1 Introduction to Xlib

Introduction to Xlib 1-1

Overview of the XWIN System 1-2

Errors 1-5

Naming and Argument Conventions within Xlib 1-6

Programming Considerations 1-8

Conventions Used in Xlib – C Language X Interface 1-9
Introduction to Xlib

The X Window System is a network-transparent window system that was designed at MIT. It runs under 4.3BSD UNIX, ULTRIX-32, many other UNIX variants, VAX/VMS, MS/DOS, as well as several other operating systems.

AT&T's XWIN™ Release 3.0 product is based on the MIT X Window System X11R3. It is streams based, includes performance enhancements, and runs on UNIX System V Release 3.2 and SVR4.0.

XWIN display servers run on computers with either monochrome or color bitmap display hardware. The server distributes user input to and accepts output requests from various client programs located either on the same machine or elsewhere in the network. Xlib is a C subroutine library that application programs (clients) use to interface with the window system by means of a stream connection. Although a client usually runs on the same machine as the XWIN server it is talking to, this need not be the case.

Xlib – C Language X Interface is a reference guide to the low-level C language interface to the X System protocol. It is neither a tutorial nor a user's guide to programming the XWIN System. Rather, it provides a detailed description of each function in the library as well as a discussion of the related background information. Xlib – C Language X Interface assumes a basic understanding of a graphics window system and of the C programming language. Other higher-level abstractions (for example, those provided by the toolkits for X) are built on top of the Xlib library. For further information about these higher-level libraries, see the appropriate toolkit documentation. The X Protocol provides the definitive word on the behavior of X. Although additional information appears here, the protocol document is the ruling document.

To provide an introduction to X programming, this chapter discusses:

- Overview of the XWIN System
- Errors
- Naming and argument conventions
- Programming considerations
- Conventions used in this document
Overview of the XWIN System

Some of the terms used in this book are unique to the XWIN System, and other terms that are common to other window systems have different meanings in XWIN. You may find it helpful to refer to the glossary, which is located at the end of the book.

All the windows in an XWIN server are arranged in strict hierarchies. At the top of the hierarchy is the root window, which covers the display screen. Each root window is partially or completely covered by child windows. All windows, except for root windows, have parents. There is usually at least one window for each application program. Child windows may in turn have their own children. In this way, an application program can create an arbitrarily deep tree. The XWIN system provides graphics, text, and raster operations for windows.

A child window can be larger than its parent. That is, part or all of the child window can extend beyond the boundaries of the parent, but all output to a window is clipped by its parent. If several children of a window have overlapping locations, one of the children is considered to be on top of or raised over the others thus obscuring them. Output to areas covered by other windows is suppressed by the window system unless the window has backing store. If a window is obscured by a second window, the second window obscures only those ancestors of the second window, which are also ancestors of the first window.

A window has a border zero or more pixels in width, which can be any pattern (pixmap) or solid color you like. A window usually but not always has a background pattern, which will be repainted by the window system when uncovered. Each window has its own coordinate system. Child windows obscure their parents unless the child windows (of the same depth) have no background, and graphic operations in the parent window usually are clipped by the children.

The XWIN server does not guarantee to preserve the contents of windows. When part or all of a window is hidden and then brought back onto the screen, its contents may be lost. The server then sends the client program an Expose event to notify it that part or all of the window needs to be repainted. Programs must be prepared to regenerate the contents of windows on demand.

The XWIN server also provides off-screen storage of graphics objects, called pixmaps. Single plane (depth 1) pixmaps are sometimes referred to as bitmaps. Pixmaps can be used in most graphics functions interchangeably with windows and are used in various graphics operations to define patterns or tiles. Windows and pixmaps together are referred to as drawables.
Most of the functions in Xlib just add requests to an output buffer. These requests later execute asynchronously on the XWIN server. Functions that return values of information stored in the server do not return (that is, they block) until an explicit reply is received or an error occurs. You can provide an error handler, which will be called when the error is reported.

If a client does not want a request to execute asynchronously, it can follow the request with a call to XSync, which blocks until all previously buffered asynchronous events have been sent and acted on. As an important side effect, the output buffer in Xlib is always flushed by a call to any function that returns a value from the server or waits for input.

Many Xlib functions will return an integer resource ID, which allows you to refer to objects stored on the XWIN server. These can be of type Window, Font, Pixmap, Colormap, Cursor, and GContext, as defined in the file `<X11/X.h>`.

These resources are created by requests and are destroyed (or freed) by requests or when connections are closed. Most of these resources are potentially sharable between applications, and in fact, windows are manipulated explicitly by window manager programs. Fonts are loaded and unloaded as needed and are shared by multiple clients. Fonts are often cached in the server. Xlib provides no support for sharing graphics contexts between applications.

Client programs are informed of events. Events may either be side effects of a request (for example, restacking windows generates Expose events) or completely asynchronous (for example, from the keyboard). A client program asks to be informed of events. Because other applications can send events to your application, programs must be prepared to handle (or ignore) events of all types.

Input events (for example, a key pressed or the pointer moved) arrive asynchronously from the server and are queued until they are requested by an explicit call (for example, XNextEvent or XWindowEvent). In addition, some library functions (for example, XRaiseWindow) generate Expose and ConfigureRequest events. These events also arrive asynchronously, but the client may wish to explicitly wait for them by calling XSync after calling a function that can cause the server to generate events.
The <> has the meaning defined by the # include statement of the C compiler and is a file relative to a well-known directory. This is /usr/X/include on XWIN systems.
Errors

Some functions return Status, an integer error indication. If the function fails, it returns a zero. If the function returns a status of zero, it has not updated the return arguments. Because C does not provide multiple return values, many functions must return their results by writing into client-passed storage.

By default, errors are handled either by a standard library function or by one that you provide. Functions that return pointers to strings return NULL pointers if the string does not exist.

The XWIN server reports protocol errors at the time that it detects them. If more than one error could be generated for a given request, the server can report any of them.

Because Xlib usually does not transmit requests to the server immediately (that is, it buffers them), errors can be reported much later than they actually occur. For debugging purposes, however, Xlib provides a mechanism for forcing synchronous behavior (see "Enabling or Disabling Synchronization" in Chapter 8). When synchronization is enabled, errors are reported as they are generated.

When Xlib detects an error, it calls an error handler, which your program can provide. If you do not provide an error handler, the error is printed, and your program terminates.
Naming and Argument Conventions within Xlib

Xlib follows a number of conventions for the naming and syntax of the functions. Given that you remember what information the function requires, these conventions are intended to make the syntax of the functions more predictable.

The major naming conventions are:

- To differentiate the XWIN symbols from the other symbols, the library uses mixed case for external symbols. It leaves lowercase for variables and all uppercase for user macros, as per existing convention.
- All Xlib functions begin with a capital X.
- The beginnings of all function names and symbols are capitalized.
- All user-visible data structures begin with a capital X. More generally, anything that a user might dereference begins with a capital X.
- Macros and other symbols do not begin with a capital X. To distinguish them from all user symbols, each word in the macro is capitalized.
- All elements or variables in a data structure are in lowercase. Compound words, where needed, are constructed with underscores (_).
- The display argument, where used, is always first in the argument list.
- All resource objects, where used, occur at the beginning of the argument list immediately after the display argument.
- When a graphics context is present together with another type of resource (most commonly, a drawable), the graphics context occurs in the argument list after the other resource. Drawables outrank all other resources.
- Source arguments always precede the destination arguments in the argument list.
- The x argument always precedes the y argument in the argument list.
- The width argument always precedes the height argument in the argument list.
- Where the x, y, width, and height arguments are used together, the x and y arguments always precede the width and height arguments.
- Where a mask is accompanied with a structure, the mask always precedes the pointer to the structure in the argument list.
Programming Considerations

The major programming considerations are:

- Keyboards are the greatest variable between different manufacturers' workstations. If you want your program to be portable, you should be particularly conservative here.

- Many display systems have limited amounts of off-screen memory. If you can, you should minimize use of pixmaps and backing store.

- The user should have control of the screen real estate. Therefore, you should write your applications to react to window management rather than presume control of the entire screen. What you do inside of your top-level window, however, is up to your application. For further information, see Chapter 9.

- Coordinates and sizes in the XWIN System are actually 16-bit quantities. They usually are declared as an "int" in the interface (int is 16 bits on some machines). Values larger than 16 bits are truncated silently. Sizes (width and height) are unsigned quantities. This decision was taken to minimize the bandwidth required for a given level of performance.
Conventions Used in Xlib – C Language X Interface

This document uses the following conventions:

- Global symbols in Xlib – C Language X Interface are printed in this special font. These can be either function names, symbols defined in include files, or structure names. Arguments are printed in italics.

- Each function is introduced by a general discussion that distinguishes it from other functions. The function declaration itself follows, and each argument is specifically explained. General discussion of the function, if any is required, follows the arguments. Where applicable, the last paragraph of the explanation lists the possible Xlib error codes that the function can generate. For a complete discussion of the Xlib error codes, see "Using the Default Error Handlers" in Chapter 8.

- To eliminate any ambiguity between those arguments that you pass and those that a function returns to you, the explanations for all arguments that you pass start with the word specifies or, in the case of multiple arguments, the word specify. The explanations for all arguments that are returned to you start with the word returns or, in the case of multiple arguments, the word return. The explanations for all arguments that you can pass and are returned start with the words specifies and returns.

- Any pointer to a structure that is used to return a value is designated as such by the _return suffix as part of its name. All other pointers passed to these functions are used for reading only. A few arguments use pointers to structures that are used for both input and output and are indicated by using the _in_out suffix.

- Xlib defines the Boolean values of True and False.

**XWIN Server Connection Close Operations**  2-19
Introduction

Before your program can use a display, you must establish a connection to the XWIN server. Once you have established a connection, you then can use the Xlib macros and functions discussed in this chapter to return information about the display. This chapter discusses how to:

- Open (connect to) the display
- Obtain information about the display, image format, and screen
- Free client-created data
- Close (disconnect from) a display

The chapter concludes with a general discussion of what occurs when the connection to the XWIN server is closed.
Opening the Display

To open a connection to the XWIN server that controls a display, use `XOpenDisplay`.

```c
Display *XOpenDisplay(display_name)
    char *display_name;
```

`display_name` Specifies the hardware display name, which determines the display and communications domain to be used. On a UNIX-based system, if the `display_name` is NULL, it defaults to the value of the DISPLAY environment variable.

On UNIX-based systems, the display name or DISPLAY environment variable is a string in the format:

```
hostname:number.screen_number
```

`hostname` Specifies the name of the host machine on which the display is physically attached. You follow the `hostname` with either a single colon (:) or a double colon (::).

`number` Specifies the number of the display server on that host machine. You may optionally follow this display number with a period (.). A single CPU can have more than one display. Multiple displays are usually numbered starting with zero.

`screen_number` Specifies the screen to be used on that server. The `screen_number` sets an internal variable that can be accessed by using the `DefaultScreen` macro or the `XDefaultScreen` function if you are using languages other than C (see "Display Macros" in Chapter 2).

For example, the following would specify screen 2 of display 0 on the machine named mit-athena:

```
mit-athena:0.2
```

The `XOpenDisplay` function returns a `Display` structure that serves as the connection to the XWIN server and that contains all the information about that XWIN server. `XOpenDisplay` connects your application to the XWIN server through TCP, UNIX domain, or StarLan (SVR3.2 only) communications protocols. If the `hostname` is a host machine name and a single colon (:) separates the `hostname` and `display_number` `XOpenDisplay` connects using TCP streams. If the
hostname is *unix* and a single colon (:) separates it from the display number, `XOpenDisplay` connects using UNIX domain IPC streams. If the hostname is not specified, Xlib uses whatever it believes is the fastest transport. A single XWIN server can support any or all of these transport mechanisms simultaneously. A particular Xlib implementation can support many more of these transport mechanisms.

If successful, `XOpenDisplay` returns a pointer to a `Display` structure, which is defined in `<X11/Xlib.h>`. If `XOpenDisplay` does not succeed, it returns NULL. After a successful call to `XOpenDisplay`, all of the screens in the display can be used by the client. The screen number specified in the `display_name` argument is returned by the `DefaultScreen` macro (or the `XDefaultScreen` function). You can access elements of the `Display` and `Screen` structures only by using the information macros or functions. For information about using macros and functions to obtain information from the `Display` structure, see "Display Macros" in Chapter 2.

XWIN servers may implement various types of access control mechanisms (see "Controlling Host Access" in Chapter 7).
Obtaining Information about the Display, Image Formats, or Screens

The Xlib library provides a number of useful macros and corresponding functions that return data from the Display structure. The macros are used for C programming, and their corresponding function equivalents are for other language bindings. This section discusses the:

- Display macros
- Image format macros
- Screen macros

All other members of the Display structure (that is, those for which no macros are defined) are private to Xlib and must not be used. Applications must never directly modify or inspect these private members of the Display structure.

The XDisplayWidth, XDisplayHeight, XDisplayCells, XDisplayPlanes, XDisplayWidthMM, and XDisplayHeightMM functions in the next sections are misnamed. These functions really should be named Screenwhatever and XScreenwhatever, not Displaywhatever or XDisplaywhatever. Our apologies for the resulting confusion.

Display Macros

Applications should not directly modify any part of the Display and Screen structures. The members should be considered read-only, although they may change as the result of other operations on the display.

The following lists the C language macros, their corresponding function equivalents that are for other language bindings, and what data they both can return.

\[ \text{AllPlanes() } \]

\[ \text{unsigned long XAllPlanes() } \]

Both return a value with all bits set to 1 suitable for use in a plane argument to a procedure.
Both BlackPixel and WhitePixel can be used in implementing a monochrome application. These pixel values are for permanently allocated entries in the default colormap. The actual RGB (red, green, and blue) values are settable on some screens and, in any case, may not actually be black or white. The names are intended to convey the expected relative intensity of the colors.

```c
BlackPixel(display, screen_number)

unsigned long XBlackPixel(display, screen_number)
    Display *display;
    int screen_number;
```

Both return the black pixel value for the specified screen.

```c
WhitePixel(display, screen_number)

unsigned long XWhitePixel(display, screen_number)
    Display *display;
    int screen_number;
```

Both return the white pixel value for the specified screen.

```c
ConnectionNumber(display)

int XConnectionNumber(display)
    Display *display;
```

Both return a connection number for the specified display. On a UNIX-based system, this is the file descriptor of the connection.

```c
DefaultColormap(display, screen_number)

Colormap XDefaultColormap(display, screen_number)
    Display *display;
    int screen_number;
```

Both return the default colormap ID for allocation on the specified screen. Most routine allocations of color should be made out of this colormap.
Obtaining Information about the Display, Image Formats, or Screens

DefaultDepth(\texttt{display}, \texttt{screen\_number})
\begin{verbatim}
int XDefaultDepth(display, screen_number)
    Display *display;
    int screen_number;
\end{verbatim}
Both return the depth (number of planes) of the default root window for the specified screen. Other depths may also be supported on this screen (see \texttt{XMatchVisualInfo}).

DefaultGC(\texttt{display}, \texttt{screen\_number})
\begin{verbatim}
GC XDefaultGC(display, screen_number)
    Display *display;
    int screen_number;
\end{verbatim}
Both return the default graphics context for the root window of the specified screen. This GC is created for the convenience of simple applications and contains the default GC components with the foreground and background pixel values initialized to the black and white pixels for the screen, respectively. You can modify its contents freely because it is not used in any Xlib function. This GC should never be freed.

DefaultRootWindow(\texttt{display})
\begin{verbatim}
Window XDefaultRootWindow(display)
    Display *display;
\end{verbatim}
Both return the root window for the default screen.

DefaultScreenOfDisplay(\texttt{display})
\begin{verbatim}
Screen *XDefaultScreenOfDisplay(display)
    Display *display;
\end{verbatim}
Both return a pointer to the default screen.

ScreenOfDisplay(\texttt{display}, \texttt{screen\_number})
\begin{verbatim}
Screen *XScreenOfDisplay(display, screen_number)
    Display *display;
    int screen_number;
\end{verbatim}
Obtaining Information about the Display, Image Formats, or Screens

Both return a pointer to the indicated screen.

```c
DefaultScreen(display)
int XDefaultScreen(display)
Display *display;
```

Both return the default screen number referenced by the XOpenDisplay function. This macro or function should be used to retrieve the screen number in applications that will use only a single screen.

```c
DefaultVisual(display, screen_number)
Visual *XDefaultVisual(display, screen_number)
Display *display;
int screen_number;
```

Both return the default visual type for the specified screen. For further information about visual types, see "Visual Types" in Chapter 3.

```c
DisplayCells(display, screen_number)
int XDisplayCells(display, screen_number)
Display *display;
int screen_number;
```

Both return the number of entries in the default colormap.

```c
DisplayPlanes(display, screen_number)
int XDisplayPlanes(display, screen_number)
Display *display;
int screen_number;
```

Both return the depth of the root window of the specified screen. For an explanation of depth, see the glossary.

```c
DisplayString(display)
char *XDisplayString(display)
Display *display;
```
Obtaining Information about the Display, Image Formats, or Screens

Both return the string that was passed to XOpenDisplay when the current display was opened. On UNIX-based systems, if the passed string was NULL, these return the value of the DISPLAY environment variable when the current display was opened.

These are useful to applications that invoke the fork system call and want to open a new connection to the same display from the child process as well as for printing error messages.

```
LastKnownRequestProcessed (display)

unsigned long XLastKnownRequestProcessed (display)
    Display *display;
```

Both extract the full serial number of the last request known by Xlib to have been processed by the XWIN server. Xlib automatically sets this number when replies, events, and errors are received.

```
NextRequest (display)

unsigned long XNextRequest (display)
    Display *display;
```

Both extract the full serial number that is to be used for the next request. Serial numbers are maintained separately for each display connection.

```
ProtocolVersion (display)

int XProtocolVersion (display)
    Display *display;
```

Both return the major version number (11) of the X protocol associated with the connected display.

```
ProtocolRevision (display)

int XProtocolRevision (display)
    Display *display;
```

Both return the minor protocol revision number of the XWIN server.

```
QLength (display)

int XQLength (display)
    Display *display;
```
Obtaining Information about the Display, Image Formats, or Screens

Both return the length of the event queue for the connected display. Note that there may be more events that have not been read into the queue yet (see XEventsQueued).

\[
\text{RootWindow}(\text{display}, \text{screen\_number})
\]
\[
\text{Window XRootWindow}(\text{display}, \text{screen\_number})
\]
\[
\text{Display *display;}
\]
\[
\text{int screen\_number;}
\]

Both return the root window. These are useful with functions that need a drawable of a particular screen and for creating top-level windows.

\[
\text{ScreenCount (display)}
\]
\[
\text{int XScreenCount(display)}
\]
\[
\text{Display *display;}
\]

Both return the number of available screens.

\[
\text{ServerVendor (display)}
\]
\[
\text{char *XServerVendor(display)}
\]
\[
\text{Display *display;}
\]

Both return a pointer to a null-terminated string that provides some identification of the owner of the XWIN server implementation.

\[
\text{VendorRelease (display)}
\]
\[
\text{int XVendorRelease(display)}
\]
\[
\text{Display *display;}
\]

Both return a number related to a vendor’s release of the XWIN server.
Obtaining Information about the Display, Image Formats, or Screens

Image Format Macros

Applications are required to present data to the XWIN server in a format that the server demands. To help simplify applications, most of the work required to convert the data is provided by Xlib (see "Transferring Images Between Client and Server" in Chapter 6, and "Manipulating Images" in Chapter 10).

The following lists the C language macros, their corresponding function equivalents that are for other language bindings, and what data they both return for the specified server and screen. These are often used by toolkits as well as by simple applications.

```
ImageByteOrder(display)
int XImageByteOrder(display)
  Display *display;
```

Both specify the required byte order for images for each scanline unit in X'f' format (bitmap) or for each pixel value in Z format. The macro or function can return either LSBFirst or MSBFirst.

```
BitmapUnit(display)
int XBitmapUnit(display)
  Display *display;
```

Both return the size of a bitmap’s scanline unit in bits. The scanline is calculated in multiples of this value.

```
BitmapBitOrder(display)
int XBitmapBitOrder(display)
  Display *display;
```

Within each bitmap unit, the left-most bit in the bitmap as displayed on the screen is either the least-significant or most-significant bit in the unit. This macro or function can return LSBFirst or MSBFirst.

```
BitmapPad(display)
int XBitmapPad(display)
  Display *display;
```
Each scanline must be padded to a multiple of bits returned by this macro or function.

\[
\text{DisplayHeight}(\text{display, screen_number})
\]

\[
\text{int XDisplayHeight(display, screen_number)}
\]

\[
\text{Display *display;}
\]

\[
\text{int screen_number;}
\]

Both return an integer that describes the height of the screen in pixels.

\[
\text{DisplayHeightMM(display, screen_number)}
\]

\[
\text{int XDisplayHeightMM(display, screen_number)}
\]

\[
\text{Display *display;}
\]

\[
\text{int screen_number;}
\]

Both return the height of the specified screen in millimeters.

\[
\text{DisplayWidth(display, screen_number)}
\]

\[
\text{int XDisplayWidth(display, screen_number)}
\]

\[
\text{Display *display;}
\]

\[
\text{int screen_number;}
\]

Both return the width of the screen in pixels.

\[
\text{DisplayWidthMM(display, screen_number)}
\]

\[
\text{int XDisplayWidthMM(display, screen_number)}
\]

\[
\text{Display *display;}
\]

\[
\text{int screen_number;}
\]

Both return the width of the specified screen in millimeters.
Screen Information Macros

The following lists the C language macros, their corresponding function equivalents that are for other language bindings, and what data they both can return. These macros or functions all take a pointer to the appropriate screen structure.

```c
BlackPixelOfScreen (screen)
unsigned long XBlackPixelOfScreen(screen)
Screen *screen;
```

Both return the black pixel value of the specified screen.

```c
WhitePixelOfScreen (screen)
unsigned long XWhitePixelOfScreen(screen)
Screen *screen;
```

Both return the white pixel value of the specified screen.

```c
CellsOfScreen (screen)
int XCellsOfScreen(screen)
Screen *screen;
```

Both return the number of colormap cells in the default colormap of the specified screen.

```c
DefaultColormapOfScreen (screen)
Colormap XDefaultColormapOfScreen(screen)
Screen *screen;
```

Both return the default colormap of the specified screen.

```c
DefaultDepthOfScreen (screen)
int XDefaultDepthOfScreen(screen)
Screen *screen;
```

Both return the depth of the root window.
Obtaining Information about the Display, Image Formats, or Screens

DefaultGCOfScreen(screen)
GC XDefaultGCOfScreen(screen)
  Screen *screen;

Both return a default graphics context (GC) of the specified screen, which has the same depth as the root window of the screen. The GC must never be freed.

