDITED flag on return, if the data are part of an expedited message. The sentence in the fourth paragraph of the DESCRIPTION now reads:

Subsequent calls to retrieve the remaining ETSDU will have T\_EXPEDITED set on return.

The description of TBADDDATA has been modified to clarify the condition under which it occurs.

[TBADDDATA] The amount of user data specified exceeds the allowed amount as returned in the info.discon field by \_open or \_getinfo.

The paragraph describing the EPROTO error has been expanded as follows:

If \_sndudata is issued from an invalid state, or if the amount of data specified in udata exceeds the TSDU size as returned by \_open or \_getinfo, the provider will generate an EPROTO protocol error (see TSYSERR below). However, the \_sndudata may not fail because EPROTO errors may not be reported immediately. In this case, a subsequent call that accesses the transport endpoint will fail with the associated TSYSERR.

The description of the TBADF value \_errno has been changed to the following:

[TBADF] The specified file descriptor does not refer to a transport endpoint.

Appendix B: Documentation Updates

Documentation Updates

The following change pages reflect last minute changes to the AT&T UNIX System V/386 Release 3.2 documentation. These change pages should be inserted into the Operations/System Administration Guide per the following instruction.

AT&T UNIX SYSTEM V/386 RELEASE 3.2
OPERATIONS/SYSTEM ADMINISTRATION GUIDE
UPDATES

This update involves the following action:

1. ACTION: Replace page 9-11 through page 9-14 of Chapter 9 with the new pages.
Setting Up RFS

In most cases, you will not need the set of tasks described in this section because the basic RFS configuration and reconfiguration can be handled using the commands described earlier in this chapter. These tasks are for those who want to go deeper into the workings of RFS or are having problems with particular components.

These tasks are run from the shell. They should be run initially in the order described.

Once these tasks are completed, go to the "Starting/Stopping RFS" section for information on starting RFS.

Prerequisites

Before you begin setting up RFS, the following must be installed and running: UNIX System V Release 3.1 (or later) software, Remote File Sharing Utilities, Networking Support Utilities, and transport provider software. (See the Remote File Sharing Release Notes and the transport provider manuals that accompany the product for installation instructions.)

You must also log in as root.

Set Node Name

CAUTION

Changing the node name of your computer requires careful coordination with all machines that communicate with yours using Remote File Sharing or other communications packages that rely on node name.

Check to see if your computer's node name is set to the name you want (uname -n). If it's not, set it by typing

    uname -S nodename

A node name that is valid for RFS can consist of up to eight characters of letters (uppercase or lowercase), digits, hyphens (-), and underscores (_).

Some networks, such as the STARLAN network, require that every node name in the network be different. RFS, however, only requires that every node name in a domain be different.
Setting Up RFS

Set Up Network Listener

If you have installed the Networking Support Utilities, the AT&T implementation of the STARLAN network, and RFS in the order described in Chapter 2, "Software Installation," you can skip this task. The listener will already be installed and set up to run automatically, and RFS will be listed as an available service.

If you are using another transport provider or suspect that your STARLAN network listener is set up improperly, this task will show how to manually set up the listener. In the following example, the STARLAN network is used. To set up the listener for other networks compatible with the AT&T Transport Interface, you should replace starlan with the name of the network (network specification) you are installing. (For more details, see the nlsadmin(1M) manual page in the User's/System Administrator's Reference Manual.)

To determine if the listener is properly installed and set up for use by RFS, type the following:

```
nlsadmin -v starlan
```

If service code 105 is listed, then the listener is configured to be used for RFS.

Run the following commands if the listener is not properly set up. If you run any of these commands and they have already been run, you will receive a message telling you so. This will not harm your listener configuration. Type

```
nlsadmin -i starlan
```

to initialize the files needed for the listener process for the network specified, in this case starlan.

Next, type

```
nlsadmin -a 105 -c /usr/net/servers/rfs/rfsetup -y "rfsetup" starlan
```

to add the RFS service (rfsetup) to the list of services available to the starlan listener.

Use the following command line to report the status of the starlan listener process installed on this machine (ACTIVE or INACTIVE):
nlsadmin -x

Next, type

nlsadmin -l "nodename.serve" -t "nodename" starlan

to register the network addresses of your machine. The listener will listen for requests for these addresses on the network. Only the -l address is required by RFS. The -t address is used only for terminal services and may not be needed on all networks.

To start the listener, type

nlsadmin -S starlan

Normally, it will be started automatically when your machine enters multi-user mode (init 2).

Set the Domain Name

Set the domain name by typing

    dname -D domain

where domain is replaced by the domain of which your machine will be a member. The domain name must:

- contain no more than 14 characters
- consist of any combination of letters (uppercase or lowercase), digits, hyphens, and underscores
- be different from the name of any other domain used on the network if there is more than one domain on your network

You can check the current domain name by typing:

    dname
Set Up RFS

Set the Transport Provider

To identify the network, you must tell RFS which network (transport provider) it should use. (In our example, this is starlan for the STARLAN network.)

dname -N starlan

This command indicates the device, relative to the /dev directory, that is used for the transport provider.

Create rfmaster File

The rfmaster file should only be created manually on the primary. If your machine is not the primary, you should skip this task; the rfmaster file for your domain will automatically be placed on your machine the first time you start RFS (rfstart -p primary_addr).

If you are on the primary, you can create an rfmaster file in the /usr/nserve directory using any standard file editor. The contents of this file will define the following:

- the primary name server for your domain
- secondary name servers for your domain
- network addresses for each of these machines

(See the section on "Multiple Domain Name Service" in this chapter for a description of other information you may want to put into the rfmaster file.)

Here is an example of an rfmaster file for a domain called peanuts, whose primary and secondary name servers' node names are charlie, linus, and lucy. Adding each machine's domain name (peanuts) to its node name, separated by a period, forms its full RFS machine name. Each line of the example translates as follows:

- For domain peanuts, the primary is peanuts.charlie.
- For domain peanuts, a secondary is peanuts.linus.
- For domain peanuts, another secondary is peanuts.lucy.

AT&T UNIX SYSTEM V/386  
RELEASE 3.2  
SOFTWARE DEVELOPMENT SET  
RELEASE NOTES

Introduction

Overview

These Release Notes contain information about the Software Development Set (SDS) package. The SDS package is useful to programmers who:

- Want to develop C language programs
- Do extensive programming in the C language
- Want to enhance the efficiency of a C program written in a UNIX system environment
- Need tools to do advanced programming and symbolic debugging
- Want to work with shared libraries
- Work in an environment where it is necessary to track and maintain versions of files and programs
- Want to optimize and streamline development of interactive, character-oriented, C application programs.

The Software Development Set runs on a computer running AT&T 386 UNIX System V/386 Release 3.2.
Introduction

The SDS software package is made up of two parts as follows:

- C Software Development Set (CSDS)
- Extended Terminal Interface (ETI).

Conventions Used in This Document

In these Release Notes, certain typesetting conventions are followed when command names, command line format, files, and directory names are described. There are also conventions for displays of terminal input and output.

- You must type words that are in bold font exactly as they appear. Also, commands, filenames, and directory names appear in bold.

- Words in italics are variables; you substitute the appropriate values. These values may be filenames or they may be data values.

- CRT or terminal output and examples of source code are presented in constant-width font.

- In output and source code examples, a backslash (\) at the end of a line indicates that the line wraps around without a break.

- A command name followed by a number, for example, prof(1), refers you to that command’s manual page, where the number refers to the section of the manual. These manual pages appear in the AT&T UNIX System V/386 Release 3.2 Programmer’s Reference Manual unless otherwise noted.
### Contents of the Release

The Software Development Set (SDS) comes in one set of five diskettes (four diskettes for CSDS and one diskette for ETI), the contents of which are displayed in the following table.

**Table 1: SDS Utilities**

Software Overview

The SDS package has two major parts: the C software development set (CSDS) and the extended terminal interface (ETI). CSDS can be used for developing, debugging, and improving the efficiency of C language programs. ETI is a set of libraries that promotes fast development of screen management applications. These two parts of the SDS package are discussed in the following subsections.

CSDS

CSDS is a collection of tools and utilities that aid you in:

- Developing C language programs
- Advanced programming, symbolic debugging, and improving C language program efficiency.
- Keeping a history of source code files by recording changes made to these files along with comments on each version.

The C Programming Language Development Tools

The main C programming language development tool is the compiler, and is called by the command cc. The other programming development tools discussed in this section are the C preprocessor, optimizer, assembler, link editor, tools for manipulating object files, and libraries.

C Compiler

The C compiler supports the C language as specified in The C Programming Language. The significant extensions to the language include the following:

- Arbitrary length names for variables and function names
- Structure assignments and arguments
- Functions returning structure values
- Enumerated data types
- Multiple external variable declarations
- Assembly language escapes from C
- Insertion of arbitrary strings into object modules (useful for version control)
- Floating point support in conformance with the Standard for Binary Floating-Point Arithmetic, ANSI/IEEE Std 754-1985
- Data type void
- Additional preprocessor directives.

cc Command

The cc command, the major command of CSDS, calls the C compiler. The cc command also controls the other phases of compilation, and, unless programmers use options to specify otherwise, cc automatically calls the C preprocessor, assembler, and link editor phases. The command options have many uses, such as suppressing the assembler or link editor or invoking the optimizer. The cc command also passes some options to these other programs.

The cc command accepts files containing C source code as input. The result of the compilation process is an executable module named a.out that reflects the contents of the source files and any referenced library routines. The cc command also accepts source files that contain assembly language code as input and passes these files directly to the assembler.

C Preprocessor

The C preprocessor [cpp(1)] is automatically called whenever the cc command is given C source input. The preprocessor performs file inclusion and macro substitution.

Optimizer

The optimizer, an optional component in the compilation process, improves the efficiency of compiler-generated assembly language code. The optimizer reduces the space requirements and speeds the execution time of the resulting object code.