DefaultVisualOfScreen(screen)
Visual *XDefaultVisualOfScreen(screen)
  Screen *screen;

Both return the default visual of the specified screen. For information on visual types, see "Visual Types" in Chapter 3.

DoesBackingStore(screen)
int XDoesBackingStore(screen)
  Screen *screen;

Both return a value indicating whether the screen supports backing stores. The value returned can be one of WhenMapped, NotUseful, or Always (see "Backing Store Attribute" in Chapter 3).

DoesSaveUnders(screen)
bool XDoesSaveUnders(screen)
  Screen *screen;

Both return a Boolean value indicating whether the screen supports save unders. If True, the screen supports save unders. If False, the screen does not support save unders (see "Save Under Flag" in Chapter 3).

DisplayOfScreen(screen)
Display *XDisplayOfScreen(screen)
  Screen *screen;

Both return the display of the specified screen.
Obtaining Information about the Display, Image Formats, or Screens

EventMaskOfScreen (screen)

long XEventMaskOfScreen(screen)
    Screen *screen;

Both return the event mask of the root window for the specified screen at connection setup time.

WidthOfScreen (screen)

int XWidthOfScreen(screen)
    Screen *screen;

Both return the width of the specified screen in pixels.

HeightOfScreen (screen)

int XHeightOfScreen(screen)
    Screen *screen;

Both return the height of the specified screen in pixels.

WidthMMOfScreen (screen)

int XWidthMMOfScreen(screen)
    Screen *screen;

Both return the width of the specified screen in millimeters.

HeightMMOfScreen (screen)

int XHeightMMOfScreen(screen)
    Screen *screen;

Both return the height of the specified screen in millimeters.

MaxCmapsOfScreen (screen)

int XMaxCmapsOfScreen(screen)
    Screen *screen;

Both return the maximum number of installed colormaps supported by the specified screen (see "Determining Resident Colormaps" in Chapter 7).
Obtaining Information about the Display, Image Formats, or Screens

**MinCmapsOfScreen** (screen)

```c
int XMinCmapsOfScreen(screen)
Screen *screen;
```

Both return the minimum number of installed colormaps supported by the specified screen (see "Determining Resident Colormaps" in Chapter 7).

**PlanesOfScreen** (screen)

```c
int XPlanesOfScreen(screen)
Screen *screen;
```

Both return the depth of the root window.

**RootWindowOfScreen** (screen)

```c
Window XRootWindowOfScreen(screen)
Screen *screen;
```

Both return the root window of the specified screen.
Generating a NoOperation Protocol Request

To execute a NoOperation protocol request, use `XNoOp`.

```
XNoOp (display)
    Display *display;
```

`display` Specifies the connection to the XWIN server.

The `XNoOp` function sends a NoOperation protocol request to the XWIN server, thereby exercising the connection.
Freeing Client-Created Data

To free any in-memory data that was created by an Xlib function, use XFree.

```c
XFree (data)

char *data;
```

data Specifies a pointer to the data that is to be freed.

The XFree function is a general-purpose Xlib routine that frees the specified data. You must use it to free any objects that were allocated by Xlib.
Closing the Display

To close a display or disconnect from the XWIN server, use XCloseDisplay.

\[
\text{XCloseDisplay} (\text{display})
\text{Display } \ast \text{display};
\]

\textit{display} \hspace{1cm} \text{Specifies the connection to the XWIN server.}

The XCloseDisplay function closes the connection to the XWIN server for the display specified in the Display structure and destroys all windows, resource IDs (Window, Font, Pixmap, Colormap, Cursor, and GContext), or other resources that the client has created on this display, unless the close-down mode of the resource has been changed (see XSetCloseDownMode). Therefore, these windows, resource IDs, and other resources should never be referenced again or an error will be generated. Before exiting, you should call XCloseDisplay explicitly so that any pending errors are reported as XCloseDisplay performs a final XSync operation.

XCloseDisplay can generate a BadGC error.
XWIN Server Connection Close Operations

When the XWIN server’s connection to a client is closed either by an explicit call to XCloseDisplay or by a process that exits, the XWIN server performs the following automatic operations:

- It disowns all selections owned by the client (see XSetSelectionOwner).
- It performs an XUngrabPointer and XUngrabKeyboard if the client has actively grabbed the pointer or the keyboard.
- It performs an XUngrabServer if the client has grabbed the server.
- It releases all passive grabs made by the client.
- It marks all resources (including colormap entries) allocated by the client either as permanent or temporary, depending on whether the close-down mode is RetainPermanent or RetainTemporary. However, this does not prevent other client applications from explicitly destroying the resources (see XSetCloseDownMode).

When the close-down mode is DestroyAll, the XWIN server destroys all of a client’s resources as follows:

- It examines each window in the client’s save-set to determine if it is an inferior (subwindow) of a window created by the client. (The save-set is a list of other clients’ windows, which are referred to as save-set windows.) If so, the XWIN server reparents the save-set window to the closest ancestor so that the save-set window is not an inferior of a window created by the client. The reparenting leaves unchanged the absolute coordinates (with respect to the root window) of the upper-left outer corner of the save-set window.
- It performs a MapWindow request on the save-set window if the save-set window is unmapped. The XWIN server does this even if the save-set window was not an inferior of a window created by the client.
- It destroys all windows created by the client.
- It performs the appropriate free request on each nonwindow resource created by the client in the server (for example, Font, Pixmap, Cursor, Colormap, and GC context).
It frees all colors and colormap entries allocated by a client application.

Additional processing occurs when the last connection to the XWIN server closes. An XWIN server goes through a cycle of having no connections and having some connections. When the last connection to the XWIN server closes as a result of a connection closing with the close_mode of DestroyAll, the XWIN server does the following:

- It resets its state as if it had just been started. The XWIN server begins by destroying all lingering resources from clients that have terminated in RetainPermanent or RetainTemporary mode.
- It deletes all but the predefined atom identifiers.
- It deletes all properties on all root windows (see Chapter 4).
- It resets all device maps and attributes (for example, key click, bell volume, and acceleration) as well as the access control list.
- It restores the standard root tiles and cursors.
- It restores the default font path.
- It restores the input focus to state PointerRoot.

However, the XWIN server does not reset if you close a connection with a close-down mode set to RetainPermanent or RetainTemporary.

Introduction

In the XWIN System, a window is a rectangular area on the screen that lets you view graphic output. Client applications can display overlapping and nested windows that are driven by XWIN servers on one or more machines. Clients who want to create windows must first connect their program to the XWIN server by calling XOpenDisplay. This chapter begins with a discussion of visual types and window attributes. The chapter continues with a discussion of the Xlib functions you can use to:

- Create windows
- Destroy windows
- Map windows
- Unmap windows
- Configure windows
- Change the stacking order
- Change window attributes
- Translate window coordinates

This chapter also identifies the window actions that may generate events.

Note that it is vital that your application conform to the established conventions for communicating with window managers for it to work well with the various window managers in use (see "Communicating with Window Managers" in Chapter 9). Toolkits generally adhere to these conventions for you, relieving you of the burden. Toolkits also often supersede many functions in this chapter with versions of their own. Refer to the documentation for the toolkit you are using for more information.
Visual Types

On some display hardware, it may be possible to deal with color resources in more than one way. For example, you may be able to deal with a screen of either 12-bit depth with arbitrary mapping of pixel to color (pseudo-color) or 24-bit depth with 8 bits of the pixel dedicated to each of red, green, and blue. These different ways of dealing with the visual aspects of the screen are called visuals. For each screen of the display, there may be a list of valid visual types supported at different depths of the screen. Because default windows and visual types are defined for each screen, most simple applications need not deal with this complexity. Xlib provides macros and functions that return the default root window, the default depth of the default root window, and the default visual type (see "Display Macros" in chapter 2 and XMatchVisualInfo).

Xlib uses a visual structure that contains information about the possible color mapping. The members of this structure pertinent to this discussion are class, red_mask, green_mask, blue_mask, bits_per_rgb, and map_entries. The class member specifies one of the possible visual classes of the screen and can be StaticGray, StaticColor, TrueColor, GrayScale, PseudoColor, or DirectColor.

The following concepts may serve to make the explanation of visual types clearer. The screen can be color or grayscale, can have a colormap that is writable or read-only, and can also have a colormap whose indices are decomposed into separate RGB pieces, provided one is not on a grayscale screen. This leads to the following diagram:

<table>
<thead>
<tr>
<th>Color</th>
<th>GrayScale</th>
</tr>
</thead>
<tbody>
<tr>
<td>R/O</td>
<td>R/W</td>
</tr>
<tr>
<td>R/W</td>
<td>R/W</td>
</tr>
<tr>
<td>Undecomposed Colormap</td>
<td></td>
</tr>
<tr>
<td>Static Color</td>
<td>Pseudo Color</td>
</tr>
<tr>
<td>Static Gray</td>
<td>Gray Scale</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Decomposed Colormap</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>True Color</td>
<td>Direct Color</td>
</tr>
</tbody>
</table>

Conceptually, as each pixel is read out of video memory for display on the screen, it goes through a look-up stage by indexing into a colormap. Colormaps can be manipulated arbitrarily on some hardware, in limited ways on other hardware, and not at all on other hardware. The visual types affect the colormap and the RGB values in the following ways:
• For PseudoColor, a pixel value indexes a colormap to produce independent RGB values, and the RGB values can be changed dynamically.

• GrayScale is treated the same way as PseudoColor except that the primary that drives the screen is undefined. Thus, the client should always store the same value for red, green, and blue in the colormaps.

• For DirectColor, a pixel value is decomposed into separate RGB subfields, and each subfield separately indexes the colormap for the corresponding value. The RGB values can be changed dynamically.

• TrueColor is treated the same way as DirectColor except that the colormap has predefined, read-only RGB values. These RGB values are server-dependent but provide linear or near-linear ramps in each primary.

• StaticColor is treated the same way as PseudoColor except that the colormap has predefined, read-only, server-dependent RGB values.

• StaticGray is treated the same way as StaticColor except that the RGB values are equal for any single pixel value, thus resulting in shades of gray. StaticGray with a two-entry colormap can be thought of as monochrome.

The red_mask, green_mask, and blue_mask members are only defined for DirectColor and TrueColor. Each has one contiguous set of bits with no intersections. The bits_per_rgb member specifies the log base 2 of the number of distinct color values (individually) of red, green, and blue. Actual RGB values are unsigned 16-bit numbers. The map_entries member defines the number of available colormap entries in a newly created colormap. For DirectColor and TrueColor, this is the size of an individual pixel subfield.

To obtain the visual ID from a Visual, use XVisualIDFromVisual.

```
VisualID XVisualIDFromVisual(visual)
    Visual *visual;
```

visual Specifies the visual type.

The XVisualIDFromVisual function returns the visual ID for the specified visual type.
Window Attributes

All InputOutput windows have a border width of zero or more pixels, an optional background, an event suppression mask (which suppresses propagation of events from children), and a property list (see "Properties and Atoms" in Chapter 4). The window border and background can be a solid color or a pattern, called a tile. All windows except the root have a parent and are clipped by their parent. If a window is stacked on top of another window, it obscures that other window for the purpose of input. If a window has a background (almost all do), it obscures the other window for purposes of output. Attempts to output to the obscured area do nothing, and no input events (for example, pointer motion) are generated for the obscured area.

Windows also have associated property lists (see "Properties and Atoms" in Chapter 4).

Both InputOutput and InputOnly windows have the following common attributes, which are the only attributes of an InputOnly window:

- win-gravity
- event-mask
- do-not-propagate-mask
- override-redirect
- cursor

If you specify any other attributes for an InputOnly window, a BadMatch error results.

InputOnly windows are used for controlling input events in situations where InputOutput windows are unnecessary. InputOnly windows are invisible; can only be used to control such things as cursors, input event generation, and grabbing; and cannot be used in any graphics requests. Note that InputOnly windows cannot have InputOutput windows as inferiors.

Windows have borders of a programmable width and pattern as well as a background pattern or tile.

Pixel values can be used for solid colors.

The background and border pixmaps can be destroyed immediately after creating the window if no further explicit references to them are to be made.
The pattern can either be relative to the parent or absolute. If ParentRelative, the parent’s background is used.

When windows are first created, they are not visible (not mapped) on the screen. Any output to a window that is not visible on the screen and that does not have backing store will be discarded.

An application may wish to create a window long before it is mapped to the screen. When a window is eventually mapped to the screen (using XMapWindow), the XWIN server generates an Expose event for the window if backing store has not been maintained.

A window manager can override your choice of size, border width, and position for a top-level window. Your program must be prepared to use the actual size and position of the top window. It is not acceptable for a client application to resize itself unless in direct response to a human command to do so. Instead, either your program should use the space given to it, or if the space is too small for any useful work, your program might ask the user to resize the window. The border of your top-level window is considered fair game for window managers.

To set an attribute of a window, set the appropriate member of the XSetWindowAttributes structure and OR in the corresponding value bitmask in your subsequent calls to XCreateWindow and XChangeWindowAttributes, or use one of the other convenience functions that set the appropriate attribute. The symbols for the value mask bits and the XSetWindowAttributes structure are:

```c
/* Window attribute value mask bits */

#define CWBackPixmap (1L<<0)
#define CWBackPixel (1L<<1)
#define CWBorderPixmap (1L<<2)
#define CWBorderPixel (1L<<3)
#define CWBitGravity (1L<<4)
#define CWWinGravity (1L<<5)
#define CWBackingStore (1L<<6)
#define CWBackingPlanes (1L<<7)
#define CWBackingPixel (1L<<8)
```
Window Attributes

```
#define CWOverrideRedirect  (1L<9)
#define CWSaveUnder  (1L<10)
#define CWEventMask  (1L<11)
#define CWDontPropagate  (1L<12)
#define CWColorMap  (1L<13)
#define CWCursor  (1L<14)

/* Values */

typedef struct {
    Pixmap backgroundPixmap; /* background, None, or ParentRelative */
    unsigned long backgroundPixel; /* background pixel */
    Pixmap borderPixmap; /* border of the window or CopyFromParent */
    unsigned long borderPixel; /* border pixel value */
    int bitGravity; /* one of bit gravity values */
    int winGravity; /* one of the window gravity values */
    int backingStore; /* NotUseful, WhenMapped, Always */
    unsigned long backingPlanes; /* planes to be preserved if possible */
    unsigned long backingPixel; /* value to use in restoring planes */
    Bool saveUnder; /* should bits under be saved? (popups) */
    long eventMask; /* set of events that should be saved */
    long doNotPropagateMask; /* set of events that should not propagate */
    Bool overrideRedirect; /* boolean value for override_redirect */
    colormap colormap; /* colormap to be associated with window */
    Cursor cursor; /* cursor to be displayed (or None) */
} XSetWindowAttributes;
```

The following lists the defaults for each window attribute and indicates whether the attribute is applicable to InputOutput and InputOnly windows:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Default</th>
<th>InputOutput</th>
<th>InputOnly</th>
</tr>
</thead>
<tbody>
<tr>
<td>background-pixmap</td>
<td>None</td>

<td>No</td>
</tr>
</tbody>
</table>

Xwin GWS: Xlib — C Language Interface
## Background Attribute

Only InputOutput windows can have a background. You can set the background of an InputOutput window by using a pixel or a pixmap.

The background-pixmap attribute of a window specifies the pixmap to be used for a window’s background. This pixmap can be of any size, although some sizes may be faster than others. The background-pixel attribute of a window specifies a pixel value used to paint a window’s background in a single color.

You can set the background-pixmap to a pixmap, None (default), or ParentRelative. You can set the background-pixel of a window to any pixel value (no default). If you specify a background-pixel, it overrides either the default background-pixmap or any value you may have set in the background-pixmap. A pixmap of an undefined size that is filled with the background-pixel is used for the background. Range checking is not performed on the background pixel; it simply is truncated to the appropriate number of bits.

If you set the background-pixmap, it overrides the default. The background-pixmap and the window must have the same depth, or a BadMatch error results. If you set background-pixmap to None, the window has no defined background. If you set the background-pixmap to ParentRelative:

Window Attributes

- The parent window’s background-pixmap is used. The child window, however, must have the same depth as its parent, or a BadMatch error results.
- If the parent window has a background-pixmap of None, the window also has a background-pixmap of None.
- A copy of the parent window’s background-pixmap is not made. The parent’s background-pixmap is examined each time the child window’s background-pixmap is required.
- The background tile origin always aligns with the parent window’s background tile origin. If the background-pixmap is not ParentRelative, the background tile origin is the child window’s origin.

Setting a new background, whether by setting background-pixmap or background-pixel, overrides any previous background. The background-pixmap can be freed immediately if no further explicit reference is made to it (the XWIN server will keep a copy to use when needed). If you later draw into the pixmap used for the background, what happens is undefined because the X implementation is free to make a copy of the pixmap or to use the same pixmap.

When no valid contents are available for regions of a window and either the regions are visible or the server is maintaining backing store, the server automatically tiles the regions with the window’s background unless the window has a background of None. If the background is None, the previous screen contents from other windows of the same depth as the window are simply left in place as long as the contents come from the parent of the window or an inferior of the parent. Otherwise, the initial contents of the exposed regions are undefined. Expose events are then generated for the regions, even if the background-pixmap is None (see Chapter 8).

Border Attribute

Only InputOutput windows can have a border. You can set the border of an InputOutput window by using a pixel or a pixmap.

The border-pixmap attribute of a window specifies the pixmap to be used for a window’s border. The border-pixel attribute of a window specifies a pixmap of undefined size filled with that pixel be used for a window’s border. Range checking is not performed on the background pixel; it simply is truncated to the
appropriate number of bits. The border tile origin is always the same as the background tile origin.

You can also set the border-pixmap to a pixmap of any size (some may be faster than others) or to CopyFromParent (default). You can set the border-pixel to any pixel value (no default).

If you set a border-pixmap, it overrides the default. The border-pixmap and the window must have the same depth, or a BadMatch error results. If you set the border-pixmap to CopyFromParent, the parent window’s border-pixmap is copied. Subsequent changes to the parent window’s border attribute do not affect the child window. However, the child window must have the same depth as the parent window, or a BadMatch error results.

The border-pixmap can be freed immediately if no further explicit reference is made to it. If you later draw into the pixmap used for the border, what happens is undefined because the X implementation is free either to make a copy of the pixmap or to use the same pixmap. If you specify a border-pixel, it overrides either the default border-pixmap or any value you may have set in the border-pixmap. All pixels in the window’s border will be set to the border-pixel. Setting a new border, whether by setting border-pixel or by setting border-pixmap, overrides any previous border.

Output to a window is always clipped to the inside of the window. Therefore, graphics operations never affect the window border.

**Gravity Attributes**

The bit gravity of a window defines which region of the window should be retained when an InputOutput window is resized. The default value for the bit-gravity attribute is ForgetGravity. The window gravity of a window allows you to define how the InputOutput or InputOnly window should be repositioned if its parent is resized. The default value for the win-gravity attribute is NorthWestGravity.

If the inside width or height of a window is not changed and if the window is moved or its border is changed, then the contents of the window are not lost but move with the window. Changing the inside width or height of the window causes its contents to be moved or lost (depending on the bit-gravity of the window) and causes children to be reconfigured (depending on their win-gravity). For a change of width and height, the (x, y) pairs are defined:
When a window with one of these bit-gravity values is resized, the corresponding pair defines the change in position of each pixel in the window. When a window with one of these win-gravities has its parent window resized, the corresponding pair defines the change in position of the window within the parent. When a window is so repositioned, a GravityNotify event is generated (see Chapter 8).

A bit-gravity of StaticGravity indicates that the contents or origin should not move relative to the origin of the root window. If the change in size of the window is coupled with a change in position (x, y), then for bit-gravity the change in position of each pixel is (−x, −y), and for win-gravity the change in position of a child when its parent is so resized is (−x, −y). Note that StaticGravity still only takes effect when the width or height of the window is changed, not when the window is moved.

A bit-gravity of ForgetGravity indicates that the window’s contents are always discarded after a size change, even if a backing store or save under has been requested. The window is tiled with its background and zero or more Expose events are generated. If no background is defined, the existing screen contents are not altered. Some XWIN servers may also ignore the specified bit-gravity and always generate Expose events.

A win-gravity of UnmapGravity is like NorthWestGravity (the window is not moved), except the child is also unmapped when the parent is resized, and an UnmapNotify event is generated.
Window Attributes

Backin Store Attribute

Some implementations of the XWIN server may choose to maintain the contents of InputOutput windows. If the XWIN server maintains the contents of a window, the off-screen saved pixels are known as backing store. The backing store advises the XWIN server on what to do with the contents of a window. The backing-store attribute can be set to NotUseful (default), WhenMapped, or Always.

A backing-store attribute of NotUseful advises the XWIN server that maintaining contents is unnecessary, although some X implementations may still choose to maintain contents and, therefore, not generate Expose events. A backing-store attribute of WhenMapped advises the XWIN server that maintaining contents of obscured regions when the window is mapped would be beneficial. In this case, the server may generate an Expose event when the window is created. A backing-store attribute of Always advises the XWIN server that maintaining contents even when the window is unmapped would be beneficial. Even if the window is larger than its parent, this is a request to the XWIN server to maintain complete contents, not just the region within the parent window boundaries. While the XWIN server maintains the window’s contents, Expose events normally are not generated, but the XWIN server may stop maintaining contents at any time.

When the contents of obscured regions of a window are being maintained, regions obscured by noninferior windows are included in the destination of graphics requests (and source, when the window is the source). However, regions obscured by inferior windows are not included.

Save Under Flag

The XWIN server implementation preserves the contents of InputOutput windows under other InputOutput windows. This is not the same as preserving the contents of a window for you. You may get better visual appeal if transient windows (for example, pop-up menus) request that the system preserve the screen contents under them, so the temporarily obscured applications do not have to repaint.
Window Attributes

You can set the save-under flag to True or False (default). If save-under is True, the XWIN server is advised that, when this window is mapped, saving the contents of windows it obscures would be beneficial.

Backing Planes and Backing Pixel Attributes

You can set backing planes to indicate (with bits set to 1) which bit planes of an InputOutput window hold dynamic data that must be preserved in backing store and during save unders. The default value for the backing-planes attribute is all bits set to 1. You can set backing pixel to specify what bits to use in planes not covered by backing planes. The default value for the backing-pixel attribute is all bits set to 0. The XWIN server is free to save only the specified bit planes in the backing store or the save under and is free to regenerate the remaining planes with the specified pixel value. Any extraneous bits in these values (that is, those bits beyond the specified depth of the window) may be simply ignored. If you request backing store or save unders, you should use these members to minimize the amount of off-screen memory required to store your window.