Assembler and Assembly Language

The assembler [as(1)] is available for developing applications that require close interaction with hardware, such as those needed to handle input/output devices and interrupts. The assembler converts assembly language code into a relocatable object module composed of machine code and symbolic information. This component provides assembly language programmers access to predefined macros using the UNIX operating system m4 macro processor.
Software Overview

Link Editor

The link editor [ld(1)] combines relocatable object modules and libraries to produce either an absolute, executable load module or a relocatable object file for use in further link edits. Executable load modules are in the Common Object File Format (COFF). The link editor performs relocation, resolves external references, and incorporates symbolic debugging information into its output file. It searches libraries to resolve all external references and only loads library routines that define an unresolved external reference.

Tools for Manipulating Object Files

CSDS provides a variety of commands used to read and manipulate object files. Here is a list of some utilities with brief descriptions of their use:

- **ar** Groups files into a single, portable archive file commonly used as a library
- **cprs** Compresses object files by removing duplicate structure and union symbolic information
- **dis** Disassembles object files to allow assembly level debugging
- **dump** Prints selected parts of the named object files
- **lorder** Generates an ordered listing of object files for efficient library link editing
- **nm** Prints the symbolic information in an object file
- **size** Reports the number of bytes of text, initialized data, and uninitialized data (and their sum) included in an object module
- **strip** Reduces file storage overhead by removing symbolic information from an object file.

Libraries

CSDS comes with libraries for object files, access to system calls, input/output, string manipulation, mathematical functions, and memory allocation.

Advanced Programming Tools and Utilities

The CSDS package contains an extensive set of tools useful for advanced application programming, debugging, improving the efficiency of your programs, and aiding you in keeping track of the different versions of your programs.

10 UNIX SYSTEM V/386 RELEASE 3.2
Programming and Debugging Utilities

The programming utilities are specialized utilities helpful in the design and development of application programs and systems. The following list gives a short description of the major programming utilities.

- **cxref** is a C cross-reference listing generator.
- **ctrace** is a statement-by-statement execution trace facility.
- **cflow** produces a graph of program dependencies.
- **lint** detects faulty and non-portable code.
- **cb** is a C code beautifier
- **regcmp** compiles regular expressions
- **mkshlib(1)** makes a shared library. Shared libraries is a feature of UNIX System V Release 3.0, and beyond, that allow several **a.out** files to simultaneously use the same object code.
- **chkshlib(1)** checks a shared library.
- **sdb(1)** a symbolic debugger used to examine C language executable files and core files and to provide a controlled environment for their execution. When testing C language programs symbolically, breakpoints can be set at executable lines of the source code. These breakpoints force the program to pause at the specified point so that an inspection can be made of the current state of the program.
- **make(1)** a tool that helps you build and maintain up-to-date versions of programs. **make** simplifies the job of keeping track of which files depend on other files, recently modified files, files that need recompiling after changes, and the sequence of operations needed to make a new version of a program.
- **lex(1)** a tool that generates programs to be used in simple lexical analysis of text. The **lex** tool reads a file containing specifications of strings to be matched and associated C code. Whenever the lexical analyzer produced by **lex** matches a specified string in its input, it executes the associated C code.
- **yacc(1)** a tool (Yet Another Compiler-Compiler) that accepts both an **LALR(1)** grammar specification and associated C code fragments that represent actions to be taken when a found grammar rule is reduced, and then produces a parser.

**Productivity Utilities**

The CSDS package has three utilities that can help an experienced programmer enhance the efficiency of a C program written in a UNIX operating system environment. These utilities are a browser called *cscope* and two profilers, *lprof* and *prof*.

A browser is an interactive program that helps you examine source files by searching for functions, function calls, macros, and variables that you specify. When it finds them, the browser puts you into an editor at the specified location. Thus, instead of thumbing through a stack of printouts to learn code or locate a bug, you can specify a function or text string and let the browser find it. Then you have the option of examining that portion of code or editing it. Whether you want to familiarize yourself with a program or edit a source file, a browser can help you accomplish your task without your reading the code line by line.

The browser in CSDS, designed for use with C code, is called *cscope*. Programmers responsible for writing programs or maintaining existing programs will be able to edit their source code more efficiently with *cscope*. It is especially helpful for a programmer working on someone else's code.

A profiler is a tool that performs dynamic analysis or analysis of a program at run time; it accomplishes this in two phases. First, the profiler collects data about the code while a program is being executed. Then it displays this data in a readily accessible format. The profiler *lprof* provides line-by-line frequency profiling, reporting how many times each line of source code is executed. To obtain a more representative sample of program performance, you can run a program profiled with *lprof* more than once and then merge the data from the multiple runs. This information can be useful in every stage of software development: designing, prototyping, coding, testing, debugging, and maintenance.

The profiler *lprof* can also be used to determine which lines of source code are executed and how much of the code is exercised. These types of output can be obtained by using the `-x` option and the `-s` option, respectively. These options are convenient for programmers who are interested only in
execution coverage and who do not need the additional information that **lprof** normally provides. For example, if you are developing a test suite and want to find out how much code is actually tested by your test suite, run **lprof** with either the `-x` or `-s` option, depending on the level of detail you want.

Another CSDS profiler you may find useful is **prof**. The **prof** profiler reports the amount of time spent in various parts of a program during execution. The use of **prof** is not required for using **lprof**, but by using these profilers together you can increase the efficiency of **lprof**. The **prof** profiler allows you to identify the most time-consuming parts of a program. By running **lprof** on only those parts of code, you can avoid generating uninformative output while targeting sections of code that need pruning. It is therefore recommended that you use **prof** and **lprof** together.

To use these utilities, you must know how to use CSDS in the UNIX system environment. These utilities do not modify code for you; they enable you to find parts of code that deserve further work on your part. For programmers who have not compiled C code or used CSDS before, the basics are covered in the *AT&T UNIX System V/386 Release 3.2 Programmer's Guide*.

**Source Code Control Utilities**

A subset of the CSDS utilities, sometimes called the source code control system (SCCS), is specifically designed for source code control. These utilities can be used to record all enhancements and changes to files, along with comments on each version, thus maintaining a history of the changes made. The major SCCS functions include:

- Retrieving any recorded version of a file with comments
- Storing a new version of a file
- Comparing two versions of an SCCS file.

SCCS takes custody of a file, and, when changes are made, identifies and stores them in the file with the original source code and/or documentation. As other changes are made, they too are identified and retained in the file. Each separate set of changes is called a delta. History data can be stored with each version: why the changes were made, who made them, when they were made, etc.

Retrieval of the original or any set of changes is possible. Any version of the file as it develops can be reconstructed for inspection or additional modification.
Here is a list of SCCS commands.

- **get**: Retrieves versions of SCCS files.
- **unget**: Undoes the effect of a `get -e` prior to the file being delta'd.
- **delta**: Applies deltas (changes) to SCCS files and creates new versions.
- **admin**: Initializes SCCS files, manipulates their descriptive text, and controls delta creation rights.
- **prs**: Prints portions of an SCCS file in user-specified format.
- **sact**: Prints information about files that are currently out for edit.
- **help**: Gives explanations of error messages.
- **rmrmdel**: Removes a delta from an SCCS file. Allows removal of deltas created by mistake.
- **cdc**: Changes the commentary associated with a delta.
- **what**: Searches any UNIX operating system file(s) for all occurrences of a special pattern and prints out what follows that pattern. Useful in finding identifying information inserted by the `get` command.
- **sccsdiff**: Shows differences between any two versions of an SCCS file.
- **comb**: Combines consecutive deltas into one to reduce the size of an SCCS file.
- **val**: Validates an SCCS file.
- **vc**: Is a filter that may be used for version control.

For instructions on how to use SCCS and detailed descriptions of SCCS commands, see the "Source Code Control System" chapter in the *AT&T UNIX System V/386 Release 3.2 Programmer's Guide.*
Extended Terminal Interface

ETI is a set of libraries that promote fast development of screen management applications. The ETI libraries are a software tool that enable you to incorporate screen management and data entry capabilities into your programs. ETI contains the following libraries:

- **Curses/Terminfo Low Level Function Library:** This library consists of routines for writing character-oriented screen management applications independent of the terminal type. Basic routines are provided for writing to a screen, reading from a screen and building windows. Advanced features are used to change screen attributes, draw line graphics and work with more than one terminal. A major new feature is the incorporation of color. You can specify both the background color for each character and the color of the character itself.

- **High-Level Function Libraries:** The high level function libraries are built on top of curses. They consist of functions that create, manipulate, and display panels, forms, and menus.
  - **Panels:** A panel is a rectangular area containing a curses window that may be displayed in whole or in part on the terminal. Panels provide a depth relationship between curses windows. Panels which are logically below other panels are properly obscured.

  - **Forms:** A form is a multi-page display that contains a set of fields. These fields may be used for data entry, labels, or messages. You can customize the look and behavior of a form or field. The rich set of form commands includes the following: inter-field and intra-field navigation, field editing, data entry, and validation.

  - **Menus:** A menu is a display presenting a collection of items. The end-user can select one or more items and this information is available to the application. You can customize the look and behavior of a menu. Menu commands are provided for item navigation, menu scrolling, and item matching.

- **Terminal Access Method (TAM) Transition Library:** The TAM Transition Library enables character mode applications developed for the UNIX PC using TAM to run on other processor/terminal configurations. The library maps TAM calls to curses routines.
Software Features

The CSOS package supports character classification and conversion and international date and time formats. The `ctype(3C)`, `ctime(3C)` and `cftime(4)` routines have been modified as described in the following subsections. Also, the dynamic tables of the CSOS components `comp` (compiler) and `as` (assembler) are described. Other CSOS features discussed in the following subsections include referencing a shared library from within a shared library, the `#hide` and `#export` directives, checking shared library versions with `chkshlib(1)`, and a proposed C language standard.