Event Mask and Do Not Propagate Mask Attributes

The event mask defines which events the client is interested in for this InputOutput or InputOnly window (or, for some event types, inferiors of that window). The do-not-propagate-mask attribute defines which events should not be propagated to ancestor windows when no client has the event type selected in this InputOutput or InputOnly window. Both masks are the bitwise inclusive OR of one or more of the valid event mask bits. You can specify that no maskable events are reported by setting NoEventMask (default).
Override Redirect Flag

To control window placement or to add decoration, a window manager often needs to intercept (redirect) any map or configure request. Pop-up windows, however, often need to be mapped without a window manager getting in the way. To control whether an InputOutput or InputOnly window is to ignore these structure control facilities, use the override-redirect flag.

The override-redirect flag specifies whether map and configure requests on this window should override a SubstructureRedirectMask on the parent. You can set the override-redirect flag to True or False (default). Window managers use this information to avoid tampering with pop-up windows (see also Chapter 9).

Colormap Attribute

The colormap attribute specifies which colormap best reflects the true colors of the InputOutput window. The colormap must have the same visual type as the window, or a BadMatch error results. XWIN servers capable of supporting multiple hardware colormaps can use this information, and window managers can use it for calls to XInstallColormap. You can set the colormap attribute to a colormap or to CopyFromParent (default).

If you set the colormap to CopyFromParent, the parent window’s colormap is copied and used by its child. However, the child window must have the same visual type as the parent, or a BadMatch error results. The parent window must not have a colormap of None, or a BadMatch error results. The colormap is copied by sharing the colormap object between the child and parent, not by making a complete copy of the colormap contents. Subsequent changes to the parent window’s colormap attribute do not affect the child window.
Cursor Attribute

The cursor attribute specifies which cursor is to be used when the pointer is in the InputOutput or InputOnly window. You can set the cursor to a cursor or None (default).

If you set the cursor to None, the parent's cursor is used when the pointer is in the InputOutput or InputOnly window, and any change in the parent's cursor will cause an immediate change in the displayed cursor. By calling XFreeCursor, the cursor can be freed immediately as long as no further explicit reference to it is made.
Creating Windows

Xlib provides basic ways for creating windows, and toolkits often supply higher-level functions specifically for creating and placing top-level windows, which are discussed in the appropriate toolkit documentation. If you do not use a toolkit, however, you must provide some standard information or hints for the window manager by using the Xlib predefined property functions (see Chapter 9).

If you use Xlib to create your own top-level windows (direct children of the root window), you must observe the following rules so that all applications interact reasonably across the different styles of window management:

- You must never fight with the window manager for the size or placement of your top-level window.
- You must be able to deal with whatever size window you get, even if this means that your application just prints a message like "Please make me bigger" in its window.
- You should only attempt to resize or move top-level windows in direct response to a user request. If a request to change the size of a top-level window fails, you must be prepared to live with what you get. You are free to resize or move the children of top-level windows as necessary. (Toolkits often have facilities for automatic relayout.)
- If you do not use a toolkit that automatically sets standard window properties, you should set these properties for top-level windows before mapping them.

XCreateWindow is the more general function that allows you to set specific window attributes when you create a window. XCreateSimpleWindow creates a window that inherits its attributes from its parent window.

The XWIN server acts as if InputOnly windows do not exist for the purposes of graphics requests, exposure processing, and VisibilityNotify events. An InputOnly window cannot be used as a drawable (that is, as a source or destination for graphics requests). InputOnly and InputOutput windows act identically in other respects (properties, grabs, input control, and so on). Extension packages can define other classes of windows.

To create an unmapped window and set its window attributes, use XCreateWindow.
Creating Windows

Window XCreateWindow (display, parent, x, y, width, height, border_width, depth, class, visual, valuemask, attributes)

Display *display;
Window parent;
int x, y;
unsigned int width, height;
unsigned int border_width;
int depth;
unsigned int class;
Visual *visual
unsigned long valuemask;
XSetWindowAttributes *attributes;

display Specifies the connection to the XWIN server.
parent Specifies the parent window.
x y Specify the x and y coordinates, which are the top-left outside corner of the created window’s borders and are relative to the inside of the parent window’s borders.
width height Specify the width and height, which are the created window’s inside dimensions and do not include the created window’s borders. The dimensions must be nonzero, or a BadValue error results.
border_width Specifies the width of the created window’s border in pixels.
depth Specifies the window’s depth. A depth of CopyFromParent means the depth is taken from the parent.
class Specifies the created window’s class. You can pass InputOutput, InputOnly, or CopyFromParent. A class of CopyFromParent means the class is taken from the parent.
visual Specifies the visual type. A visual of CopyFromParent means the visual type is taken from the parent.
valuemask Specifies which window attributes are defined in the attributes argument. This mask is the bitwise inclusive OR of the valid attribute mask bits. If valuemask is zero, the attributes are ignored and are not referenced.
**attributes**

Specifies the structure from which the values (as specified by the value mask) are to be taken. The value mask should have the appropriate bits set to indicate which attributes have been set in the structure.

The `XCreateWindow` function creates an unmapped subwindow for a specified parent window, returns the window ID of the created window, and causes the XWIN server to generate a `CreateNotify` event. The created window is placed on top in the stacking order with respect to siblings.

The border width for an `InputOnly` window must be zero, or a BadMatch error results. For class `InputOutput`, the visual type and depth must be a combination supported for the screen, or a BadMatch error results. The depth need not be the same as the parent, but the parent must not be a window of class `InputOnly`, or a BadMatch error results. For an `InputOnly` window, the depth must be zero, and the visual must be one supported by the screen. If either condition is not met, a BadMatch error results. The parent window, however, may have any depth and class. If you specify any invalid window attribute for a window, a BadMatch error results.

The created window is not yet displayed (mapped) on the user's display. To display the window, call `XMapWindow`. The new window initially uses the same cursor as its parent. A new cursor can be defined for the new window by calling `XDefineCursor`.

The window will not be visible on the screen unless it and all of its ancestors are mapped and it is not obscured by any of its ancestors.

`XCreateWindow` can generate BadAlloc, BadColor, BadCursor, BadMatch, BadPixmap, BadValue, and BadWindow errors.

To create an unmapped `InputOutput` subwindow of a given parent window, use `XCreateSimpleWindow`. 

---

*Window Functions*
Window XCreateSimpleWindow (display, parent, x, y, width, height, border_width, border, background)

Display *display;
Window parent;
int x, y;
unsigned int width, height;
unsigned int border_width;
unsigned long border;
unsigned long background;

display Specifies the connection to the XWIN server.
parent Specifies the parent window.
x y Specify the x and y coordinates, which are the top-left outside corner of the new window’s borders and are relative to the inside of the parent window’s borders.
width height Specify the width and height, which are the created window’s inside dimensions and do not include the created window’s borders. The dimensions must be nonzero, or a BadValue error results.
border_width Specifies the width of the created window’s border in pixels.
border Specifies the border pixel value of the window.
background Specifies the background pixel value of the window.

The XCreateSimpleWindow function creates an unmapped InputOutput subwindow for a specified parent window, returns the window ID of the created window, and causes the XWIN server to generate a CreateNotify event. The created window is placed on top in the stacking order with respect to siblings. Any part of the window that extends outside its parent window is clipped. The border_width for an InputOnly window must be zero, or a BadMatch error results. XCreateSimpleWindow inherits its depth, class, and visual from its parent. All other window attributes, except background and border, have their default values.

XCreateSimpleWindow can generate BadAlloc, BadMatch, BadValue, and BadWindow errors.
Destroying Windows

Xlib provides functions that you can use to destroy a window or destroy all subwindows of a window.

To destroy a window and all of its subwindows, use XDestroyWindow.

\[
\text{XDestroyWindow}(\text{display}, w)
\]

\[
\text{Display } *\text{display};
\]

\[
\text{Window } w;
\]

\[
\text{display} \quad \text{Specifies the connection to the XWIN server.}
\]

\[
w \quad \text{Specifies the window.}
\]

The XDestroyWindow function destroys the specified window as well as all of its subwindows and causes the XWIN server to generate a DestroyNotify event for each window. The window should never be referenced again. If the window specified by the \( w \) argument is mapped, it is unmapped automatically. The ordering of the DestroyNotify events is such that for any given window being destroyed, DestroyNotify is generated on any inferiors of the window before being generated on the window itself. The ordering among siblings and across subhierarchies is not otherwise constrained. If the window you specified is a root window, no windows are destroyed. Destroying a mapped window will generate Expose events on other windows that were obscured by the window being destroyed.

XDestroyWindow can generate a BadWindow error.

To destroy all subwindows of a specified window, use XDestroySubwindows.

\[
\text{XDestroySubwindows}(\text{display}, w)
\]

\[
\text{Display } *\text{display};
\]

\[
\text{Window } w;
\]

\[
\text{display} \quad \text{Specifies the connection to the XWIN server.}
\]

\[
w \quad \text{Specifies the window.}
\]

The XDestroySubwindows function destroys all inferior windows of the specified window, in bottom-to-top stacking order. It causes the XWIN server to generate a DestroyNotify event for each window. If any mapped subwindows were actually destroyed, XDestroySubwindows causes the XWIN server to generate Expose events on the specified window. This is much more efficient than deleting many windows one at a time because much of the work need be
Destroying Windows

performed only once for all of the windows, rather than for each window. The subwindows should never be referenced again.

**XDestroySubwindows** can generate a **BadWindow** error.
Mapping Windows

A window is considered mapped if an \texttt{XMapWindow} call has been made on it. It may not be visible on the screen for one of the following reasons:

- It is obscured by another opaque window.
- One of its ancestors is not mapped.
- It is entirely clipped by an ancestor.

Expose events are generated for the window when part or all of it becomes visible on the screen. A client receives the \texttt{Expose} events only if it has asked for them. Windows retain their position in the stacking order when they are unmapped.

A window manager may want to control the placement of subwindows. If \texttt{SubstructureRedirectMask} has been selected by a window manager on a parent window (usually a root window), a map request initiated by other clients on a child window is not performed, and the window manager is sent a \texttt{MapRequest} event. However, if the override-redirect flag on the child had been set to True (usually only on pop-up menus), the map request is performed.

A tiling window manager might decide to reposition and resize other client’s windows and then decide to map the window to its final location. A window manager that wants to provide decoration might reparent the child into a frame first. For further information, see "Override Redirect Flag" in this Chapter and Chapter 8. Only a single client at a time can select for \texttt{SubstructureRedirectMask}.

Similarly, a single client can select for \texttt{ResizeRedirectMask} on a parent window. Then, any attempt to resize the window by another client is suppressed, and the client receives a \texttt{ResizeRequest} event.

To map a given window, use \texttt{XMapWindow}.

\begin{verbatim}
XMapWindow (display, w)
    Display *display;
    Window w;
\end{verbatim}

\texttt{display} \hspace{1cm} Specifies the connection to the XWIN server.
\texttt{w} \hspace{1cm} Specifies the window.
The `XMapWindow` function maps the window and all of its subwindows that have had map requests. Mapping a window that has an unmapped ancestor does not display the window but marks it as eligible for display when the ancestor becomes mapped. Such a window is called unviewable. When all its ancestors are mapped, the window becomes viewable and will be visible on the screen if it is not obscured by another window. This function has no effect if the window is already mapped.

If the override-redirect of the window is `False` and if some other client has selected `SubstructureRedirectMask` on the parent window, then the `XWin` server generates a `MapRequest` event, and the `XMapWindow` function does not map the window. Otherwise, the window is mapped, and the `XWin` server generates a `MapNotify` event.

If the window becomes viewable and no earlier contents for it are remembered, the `XWin` server tiles the window with its background. If the window’s background is undefined, the existing screen contents are not altered, and the `XWin` server generates zero or more `Expose` events. If backing-store was maintained while the window was unmapped, no `Expose` events are generated. If backing-store will now be maintained, a full-window exposure is always generated. Otherwise, only visible regions may be reported. Similar tiling and exposure take place for any newly viewable inferiors.

If the window is an `InputOutput` window, `XMapWindow` generates `Expose` events on each `InputOutput` window that it causes to be displayed. If the client maps and paints the window and if the client begins processing events, the window is painted twice. To avoid this, first ask for `Expose` events and then map the window, so the client processes input events as usual. The event list will include `Expose` for each window that has appeared on the screen. The client’s normal response to an `Expose` event should be to repaint the window. This method usually leads to simpler programs and to proper interaction with window managers.

`XMapWindow` can generate a `BadWindow` error.

To map and raise a window, use `XMapRaised`.

```c
XMapRaised(display, w)
    Display *display;
    Window w;
```
Specifies the connection to the XWIN server.

Specifies the window.

The \texttt{XMapRaised} function essentially is similar to \texttt{XMapWindow} in that it maps the window and all of its subwindows that have had map requests. However, it also raises the specified window to the top of the stack. For additional information, see \texttt{XMapWindow}.

\texttt{XMapRaised} can generate multiple \texttt{BadWindow} errors.

To map all subwindows for a specified window, use \texttt{XMapSubwindows}.

```
XMapSubwindows (display, w)
Display *display;
Window w;
```

Specifies the connection to the XWIN server.

Specifies the window.

The \texttt{XMapSubwindows} function maps all subwindows for a specified window in top-to-bottom stacking order. The XWIN server generates \texttt{Expose} events on each newly displayed window. This may be much more efficient than mapping many windows one at a time because the server needs to perform much of the work only once, for all of the windows, rather than for each window.

\texttt{XMapSubwindows} can generate a \texttt{BadWindow} error.
Unmapping Windows

Xlib provides functions that you can use to unmap a window or all subwindows.

To unmap a window, use \texttt{XUnmapWindow}.

\begin{verbatim}
XUnmapWindow(display, w)
    Display *display;
    Window w;
\end{verbatim}

\textit{display} \hspace{1cm} Specifies the connection to the XWIN server.
\textit{w} \hspace{1cm} Specifies the window.

The \texttt{XUnmapWindow} function unmaps the specified window and causes the XWIN server to generate an \texttt{UnmapNotify} event. If the specified window is already unmapped, \texttt{XUnmapWindow} has no effect. Normal exposure processing on formerly obscured windows is performed. Any child window will no longer be visible until another map call is made on the parent. In other words, the subwindows are still mapped but are not visible until the parent is mapped. Unmapping a window will generate \texttt{Expose} events on windows that were formerly obscured by it.

\texttt{XUnmapWindow} can generate a BadWindow error.

To unmap all subwindows for a specified window, use \texttt{XUnmapSubwindows}.

\begin{verbatim}
XUnmapSubwindows(display, w)
    Display *display;
    Window w;
\end{verbatim}

\textit{display} \hspace{1cm} Specifies the connection to the XWIN server.
\textit{w} \hspace{1cm} Specifies the window.

The \texttt{XUnmapSubwindows} function unmaps all subwindows for the specified window in bottom-to-top stacking order. It causes the XWIN server to generate an \texttt{UnmapNotify} event on each subwindow and \texttt{Expose} events on formerly obscured windows. Using this function is much more efficient than unmapping multiple windows one at a time because the server needs to perform much of the work only once, for all of the windows, rather than for each window.

\texttt{XUnmapSubwindows} can generate a BadWindow error.
Configuring Windows

Xlib provides functions that you can use to move a window, resize a window, move and resize a window, or change a window’s border width. To change one of these parameters, set the appropriate member of the XWindowChanges structure and OR in the corresponding value mask in subsequent calls to XConfigureWindow. The symbols for the value mask bits and the XWindowChanges structure are:

/* Configure window value mask bits */

```c
#define CWX (1<<0)
define CWY (1<<1)
define CWWidth (1<<2)
define CWHeight (1<<3)
define CWBorderWidth (1<<4)
define CWSibling (1<<5)
define CWStackMode (1<<6)
```

/* Values */

```c
typedef struct {
  int x, y;
  int width, height;
  int border_width;
  Window sibling;
  int stack_mode;
} XWindowChanges;
```

The x and y members are used to set the window’s x and y coordinates, which are relative to the parent’s origin and indicate the position of the upper-left outer corner of the window. The width and height members are used to set the inside size of the window, not including the border, and must be nonzero, or a BadValue error results. Attempts to configure a root window have no effect.

The border_width member is used to set the width of the border in pixels. Note that setting just the border width leaves the outer-left corner of the window in a fixed position but moves the absolute position of the window’s origin. If you attempt to set the border-width attribute of an InputOnly window nonzero, a BadMatch error results.
The sibling member is used to set the sibling window for stacking operations. The stack_mode member is used to set how the window is to be restacked and can be set to Above, Below, TopIf, BottomIf, or Opposite.

If the override-redirect flag of the window is False and if some other client has selected SubstructureRedirectMask on the parent, the XWIN server generates a ConfigureRequest event, and no further processing is performed. Otherwise, if some other client has selected ResizeRedirectMask on the window and the inside width or height of the window is being changed, a ResizeRequest event is generated, and the current inside width and height are used instead. Note that the override-redirect flag of the window has no effect on ResizeRedirectMask and that SubstructureRedirectMask on the parent has precedence over ResizeRedirectMask on the window.

When the geometry of the window is changed as specified, the window is restacked among siblings, and a ConfigureNotify event is generated if the state of the window actually changes. GravityNotify events are generated after ConfigureNotify events. If the inside width or height of the window has actually changed, children of the window are affected as specified.

If a window's size actually changes, the window's subwindows move according to their window gravity. Depending on the window's bit gravity, the contents of the window also may be moved (see "Gravity Attributes" in this chapter).

If regions of the window were obscured but now are not, exposure processing is performed on these formerly obscured windows, including the window itself and its inferiors. As a result of increasing the width or height, exposure processing is also performed on any new regions of the window and any regions where window contents are lost.

The restack check (specifically, the computation for BottomIf, TopIf, and Opposite) is performed with respect to the window's final size and position (as controlled by the other arguments of the request), not its initial position. If a sibling is specified without a stack_mode, a BadMatch error results.

If a sibling and a stack_mode are specified, the window is restacked as follows:
Configuring Windows

Above The window is placed just above the sibling.
Below The window is placed just below the sibling.
TopIf If the sibling occludes the window, the window is placed at the top of the stack.
BottomIf If the window occludes the sibling, the window is placed at the bottom of the stack.
Opposite If the sibling occludes the window, the window is placed at the top of the stack. If the window occludes the sibling, the window is placed at the bottom of the stack.

If a stack_mode is specified but no sibling is specified, the window is restacked as follows:

Above The window is placed at the top of the stack.
Below The window is placed at the bottom of the stack.
TopIf If any sibling occludes the window, the window is placed at the top of the stack.
BottomIf If the window occludes any sibling, the window is placed at the bottom of the stack.
Opposite If any sibling occludes the window, the window is placed at the top of the stack. If the window occludes any sibling, the window is placed at the bottom of the stack.

Attempts to configure a root window have no effect.

To configure a window’s size, location, stacking, or border, use XConfigureWindow.

XConfigureWindow(display, w, value_mask, values)
    Display *display;
    Window w;
    unsigned int value_mask;
    XWindowChanges *values;
Configuring Windows

**display**
- Specifies the connection to the XWIN server.

**w**
- Specifies the window to be reconfigured.

**value_mask**
- Specifies which values are to be set using information in the values structure. This mask is the bitwise inclusive OR of the valid configure window values bits.

**values**
- Specifies a pointer to the XWindowChanges structure.

The `XConfigureWindow` function uses the values specified in the XWindowChanges structure to reconfigure a window's size, position, border, and stacking order. Values not specified are taken from the existing geometry of the window.

If a sibling is specified without a stack_mode or if the window is not actually a sibling, a BadMatch error results. Note that the computations for BottomIf, TopIf, and Opposite are performed with respect to the window's final geometry (as controlled by the other arguments passed to `XConfigureWindow`), not its initial geometry. Any backing store contents of the window, its inferiors, and other newly visible windows are either discarded or changed to reflect the current screen contents (depending on the implementation).

`XConfigureWindow` can generate BadMatch, BadValue, and BadWindow errors.

To move a window without changing its size, use `XMoveWindow`.

```c
XMoveWindow (display, w, x, y)
Display *display;
Window w;
int x, y;
```

**display**
- Specifies the connection to the XWIN server.

**w**
- Specifies the window to be moved.

**x**

**y**
- Specify the x and y coordinates, which define the new location of the top-left pixel of the window's border or the window itself if it has no border.
The `XMoveWindow` function moves the specified window to the specified x and y coordinates, but it does not change the window's size, raise the window, or change the mapping state of the window. Moving a mapped window may or may not lose the window’s contents depending on if the window is obscured by nonchildren and if no backing store exists. If the contents of the window are lost, the XWIN server generates Expose events. Moving a mapped window generates Expose events on any formerly obscured windows.

If the override-redirect flag of the window is `false` and some other client has selected `SubstructureRedirectMask` on the parent, the XWIN server generates a `ConfigureRequest` event, and no further processing is performed. Otherwise, the window is moved.

`XMoveWindow` can generate a `BadWindow` error.

To change a window’s size without changing the upper-left coordinate, use `XResizeWindow`.

```c
XResizeWindow(display, w, width, height)

Display *display;
Window w;
unsigned int width, height;
```

display

Specifies the connection to the XWIN server.

w

Specifies the window.

width

height

Specify the width and height, which are the interior dimensions of the window after the call completes.

The `XResizeWindow` function changes the inside dimensions of the specified window, not including its borders. This function does not change the window’s upper-left coordinate or the origin and does not restack the window. Changing the size of a mapped window may lose its contents and generate Expose events. If a mapped window is made smaller, changing its size generates Expose events on windows that the mapped window formerly obscured.

If the override-redirect flag of the window is `false` and some other client has selected `SubstructureRedirectMask` on the parent, the XWIN server generates a `ConfigureRequest` event, and no further processing is performed. If either width or height is zero, a `BadValue` error results.
Configuring Windows

XResi`eWindow can generate BadValue and BadWindow errors.

To change the size and location of a window, use XMoveResizeWindow.

\[
\text{XMoveResizeWindow}(\text{display, w, x, y, width, height})
\]

- \text{display} \quad \text{Specifies the connection to the XWIN server.}
- \text{w} \quad \text{Specifies the window to be reconfigured.}
- \text{x, y} \quad \text{Specify the x and y coordinates, which define the new position of the window relative to its parent.}
- \text{width, height} \quad \text{Specify the width and height, which define the interior size of the window.}

The XMoveResizeWindow function changes the size and location of the specified window without raising it. Moving and resizing a mapped window may generate an Expose event on the window. Depending on the new size and location parameters, moving and resizing a window may generate Expose events on windows that the window formerly obscured.