**ctype(3C)**

The classification of characters (what constitutes alphabetic, printable, uppercase or lowercase) varies from language to language. The `ctype(3C)` library routines that are used to classify character-coded integer values have been enhanced to recognize other code sets or classifications. Among these is the routine `setchrclass(3C)`, which is a new routine used to initialize the character classification and conversion table. It is invoked at program startup and can be invoked directly from users’ programs. This means the character set specific table can change dynamically.

**ctime(3C)**

The `ctime(3C)` routines allow the user to manipulate date and time formats. Several new library functions (`cftime`, `ascftime`, and an enhanced `tzset`) have been added to `ctime(3C)`. These routines support the following features:

- The ability to specify fractional time zones
- The ability to specify start and end dates and times of alternate time zones
- The ability to specify time and date formats with new format field descriptors
- The ability to specify native language translations of month and weekday names.
Software Features

**cftime(4)**

The *cftime(4)* manual page describes how to create language specific files. These files contain detailed information such as full and abbreviated month names, full and abbreviated weekday names, and default local time and date formats.

For more information on how to use these features, see *ctime(3C)*, *ctype(3C)*, *cftime(4)*, and *environ(5)* in the *AT&T UNIX System V/386 Release 3.2 Programmer's Reference Manual*.

**Dynamic Tables**

Though the C language tends to encourage small functions and source files, some existing applications contained very large source files that failed to compile under previous issues of CSDS because of the fixed size of some tables in the compilation system. In this issue, the tables in the compiler and the assembler are allocated dynamically.

In the compiler, successful compilation is no longer constrained by the number of symbols, the number of cases in a switch, the number of arguments to a function, etc., except as limited by the amount of memory on your machine. Similarly, the assembler's constraint on the number of symbols has been removed.

**Referencing a Shared Library from Within a Shared Library**

At times you might need to allow one shared library to directly reference routines in another shared library. One way to do this is with imported symbols. Another way is to reference routines in one shared library from another shared library; use the keyword *noload*, with the *#objects* directive in the shared library specification file. When the *#objects noload* directive is used, the *mkshlib* command will search the libraries listed for unresolved references. You will want to use this feature only when you cannot import symbols explicitly.
The #hide and #export Directives

Two directives, #hide and #export, can be used in the library specification file to control the visibility of external symbols.

Checking Shared Library Versions with chkshlib(1)

The chkshlib(1) command allows you to compare versions of shared libraries to see if they are compatible. This command accepts various combinations of executable files, target shared libraries, and host shared libraries as input and tells you if the library versions are compatible, or if the specified executable could have been built by or can run with the specified host or target shared library.

For more information about shared libraries, see the chapter on shared libraries in the AT&T UNIX System V/386 Release 3.2 Programmer's Guide. The AT&T UNIX System V/386 Release 3.2 Programmer's Reference Manual contains more information about chkshlib(1) and mkshlib(1).

Proposed Standard for C

As these Release Notes were published, no official standard for the C programming language existed. The language accepted by AT&T C compilers follows the definition given in The C Programming Language by B. Kernighan and D. Ritchie (Prentice-Hall, 1978). The CSDS package also supports the following extensions.

- Flexnames
  
  This extension allows variable and function name tokens to be distinct to at least the first 100 characters (rather than the first 8 characters).

- Structure assignments and return values
  
  This extension allows variables of the same structure type to be assigned to one another. The return value of functions can also be a structure.
Software Features

- Enumeration types
- Multiple external variable declarations

This extension makes it possible to have the declaration

```c
int i;
```

in multiple source files. All these multiple references resolve to the same address at link edit time.

Currently the X3/J11 task force of the American National Standards Institute (ANSI) is defining a standard for the C language (Draft Proposed American National Standard for Information Systems — Programming Language C, October 1986). The standard proposed by ANSI will allow most current legal C programs to be compiled without any changes. Nevertheless, to ease the possible transition process to the standard, the AT&T C compiler included with CSDS warns about the use of some constructs that may not be legal in the future or may cause portability problems. The following are examples of such constructs.

- Declarations, such as,

```c
int i;
static int i;
```

produce the warning message

```text
warning: i previously declared extern, becomes static.
```

- Structure definitions missing semicolons, such as

```c
struct x {
    int i
}
```

produce the warning message

```text
warning: syntax requires ; at end of struct/union decl
```
Installation Notes

The following text describes the space dependencies and version control as it relates to the installation of the SDS package. For complete installation procedures, see the Operations/System Administration Guide.

Space Dependencies

The SDS package is installed using the installpkg(1) command. The installpkg(1) command checks to determine that sufficient free space is available in the root and /usr file systems. You need approximately 7,900 blocks (512-byte blocks) of memory to install the SDS package.

Version Control

The C software development set portion of the SDS package uses a per file method of version control. If the file being installed already exists on the system and has a release number greater than the file belonging to the package being installed, the existing file will not be overwritten. Files without valid release information are assumed to be older than those belonging to the package being installed.

Verification

After installing SDS, verify the correct SDS version (4.1.5) by using cc -V.
Software Notes

This section offers some tips on using the SDS package and some software tips that enhance the usability of the package.

1. Functions of type float or double need to be declared in scope whether or not their return values are being used.

2. Elements of type char will be sign extended. For zero extension, unsigned char must be used.

3. If you are compiling your programs with the -g option enabled so that you can do debugging, it is advisable NOT to use the -O option as well. In some cases, the two options invoked jointly will produce multiply defined labels. In addition, you should not use -O when compiling -ql because this in turn turns on the -g flag.

4. The default response to the invalid operation, divide by zero, and overflow exceptions is to take a trap. This behavior may be altered by using the `fpsetmask(3)` function.

5. When an Intel 80287 co-processor is installed, use of denormalized floating point numbers results in a core dump. The problem is that the 80287 chip does not normalize a denormal number when it is loaded and produces an invalid operation exception when a denormal number is stored to memory. If such problems are encountered, one workaround is to enable the denormalized operand exception and provide a signal handler which normalizes a denormal number. This signal handler must also recognize any other enabled traps (signals).

6. Without an Intel 80287 or 80387 coprocessor installed, the floating point emulator incorrectly returns 0 rather than NaN for any operation on NaN.

7. The IEEE 754 standard for floating point (IEEE Standard for binary Floating-Point Arithmetic, ANSI/IEEE Std. 754-1985) allows several different methods for detecting overflow. As a result, you should not rely on a particular implementation to signal overflow for a particular operation.

8. Floating point comparisons where one operand is an NaN always result in an invalid operation exception. This is because the Intel 80287 lacks an instruction to make this comparison without getting the exception.
9. *dis(1)* and *sdb(1)* do not recognize the *Intel 80387* specific instructions.

10. *pipe(2)* — The documentation states that the maximum number of bytes in a pipe (PIPE_MAX) is defined to be 5120. The system sets PIPE_MAX to 10240.

11. *ioctl(2)* — The V_ADDBAD command (notifies the device drivers of bad sectors) in *ioctl(2)* updates only the table currently in memory and does not update the table on the hard disk. Therefore, all the changes made using *ioctl(2)* with V_ADDBAD will be lost when the system is rebooted. Also, if an assigned alternate sector goes bad, there is no way to recover.

12. *ioctl(2)* — The V_GETPARMS command in *ioctl(2)* returns the incorrect number of sectors for a 360KB device. The number of sectors reported is 1440; however, the correct value is 720.

13. The Graphics Programming Utilities (GPU) has been renamed extended terminal interface (ETI).

14. A new function, *gethz0*, is added to *libc* that gets the HZ value from the environment.

15. The *-s* option is added to the symbolic debugger (*sdb*). The system will not catch the trap specified by the *-s* option. For example, if you specified *sdb* *-s2*, it will not trap on error number 2.

16. The *-Zp[n124] option is added to *cc*. This option packs structure members in memory. Normally, structure members are aligned as follows: items of type char are byte-aligned, items of type short are aligned on 2-byte boundaries, and all other types of structure members are word-aligned. Specifying an option to *-Zp* will force alignment on the given byte boundary. If no option is used with *-Zp*, structure members will be packed on 1-byte boundaries. The alignment may be altered with the #pragma pack preprocessor directive.

17. The *-x* option is added to *convert*. This is required to convert a Xenix archive. Using this option will convert the general archive structure but leave archive members unmodified.
Compatibility

This section describes the changes made in this issue of the SDS package that may have an effect on the compatibility of your programs.

The Compiler and cc

The following compatibility notes concern changes made to the CSDS cc command or the compiler, comp, in this issue of the SDS. These notes apply only if you are porting C programs compiled on an AT&T compilation system (release number less than 4.1) for a different machine.

- The -B and -t options have been removed from the cc command. Previous releases printed a warning message that these options would disappear.

- The handling of aggregate initialization has been changed to conform to the definition given by Kernighan and Ritchie. Initialization where all braces are specified or where only the outermost braces are specified continues to work as before.

- cc and comp can no longer take the address of a label.

The following illegal C code will no longer compile:

```c
f()
   { int i;
     lab:
     i = (int) &lab;
   }
```

- Bad structure code, such as the following, is disallowed:

  taking the address of the return value of a function which returns a structure:

  ```c
  pst = &(stcall());
  ```

  using a function return value as an L-value:

  ```c
  stcall() = *pst;
  ```

  taking the address of a structure assignment:

  ```c
  pst = &(st1=st2);
  ```
Compatibility

cpp

The following change was made to cpp in this issue of the SDS.

- A missing or invalid macro name in ifdef, ifndef, undef, or define is now a fatal error.

For example:

```cpp
#ifdef 202
#undef
#undef 1abc
```

Changes in C Library Functions

The following list describes changes made to functions in the C library in this issue of the SDS.

**ctime(3C)** An a.out compiled with previous versions of the ctime functions when used with some new legal TZ values will give unexpected results.