If the override-redirect flag of the window is False and some other client has selected SubstructureRedirectMask on the parent, the XWIN server generates a ConfigureRequest event, and no further processing is performed. Otherwise, the window size and location are changed.

XMoveResizeWindow can generate BadValue and BadWindow errors.

To change the border width of a given window, use XSetWindowBorderWidth.

\[
\text{XSetWindowBorderWidth}(\text{display, w, width})
\]

- \text{display} \quad \text{Specifies the connection to the XWIN server.}
- \text{w} \quad \text{Specifies the window to be reconfigured.}
- \text{width} \quad \text{Specify the width, which define the border width of the window.}
Configuring Windows

- **display**: Specifies the connection to the XWIN server.
- **w**: Specifies the window.
- **width**: Specifies the width of the window border.

The `XSetWindowBorderWidth` function sets the specified window's border width to the specified width.

`XSetWindowBorderWidth` can generate a `BadWindow` error.
Changing Window Stacking Order

Xlib provides functions that you can use to raise, lower, circulate, or restack windows.

To raise a window so that no sibling window obscures it, use XRaiseWindow.

```
XRaiseWindow(display, w)
```

- `display` Specifies the connection to the XWIN server.
- `w` Specifies the window.

The XRaiseWindow function raises the specified window to the top of the stack so that no sibling window obscures it. If the windows are regarded as overlapping sheets of paper stacked on a desk, then raising a window is analogous to moving the sheet to the top of the stack but leaving its x and y location on the desk constant. Raising a mapped window may generate Expose events for the window and any mapped subwindows that were formerly obscured.

If the override-redirect attribute of the window is False and some other client has selected SubstructureRedirectMask on the parent, the XWIN server generates a ConfigureRequest event, and no processing is performed. Otherwise, the window is raised.

XRaiseWindow can generate a BadWindow error.

To lower a window so that it does not obscure any sibling windows, use XLowerWindow.

```
XLowerWindow(display, w)
```

- `display` Specifies the connection to the XWIN server.
- `w` Specifies the window.

The XLowerWindow function lowers the specified window to the bottom of the stack so that it does not obscure any sibling windows. If the windows are regarded as overlapping sheets of paper stacked on a desk, then lowering a window is analogous to moving the sheet to the bottom of the stack but leaving
its x and y location on the desk constant. Lowering a mapped window will generate Expose events on any windows it formerly obscured.

If the override-redirect attribute of the window is False and some other client has selected SubstructureRedirectMask on the parent, the XWIN server generates a ConfigureRequest event, and no processing is performed. Otherwise, the window is lowered to the bottom of the stack.

XLowerWindow can generate a BadWindow error.

To circulate a subwindow up or down, use XCirculateSubwindows.

```
X CirculateSubwindows (display, w, direction)
Display *display;
Window w;
int direction;
```

- **display**: Specifies the connection to the XWIN server.
- **w**: Specifies the window.
- **direction**: Specifies the direction (up or down) that you want to circulate the window. You can pass RaiseLowest or LowerHighest.

The XCirculateSubwindows function circulates children of the specified window in the specified direction. If you specify RaiseLowest, XCirculateSubwindows raises the lowest mapped child (if any) that is occluded by another child to the top of the stack. If you specify LowerHighest, XCirculateSubwindows lowers the highest mapped child (if any) that occludes another child to the bottom of the stack. Exposure processing is then performed on formerly obscured windows. If some other client has selected SubstructureRedirectMask on the window, the XWIN server generates a CirculateRequest event, and no further processing is performed. If a child is actually restacked, the XWIN server generates a CirculateNotify event.

XCirculateSubwindows can generate BadValue and BadWindow errors.

To raise the lowest mapped child of a window that is partially or completely occluded by another child, use XCirculateSubwindowsUp.

```
X CirculateSubwindowsUp (display, w)
Display *display;
Window w;
```
Changing Window Stacking Order

display Specifies the connection to the XWIN server.

w Specifies the window.

The XCirculateSubwindowsUp function raises the lowest mapped child of the specified window that is partially or completely occluded by another child. Completely unobscured children are not affected. This is a convenience function equivalent to XCirculateSubwindows with RaiseLowest specified.

XCirculateSubwindowsUp can generate a BadWindow error.

To lower the highest mapped child of a window that partially or completely occludes another child, use XCirculateSubwindowsDown.

```
 XCirculateSubwindowsDown (display, w)
    Display *display;
    Window w;
```

display Specifies the connection to the XWIN server.

w Specifies the window.

The XCirculateSubwindowsDown function lowers the highest mapped child of the specified window that partially or completely occludes another child. Completely unobscured children are not affected. This is a convenience function equivalent to XCirculateSubwindows with LowerHighest specified.

XCirculateSubwindowsDown can generate a BadWindow error.

To restack a set of windows from top to bottom, use XRestackWindows.

```
 XRestackWindows (display, windows, nwindows);
    Display *display;
    Window windows[];
    int nwindows;
```

display Specifies the connection to the XWIN server.

windows Specifies an array containing the windows to be restacked.

nwindows Specifies the number of windows to be restacked.
The XRestackWindows function restacks the windows in the order specified, from top to bottom. The stacking order of the first window in the windows array is unaffected, but the other windows in the array are stacked underneath the first window, in the order of the array. The stacking order of the other windows is not affected. For each window in the window array that is not a child of the specified window, a BadMatch error results.

If the override-redirect attribute of a window is False and some other client has selected SubstructureRedirectMask on the parent, the XWIN server generates ConfigureRequest events for each window whose override-redirect flag is not set, and no further processing is performed. Otherwise, the windows will be restacked in top to bottom order.

XRestackWindows can generate a BadWindow error.
Changing Window Attributes

Xlib provides functions that you can use to set window attributes. \texttt{XChangeWindowAttributes} is the more general function that allows you to set one or more window attributes provided by the \texttt{XSetWindowAttributes} structure. The other functions described in this section allow you to set one specific window attribute, such as a window's background.

To change one or more attributes for a given window, use \texttt{XChangeWindowAttributes}.

\begin{verbatim}
XChangeWindowAttributes (display, w, valuemask, attributes)
  Display *display;
  Window w;
  unsigned long valuemask;
  XSetWindowAttributes *attributes;
\end{verbatim}

- \texttt{display} specifies the connection to the XWIN server.
- \texttt{w} specifies the window.
- \texttt{valuemask} specifies which window attributes are defined in the \texttt{attributes} argument. This mask is the bitwise inclusive OR of the valid attribute mask bits. If \texttt{valuemask} is zero, the attributes are ignored and are not referenced. The values and restrictions are the same as for \texttt{XCreateWindow}.
- \texttt{attributes} specifies the structure from which the values (as specified by the \texttt{valuemask}) are to be taken. The \texttt{valuemask} should have the appropriate bits set to indicate which attributes have been set in the structure (see "Window Attributes" in this chapter).

Depending on the \texttt{valuemask}, the \texttt{XChangeWindowAttributes} function uses the window attributes in the \texttt{XSetWindowAttributes} structure to change the specified window attributes. Changing the background does not cause the window contents to be changed. To repaint the window and its background, use \texttt{XClearWindow}. Setting the border or changing the background such that the border tile origin changes causes the border to be repainted. Changing the background of a root window to \texttt{None} or \texttt{ParentRelative} restores the default background pixmap. Changing the border of a root window to \texttt{CopyFromParent} restores the default border pixmap. Changing the \texttt{win-gravity} does not affect the current position of the window. Changing the backing-store of an obscured window to \texttt{WhenMapped} or \texttt{Always}, or changing the backing-planes, backing-pixel, or save-under of a mapped window may have no immediate
Changing Window Attributes

effect. Changing the colormap of a window (that is, defining a new map, not changing the contents of the existing map) generates a ColormapNotify event. Changing the colormap of a visible window may have no immediate effect on the screen because the map may not be installed (see XInstallColormap). Changing the cursor of a root window to None restores the default cursor. Whenever possible, you are encouraged to share colormaps.

Multiple clients can select input on the same window. Their event masks are maintained separately. When an event is generated, it is reported to all interested clients. However, only one client at a time can select for StructureRedirectMask, ResizeRedirectMask, and ButtonPressMask. If a client attempts to select any of these event masks and some other client has already selected one, a BadAccess error results. There is only one do-not-propagate-mask for a window, not one per client.

XChangeWindowAttributes can generate BadAccess, BadColor, BadCursor, BadMatch, BadPixmap, BadValue, and BadWindow errors.

To set the background of a window to a given pixel, use XSetWindowBackground.

```c
XSetWindowBackground (display, w, background_pixel)
Display *display;
Window w;
unsigned long background_pixel;
```

display Specifies the connection to the XWIN server.
w Specifies the window.
background_pixel Specifies the pixel that is to be used for the background.

The XSetWindowBackground function sets the background of the window to the specified pixel value. Changing the background does not cause the window contents to be changed. XSetWindowBackground uses a pixmap of undefined size filled with the pixel value you passed. If you try to change the background of an InputOnly window, a BadMatch error results.

XSetWindowBackground can generate BadMatch and BadWindow errors.

To set the background of a window to a given pixmap, use XSetWindowBackgroundPixmap.
Changing Window Attributes

XSetWindowBackgroundPixmap(display, w, background_pixmap)

Display *display;
Window w;
Pixmap background_pixmap;

display        Specifies the connection to the XWIN server.
w             Specifies the window.
background_pixmap        Specifies the background pixmap, ParentRelative, or None.

The XSetWindowBackgroundPixmap function sets the background pixmap of the window to the specified pixmap. The background pixmap can immediately be freed if no further explicit references to it are to be made. If ParentRelative is specified, the background pixmap of the window’s parent is used, or on the root window, the default background is restored. If you try to change the background of an InputOnly window, a BadMatch error results. If the background is set to None, the window has no defined background.

XSetWindowBackgroundPixmap can generate BadMatch, BadPixmap, and BadWindow errors.

NOTE
XSetWindowBackground and XSetWindowBackgroundPixmap do not change the current contents of the window.

To change and repaint a window’s border to a given pixel, use XSetWindowBorder.

XSetWindowBorder(display, w, border_pixel)

Display *display;
Window w;
unsigned long border_pixel;

display        Specifies the connection to the XWIN server.
w             Specifies the window.
Changing Window Attributes

border_pixel  Specifies the entry in the colormap.

The XSetWindowBorder function sets the border of the window to the pixel value you specify. If you attempt to perform this on an InputOnly window, a BadMatch error results.

XSetWindowBorder can generate BadMatch and BadWindow errors.

To change and repaint the border tile of a given window, use XSetWindowBorderPixmap.

  XSetWindowBorderPixmap (display, w, border pixmap)
  
  Display *display;
  Window w;
  Pixmap border pixmap;

display  Specifies the connection to the XWIN server.

w  Specifies the window.

border pixmap  Specifies the border pixmap or CopyFromParent.

The XSetWindowBorderPixmap function sets the border pixmap of the window to the pixmap you specify. The border pixmap can be freed immediately if no further explicit references to it are to be made. If you specify CopyFromParent, a copy of the parent window's border pixmap is used. If you attempt to perform this on an InputOnly window, a BadMatch error results.

XSetWindowBorderPixmap can generate BadMatch, BadPixmap, and BadWindow errors.
Translating Window Coordinates

Applications, mostly window managers, often need to perform a coordinate transformation from the coordinate space of one window to another window or need to determine which subwindow a coordinate lies in. XTranslateCoordinates fulfills these needs (and avoids any race conditions) by asking the XWIN server to perform this operation.

```c
Bool XTranslateCoordinates (display, src_w, dest_w, src_x, src_y, dest_x_return,
                          dest_y_return, child_return)

Display *display;
Window src_w, dest_w;
int src_x, src_y;
int *dest_x_return, *dest_y_return;
Window *child_return;
```

- `display`: Specifies the connection to the XWIN server.
- `src_w`: Specifies the source window.
- `dest_w`: Specifies the destination window.
- `src_x`, `src_y`: Specify the x and y coordinates within the source window.
- `dest_x_return`: Return the x and y coordinates within the destination window.
- `dest_y_return`: Return the x and y coordinates within the destination window.
- `child_return`: Returns the child if the coordinates are contained in a mapped child of the destination window.

The XTranslateCoordinates function takes the `src_x` and `src_y` coordinates relative to the source window’s origin and returns these coordinates to `dest_x_return` and `dest_y_return` relative to the destination window’s origin. If XTranslateCoordinates returns zero, `src_w` and `dest_w` are on different screens, and `dest_x_return` and `dest_y_return` are zero. If the coordinates are contained in a mapped child of `dest_w`, that child is returned to `child_return`. Otherwise, `child_return` is set to `None`.

XTranslateCoordinates can generate a BadWindow error.
4 Window Information Functions

Introduction 4-1

Obtaining Window Information 4-2

Properties and Atoms 4-8

Obtaining and Changing Window Properties 4-12

Selections 4-18
Introduction

After you connect the display to the XWIN server and create a window, you can use the Xlib window information functions to:

- Obtain information about a window
- Manipulate property lists
- Obtain and change window properties
- Manipulate selections
Obtaining Window Information

Xlib provides functions that you can use to obtain information about the window tree, the window’s current attributes, the window’s current geometry, or the current pointer coordinates. Because they are most frequently used by window managers, these functions all return a status to indicate whether the window still exists.

To obtain the parent, a list of children, and number of children for a given window, use XQueryTree.

```
Status XQueryTree(display, w, root_return, parent_return, children_return, nchildren_return)

Display *display;
Window w;
Window *root_return;
Window *parent_return;
Window **children_return;
unsigned int *nchildren_return;
```

- `display` Specifies the connection to the XWIN server.
- `w` Specifies the window whose list of children, root, parent, and number of children you want to obtain.
- `root_return` Returns the root window.
- `parent_return` Returns the parent window.
- `children_return` Returns a pointer to the list of children.
- `nchildren_return` Returns the number of children.

The XQueryTree function returns the root ID, the parent window ID, a pointer to the list of children windows, and the number of children in the list for the specified window. The children are listed in current stacking order, from bottommost (first) to topmost (last). XQueryTree returns zero if it fails and nonzero if it succeeds. To free this list when it is no longer needed, use XFree.

To obtain the current attributes of a given window, use XGetWindowAttributes.

```
Status XGetWindowAttributes(display, w, window_attributes_return)

Display *display;
Window w;
XWindowAttributes *window_attributes_return;
```
display  Specifies the connection to the XWIN server.

w  Specifies the window whose current attributes you want to obtain.

window_attributes_return
Returns the specified window's attributes in the XWindowAttributes structure.

The XGetWindowAttributes function returns the current attributes for the specified window to an XWindowAttributes structure.

typedef struct {
    int x, y;  /* location of window */
    int width, height;  /* width and height of window */
    int border_width;  /* border width of window */
    int depth;  /* depth of window */
    Visual *visual;  /* the associated visual structure */
    Window root;  /* root of screen containing window */
    int class;  /* InputOutput, InputOnly */
    int bit_gravity;  /* one of the bit gravity values */
    int win_gravity;  /* one of the window gravity values */
    int backing_store;  /* NotUseful, WhenMapped, Always */
    unsigned long backing_planes;  /* planes to be preserved if possible */
    unsigned long backing_pixel;  /* value to be used when restoring planes */
    Bool save_under;  /* boolean, should bits under be saved? */
    Colormap colormap;  /* color map to be associated with window */
    Bool map_installed;  /* boolean, is color map currently installed */
    int map_state;  /* IsUnmapped, IsUnviewable, IsViewable */
    long all_event_masks;  /* set of events all people have interest in */
    long your_event_mask;  /* my event mask */
    long do_not_propagate_mask;  /* set of events that should not propagate */
    Bool override_redirect;  /* boolean value for override-redirect */
    Screen *screen;  /* back pointer to correct screen */
} XWindowAttributes;

The x and y members are set to the upper-left outer corner relative to the parent window's origin. The width and height members are set to the inside size of the window, not including the border. The border_width member is set to the window's border width in pixels. The depth member is set to the depth of the window (that is, bits per pixel for the object). The visual member is a pointer to the screen's associated Visual structure. The root member is set to the root.
window of the screen containing the window. The class member is set to the window's class and can be either InputOutput or InputOnly.

The bit_gravity member is set to the window's bit gravity and can be one of the following:

- `ForgetGravity`
- `NorthWestGravity`
- `NorthGravity`
- `NorthEastGravity`
- `WestGravity`
- `CenterGravity`
- `EastGravity`
- `SouthGravity`
- `SouthEastGravity`
- `SouthWestGravity`
- `StaticGravity`

The win_gravity member is set to the window's window gravity and can be one of the following:

- `UnmapGravity`
- `NorthWestGravity`
- `NorthGravity`
- `NorthEastGravity`
- `WestGravity`
- `CenterGravity`
- `EastGravity`
- `SouthGravity`
- `SouthEastGravity`
- `SouthWestGravity`
- `StaticGravity`

For additional information on gravity, see "Creating Windows" in Chapter 3.

The backing_store member is set to indicate how the XWIN server should maintain the contents of a window and can be `WhenMapped`, `Always`, or `NotUseful`. The backing_planes member is set to indicate (with bits set to 1) which bit planes of the window hold dynamic data that must be preserved in backing stores and during save unders. The backing_pixel member is set to indicate what values to use for planes not set in backing planes.

The save_under member is set to `True` or `False`. The colormap member is set to the colormap for the specified window and can be a colormap ID or `None`. The map_installed member is set to indicate whether the colormap is currently installed and can be `True` or `False`. The map_state member is set to indicate the state of the window and can be `IsUnmapped`, `IsUnviewable`, or `IsViewable`. `IsUnviewable` is used if the window is mapped but some ancestor is unmapped.
The all_event_masks member is set to the bitwise inclusive OR of all event masks selected on the window by all clients. The your_event_mask member is set to the bitwise inclusive OR of all event masks selected by the querying client. The do_not_propagate_mask member is set to the bitwise inclusive OR of the set of events that should not propagate.

The override_redirect member is set to indicate whether this window overrides structure control facilities and can be True or False. Window manager clients should ignore the window if this member is True.

The screen member is set to a screen pointer that gives you a back pointer to the correct screen. This makes it easier to obtain the screen information without having to loop over the root window fields to see which field matches.

XGetWindowAttributes can generate BadDrawable and BadWindow errors.

To obtain the current geometry of a given drawable, use XGetGeometry.

```c
Status XGetGeometry( display, d, root_return, x_return, y_return, width_return,
                      height_return, border_width_return, depth_return )

Display *display;
Drawable d;
Window *root_return;
int *x_return, *y_return;
unsigned int *width_return, *height_return;
unsigned int *border_width_return;
unsigned int *depth_return;
```

display Specifies the connection to the XWIN server.
d Specifies the drawable, which can be a window or a pixmap.
root_return Returns the root window.
x_return y_return Return the x and y coordinates that define the location of the drawable. For a window, these coordinates specify the upper-left outer corner relative to its parent's origin. For pixmaps, these coordinates are always zero.

width_return height_return Return the drawable's dimensions (width and height). For a window, these dimensions specify the inside size, not including the border.
Obtaining Window Information

border_width_return
Returns the border width in pixels. If the drawable is a pixmap, it returns zero.

depth_return
Returns the depth of the drawable (bits per pixel for the object).

The XGetGeometry function returns the root window and the current geometry of the drawable. The geometry of the drawable includes the x and y coordinates, width and height, border width, and depth. These are described in the argument list. It is legal to pass to this function a window whose class is InputOnly.

To obtain the root window the pointer is currently on and the pointer coordinates relative to the root's origin, use XQueryPointer.

Bool XQueryPointer(display, w, root_return, child_return, root_x_return, root_y_return, win_x_return, win_y_return, mask_return)

Display *display;
Window w;
Window *root_return, *child_return;
it *root_x_return, *root_y_return;
it *win_x_return, *win_y_return;
unsigned int *mask_return;

display
Specifies the connection to the XWIN server.
w
Specifies the window.
root_return
Returns the root window that the pointer is in.
child_return
Returns the child window that the pointer is located in, if any.
root_x_return
root_y_return
Return the pointer coordinates relative to the root window's origin.

win_x_return
win_y_return
Return the pointer coordinates relative to the specified window.

mask_return
Returns the current state of the modifier keys and pointer buttons.
The XQueryPointer function returns the root window the pointer is logically on and the pointer coordinates relative to the root window's origin. If XQueryPointer returns False, the pointer is not on the same screen as the specified window, and XQueryPointer returns None to child_return and zero to win_x_return and win_y_return. If XQueryPointer returns True, the pointer coordinates returned to win_x_return and win_y_return are relative to the origin of the specified window. In this case, XQueryPointer returns the child that contains the pointer, if any, or else None to child_return.

XQueryPointer returns the current logical state of the keyboard buttons and the modifier keys in mask_return. It sets mask_return to the bitwise inclusive OR of one or more of the button or modifier key bitmasks to match the current state of the mouse buttons and the modifier keys.

Note that the logical state of a device (as seen through Xlib) may lag the physical state if device event processing is frozen (see "Pointer Grabbing" in Chapter 7).

XQueryPointer can generate a BadWindow error.
Properties and Atoms

A property is a collection of named, typed data. The window system has a set of predefined properties (for example, the name of a window, size hints, and so on), and users can define any other arbitrary information and associate it with windows. Each property has a name, which is an ISO Latin-1 string. For each named property, a unique identifier (atom) is associated with it. A property also has a type, for example, string or integer. These types are also indicated using atoms, so arbitrary new types can be defined. Data of only one type may be associated with a single property name. Clients can store and retrieve properties associated with windows. For efficiency reasons, an atom is used rather than a character string. XInternAtom can be used to obtain the atom for property names.

A property is also stored in one of several possible formats. The XWIN server can store the information as 8-bit quantities, 16-bit quantities, or 32-bit quantities. This permits the XWIN server to present the data in the byte order that the client expects.

If you define further properties of complex type, you must encode and decode them yourself. These functions must be carefully written if they are to be portable. For further information about how to write a library extension, see appendix C.

The type of a property is defined by an atom, which allows for arbitrary extension in this type scheme.

Certain property names are predefined in the server for commonly used functions. The atoms for these properties are defined in < X11/Xatom.h >. To avoid name clashes with user symbols, the #define name for each atom has the XA_ prefix. For definitions of these properties, see "Obtaining and Changing Window Properties" in Chapter 4. For an explanation of the functions that let you get and set much of the information stored in these predefined properties, see Chapter 9.

You can use properties to communicate other information between applications. The functions described in this section let you define new properties and get the unique atom IDs in your applications.

Although any particular atom can have some client interpretation within each of the name spaces, atoms occur in five distinct name spaces within the protocol:
Properties and Atoms

- Selections
- Property names
- Property types
- Font properties
- Type of a ClientMessage event (none are built into the XWin server)

The built-in selection property names are:

- PRIMARY
- SECONDARY

The built-in property names are:

- CUT_BUFFER0
- CUT_BUFFER1
- CUT_BUFFER2
- CUT_BUFFER3
- CUT_BUFFER4
- CUT_BUFFER5
- CUT_BUFFER6
- CUT_BUFFER7
- RGB_BEST_MAP
- RGB_BLUE_MAP
- RGB_DEFAULT_MAP
- RGB_GRAY_MAP
- RGB_GREEN_MAP
- RGB_RED_MAP
- RESOURCE_MANAGER
- WM_CLASS
- WM_CLIENT_MACHINE
- WM_COMMAND
- WM_HINTS
- WM_ICON_NAME
- WM_ICON_SIZE
- WM_NAME
- WM_NORMAL_HINTS
- WM_ZOOM_HINTS
- WM_TRANSIENT_FOR

The built-in property types are:

- ARC
- ATOM
- BITMAP
- CARDINAL
- COLORMAP
- CURSOR
- DRAWABLE
- POINT
- RGB_COLOR_MAP
- RECTANGLE
- STRING
- VISUALID
- WINDOW
- WM_HINTS
The built-in font property names are:

- **MIN_SPACE**
- **NORM_SPACE**
- **MAX_SPACE**
- **END_SPACE**
- **SUPERSCRIPT_X**
- **SUPERSCRIPT_Y**
- **SUBSCRIPT_X**
- **SUBSCRIPT_Y**
- **UNDERLINE_POSITION**
- **UNDERLINE_THICKNESS**
- **FONT_NAME**
- **FULL_NAME**
- **STRIKEOUT_DESCENT**
- **STRIKEOUT_ASCENT**
- **ITALIC_ANGLE**
- **X_HEIGHT**
- **QUAD_WIDTH**
- **WEIGHT**
- **POINT_SIZE**
- **RESOLUTION**
- **COPYRIGHT**
- **NOTICE**
- **FAMILY_NAME**
- **CAP_HEIGHT**

For further information about font properties, see "Font Metrics" in Chapter 6.

To return an atom for a given name, use `XInternAtom`.

```c
Atom XInternAtom(display, atom_name, only_if_exists)
    Display *display;
    char *atom_name;
    Bool only_if_exists;
```

- **display** Specifies the connection to the XWIN server.
- **atom_name** Specifies the name associated with the atom you want returned.
- **only_if_exists** Specifies a Boolean value that indicates whether `XInternAtom` creates the atom.

The `XInternAtom` function returns the atom identifier associated with the specified atom_name string. If only_if_exists is `false`, the atom is created if it does not exist. Therefore, `XInternAtom` can return `None`. You should use a null-terminated ISO Latin-1 string for atom_name. Case matters; the strings `thing`, `Thing`, and `thinG` all designate different atoms. The atom will remain defined even after the client's connection closes. It will become undefined only when the last connection to the XWIN server closes.
XInternAtom can generate BadAlloc and BadValue errors.

To return a name for a given atom identifier, use XGetAtomName.

```c
char *XGetAtomName (display, atom)
    Display *display;
    Atom atom;

display  Specifies the connection to the XWIN server.
atom     Specifies the atom for the property name you want returned.
```

The XGetAtomName function returns the name associated with the specified atom. To free the resulting string, call XFree.

XGetAtomName can generate a BadAtom error.
Obtaining and Changing Window Properties

You can attach a property list to every window. Each property has a name, a type, and a value (see "Properties and Atoms" in Chapter 4). The value is an array of 8-bit, 16-bit, or 32-bit quantities, whose interpretation is left to the clients.

Xlib provides functions that you can use to obtain, change, update, or interchange window properties. In addition, Xlib provides other utility functions for predefined property operations (see Chapter 9).

To obtain the type, format, and value of a property of a given window, use XGetWindowProperty.

```c
int XGetWindowProperty (display, w, property, long_offset, long_length, delete, req_type,
                        actual_type_return, actual_format_return, nitems_return, bytes_after_return,
                        prop_return)
```

- `display` Specifies the connection to the XWIN server.
- `w` Specifies the window whose property you want to obtain.
- `property` Specifies the property name.
- `long_offset` Specifies the offset in the specified property (in 32-bit quantities) where the data is to be retrieved.
- `long_length` Specifies the length in 32-bit multiples of the data to be retrieved.
- `delete` Specifies a Boolean value that determines whether the property is deleted.

Xwin GWS: Xlib – C Language Interface
Obtaining and Changing Window Properties

req_type Specifies the atom identifier associated with the property type or AnyPropertyType.

actual_type_return Returns the atom identifier that defines the actual type of the property.

actual_format_return Returns the actual format of the property.

nitems_return Returns the actual number of 8-bit, 16-bit, or 32-bit items stored in the prop_return data.

bytes_after_return Returns the number of bytes remaining to be read in the property if a partial read was performed.

prop_return Returns a pointer to the data in the specified format.

The XGetWindowProperty function returns the actual type of the property; the actual format of the property; the number of 8-bit, 16-bit, or 32-bit items transferred; the number of bytes remaining to be read in the property; and a pointer to the data actually returned. XGetWindowProperty sets the return arguments as follows:

- If the specified property does not exist for the specified window, XGetWindowProperty returns None to actual_type_return and the value zero to actual_format_return and bytes_after_return. The nitems_return argument is empty. In this case, the delete argument is ignored.

- If the specified property exists but its type does not match the specified type, XGetWindowProperty returns the actual property type to actual_type_return, the actual property format (never zero) to actual_format_return, and the property length in bytes (even if the actual_format_return is 16 or 32) to bytes_after_return. It also ignores the delete argument. The nitems_return argument is empty.

- If the specified property exists and either you assign AnyPropertyType to the req_type argument or the specified type matches the actual property type, XGetWindowProperty returns the actual property type to actual_type_return and the actual property format (never zero) to
actual_format_return. It also returns a value to bytes_after_return and
nitems_return, by defining the following values:

\[ N = \text{actual length of the stored property in bytes} \]
(even if the format is 16 or 32)

\[ I = 4 \times \text{long_offset} \]

\[ T = N - I \]

\[ L = \text{MINIMUM}(T, 4 \times \text{long_length}) \]

\[ A = N - (I + L) \]

The returned value starts at byte index \( I \) in the property (indexing from zero), and its length in bytes is \( L \). If the value for \( \text{long_offset} \) causes \( L \) to be negative, a \text{BadValue} error results. The value of \text{bytes_after_return} is \( A \), giving the number of trailing unread bytes in the stored property.

\text{XGetWindowProperty} always allocates one extra byte in prop_return (even if the property is zero length) and sets it to ASCII null so that simple properties consisting of characters do not have to be copied into yet another string before use. If delete is \text{True} and bytes_after_return is zero, \text{XGetWindowProperty} deletes the property from the window and generates a \text{PropertyNotify} event on the window.

The function returns \text{Success} if it executes successfully. To free the resulting data, use \text{XFree}.

\text{XGetWindowProperty} can generate \text{BadAtom}, \text{BadValue}, and \text{BadWindow} errors.

To obtain a given window's property list, use \text{XListProperties}.

\begin{verbatim}
Atom *XListProperties(display, w, num_prop_return)
    Display *display;
    Window w;
    int *num_prop_return;

    display Specifies the connection to the XWIN server.
    w Specifies the window whose property list you want to obtain.
    num_prop_return
        Returns the length of the properties array.
\end{verbatim}
Obtaining and Changing Window Properties

The XListProperties function returns a pointer to an array of atom properties that are defined for the specified window or returns NULL if no properties were found. To free the memory allocated by this function, use XFree.

XListProperties can generate a BadWindow error.

To change a property of a given window, use XChangeProperty.

\[
\text{XChangeProperty}(display, w, property, type, format, mode, data, nelements)
\]

- \text{display}
  Specifies the connection to the XWIN server.
- \text{w}
  Specifies the window whose property you want to change.
- \text{property}
  Specifies the property name.
- \text{type}
  Specifies the type of the property. The XWIN server does not interpret the type but simply passes it back to an application that later calls XGetWindowProperty.
- \text{format}
  Specifies whether the data should be viewed as a list of 8-bit, 16-bit, or 32-bit quantities. Possible values are 8, 16, and 32. This information allows the XWIN server to correctly perform byte-swap operations as necessary. If the format is 16-bit or 32-bit, you must explicitly cast your data pointer to a (char *) in the call to XChangeProperty.
- \text{mode}
  Specifies the mode of the operation. You can pass PropModeReplace, PropModePrepend, or PropModeAppend.
- \text{data}
  Specifies the property data.
- \text{nelements}
  Specifies the number of elements of the specified data format.

The XChangeProperty function alters the property for the specified window and causes the XWIN server to generate a PropertyNotify event on that window. XChangeProperty performs the following:
Obtaining and Changing Window Properties

- If mode is PropModeReplace, XChangeProperty discards the previous property value and stores the new data.
- If mode is PropModePrepend or PropModeAppend, XChangeProperty inserts the specified data before the beginning of the existing data or onto the end of the existing data, respectively. The type and format must match the existing property value, or a BadMatch error results. If the property is undefined, it is treated as defined with the correct type and format with zero-length data.

The lifetime of a property is not tied to the storing client. Properties remain until explicitly deleted, until the window is destroyed, or until the server resets. For a discussion of what happens when the connection to the XWIN server is closed, see "Closing the Display" in Chapter 2. The maximum size of a property is server dependent and can vary dynamically depending on the amount of memory the server has available. (If there is insufficient space, a BadAlloc error results.)

XChangeProperty can generate BadAlloc, BadAtom, BadMatch, BadValue, and BadWindow errors.

To rotate a window's property list, use XRotateWindowProperties.

```c
XRotateWindowProperties (display, w, properties, num_prop, npositions)
    Display *display;
    Window w;
    Atom properties[];
    int num_prop;
    int npositions;

    // Specifies the connection to the XWIN server.
    display
    // Specifies the window.
    w
    // Specifies the array of properties that are to be rotated.
    properties
    // Specifies the length of the properties array.
    num_prop
    // Specifies the rotation amount.
    npositions
```

The XRotateWindowProperties function allows you to rotate properties on a window and causes the XWIN server to generate PropertyNotify events. If the property names in the properties array are viewed as being numbered starting from zero and if there are num_prop property names in the list, then the value
associated with property name \( I \) becomes the value associated with property name \((I + \text{npositions}) \mod N\) for all \( I \) from zero to \( N - 1 \). The effect is to rotate the states by \text{npositions} places around the virtual ring of property names (right for positive \text{npositions}, left for negative \text{npositions}). If \text{npositions} mod \( N \) is nonzero, the XWIN server generates a PropertyNotify event for each property in the order that they are listed in the array. If an atom occurs more than once in the list or no property with that name is defined for the window, a BadMatch error results. If a BadAtom or BadMatch error results, no properties are changed.

XRotateWindowProperties can generate BadAtom, BadMatch, and BadWindow errors.

To delete a property on a given window, use XDeleteProperty.

\[
\text{XDeleteProperty (display, w, property)}
\]

- **display**: Specifies the connection to the XWIN server.
- **w**: Specifies the window whose property you want to delete.
- **property**: Specifies the property name.

The XDeleteProperty function deletes the specified property only if the property was defined on the specified window and causes the XWIN server to generate a PropertyNotify event on the window unless the property does not exist.

XDeleteProperty can generate BadAtom and BadWindow errors.
Selections

Selections are one method used by applications to exchange data. By using the property mechanism, applications can exchange data of arbitrary types and can negotiate the type of the data. A selection can be thought of as an indirect property with a dynamic type. That is, rather than having the property stored in the XWIN server, the property is maintained by some client (the owner). A selection is global in nature (considered to belong to the user but be maintained by clients) rather than being private to a particular window subhierarchy or a particular set of clients.

Xlib provides functions that you can use to set, get, or request conversion of selections. This allows applications to implement the notion of current selection, which requires that notification be sent to applications when they no longer own the selection. Applications that support selection often highlight the current selection and so must be informed when another application has acquired the selection so that they can unhighlight the selection.

When a client asks for the contents of a selection, it specifies a selection target type. This target type can be used to control the transmitted representation of the contents. For example, if the selection is “the last thing the user clicked on” and that is currently an image, then the target type might specify whether the contents of the image should be sent in XY format or Z format.

The target type can also be used to control the class of contents transmitted, for example, asking for the “looks” (fonts, line spacing, indentation, and so forth) of a paragraph selection, not the text of the paragraph. The target type can also be used for other purposes. The protocol does not constrain the semantics.

To set the selection owner, use XSetSelectionOwner.

\[
\text{XSetSelectionOwner}(\text{display}, \text{selection}, \text{owner}, \text{time})
\]

\[
\begin{align*}
\text{Display} & \quad \text{display;} \\
\text{Atom} & \quad \text{selection;} \\
\text{Window} & \quad \text{owner;} \\
\text{Time} & \quad \text{time;}
\end{align*}
\]

- \text{display} \quad \text{Specifies the connection to the XWIN server.}
- \text{selection} \quad \text{Specifies the selection atom.}
- \text{owner} \quad \text{Specifies the owner of the specified selection atom. You can pass a window or None.}
Selections

*time* Specifies the time. You can pass either a timestamp or `currentTime`.

The `XSetSelectionOwner` function changes the owner and last-change time for the specified selection and has no effect if the specified time is earlier than the current last-change time of the specified selection or is later than the current XWIN server time. Otherwise, the last-change time is set to the specified time, with `currentTime` replaced by the current server time. If the owner window is specified as `None`, then the owner of the selection becomes `None` (that is, no owner). Otherwise, the owner of the selection becomes the client executing the request.

If the new owner (whether a client or `None`) is not the same as the current owner of the selection and the current owner is not `None`, the current owner is sent a `SelectionClear` event. If the client that is the owner of a selection is later terminated (that is, its connection is closed) or if the owner window it has specified in the request is later destroyed, the owner of the selection automatically reverts to `None`, but the last-change time is not affected. The selection atom is uninterpreted by the XWIN server. `XGetSelectionOwner` returns the owner window, which is reported in `SelectionRequest` and `SelectionClear` events. Selections are global to the XWIN server.

`XGetSelectionOwner` can generate `BadAtom` and `BadWindow` errors.

To return the selection owner, use `XGetSelectionOwner`.

```c
Window XGetSelectionOwner(display, selection)
    Display *display;
    Atom selection;

    display Specifies the connection to the XWIN server.
    selection Specifies the selection atom whose owner you want returned.
```

The `XGetSelectionOwner` function returns the window ID associated with the window that currently owns the specified selection. If no selection was specified, the function returns the constant `None`. If `None` is returned, there is no owner for the selection.

`XGetSelectionOwner` can generate a `BadAtom` error.
To request conversion of a selection, use `XConvertSelection`.

```c
XConvertSelection (display, selection, target, property, requestor, time)
```

- **display**: Specifies the connection to the XWIN server.
- **selection**: Specifies the selection atom.
- **target**: Specifies the target atom.
- **property**: Specifies the property name. You also can pass `None`.
- **requestor**: Specifies the requestor.
- **time**: Specifies the time. You can pass either a timestamp or `CurrentTime`.

`XConvertSelection` requests that the specified selection be converted to the specified target type:

- If the specified selection has an owner, the XWIN server sends a `SelectionRequest` event to that owner.
- If no owner for the specified selection exists, the XWIN server generates a `SelectionNotify` event to the requestor with property `None`.

In either event, the arguments are passed on unchanged. There are two predefined selection atoms: `PRIMARY` and `SECONDARY`.

`XConvertSelection` can generate `BadAtom` and `BadWindow` errors.
5 Graphics Resource Functions

Setting the Fill Tile and Stipple 5-35
Setting the Current Font 5-39
Setting the Clip Region 5-39
Setting the Arc Mode, Subwindow Mode, and Graphics Exposure 5-41
Introduction

After you connect your program to the XWIN server by calling XOpenDisplay, you can use the Xlib graphics resource functions to:

- Create, copy, and destroy colormaps
- Allocate, modify, and free color cells
- Read entries in a colormap
- Create and free pixmaps
- Create, copy, change, and destroy graphics contexts

A number of resources are used when performing graphics operations in X. Most information about performing graphics (for example, foreground color, background color, line style, and so on) are stored in resources called graphics contexts (GC). Most graphics operations (see Chapter 6) take a GC as an argument. Although in theory it is possible to share GCs between applications, it is expected that applications will use their own GCs when performing operations. Sharing of GCs is highly discouraged because the library may cache GC state.

Each X window always has an associated colormap that provides a level of indirection between pixel values and colors displayed on the screen. Many of the hardware displays built today have a single colormap, so the primitives are written to encourage sharing of colormap entries between applications. Because colormaps are associated with windows, X will support displays with multiple colormaps and, indeed, different types of colormaps. If there are not sufficient colormap resources in the display, some windows may not be displayed in their true colors. A client or window manager can control which windows are displayed in their true colors if more than one colormap is required for the color resources the applications are using.

Off-screen memory or pixmaps are often used to define frequently used images for later use in graphics operations. Pixmaps are also used to define tiles or patterns for use as window backgrounds, borders, or cursors. A single bit-plane pixmap is sometimes referred to as a bitmap.

Note that some screens have very limited off-screen memory. Therefore, you should regard off-screen memory as a precious resource.

Graphics operations can be performed to either windows or pixmaps, which collectively are called drawables. Each drawable exists on a single screen and can only be used on that screen. GCs can also only be used with drawables of matching screens and depths.
Colormap Functions

Xlib provides functions that you can use to manipulate a colormap. This section discusses how to:

- Create, copy, and destroy a colormap
- Allocate, modify, and free color cells
- Read entries in a colormap

The following functions manipulate the representation of color on the screen. For each possible value that a pixel can take in a window, there is a color cell in the colormap. For example, if a window is 4 bits deep, pixel values 0 through 15 are defined. A colormap is a collection of color cells. A color cell consists of a triple of red, green, and blue. As each pixel is read out of display memory, its value is taken and looked up in the colormap. The values of the cell determine what color is displayed on the screen. On a multiplane display with a black-and-white monitor (with grayscale but not color), these values can be combined to determine the brightness on the screen.

Screens always have a default colormap, and programs typically allocate cells out of this colormap. You should not write applications that monopolize color resources. On a screen that either cannot load the colormap or cannot have a fully independent colormap, only certain kinds of allocations may work. Depending on the hardware, one or more colormaps may be resident (installed) at one time. To install a colormap, use XInstallColormap. The DefaultColormap macro returns the default colormap. The DefaultVisual macro returns the default visual type for the specified screen. Colormaps are local to a particular screen. Possible visual types are StaticGray, GrayScale, StaticColor, PseudoColor, TrueColor, or DirectColor (see "Visual Types" in Chapter 3).

The functions discussed in this section operate on an XColor structure, which contains:

```c
typedef struct {
    unsigned long pixel;          /* pixel value */
    unsigned short red, green, blue; /* rgb values */
    char flags;                  /* DoRed, DoGreen, DoBlue */
    char pad;
} XColor;
```
The red, green, and blue values are scaled between 0 and 65535. On full in a color is a value of 65535 independent of the number of bits actually used in the display hardware. Half brightness in a color is a value of 32767, and off is 0. This representation gives uniform results for color values across different screens. In some functions, the flags member controls which of the red, green, and blue members is used and can be one or more of DoRed, DoGreen, and DoBlue.

The introduction of color changes the view a programmer should take when dealing with a bitmap display. For example, when printing text, you write a pixel value, which is defined as a specific color, rather than setting or clearing bits. Hardware will impose limits (the number of significant bits, for example) on these values. Typically, one allocates color cells or sets of color cells. If read-only, the pixel values for these colors can be shared among multiple applications, and the RGB values of the cell cannot be changed. If read/write, they are exclusively owned by the program, and the color cell associated with the pixel value may be changed at will.

Creating, Copying, and Destroying Colormaps

To create a colormap for a screen, use XCreateColormap.

```c
Colormap XCreateColormap(display, w, visual, alloc)
    Display *display;
    Window w;
    Visual *visual;
    int alloc;
```

- `display` Specifies the connection to the XWIN server.
- `w` Specifies the window on whose screen you want to create a colormap.
- `visual` Specifies a pointer to a visual type supported on the screen. If the visual type is not one supported by the screen, a BadMatch error results.
- `alloc` Specifies the colormap entries to be allocated. You can pass AllocNone or AllocAll.
The XCreateColormap function creates a colormap of the specified visual type for the screen on which the specified window resides and returns the colormap ID associated with it. Note that the specified window is only used to determine the screen.

The initial values of the colormap entries are undefined for the visual classes GrayScale, PseudoColor, and DirectColor. For StaticGray, StaticColor, and TrueColor, the entries have defined values, but those values are specific to the visual and are not defined by X. For StaticGray, StaticColor, and TrueColor, alloc must be AllocNone, or a BadMatch error results. For the other visual classes, if alloc is AllocNone, the colormap initially has no allocated entries, and clients can allocate them. For information about the visual types, see "Visual Types" in Chapter 3.

If alloc is AllocAll, the entire colormap is allocated writable. The initial values of all allocated entries are undefined. For GrayScale and PseudoColor, the effect is as if an XAllocColorCells call returned all pixel values from zero to \( N - 1 \), where \( N \) is the colormap entries value in the specified visual. For DirectColor, the effect is as if an XAllocColorPlanes call returned a pixel value of zero and red_mask, green_mask, and blue_mask values containing the same bits as the corresponding masks in the specified visual. However, in all cases, none of these entries can be freed by using XFreeColors.

XCreateColormap can generate BadAlloc, BadMatch, BadValue, and BadWindow errors.

To create a new colormap when the allocation out of a previously shared colormap has failed because of resource exhaustion, use XCopyColormapAndFree.

```c
Colormap XCopyColormapAndFree(display, colormap)
    Display *display;
    Colormap colormap;
```

`display` Specifies the connection to the XWIN server.

`colormap` Specifies the colormap.

The XCopyColormapAndFree function creates a colormap of the same visual type and for the same screen as the specified colormap and returns the new colormap ID. It also moves all of the client's existing allocation from the specified colormap to the new colormap with their color values intact and their read-only or writable characteristics intact and frees those entries in the specified colormap. Color values in other entries in the new colormap are
undefined. If the specified colormap was created by the client with alloc set to AllocAll, the new colormap is also created with AllocAll, all color values for all entries are copied from the specified colormap, and then all entries in the specified colormap are freed. If the specified colormap was not created by the client with AllocAll, the allocations to be moved are all those pixels and planes that have been allocated by the client using XAllocColor, XAllocNamedColor, XAllocColorCells, or XAllocColorPlanes and that have not been freed since they were allocated.