**ctime(3C)** ctime now defaults to GMT if TZ is not set.

In previous releases it defaulted to EST.

**fgets(3S)** A call to fgets on a write-only file returns NULL. In earlier releases, fgets always returned the address of the buffer passed to it.

**fread(3S), fwrite(3S)**

The fread and fwrite functions return zero when size is zero or huge.

In an earlier release, these two functions always returned nitems. size and count are multiplied to give the number of bytes to be transferred. If the result is larger than the remaining bytes of the file or is not representable within the precision of an integer, fewer items will be read than requested and the number of items actually read will be returned.
**Compatibility**

```text

c**scanf**(3S)  Calls to scanf now return EOF on end-of-file. In an earlier release, scanf erroneously returned zero.
```

**Environment Variables**

The variables CFTIME, CHRCLASS, and LANGUAGE are environment variables in CSDS. Setting them may cause C library functions to change their behavior. Also, the TZ environment variable may be interpreted differently. The following table lists the library functions affected by these variables.

<table>
<thead>
<tr>
<th>Function</th>
<th>Environment Variables</th>
</tr>
</thead>
<tbody>
<tr>
<td>ctime</td>
<td>TZ</td>
</tr>
<tr>
<td>isalnum</td>
<td>CHRCLASS</td>
</tr>
<tr>
<td>isalpha</td>
<td>CHRCLASS</td>
</tr>
<tr>
<td>iscntrl</td>
<td>CHRCLASS</td>
</tr>
<tr>
<td>isdigit</td>
<td>CHRCLASS</td>
</tr>
<tr>
<td>isgraph</td>
<td>CHRCLASS</td>
</tr>
<tr>
<td>islower</td>
<td>CHRCLASS</td>
</tr>
<tr>
<td>isprint</td>
<td>CHRCLASS</td>
</tr>
<tr>
<td>ispunct</td>
<td>CHRCLASS</td>
</tr>
<tr>
<td>isupper</td>
<td>CHRCLASS</td>
</tr>
<tr>
<td>localtime</td>
<td>TZ</td>
</tr>
<tr>
<td>tolower</td>
<td>CHRCLASS</td>
</tr>
<tr>
<td>toupper</td>
<td>CHRCLASS</td>
</tr>
</tbody>
</table>

**The mkshlib Command**

Uninitialized external variables (common symbols) are illegal in a shared library. Previously, the use of common symbols was discouraged by both the documentation and a mkshlib warning message. This warning message is now a fatal error.
Future Directions

This section describes areas of the SDS product that are likely to change in future releases.

1. It is likely that some of the functions defined in \texttt{libPW} will be removed in a future release of this product. If you have any code that relies on \texttt{libPW}, AT&T recommends that you reimplement it using existing functions in the standard C library or that you retain copies of the \texttt{libPW} functions that you need.

2. The \texttt{list(1)} command will be removed in a future release of this product.

3. AT&T expects, in a future release of the SDS, to support the ANSI Standard for the C language once the standard is accepted. That standard introduces the keywords \texttt{const}, \texttt{signed}, and \texttt{volatile}. Programmers should therefore avoid using these words as identifiers in programs.

4. A major feature of the extended terminal interface (ETI) is the ability to turn on and off any of several video attributes, such as bold, dim, blinking, underlining, reverse video, and others. Future enhancements of ETI will include additional video attributes that enable your programs to use the color capabilities of a wide range of terminals.

5. In keeping with AT&T's ongoing internationalization of the UNIX system, future users will be able to use ETI with keyboards using foreign language character sets, such as Kanga.
Documentation

Essential documentation is provided with the SDS software package when purchased. Additional sets of the Software Development documentation (of which these Release Notes are a part) are available and can be ordered. See the Product Overview/Documentation Roadmap for more details. The Product Overview/Documentation Roadmap can be ordered separately by using the 9-digit number 999-300-527.
Appendix A: Documentation Updates

The following change pages reflect last minute changes to the UNIX System V/386 Release 3.2 documentation. These change pages should be inserted into the Programmer's Reference Manual.

AT&T UNIX SYSTEM V/386
RELEASE 3.2
PROGRAMMER'S REFERENCE MANUAL
UPDATES

This update involves the following actions:

1. **ACTION**: Replace RMDIR(2) pages 1 and 2 with the new pages.
2. **ACTION**: Replace SEMGET(2) pages 1 and 2 with the new pages.
3. **ACTION**: Replace UNLINK(2) pages 1 and 2 with the new pages.
NAME
rmdir – remove a directory

SYNOPSIS
int rmdir (path)
char *path;

DESCRIPTION
rmdir removes the directory named by the path name pointed to by path. The directory must not have any entries other than "." and "..".