XCopyColormapAndFree can generate BadAlloc and BadColor errors.

To set the colormap of a given window, use XSetWindowColormap.

```c
XSetWindowColormap (display, w, colormap)
Display *display;
Window w;
Colormap colormap;
```

- **display** Specifies the connection to the XWIN server.
- **w** Specifies the window.
- **colormap** Specifies the colormap.

The XSetWindowColormap function sets the specified colormap of the specified window. The colormap must have the same visual type as the window, or a BadMatch error results.

XSetWindowColormap can generate BadColor, BadMatch, and BadWindow errors.

To destroy a colormap, use XFreeColormap.

```c
XFreeColormap (display, colormap)
Display *display;
Colormap colormap;
```

- **display** Specifies the connection to the XWIN server.
- **colormap** Specifies the colormap that you want to destroy.
The XFreeColormap function deletes the association between the colormap resource ID and the colormap and frees the colormap storage. However, this function has no effect on the default colormap for a screen. If the specified colormap is an installed map for a screen, it is uninstalled (see XUninstallColormap). If the specified colormap is defined as the colormap for a window (by XCreateWindow, XSetWindowColormap, or XChangeWindowAttributes), XFreeColormap changes the colormap associated with the window to None and generates a ColormapNotify event. X does not define the colors displayed for a window with a colormap of None.

XFreeColormap can generate a BadColor error.

### Allocating, Modifying, and Freeing Color Cells

There are two ways of allocating color cells: explicitly as read-only entries by pixel value or read/write, where you can allocate a number of color cells and planes simultaneously. The read/write cells you allocate do not have defined colors until set with XStoreColor or XStoreColors.

To determine the color names, the XWIN server uses a color database.

Although you can change the values in a read/write color cell that is allocated by another application, this is considered "antisocial" behavior.

To allocate a read-only color cell, use XAllocColor.

```
Status XAllocColor (display, colormap, screen_in_out)
    Display *display;
    Colormap colormap;
    XColor *screen_in_out;
```

- **display**: Specifies the connection to the XWIN server.
- **colormap**: Specifies the colormap.
- **screen_in_out**: Specifies and returns the values actually used in the colormap.

The XAllocColor function allocates a read-only colormap entry corresponding to the closest RGB values supported by the hardware. XAllocColor returns the pixel value of the color closest to the specified RGB elements supported by the hardware and returns the RGB values actually used. The corresponding
colormap cell is read-only. In addition, XAllocColor returns nonzero if it succeeded or zero if it failed.

Read-only colormap cells are shared among clients. When the last client deallocates a shared cell, it is deallocated. XAllocColor does not use or affect the flags in the XColor structure.

XAllocColor can generate a BadColor error.

To allocate a read-only color cell by name and return the closest color supported by the hardware, use XAllocNamedColor.

\[
\text{Status } \text{XAllocNamedColor}(\text{display, colormap, color_name, screen_def_return, exact_def_return})
\]\[
\begin{align*}
\text{Display } & \text{display;} \\
\text{Colormap } & \text{colormap;} \\
\text{char } & \text{color_name;} \\
\text{XColor } & \text{screen_def_return, exact_def_return;}
\end{align*}
\]

display \hspace{1cm} \text{Specifies the connection to the XWIN server.}
colormap \hspace{1cm} \text{Specifies the colormap.}
color_name \hspace{1cm} \text{Specifies the color name string (for example, red) whose color definition structure you want returned.}
screen_def_return \hspace{1cm} \text{Returns the closest RGB values provided by the hardware.}
exact_def_return \hspace{1cm} \text{Returns the exact RGB values.}

The XAllocNamedColor function looks up the named color with respect to the screen that is associated with the specified colormap. It returns both the exact database definition and the closest color supported by the screen. The allocated color cell is read-only. You should use the ISO Latin-1 encoding; uppercase and lowercase do not matter.

XAllocNamedColor can generate a BadColor error.

To look up the name of a color, use XLookupColor.
Colormap Functions

Status XLookupColor (display, colormap, color_name, exact_def_return, screen_def_return)

Display *display;
Colormap colormap;
char *color_name;
XColor *exact_def_return, *screen_def_return;

*display Specifies the connection to the XWIN server.
*colormap Specifies the colormap.
*color_name Specifies the color name string (for example, red) whose color definition structure you want returned.
*exact_def_return Returns the exact RGB values.
*screen_def_return Returns the closest RGB values provided by the hardware.

The XLookupColor function looks up the string name of a color with respect to the screen associated with the specified colormap. It returns both the exact color values and the closest values provided by the screen with respect to the visual type of the specified colormap. You should use the ISO Latin-1 encoding; uppercase and lowercase do not matter. XLookupColor returns nonzero if the name existed in the color database or zero if it did not exist.

To allocate read/write color cell and color plane combinations for a PseudoColor model, use XAllocColorCells.

Status XAllocColorCells (display, colormap, contig, plane_masks_return, nplanes, pixels_return, npixels)

Display *display;
Colormap colormap;
Bool contig;
unsigned long plane_masks_return[];
unsigned int nplanes;
unsigned long pixels_return[];
unsigned int npixels;

*display Specifies the connection to the XWIN server.
*colormap Specifies the colormap.
**contig**

Specifies a Boolean value that indicates whether the planes must be contiguous.

**plane_mask_return**

Returns an array of plane masks.

**nplanes**

Specifies the number of plane masks that are to be returned in the plane masks array.

**pixels_return**

Returns an array of pixel values.

**npixels**

Specifies the number of pixel values that are to be returned in the pixels_return array.

The `XAllocColorCells` function allocates read/write color cells. The number of colors must be positive and the number of planes nonnegative, or a `BadValue` error results. If `ncolors` and `nplanes` are requested, then `ncolors` pixels and `nplane` plane masks are returned. No mask will have any bits set to 1 in common with any other mask or with any of the pixels. By ORing together each pixel with zero or more masks, `ncolors * 2^{nplanes}` distinct pixels can be produced. All of these are allocated writable by the request. For GrayScale or PseudoColor, each mask has exactly one bit set to 1. For DirectColor, each has exactly three bits set to 1. If `contig` is `True` and if all masks are ORed together, a single contiguous set of bits set to 1 will be formed for GrayScale or PseudoColor and three contiguous sets of bits set to 1 (one within each pixel subfield) for DirectColor. The RGB values of the allocated entries are undefined. `XAllocColorCells` returns nonzero if it succeeded or zero if it failed.

`XAllocColorCells` can generate `BadColor` and `BadValue` errors.

To allocate read/write color resources for a DirectColor model, use `XAllocColorPlanes`. 
Colormap Functions

```c
Status XAllocColorPlanes (display, colormap, contig, pixels_return, ncolors, nreds, ngreens, nblues, rmask_return, gmask_return, bmask_return)

Display *display;
Colormap colormap;
Bool contig;
unsigned long pixels_return[];
int ncolors;
int nreds, ngreens, nblues;
unsigned long *rmask_return, *gmask_return, *bmask_return;
```

display Specifies the connection to the XWIN server.
colormap Specifies the colormap.
contig Specifies a Boolean value that indicates whether the planes must be contiguous.
pixels_return Returns an array of pixel values. XAllocColorPlanes returns the pixel values in this array.
ncolors Specifies the number of pixel values that are to be returned in the pixels_return array.
nreds ngreens nblues Specify the number of red, green, and blue planes. The value you pass must be nonnegative.
rmask_return gmask_return bmask_return Return bit masks for the red, green, and blue planes.

The specified ncolors must be positive; and nreds, ngreens, and nblues must be nonnegative, or a BadValue error results. If ncolors colors, nreds reds, ngreens greens, and nblues blues are requested, ncolors pixels are returned; and the masks have nreds, ngreens, and nblues bits set to 1, respectively. If contig is True, each mask will have a contiguous set of bits set to 1. No mask will have any bits set to 1 in common with any other mask or with any of the pixels. For DirectColor, each mask will lie within the corresponding pixel subfield. By ORing together subsets of masks with each pixel value, ncolors * \(2^{(nreds + ngreens + nblues)}\) distinct pixel values can be produced. All of these are allocated by the request. However, in the colormap, there are only ncolors * \(2^{nreds}\) independent red entries, ncolors * \(2^{ngreens}\) independent green entries, and ncolors
* $2^n$ independent blue entries. This is true even for PseudoColor. When the colormap entry of a pixel value is changed (using XStoreColors, XStoreColor, or XStoreNamedColor), the pixel is decomposed according to the masks, and the corresponding independent entries are updated. XAllocColorPlanes returns nonzero if it succeeded or zero if it failed.

XAllocColorPlanes can generate BadColor and BadValue errors.

To store RGB values into colormap cells, use XStoreColors.

XStoreColors (display, colormap, color, ncolors)

Display *display;
Colormap colormap;
XColor color[];
int ncolors;

display Specifies the connection to the XWIN server.
colormap Specifies the colormap.
color Specifies an array of color definition structures to be stored.
ncolors Specifies the number of XColor structures in the color definition array.

The XStoreColors function changes the colormap entries of the pixel values specified in the pixel members of the XColor structures. You specify which color components are to be changed by setting DoRed, DoGreen, and/or DoBlue in the flags member of the XColor structures. If the colormap is an installed map for its screen, the changes are visible immediately. XStoreColors changes the specified pixels if they are allocated writable in the colormap by any client, even if one or more pixels generates an error. If a specified pixel is not a valid index into the colormap, a BadValue error results. If a specified pixel either is unallocated or is allocated read-only, a BadAccess error results. If more than one pixel is in error, the one that gets reported is arbitrary.

XStoreColors can generate BadAccess, BadColor, and BadValue errors.

To store an RGB value in a single colormap cell, use XStoreColor.

XStoreColor (display, colormap, color)

Display *display;
Colormap colormap;
XColor *color;
Colormap Functions

The `XStoreColor` function changes the colormap entry of the pixel value specified in the pixel member of the `XColor` structure. You specified this value in the pixel member of the `XColor` structure. This pixel value must be a read/write cell and a valid index into the colormap. If a specified pixel is not a valid index into the colormap, a BadValue error results. `XStoreColor` also changes the red, green, and/or blue color components. You specify which color components are to be changed by setting `DoRed`, `DoGreen`, and/or `DoBlue` in the flags member of the `XColor` structure. If the colormap is an installed map for its screen, the changes are visible immediately.

`XStoreColor` can generate BadAccess, BadColor, and BadValue errors.

To set the color of a pixel to a named color, use `XStoreNamedColor`.

```
XStoreNamedColor(display, colormap, color, pixel, flags)
```

- `display` Specifies the connection to the XWIN server.
- `colormap` Specifies the colormap.
- `color` Specifies the pixel and RGB values.
- `pixel` Specifies the entry in the colormap.
- `flags` Specifies which red, green, and blue components are set.

The `XStoreNamedColor` function looks up the named color with respect to the screen associated with the colormap and stores the result in the specified colormap. The pixel argument determines the entry in the colormap. The flags argument determines which of the red, green, and blue components are set. You can set this member to the bitwise inclusive OR of the bits `DoRed`, `DoGreen`, and `DoBlue`. If the specified pixel is not a valid index into the colormap, a BadValue error results. If the specified pixel either is unallocated or is allocated
read-only, a BadAccess error results. You should use the ISO Latin-1 encoding; uppercase and lowercase do not matter.

XStoreNamedColor can generate BadAccess, BadColor, BadName, and BadValue errors.

To free colormap cells, use XFreeColors.

```c
XFreeColors (display, colormap, pixels, npixels, planes)

Display *display;
Colormap colormap;
unsigned long pixels[];
int npixels;
unsigned long planes;
```

display Specifies the connection to the XWIN server.
colormap Specifies the colormap.
pixels Specifies an array of pixel values that map to the cells in the specified colormap.
npixels Specifies the number of pixels.
planes Specifies the planes you want to free.

The XFreeColors function frees the cells represented by pixels whose values are in the pixels array. The planes argument should not have any bits set to 1 in common with any of the pixels. The set of all pixels is produced by ORing together subsets of the planes argument with the pixels. The request frees all of these pixels that were allocated by the client (using XAllocColor, XAllocNamedColor, XAllocColorCells, and XAllocColorPlanes). Note that freeing an individual pixel obtained from XAllocColorPlanes may not actually allow it to be reused until all of its related pixels are also freed.

All specified pixels that are allocated by the client in the colormap are freed, even if one or more pixels produce an error. If a specified pixel is not a valid index into the colormap, a BadValue error results. If a specified pixel is not allocated by the client (that is, is unallocated or is only allocated by another client), a BadAccess error results. If more than one pixel is in error, the one that gets reported is arbitrary.

XFreeColors can generate BadAccess, BadColor, and BadValue errors.
Reading Entries in a Colormap

The XQueryColor and XQueryColors functions return the RGB values stored in the specified colormap for the pixel value you pass in the pixel member of the XColor structure(s). The values returned for an unallocated entry are undefined. These functions also set the flags member in the XColor structure to all three colors. If a pixel is not a valid index into the specified colormap, a BadValue error results. If more than one pixel is in error, the one that gets reported is arbitrary.

To query the RGB values of a single specified pixel value, use XQueryColor.

```
XQueryColor (display, colormap, def_in_out)
      Display *display;
      Colormap colormap;
      XColor *def_in_out;
```

display Specifies the connection to the XWIN server.

colormap Specifies the colormap.

def_in_out Specifies and returns the RGB values for the pixel specified in the structure.

The XQueryColor function returns the RGB values for each pixel in the XColor structures and sets the DoRed, DoGreen, and DoBlue flags.

XQueryColor can generate BadColor and BadValue errors.

To query the RGB values of an array of pixels stored in color structures, use XQueryColors.

```
XQueryColors (display, colormap, def_in_out, ncolors)
      Display *display;
      Colormap colormap;
      XColor def_in_out[];
      int ncolors;
```

display Specifies the connection to the XWIN server.

colormap Specifies the colormap.
Colormap Functions

defs_in_out Specifies and returns an array of color definition structures for the pixel specified in the structure.

ncolors Specifies the number of XColor structures in the color definition array.

The XQueryColors function returns the RGB values for each pixel in the XColor structures and sets the DoRed, DoGreen, and DoBlue flags.

XQueryColors can generate BadColor and BadValue errors.
Creating and Freeing Pixmaps

Pixmaps can only be used on the screen on which they were created. Pixmaps are off-screen resources that are used for various operations, for example, defining cursors as tiling patterns or as the source for certain raster operations. Most graphics requests can operate either on a window or on a pixmap. A bitmap is a single bit-plane pixmap.

To create a pixmap of a given size, use XCreatePixmap.

```c
Pixmap XCreatePixmap(display, drawable, width, height, depth)

Display *display;
Drawable drawable;
unsigned int width, height;
unsigned int depth;
```

- `display` Specifies the connection to the XWIN server.
- `drawable` Specifies which screen the pixmap is created on.
- `width` Specify the width and height, which define the dimensions of the pixmap.
- `height` Specifies the depth of the pixmap.

The XCreatePixmap function creates a pixmap of the width, height, and depth you specified and returns a pixmap ID that identifies it. It is valid to pass an InputOnly window to the drawable argument. The width and height arguments must be nonzero, or a BadValue error results. The depth argument must be one of the depths supported by the screen of the specified drawable, or a BadValue error results.

The server uses the specified drawable to determine on which screen to create the pixmap. The pixmap can be used only on this screen and only with other drawables of the same depth (see XCopyPlane for an exception to this rule). The initial contents of the pixmap are undefined.

XCreatePixmap can generate BadAlloc, BadDrawable, and BadValue errors.

To free all storage associated with a specified pixmap, use XFreePixmap.

```c
XFreePixmap(display, pixmap)

Display *display;
Pixmap pixmap;
```
Creating and Freeing Pixmaps

\textit{display} \quad \text{Specifies the connection to the XWIN server.}

\textit{pixmap} \quad \text{Specifies the pixmap.}

The XFreePixmap function first deletes the association between the pixmap ID and the pixmap. Then, the XWIN server frees the pixmap storage when there are no references to it. The pixmap should never be referenced again.

XFreePixmap can generate a BadPixmap error.
Manipulating Graphics Context/State

Most attributes of graphics operations are stored in Graphic Contexts (GCs). These include line width, line style, plane mask, foreground, background, tile, stipple, clipping region, end style, join style, and so on. Graphics operations (for example, drawing lines) use these values to determine the actual drawing operation. Extensions to X may add additional components to GCs. The contents of a GC are private to Xlib.

Xlib implements a write-back cache for all elements of a GC that are not resource IDs to allow Xlib to implement the transparent coalescing of changes to GCs. For example, a call to XSetForeground of a GC followed by a call to XSetLineAttributes results in only a single-change GC protocol request to the server. GCs are neither expected nor encouraged to be shared between client applications, so this write-back caching should present no problems. Applications cannot share GCs without external synchronization. Therefore, sharing GCs between applications is highly discouraged.

To set an attribute of a GC, set the appropriate member of the XGCValues structure and OR in the corresponding value bitmask in your subsequent calls to XCreateGC. The symbols for the value mask bits and the XGCValues structure are:

/* GC attribute value mask bits */

#define GCForeground (1L<<0)
#define GCPlaneMask (1L<<1)
#define GCPixelFormat (1L<<2)
#define GCBetterMask (1L<<3)
#define GCLineWidth (1L<<4)
#define GCLineStyle (1L<<5)

Note that foreground and background are not set to any values likely to be useful in a window.
The function attributes of a GC are used when you update a section of a drawable (the destination) with bits from somewhere else (the source). The function in a GC defines how the new destination bits are to be computed from the source bits and the old destination bits. GXcopy is typically the most useful because it will work on a color display, but special applications may use other functions, particularly in concert with particular planes of a color display. The 16 GC functions, defined in `<X11/X.h>`, are:

<table>

</table>

Many graphics operations depend on either pixel values or planes in a GC. The planes attribute is of type long, and it specifies which planes of the destination are to be modified, one bit per plane.

A monochrome display has only one plane and will be the least-significant bit of the word. As planes are added to the display hardware, they will occupy more significant bits in the plane mask.
In graphics operations, given a source and destination pixel, the result is computed bitwise on corresponding bits of the pixels. That is, a Boolean operation is performed in each bit plane. The plane_mask restricts the operation to a subset of planes. A macro constant AllPlanes can be used to refer to all planes of the screen simultaneously. The result is computed by the following:

\[
((\text{src} \\text{FUN} \\text{e}\text{ dst}) \\text{AND} \text{ plane-mask}) \text{ OR (dst AND (NOT plane-mask)))}
\]

Range checking is not performed on the values for foreground, background, or plane_mask. They are simply truncated to the appropriate number of bits. The line-width is measured in pixels and either can be greater than or equal to one (wide line) or can be the special value zero (thin line).

Wide lines are drawn centered on the path described by the graphics request. Unless otherwise specified by the join-style or cap-style, the bounding box of a wide line with endpoints \([x_1, y_1], [x_2, y_2]\) and width \(w\) is a rectangle with vertices at the following real coordinates:

\[
[x_1-(w*\sin\theta/2), y_1+(w*\cos\theta/2)], [x_1+(w*\sin\theta/2), y_1-(w*\cos\theta/2)],
[x_2-(w*\sin\theta/2), y_2+(w*\cos\theta/2)], [x_2+(w*\sin\theta/2), y_2-(w*\cos\theta/2)]
\]

Here \(\sin\theta\) is the sine of the angle of the line, and \(\cos\theta\) is the cosine of the angle of the line. A pixel is part of the line and so is drawn if the center of the pixel is fully inside the bounding box (which is viewed as having infinitely thin edges). If the center of the pixel is exactly on the bounding box, it is part of the line if and only if the interior is immediately to its right (\(x\) increasing direction). Pixels with centers on a horizontal edge are a special case and are part of the line if and only if the interior or the boundary is immediately below (\(y\) increasing direction) and the interior or the boundary is immediately to the right (\(x\) increasing direction).

Thin lines (zero line-width) are one-pixel-wide lines drawn using an unspecified, device-dependent algorithm. There are only two constraints on this algorithm.

1. If a line is drawn unclipped from \([x_1, y_1]\) to \([x_2, y_2]\) and if another line is drawn unclipped from \([x_1+dx, y_1+dy]\) to \([x_2+dx, y_2+dy]\), a point \([x, y]\) is touched by drawing the first line if and only if the point \([x+dx, y+dy]\) is touched by drawing the second line.

2. The effective set of points comprising a line cannot be affected by clipping. That is, a point is touched in a clipped line if and only if the point lies inside the clipping region and the point would be touched by the line when drawn unclipped.
A wide line drawn from \([x_1,y_1]\) to \([x_2,y_2]\) always draws the same pixels as a
wide line drawn from \([x_2,y_2]\) to \([x_1,y_1]\), not counting cap-style and join-style. It
is recommended that this property be true for thin lines, but this is not required.
A line-width of zero may differ from a line-width of one in which pixels are
drawn. This permits the use of many manufacturers' line drawing hardware,
which may run many times faster than the more precisely specified wide lines.

In general, drawing a thin line will be faster than drawing a wide line of width
one. However, because of their different drawing algorithms, thin lines may not
mix well aesthetically with wide lines. If it is desirable to obtain precise and
uniform results across all displays, a client should always use a line-width of
one rather than a line-width of zero.

The line-style defines which sections of a line are drawn:

- **LineSolid**: The full path of the line is drawn.
- **LineDoubleDash**: The full path of the line is drawn, but the even dashes are filled dif-
  ferently than the odd dashes (see fill-style) with CapButt style used where even and odd dashes meet.
- **LineOnOffDash**: Only the even dashes are drawn, and cap-style applies to all internal
  ends of the individual dashes, except CapNotLast is treated as CapButt.

The cap-style defines how the endpoints of a path are drawn:

- **CapNotLast**: This is equivalent to CapButt except that for a line-width of zero the
  final endpoint is not drawn.
- **CapButt**: The line is square at the endpoint (perpendicular to the slope of the
  line) with no projection beyond.
- **CapRound**: The line has a circular arc with the diameter equal to the line-width,
  centered on the endpoint. (This is equivalent to CapButt for line-
  width of zero).
- **CapProjecting**: The line is square at the end, but the path continues beyond the end-
  point for a distance equal to half the line-width. (This is equivalent to CapButt for line-width of zero).
The join-style defines how corners are drawn for wide lines:

- **JoinMiter**: The outer edges of two lines extend to meet at an angle. However, if the angle is less than 11 degrees, then a JoinBevel join-style is used instead.

- **JoinRound**: The corner is a circular arc with the diameter equal to the line-width, centered on the joinpoint.

- **JoinBevel**: The corner has CapButt endpoint styles with the triangular notch filled.