The named directory is removed unless one or more of the following is true:

- [EINVAL] The current directory may not be removed.
- [EINVAL] The "." entry of a directory may not be removed.
- [EXIST] The directory contains entries other than those for "." and "..".
- [ENOTDIR] A component of the path prefix is not a directory.
- [ENOENT] The named directory does not exist.
- [EACCES] Search permission is denied for a component of the path prefix.
- [EACCES] Write permission is denied on the directory containing the directory to be removed.
- [EBUSY] The directory to be removed is the mount point for a mounted file system.
- [EROFS] The directory entry to be removed is part of a read-only file system.
- [EFAULT] Path points outside the process’s allocated address space.
- [EIO] An I/O error occurred while accessing the file system.
- [ENOLINK] Path points to a remote machine, and the link to that machine is no longer active.
- [EMULTIHOP] Components of path require hopping to multiple remote machines.

In addition, a directory will not be removed when all of the following is true:

the parent directory has the sticky bit set
the parent directory is not owned by the user
the target directory is not owned by the user
the target directory is not writable by the user
the user is not super-user
SEE ALSO
mkdir(2).
rm(1), and mkdir(1) in the User's/System Administrator's Reference Manual.

DIAGNOSTICS
Upon successful completion, a value of 0 is returned. Otherwise, a value of
-1 is returned and errno is set to indicate the error.
NAME
semget – get set of semaphores

SYNOPSIS
#include <sys/types.h>
#include <sys/ipc.h>
#include <sys/sem.h>
int semget (key, nsems, semflg)
  key_t key;
  int nsems, semflg;

DESCRIPTION
The semget system call returns the semaphore identifier associated with key.
A semaphore identifier and associated data structure and set containing
nsems semaphores [see intro(2)] are created for key if one of the following is
true:

  Key is equal to IPC_PRIVATE.
  Key does not already have a semaphore identifier associated with it,
  and (semflg & IPC_CREAT) is "true".

Upon creation, the data structure associated with the new semaphore iden-
tifier is initialized as follows:

  Sem_perm.uid,  sem_perm.uid,  sem_perm.gid,  and
  sem_perm.gid are set equal to the effective user ID and effective
  group ID, respectively, of the calling process.

  The low-order 9 bits of sem_perm.mode are set equal to the low-
  order 9 bits of semflg.

  Sem_nsems is set equal to the value of nsems.

  Sem_otime is set equal to 0 and sem_ctime is set equal to the
current time.

The data structure associated with each semaphore in the set is not initial-
ized. The function semctl with the command setval or setall can be used to
initialize each semaphore.

The semget system call fails if one or more of the following is true:

  [EINVAL]  Nsems is either less than or equal to zero or greater than
            the system-imposed limit.

  [EACCES]  A semaphore identifier exists for key, but operation permis-
            sion [see intro(2)] as specified by the low-order 9 bits of
            semflg would not be granted.

  [EINVAL]  A semaphore identifier exists for key, but the number of
            semaphores in the set associated with it is less than nsems,
            and nsems is not equal to zero.

  [ENOENT]  A semaphore identifier does not exist for key, and (semflg &
            IPC_CREAT) is "false".
A semaphore identifier is to be created, but the system-imposed limit on the maximum number of allowed semaphore identifiers system wide would be exceeded.

A semaphore identifier exists for key, but \((\text{semflg} \& \text{IPC_CREAT})\) and \((\text{semflg} \& \text{IPC_EXCL})\) are “true”.

SEE ALSO
intro(2), semctl(2), semop(2).

DIAGNOSTICS
Upon successful completion, a non-negative integer, namely a semaphore identifier, is returned. Otherwise, a value of -1 is returned, and errno is set to indicate the error.
NAME
unlink – remove directory entry

SYNOPSIS
    int unlink (path)
    char *path;

DESCRIPTION
    unlink removes the directory entry named by the path name pointed to by
    path.

    The named file is unlinked unless one or more of the following is true:
    [ENOTDIR] A component of the path prefix is not a directory.
    [ENOENT] The named file does not exist.
    [EACCES] Search permission is denied for a component of the path
    prefix.
    [EACCES] Write permission is denied on the directory containing the
    link to be removed.
    [EPERM] The named file is a directory and the effective user ID of
    the process is not super-user.
    [EBUSY] The entry to be unlinked is the mount point for a mounted
    file system.
    [ETXTBSY] The entry to be unlinked is the last link to a pure pro­
    cedure (shared text) file that is being executed.
    [EROFS] The directory entry to be unlinked is part of a read-only file
    system.
    [EFAULT] Path points outside the process’s allocated address space.
    [EINVAL] A signal was caught during the unlink system call.
    [ENOLINK] Path points to a remote machine and the link to that
    machine is no longer active.
    [EMULTIHOP] Components of path require hopping to multiple remote
    machines.

A file will not be unlinked when all of the following is true:
    the parent directory has the sticky bit set
    the file is not writable by the user
    the user does not own the parent directory
    the user does not own the file
    the user is not super-user

When all links to a file have been removed and no process has the file
open, the space occupied by the file is freed and the file ceases to exist. If
one or more processes have the file open when the last link is removed, the
removal is postponed until all references to the file have been closed.

SEE ALSO
    close(2), link(2), open(2).
DIAGNOSTICS
Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and *errno* is set to indicate the error.