For a line with coincident endpoints \((x_1=x_2, y_1=y_2)\), when the cap-style is applied to both endpoints, the semantics depends on the line-width and the cap-style:

- **CapRound** thin: The results are device-dependent, but the desired effect is that nothing is drawn.

- **CapButt** thin: The results are device-dependent, but the desired effect is that a single pixel is drawn.

- **CapRound** thin: The results are the same as for CapButt/thin.

- **CapProjecting** thin: The results are the same as for Butt/thin.

- **CapRound** wide: Nothing is drawn.

- **CapRound** wide: The closed path is a circle, centered at the endpoint, and with the diameter equal to the line-width.

- **CapProjecting** wide: The closed path is a square, aligned with the coordinate axes, centered at the endpoint, and with the sides equal to the line-width.

For a line with coincident endpoints \((x_1=x_2, y_1=y_2)\), when the join-style is applied at one or both endpoints, the effect is as if the line was removed from the overall path. However, if the total path consists of or is reduced to a single point joined with itself, the effect is the same as when the cap-style is applied at both endpoints.

The tile/stipple and clip origins are interpreted relative to the origin of whatever destination drawable is specified in a graphics request. The tile pixmap must have the same root and depth as the GC, or a BadMatch error results. The stipple pixmap must have depth one and must have the same root as the GC, or...
a BadMatch error results. For stipple operations where the fill-style is FillStippled but not FillOpaqueStippled, the stipple pattern is tiled in a single plane and acts as an additional clip mask to be ANDed with the clip-mask. Although some sizes may be faster to use than others, any size pixmap can be used for tiling or stippling.

The fill-style defines the contents of the source for line, text, and fill requests. For all text and fill requests (for example, XDrawText, XDrawText16, XFillRectangle, XFillPolygon, and XFillArc); for line requests with line-style LineSolid (for example, XDrawLine, XDrawSegments, XDrawRectangle, XDrawArc); and for the even dashes for line requests with line-style LineOnOffDash or LineDoubleDash, the following apply:

- **FillSolid**
  - Foreground

- **FillTiled**
  - Tile

- **FillOpaqueStippled**
  - A tile with the same width and height as stipple, but with background everywhere stipple has a zero and with foreground everywhere stipple has a one

- **FillStippled**
  - Foreground masked by stipple

When drawing lines with line-style LineDoubleDash, the odd dashes are controlled by the fill-style in the following manner:

- **FillSolid**
  - Background

- **FillTiled**
  - Same as for even dashes

- **FillOpaqueStippled**
  - Same as for even dashes

- **FillStippled**
  - Background masked by stipple

Storing a pixmap in a GC might or might not result in a copy being made. If the pixmap is later used as the destination for a graphics request, the change might or might not be reflected in the GC. If the pixmap is used simultaneously in a graphics request both as a destination and as a tile or stipple, the results are undefined.
Manipulating Graphics Context/State

For optimum performance, you should draw as much as possible with the same GC (without changing its components). The costs of changing GC components relative to using different GCs depend upon the display hardware and the server implementation. It is quite likely that some amount of GC information will be cached in display hardware and that such hardware can only cache a small number of GCs.

The dashes value is actually a simplified form of the more general patterns that can be set with XSetDashes. Specifying a value of $N$ is equivalent to specifying the two-element list $[N, N]$ in XSetDashes. The value must be nonzero, or a BadValue error results.

The clip-mask restricts writes to the destination drawable. If the clip-mask is set to a pixmap, it must have depth one and have the same root as the GC, or a BadMatch error results. If clip-mask is set to None, the pixels are always drawn regardless of the clip origin. The clip-mask also can be set by calling the XSetClipRectangles or XSetRegion functions. Only pixels where the clip-mask has a bit set to 1 are drawn. Pixels are not drawn outside the area covered by the clip-mask or where the clip-mask has a bit set to 0. The clip-mask affects all graphics requests. The clip-mask does not clip sources. The clip-mask origin is interpreted relative to the origin of whatever destination drawable is specified in a graphics request.

You can set the subwindow-mode to ClipByChildren or IncludeInferiors. For ClipByChildren, both source and destination windows are additionally clipped by all viewable InputOutput children. For IncludeInferiors, neither source nor destination window is clipped by inferiors. This will result in including subwindow contents in the source and drawing through subwindow boundaries of the destination. The use of IncludeInferiors on a window of one depth with mapped inferiors of differing depth is not illegal, but the semantics are undefined by the core protocol.

The fill-rule defines what pixels are inside (drawn) for paths given in XFillPolygon requests and can be set to EvenOddRule or WindingRule. For EvenOddRule, a point is inside if an infinite ray with the point as origin crosses the path an odd number of times. For WindingRule, a point is inside if an infinite ray with the point as origin crosses an unequal number of clockwise and counterclockwise directed path segments. A clockwise directed path segment is one that crosses the ray from left to right as observed from the point. A counterclockwise segment is one that crosses the ray from right to left as observed from the point. The case where a directed line segment is coincident with the
ray is uninteresting because you can simply choose a different ray that is not coincident with a segment.

For both EvenOddRule and WindingRule, a point is infinitely small, and the path is an infinitely thin line. A pixel is inside if the center point of the pixel is inside and the center point is not on the boundary. If the center point is on the boundary, the pixel is inside if and only if the polygon interior is immediately to its right (x increasing direction). Pixels with centers on a horizontal edge are a special case and are inside if and only if the polygon interior is immediately below (y increasing direction).

The arc-mode controls filling in the XFillArcs function and can be set to ArcPieSlice or ArcChord. For ArcPieSlice, the arcs are pie-slice filled. For ArcChord, the arcs are chord filled.

The graphics-exposure flag controls GraphicsExpose event generation for XCopyArea and XCopyPlane requests (and any similar requests defined by extensions).

To create a new GC that is usable on a given screen with a depth of drawable, use XCreateGC.

```c
GC XCreateGC(Display *display, Drawable d, unsigned long valuemask, XGCValues *values);
```

*display* Specifies the connection to the XWIN server.

*d* Specifies the drawable.

*valuemask* Specifies which components in the GC are to be set using the information in the specified values structure. This argument is the bitwise inclusive OR of one or more of the valid GC component mask bits.

*values* Specifies any values as specified by the valuemask.

The XCreateGC function creates a graphics context and returns a GC. The GC can be used with any destination drawable having the same root and depth as the specified drawable. Use with other drawables results in a BadMatch error.
Manipulating Graphics Context/State

XCreateGC can generate BadAlloc, BadDrawable, BadFont, BadMatch, BadPixmap, and BadValue errors.

To copy components from a source GC to a destination GC, use XCopyGC.

\[
\text{XCopyGC}(\text{display, src, valuemask, dest})
\]

- **display**: Specifies the connection to the XWIN server.
- **src**: Specifies the components of the source GC.
- **valuemask**: Specifies which components in the GC are to be copied to the destination GC. This argument is the bitwise inclusive OR of one or more of the valid GC component mask bits.
- **dest**: Specifies the destination GC.

The XCopyGC function copies the specified components from the source GC to the destination GC. The source and destination GCs must have the same root and depth, or a BadMatch error results. The valuemask specifies which component to copy, as for XCreateGC.

XCopyGC can generate BadAlloc, BadGC, and BadMatch errors.

To change the components in a given GC, use XChangeGC.

\[
\text{XChangeGC}(\text{display, gc, valuemask, values})
\]

- **display**: Specifies the connection to the XWIN server.
- **gc**: Specifies the GC.
- **valuemask**: Specifies which components in the GC are to be changed using information in the specified values structure. This argument is the bitwise inclusive OR of one or more of the valid GC component mask bits.
Manipulating Graphics Context/State

values Specifies any values as specified by the valuemask.

The XChangeGC function changes the components specified by valuemask for the specified GC. The values argument contains the values to be set. The values and restrictions are the same as for XCreateGC. Changing the clip-mask overrides any previous XSetClipRectangles request on the context. Changing the dash-offset or dash-list overrides any previous XSetDashes request on the context. The order in which components are verified and altered is server-dependent. If an error is generated, a subset of the components may have been altered.

XChangeGC can generate BadAlloc, BadFont, BadGe, BadMatch, BadPixmap, and BadValue errors.

To free a given GC, use XFreeGC.

```c
XFreeGC(display, gc)
Display *display;
GC gc;
```

display Specifies the connection to the XWIN server.

gc Specifies the GC.

The XFreeGC function destroys the specified GC as well as all the associated storage.

XFreeGC can generate a BadGC error.

To obtain the GContext resource ID for a given GC, use XGContextFromGC.

```c
GContext XGContextFromGC(gc)
GC gc;
```

gc Specifies the GC for which you want the resource ID.
Using GC Convenience Routines

This section discusses how to set the:

- Foreground, background, plane mask, or function components
- Line attributes and dashes components
- Fill style and fill rule components
- Fill tile and stipple components
- Font component
- Clip region component
- Arc mode, subwindow mode, and graphics exposure components

Setting the Foreground, Background, Function, or Plane Mask

To set the foreground, background, plane mask, and function components for a given GC, use XSetState.

```c
XSetState(display, gc, foreground, background, function, plane_mask)
```

- `display`: Specifies the connection to the XWIN server.
- `gc`: Specifies the GC.
- `foreground`: Specifies the foreground you want to set for the specified GC.
- `background`: Specifies the background you want to set for the specified GC.
- `function`: Specifies the function you want to set for the specified GC.
- `plane_mask`: Specifies the plane mask.

XSetState can generate BadAlloc, BadGC, and BadValue errors.
Using GC Convenience Routines

To set the foreground of a given GC, use XSetForeground.

\[
\text{XSetForeground}(\text{display, gc, foreground}) \\
\text{Display *display;} \\
\text{GC gc;} \\
\text{unsigned long foreground;}
\]

- \textit{display} specifies the connection to the XWIN server.
- \textit{gc} specifies the GC.
- \textit{foreground} specifies the foreground you want to set for the specified GC.

\text{XSetForeground} can generate \textit{BadAlloc} and \textit{BadGC} errors.

To set the background of a given GC, use XSetBackground.

\[
\text{XSetBackground}(\text{display, gc, background}) \\
\text{Display *display;} \\
\text{GC gc;} \\
\text{unsigned long background;}
\]

- \textit{display} specifies the connection to the XWIN server.
- \textit{gc} specifies the GC.
- \textit{background} specifies the background you want to set for the specified GC.

\text{XSetBackground} can generate \textit{BadAlloc} and \textit{BadGC} errors.

To set the display function in a given GC, use XSetFunction.

\[
\text{XSetFunction}(\text{display, gc, function}) \\
\text{Display *display;} \\
\text{GC gc;} \\
\text{int function;}
\]

- \textit{display} specifies the connection to the XWIN server.
- \textit{gc} specifies the GC.
- \textit{function} specifies the function you want to set for the specified GC.
Using GC Convenience Routines

XSetFunction can generate BadAlloc, BadGC, and BadValue errors.

To set the plane mask of a given GC, use XSetPlaneMask.

\[
\text{XSetPlaneMask}(\text{display, gc, plane}\_\text{mask})
\]

Display *display;
GC gc;
unsigned long plane\_mask;

display  \quad \text{Specifies the connection to the XWIN server.}
gc  \quad \text{Specifies the GC.}
plane\_mask  \quad \text{Specifies the plane mask.}

XSetPlaneMask can generate BadAlloc and BadGC errors.

Setting the Line Attributes and Dashes

To set the line drawing components of a given GC, use XSetLineAttributes.

\[
\text{XSetLineAttributes}(\text{display, gc, line}\_\text{width, line}\_\text{style, cap}\_\text{style, join}\_\text{style})
\]

Display *display;
GC gc;
unsigned int line\_width;
int line\_style;
int cap\_style;
int join\_style;

display  \quad \text{Specifies the connection to the XWIN server.}
gc  \quad \text{Specifies the GC.}
line\_width  \quad \text{Specifies the line-width you want to set for the specified GC.}
line\_style  \quad \text{Specifies the line-style you want to set for the specified GC.}
You can pass LineSolid, LineOnOffDash, or LineDoubleDash.
cap\_style  \quad \text{Specifies the line-style and cap-style you want to set for the specified GC. You can pass CapNotLast, CapButt, CapRound, or CapProjecting.}
join_style Specifies the line join-style you want to set for the specified GC. You can pass JoinMiter, JoinRound, or JoinBevel.

XSetLineAttributes can generate BadAlloc, BadGC, and BadValue errors.

To set the dash-offset and dash-list for dashed line styles of a given GC, use XSetDashes.

\[ \text{XSetDashes}(\text{display}, gc, \text{dash_offset}, \text{dash_list}, n) \]
\begin{verbatim}
Display *display;
GC gc;
int dash_offset;
char dash_list[];
int n;
\end{verbatim}

\textit{display} Specifies the connection to the XWIN server.

\textit{gc} Specifies the GC.

\textit{dash_offset} Specifies the phase of the pattern for the dashed line-style you want to set for the specified GC.

\textit{dash_list} Specifies the dash-list for the dashed line-style you want to set for the specified GC.

\textit{n} Specifies the number of elements in dash_list.

The \texttt{XSetDashes} function sets the dash-offset and dash-list attributes for dashed line styles in the specified GC. There must be at least one element in the specified dash_list, or a BadValue error results. The initial and alternating elements (second, fourth, and so on) of the dash_list are the even dashes, and the others are the odd dashes. Each element specifies a dash length in pixels. All of the elements must be nonzero, or a BadValue error results. Specifying an odd-length list is equivalent to specifying the same list concatenated with itself to produce an even-length list.

The dash-offset defines the phase of the pattern, specifying how many pixels into the dash-list the pattern should actually begin in any single graphics request. Dashing is continuous through path elements combined with a join-style but is reset to the dash-offset each time a cap-style is applied at a line endpoint.
The unit of measure for dashes is the same for the ordinary coordinate system. Ideally, a dash length is measured along the slope of the line, but implementations are only required to match this ideal for horizontal and vertical lines. Failing the ideal semantics, it is suggested that the length be measured along the major axis of the line. The major axis is defined as the x axis for lines drawn at an angle of between −45 and +45 degrees or between 315 and 225 degrees from the x axis. For all other lines, the major axis is the y axis.

XSetDashes can generate BadAlloc, BadGC, and BadValue errors.

### Setting the Fill Style and Fill Rule

To set the fill-style of a given GC, use XSetFillStyle.

```c
XSetFillStyle(display, gc, fill_style)
Display *display;
GC gc;
int fill_style;
```

- `display`: Specifies the connection to the XWIN server.
- `gc`: Specifies the GC.
- `fill_style`: Specifies the fill-style you want to set for the specified GC. You can pass FillSolid, FillTiled, FillStippled, or FillOpaqueStippled.

XSetFillStyle can generate BadAlloc, BadGC, and BadValue errors.

To set the fill-rule of a given GC, use XSetFillRule.

```c
XSetFillRule(display, gc, fill_rule)
Display *display;
GC gc;
int fill_rule;
```

- `display`: Specifies the connection to the XWIN server.
- `gc`: Specifies the GC.
fill_rule Specifies the fill-rule you want to set for the specified GC. You can pass EvenOddRule or WindingRule.

XSetFillRule can generate BadAlloc, BadGC, and BadValue errors.

Setting the Fill Tile and Stipple

Some displays have hardware support for tiling or stippling with patterns of specific sizes. Tiling and stippling operations that restrict themselves to those specific sizes run much faster than such operations with arbitrary size patterns. Xlib provides functions that you can use to determine the best size, tile, or stipple for the display as well as to set the tile or stipple shape and the tile or stipple origin.

To obtain the best size of a tile, stipple, or cursor, use XQueryBestSize.

```
Status XQueryBestSize (display, class, which_screen, width, height, width_return, height_return)
  Display *display;
  int class;
  Drawable which_screen;
  unsigned int width, height;
  unsigned int *width_return, *height_return;
```

display Specifies the connection to the XWIN server.
class Specifies the class that you are interested in. You can pass TileShape, CursorShape, or StippleShape.
which_screen Specifies any drawable on the screen.
width Specify the width and height.
height
width_return
height_return Return the width and height of the object best supported by the display hardware.
Using GC Convenience Routines

The XQueryBestSize function returns the best or closest size to the specified size. For CursorShape, this is the largest size that can be fully displayed on the screen specified by which_screen. For TileShape, this is the size that can be tiled fastest. For StippleShape, this is the size that can be stippled fastest. For CursorShape, the drawable indicates the desired screen. For TileShape and StippleShape, the drawable indicates the screen and possibly the window class and depth. An InputOnly window cannot be used as the drawable for TileShape or StippleShape, or a BadMatch error results.

XQueryBestSize can generate BadDrawable, BadMatch, and BadValue errors.

To obtain the best fill tile shape, use XQueryBestTile.

```c
Status XQueryBestTile(display, which_screen, width, height, width_return, height_return)
    Display *display;
    Drawable which_screen;
    unsigned int width, height;
    unsigned int *width_return, *height_return;

    display Specifies the connection to the XWIN server.
    which_screen Specifies any drawable on the screen.
    width Specify the width and height.
    height
    width_return Return the width and height of the object best supported by the display hardware.
    height_return
```

The XQueryBestTile function returns the best or closest size, that is, the size that can be tiled fastest on the screen specified by which_screen. The drawable indicates the screen and possibly the window class and depth. If an InputOnly window is used as the drawable, a BadMatch error results.

XQueryBestTile can generate BadDrawable and BadMatch errors.

To obtain the best stipple shape, use XQueryBestStipple.
Status XQueryBestStipple (display, which_screen, width, height, width_return, height_return)
    Display *display;
    Drawable which_screen;
    unsigned int width, height;
    unsigned int *width_return, *height_return;

display          Specifies the connection to the XWIN server.
which_screen      Specifies any drawable on the screen.
width             Specify the width and height.
height            Return the width and height of the object best supported by the
display hardware.

The XQueryBestStipple function returns the best or closest size, that is, the
size that can be stippled fastest on the screen specified by which_screen. The
drawable indicates the screen and possibly the window class and depth. If an
InputOnly window is used as the drawable, a BadMatch error results.

XQueryBestStipple can generate BadDrawable and BadMatch errors.

To set the fill tile of a given GC, use XSetTile.

XSetTile (display, gc, tile)
    Display *display;
    GC gc;
    Pixmap tile;

display          Specifies the connection to the XWIN server.
gc               Specifies the GC.
tile             Specifies the fill tile you want to set for the specified GC.

The tile and GC must have the same depth, or a BadMatch error results.

XSetTile can generate BadAlloc, BadGC, BadMatch, and BadPixmap errors.

To set the stipple of a given GC, use XSetStipple.
Using GC Convenience Routines

\[ \text{XSetStipple}(\text{display, gc, stipple}) \]
\[
\begin{align*}
\text{Display } & \display \ast ; \\
\text{GC } & \text{gc;} \\
\text{Pixmap } & \text{stipple;} \\
\end{align*}
\]

display Specifies the connection to the XWIN server.

gc Specifies the GC.

stipple Specifies the stipple you want to set for the specified GC.

The stipple and GC must have the same depth, or a BadMatch error results.

\text{XSetStipple} can generate BadAlloc, BadGC, BadMatch, and BadPixmap errors.

To set the tile or stipple origin of a given GC, use \text{XSetTSSOrigin}.

\[ \text{XSetTSSOrigin}(\text{display, gc, ts_x_origin, ts_y_origin}) \]
\[
\begin{align*}
\text{Display } & \display \ast ; \\
\text{GC } & \text{gc;} \\
\text{int } & \text{ts_x_origin, ts_y_origin;} \\
\end{align*}
\]

display Specifies the connection to the XWIN server.

gc Specifies the GC.

ts_x_origin Specify the x and y coordinates of the tile and stipple origin.

ts_y_origin

When graphics requests call for tiling or stippling, the parent's origin will be interpreted relative to whatever destination drawable is specified in the graphics request.

\text{XSetTSSOrigin} can generate BadAlloc and BadGC error.
Using GC Convenience Routines

Setting the Current Font

To set the current font of a given GC, use XSetFont.

```c
XSetFont (display, gc, font)
Display *display;
GC gc;
Font font;
```

display Specifies the connection to the XWIN server.
gc Specifies the GC.
font Specifies the font.

XSetFont can generate BadAlloc, BadFont, and BadGC errors.

Setting the Clip Region

Xlib provides functions that you can use to set the clip-origin and the clip-mask or set the clip-mask to a list of rectangles.

To set the clip-origin of a given GC, use XSetClipOrigin.

```c
XSetClipOrigin (display, gc, clip_x_origin, clip_y_origin)
Display *display;
GC gc;
int clip_x_origin, clip_y_origin;
```

display Specifies the connection to the XWIN server.
gc Specifies the GC.
clip_x_origin Specify the x and y coordinates of the clip-mask origin.
clip_y_origin Specify the x and y coordinates of the clip-mask origin.

The clip-mask origin is interpreted relative to the origin of whatever destination drawable is specified in the graphics request.
XSetClipOrigin can generate BadAlloc and BadGC errors.

To set the clip-mask of a given GC to the specified pixmap, use XSetClipMask.

```c
XSetClipMask (display, gc, pixmap)

Display *display;
GC gc;
Pixmap pixmap;
```

- **display**: Specifies the connection to the XWIN server.
- **gc**: Specifies the GC.
- **pixmap**: Specifies the pixmap or None.

If the clip-mask is set to None, the pixels are always drawn (regardless of the clip-origin).

XSetClipMask can generate BadAlloc, BadGC, BadMatch, and BadValue errors.

To set the clip-mask of a given GC to the specified list of rectangles, use XSetClipRectangles.

```c
XSetClipRectangles (display, gc, clip_x_origin, clip_y_origin, rectangles, n, ordering)

Display *display;
GC gc;
int clip_x_origin, clip_y_origin;
XRectangle rectangles[];
int n;
int ordering;
```

- **display**: Specifies the connection to the XWIN server.
- **gc**: Specifies the GC.
- **clip_x_origin**: Specify the x and y coordinates of the clip-mask origin.
- **clip_y_origin**: Specify the x and y coordinates of the clip-mask origin.
- **rectangles**: Specifies an array of rectangles that define the clip-mask.
- **n**: Specifies the number of rectangles.
- **ordering**: Specifies the ordering relations on the rectangles. You can pass Unsorted, YSorted, YXSorted, or YXBanded.
The XSetClipRectangles function changes the clip-mask in the specified GC to the specified list of rectangles and sets the clip origin. The output is clipped to remain contained within the rectangles. The clip-origin is interpreted relative to the origin of whatever destination drawable is specified in a graphics request. The rectangle coordinates are interpreted relative to the clip-origin. The rectangles should be nonintersecting, or the graphics results will be undefined. Note that the list of rectangles can be empty, which effectively disables output. This is the opposite of passing None as the clip-mask in XCreateGC, XChangeGC, and XSetClipMask.

If known by the client, ordering relations on the rectangles can be specified with the ordering argument. This may provide faster operation by the server. If an incorrect ordering is specified, the XWIN server may generate a BadMatch error, but it is not required to do so. If no error is generated, the graphics results are undefined. Unsorted means the rectangles are in arbitrary order. YSorted means that the rectangles are nondecreasing in their Y origin. YXSorted additionally constrains YSorted order in that all rectangles with an equal Y origin are nondecreasing in their X origin. YXBanded additionally constrains YXSorted by requiring that, for every possible Y scanline, all rectangles that include that scanline have an identical Y origins and Y extents.

XSetClipRectangles can generate BadAlloc, BadGC, BadMatch, and BadValue errors.

Xlib provides a set of basic functions for performing region arithmetic. For information about these functions, see Chapter 10.

**Setting the Arc Mode, Subwindow Mode, and Graphics Exposure**

To set the arc mode of a given GC, use XSetArcMode.

```
xSetArcMode(display, gc, arc_mode)
    Display *display;
    GC gc;
    int arc_mode;
```
Using GC Convenience Routines

`display` Specifies the connection to the XWIN server.

`gc` Specifies the GC.

`arc_mode` Specifies the arc mode. You can pass ArcChord or ArcPieSlice.

XSetArcMode can generate BadAlloc, BadGC, and BadValue errors.

To set the subwindow mode of a given GC, use XSetSubwindowMode.

```
xSetSubwindowMode (display, gc, subwindow_mode)
    Display *display;
    GC gc;
    int subwindow_mode;
```

`display` Specifies the connection to the XWIN server.

`gc` Specifies the GC.

`subwindow_mode` Specifies the subwindow mode. You can pass ClipByChildren or IncludeInferiors.

XSetSubwindowMode can generate BadAlloc, BadGC, and BadValue errors.

To set the graphics-exposures flag of a given GC, use XSetGraphicsExposures.

```
xSetGraphicsExposures (display, gc, graphics_exposures)
    Display *display;
    GC gc;
    Bool graphics_exposures;
```

`display` Specifies the connection to the XWIN server.

`gc` Specifies the GC.

`graphics_exposures` Specifies a Boolean value that indicates whether you want GraphicsExpose and NoExpose events to be reported when calling XCopyArea and XCopyPlane with this GC.

XSetGraphicsExposures can generate BadAlloc, BadGC, and BadValue errors.

Creating a Cursor
Changing and Destroying Cursors
Defining the Cursor
Introduction

Once you have connected the display to the XWIN server, you can use the Xlib graphics functions to:

- Clear and copy areas
- Draw points, lines, rectangles, and arcs
- Fill areas
- Manipulate fonts
- Draw text
- Transfer images between clients and the server
- Manipulate cursors

If the same drawable and GC is used for each call, Xlib batches back-to-back calls to XDrawPoint, XDrawLine, XDrawRectangle, XFillArc, and XFillRectangle. Note that this reduces the total number of requests sent to the server.
Clearing Areas

Xlib provides functions that you can use to clear an area or the entire window. Because pixmaps do not have defined backgrounds, they cannot be filled by using the functions described in this section. Instead, to accomplish an analogous operation on a pixmap, you should use XFillRectangle, which sets the pixmap to a known value.

To clear a rectangular area of a given window, use XClearArea.

```
XClearArea (display, w, x, y, width, height, exposures)
```

- **display** Specifies the connection to the XWIN server.
- **w** Specifies the window.
- **x** Specify the x and y coordinates, which are relative to the origin of the window and specify the upper-left corner of the rectangle.
- **y** Specify the width and height, which are the dimensions of the rectangle.
- **width** Specify the width and height, which are the dimensions of the rectangle.
- **height** Specify a Boolean value that indicates if Expose events are to be generated.

The XClearArea function paints a rectangular area in the specified window according to the specified dimensions with the window's background pixel or pixmap. The subwindow-mode effectively is ClipByChildren. If width is zero, it is replaced with the current width of the window minus x. If height is zero, it is replaced with the current height of the window minus y. If the window has a defined background tile, the rectangle clipped by any children is filled with this tile. If the window has background None, the contents of the window are not changed. In either case, if exposures is True, one or more Expose events are generated for regions of the rectangle that are either visible or are being retained in a backing store. If you specify a window whose class is InputOnly, a BadMatch error results.
XClearArea can generate BadMatch, BadValue, and BadWindow errors.

To clear the entire area in a given window, use XClearWindow.

    XClearWindow (display, w)
    Display *display;
    Window w;

*display Specifies the connection to the XWIN server.

*w Specifies the window.

The XClearWindow function clears the entire area in the specified window and is equivalent to XClearArea (display, w, 0, 0, 0, 0, False). If the window has a defined background tile, the rectangle is tiled with a plane-mask of all ones and GXcopy function. If the window has background None, the contents of the window are not changed. If you specify a window whose class is InputOnly, a BadMatch error results.

XClearWindow can generate BadMatch and BadWindow errors.
Copying Areas

Xlib provides functions that you can use to copy an area or a bit plane.

To copy an area between drawables of the same root and depth, use XCopyArea.

\[
\text{XCopyArea}(\text{display}, \text{src}, \text{dest}, \text{gc}, \text{src}_x, \text{src}_y, \text{width}, \text{height}, \text{dest}_x, \text{dest}_y)
\]

- \text{display}\quad \text{Specifies the connection to the XWIN server.}
- \text{src}\quad \text{Specify the source and destination rectangles to be combined.}
- \text{dest}\quad \text{Specify the source and destination rectangles to be combined.}
- \text{gc}\quad \text{Specifies the GC.}
- \text{src}_x, \text{src}_y\quad \text{Specify the x and y coordinates, which are relative to the origin of the source rectangle and specify its upper-left corner.}
- \text{width, height}\quad \text{Specify the width and height, which are the dimensions of both the source and destination rectangles.}
- \text{dest}_x, \text{dest}_y\quad \text{Specify the x and y coordinates, which are relative to the origin of the destination rectangle and specify its upper-left corner.}

The XCopyArea function combines the specified rectangle of src with the specified rectangle of dest. The drawables must have the same root and depth, or a BadMatch error results.

If regions of the source rectangle are obscured and have not been retained in backing store or if regions outside the boundaries of the source drawable are specified, those regions are not copied. Instead, the following occurs on all corresponding destination regions that are either visible or are retained in backing store. If the destination is a window with a background other than None, corresponding regions of the destination are tiled with that background (with plane-mask of all ones and GXcopy function). Regardless of tiling or whether the destination is a window or a pixmap, if graphics-exposures is True, then GraphicsExpose events for all corresponding destination regions are generated.
If graphics-exposures is True but no GraphicsExpose events are generated, a NoExpose event is generated. Note that by default graphics-exposures is True in new GCs.

This function uses these GC components: function, plane-mask, subwindow-mode, graphics-exposures, clip-x-origin, clip-y-origin, and clip-mask.

XCopyArea can generate BadDrawable, BadGC, and BadMatch errors.

To copy a single bit plane of a given drawable, use XCopyPlane.

\[ \text{XCopyPlane} \left( \text{display}, \text{src}, \text{dest}, \text{gc}, \text{src}_x, \text{src}_y, \text{width}, \text{height}, \text{dest}_x, \text{dest}_y, \text{plane} \right) \]

- **display** Specifies the connection to the XWIN server.
- **src** Specifies the source and destination rectangles to be combined.
- **dest** Specifies the GC.
- **src\_x** Specify the x and y coordinates, which are relative to the origin of the source rectangle and specify its upper-left corner.
- **src\_y**
- **width** Specify the width and height, which are the dimensions of both the source and destination rectangles.
- **height**
- **dest\_x** Specify the x and y coordinates, which are relative to the origin of the destination rectangle and specify its upper-left corner.
- **dest\_y**
- **plane** Specifies the bit plane. You must set exactly one bit to 1.

The \text{XCopyPlane} function uses a single bit plane of the specified source rectangle combined with the specified GC to modify the specified rectangle of dest. The drawables must have the same root but need not have the same depth. If the drawables do not have the same root, a BadMatch error results. If plane...
does not have exactly one bit set to 1 and the values of planes must be less than $2^n$, where $n$ is the depth of src, a BadValue error results.

Effectively, XCopyPlane forms a pixmap of the same depth as the rectangle of dest and with a size specified by the source region. It uses the foreground/background pixels in the GC (foreground everywhere the bit plane in src contains a bit set to 1, background everywhere the bit plane in src contains a bit set to 0) and the equivalent of a CopyArea protocol request is performed with all the same exposure semantics. This can also be thought of as using the specified region of the source bit plane as a stipple with a fill-style of FillOpaqueStippled for filling a rectangular area of the destination.

This function uses these GC components: function, plane-mask, foreground, background, subwindow-mode, graphics-exposures, clip-x-origin, clip-y-origin and clip-mask.

XCopyPlane can generate BadDrawable, BadGC, BadMatch, and BadValue errors.
Drawing Points, Lines, Rectangles, and Arcs

Xlib provides functions that you can use to draw:

- A single point or multiple points
- A single line or multiple lines
- A single rectangle or multiple rectangles
- A single arc or multiple arcs

Some of the functions described in the following sections use these structures:

```c
typedef struct {
    short x1, y1, x2, y2;
} XSegment;

typedef struct {
    short x, y;
} XPoint;

typedef struct {
    short x, y;
    unsigned short width, height;
} XRectangle;

typedef struct {
    short x, y;
    unsigned short width, height;
    short angle1, angle2;  /* Degrees * 64 */
} XArc;
```

All x and y members are 16-bit signed integers. The width and height members are 16-bit unsigned integers. You should be careful not to generate coordinates and sizes out of the 16-bit ranges, because the protocol only has 16-bit fields for these values.
Drawing Single and Multiple Points

To draw a single point in a given drawable, use XDrawPoint.

\[
XDrawPoint (display, d, gc, x, y)
\]

- \textit{display} Specifies the connection to the XWIN server.
- \textit{d} Specifies the drawable.
- \textit{gc} Specifies the GC.
- \textit{x}, \textit{y} Specify the x and y coordinates where you want the point drawn.

To draw multiple points in a given drawable, use XDrawPoints.

\[
XDrawPoints (display, d, gc, points, npoints, mode)
\]

- \textit{display} Specifies the connection to the XWIN server.
- \textit{d} Specifies the drawable.
- \textit{gc} Specifies the GC.
- \textit{points} Specifies a pointer to an array of points.
- \textit{npoints} Specifies the number of points in the array.
- \textit{mode} Specifies the coordinate mode. You can pass CoordModeOrigin or CoordModePrevious.
Drawing Points, Lines, Rectangles, and Arcs

The XDrawPoint function uses the foreground pixel and function components of the GC to draw a single point into the specified drawable; XDrawPoints draws multiple points this way. CoordModeOrigin treats all coordinates as relative to the origin, and CoordModePrevious treats all coordinates after the first as relative to the previous point. XDrawPoints draws the points in the order listed in the array.

Both functions use these GC components: function, plane-mask, foreground, subwindow-mode, clip-x-origin, clip-y-origin, and clip-mask.

XDrawPoint can generate BadDrawable, BadGC, and BadMatch errors. XDrawPoints can generate BadDrawable, BadGC, BadMatch, and BadValue errors.

Drawing Single and Multiple Lines

To draw a single line between two points in a given drawable, use XDrawLine.

\[
\text{XDrawLine}(\text{display}, d, gc, x1, y1, x2, y2)
\]

- \(\text{Display} \cdot \text{display}\);
- \(\text{Drawable} \cdot d\);
- \(\text{GC} \cdot gc\);
- \(\text{int} \cdot x1, y1, x2, y2\);

- \(\text{display}\) : Specifies the connection to the XWIN server.
- \(d\) : Specifies the drawable.
- \(gc\) : Specifies the GC.
- \(x1\), \(y1\), \(x2\), \(y2\) : Specify the points \((x1, y1)\) and \((x2, y2)\) to be connected.

To draw multiple lines in a given drawable, use XDrawLines.
Drawing Points, Lines, Rectangles, and Arcs

XDrawLines (display, d, gc, points, npoints, mode)

Display *display;
Drawable d;
GC gc;
XPoint *points;
int npoints;
int mode;

display Specifies the connection to the XWIN server.
d Specifies the drawable.
gc Specifies the GC.
points Specifies a pointer to an array of points.
npoints Specifies the number of points in the array.
mode Specifies the coordinate mode. You can pass CoordModeOrigin or CoordModePrevious.

To draw multiple, unconnected lines in a given drawable, use XDrawSegments.

XDrawSegments (display, d, gc, segments, nsegments)

Display *display;
Drawable d;
GC gc;
XSegment *segments;
int nsegments;

display Specifies the connection to the XWIN server.
d Specifies the drawable.
gc Specifies the GC.
segments Specifies a pointer to an array of segments.
nsegments Specifies the number of segments in the array.

The XDrawLine function uses the components of the specified GC to draw a line between the specified set of points (x1, y1) and (x2, y2). It does not perform joining at coincident endpoints. For any given line, XDrawLine does not draw a pixel more than once. If lines intersect, the intersecting pixels are drawn multiple times.
The \texttt{XDrawLines} function uses the components of the specified GC to draw \( n + 1 \) lines between each pair of points (\texttt{point}[i], \texttt{point}[i+1]) in the array of \texttt{XPoint} structures. It draws the lines in the order listed in the array. The lines join correctly at all intermediate points, and if the first and last points coincide, the first and last lines also join correctly. For any given line, \texttt{XDrawLines} does not draw a pixel more than once. If thin (zero line-width) lines intersect, the intersecting pixels are drawn multiple times. If wide lines intersect, the intersecting pixels are drawn only once, as though the entire \texttt{PolyLine} protocol request were a single, filled shape. \texttt{CoordModeOrigin} treats all coordinates as relative to the origin, and \texttt{CoordModePrevious} treats all coordinates after the first as relative to the previous point.

The \texttt{XDrawSegments} function draws multiple, unconnected lines. For each segment, \texttt{XDrawSegments} draws a line between (\( x_1, y_1 \)) and (\( x_2, y_2 \)). It draws the lines in the order listed in the array of \texttt{XSegment} structures and does not perform joining at coincident endpoints. For any given line, \texttt{XDrawSegments} does not draw a pixel more than once. If lines intersect, the intersecting pixels are drawn multiple times.

All three functions use these GC components: function, plane-mask, line-width, line-style, cap-style, fill-style, subwindow-mode, clip-x-origin, clip-y-origin, and clip-mask. The \texttt{XDrawLines} function also uses the join-style GC component. All three functions also use these GC mode-dependent components: foreground, background, tile, stipple, tile-stipple-x-origin, tile-stipple-y-origin, dash-offset, and dash-list.

\texttt{XDrawLine}, \texttt{XDrawLines}, and \texttt{XDrawSegments} can generate \texttt{BadDrawable}, \texttt{BadGC}, and \texttt{BadMatch} errors. \texttt{XDrawLines} also can generate \texttt{BadValue} errors.

\section*{Drawing Single and Multiple Rectangles}

To draw the outline of a single rectangle in a given drawable, use \texttt{XDrawRectangle}. 

\section*{Graphics Functions}
Drawing Points, Lines, Rectangles, and Arcs

**XDrawRectangle** (*display, d, gc, x, y, width, height*)

*display* Displays the connection to the XWIN server.
*d* Specifies the drawable.
*gc* Specifies the GC.
*x* Specifies the x and y coordinates, which specify the upper-left corner of the rectangle.
*y* Specify the width and height, which specify the dimensions of the rectangle.

To draw the outline of multiple rectangles in a given drawable, use **XDrawRectangles**.

**XDrawRectangles** (*display, d, gc, rectangles, nrectangles*)

*display* Specifies the connection to the XWIN server.
*d* Specifies the drawable.
*gc* Specifies the GC.
*rectangles* Specifies a pointer to an array of rectangles.
*nrectangles* Specifies the number of rectangles in the array.
The XDrawRectangle and XDrawRectangles functions draw the outlines of the specified rectangle or rectangles as if a five-point PolyLine protocol request were specified for each rectangle:

\[ [x, y] [x+width, y] [x+width, y+height] [x, y+height] [x, y] \]

For the specified rectangle or rectangles, these functions do not draw a pixel more than once. XDrawRectangles draws the rectangles in the order listed in the array. If rectangles intersect, the intersecting pixels are drawn multiple times.

Both functions use these GC components: function, plane-mask, line-width, line-style, join-style, fill-style, subwindow-mode, clip-x-origin, clip-y-origin, and clip-mask. They also use these GC mode-dependent components: foreground, background, tile, stipple, tile-stipple-x-origin, tile-stipple-y-origin, dash-offset, and dash-list.

XDrawRectangle and XDrawRectangles can generate BadDrawable, BadGC, and BadMatch errors.

**Drawing Single and Multiple Arcs**

To draw a single arc in a given drawable, use XDrawArc.

\[
\text{XDrawArc} (\text{display}, d, \text{gc}, x, y, width, height, angle1, angle2)
\]

- \text{display} Specifies the connection to the XWIN server.
- \text{d} Specifies the drawable.
- \text{gc} Specifies the GC.
- \text{x} \text{y} Specify the x and y coordinates, which are relative to the origin of the drawable and specify the upper-left corner of the bounding rectangle.
width height

Specify the width and height, which are the major and minor axes of the arc.

angle1

Specifies the start of the arc relative to the three-o’clock position from the center, in units of degrees * 64.

angle2

Specifies the path and extent of the arc relative to the start of the arc, in units of degrees * 64.

To draw multiple arcs in a given drawable, use XDrawArcs.

XDrawArcs (display, d, gc, arcs, narcs)

Display *display;
Drawable d;
GC gc;
XArc *arcs;
int narcs;

display

Specifies the connection to the XWIN server.

d

Specifies the drawable.

gc

Specifies the GC.

arcs

Specifies a pointer to an array of arcs.

narcs

Specifies the number of arcs in the array.

XDrawArc draws a single circular or elliptical arc, and XDrawArcs draws multiple circular or elliptical arcs. Each arc is specified by a rectangle and two angles. The center of the circle or ellipse is the center of the rectangle, and the major and minor axes are specified by the width and height. Positive angles indicate counterclockwise motion, and negative angles indicate clockwise motion. If the magnitude of angle2 is greater than 360 degrees, XDrawArc or XDrawArcs truncates it to 360 degrees.

For an arc specified as \([x, y, width, height, angle1, angle2]\), the origin of the major and minor axes is at \([x + \frac{width}{2}, y + \frac{height}{2}]\), and the infinitely thin path describing the entire circle or ellipse intersects the horizontal axis at \([x, y + \frac{height}{2}]\) and \([x + width, y + \frac{height}{2}]\) and intersects the vertical axis at \([x + \frac{width}{2}, y]\) and \([x + \frac{width}{2}, y + height]\). These coordinates can be fractional and
so are not truncated to discrete coordinates. The path should be defined by the ideal mathematical path. For a wide line with line-width lw, the bounding outlines for filling are given by the two infinitely thin paths consisting of all points whose perpendicular distance from the path of the circle/ellipse is equal to lw/2 (which may be a fractional value). The cap-style and join-style are applied the same as for a line corresponding to the tangent of the circle/ellipse at the endpoint.

For an arc specified as \([x, y, width, height, angle1, angle2]\), the angles must be specified in the effectively skewed coordinate system of the ellipse (for a circle, the angles and coordinate systems are identical). The relationship between these angles and angles expressed in the normal coordinate system of the screen (as measured with a protractor) is as follows:

\[
\text{skewed-angle} = \text{atan} \left( \tan(\text{normal-angle}) \frac{width}{height} \right) + \text{adjust}
\]

The skewed-angle and normal-angle are expressed in radians (rather than in degrees scaled by 64) in the range \([0, 2\pi]\) and where \(\text{atan}\) returns a value in the range \([-\frac{\pi}{2}, \frac{\pi}{2}]\) and adjust is:

\[
\begin{align*}
0 & \quad \text{for normal-angle in the range } [0, \frac{\pi}{2}] \\
\pi & \quad \text{for normal-angle in the range } [\frac{\pi}{2}, \frac{3\pi}{2}] \\
2\pi & \quad \text{for normal-angle in the range } [\frac{3\pi}{2}, 2\pi]
\end{align*}
\]

For any given arc, \(\text{XDrawArc}\) and \(\text{XDrawArcs}\) do not draw a pixel more than once. If two arcs join correctly and if the line-width is greater than zero and the arcs intersect, \(\text{XDrawArc}\) and \(\text{XDrawArcs}\) do not draw a pixel more than once. Otherwise, the intersecting pixels of intersecting arcs are drawn multiple times. Specifying an arc with one endpoint and a clockwise extent draws the same pixels as specifying the other endpoint and an equivalent counterclockwise extent, except as it affects joins.

If the last point in one arc coincides with the first point in the following arc, the two arcs will join correctly. If the first point in the first arc coincides with the last point in the last arc, the two arcs will join correctly. By specifying one axis to be zero, a horizontal or vertical line can be drawn. Angles are computed based solely on the coordinate system and ignore the aspect ratio.
Both functions use these GC components: function, plane-mask, line-width, line-style, cap-style, join-style, fill-style, subwindow-mode, clip-x-origin, clip-y-origin, and clip-mask. They also use these GC mode-dependent components: foreground, background, tile, stipple, tile-stipple-x-origin, tile-stipple-y-origin, dash-offset, and dash-list.

XDrawArc and XDrawArcs can generate BadDrawable, BadGC, and BadMatch errors.
Filling Areas

Xlib provides functions that you can use to fill:

- A single rectangle or multiple rectangles
- A single polygon
- A single arc or multiple arcs

Filling Single and Multiple Rectangles

To fill a single rectangular area in a given drawable, use XFillRectangle.

\[
\text{XFillRectangle}(display, \, d, \, gc, \, x, \, y, \, width, \, height)
\]

- \textit{Display} \textit{display};
- \textit{Drawable} \textit{d};
- \textit{GC} \textit{gc};
- \texttt{int} \textit{x}, \textit{y};
- \texttt{unsigned int} \textit{width}, \textit{height};

- \textit{display} \quad \text{Specifies the connection to the XWIN server.}
- \textit{d} \quad \text{Specifies the drawable.}
- \textit{gc} \quad \text{Specifies the GC.}
- \textit{x, y} \quad \text{Specify the x and y coordinates, which are relative to the origin of the drawable and specify the upper-left corner of the rectangle.}
- \textit{width, height} \quad \text{Specify the width and height, which are the dimensions of the rectangle to be filled.}

To fill multiple rectangular areas in a given drawable, use XFillRectangles.
Filling Areas

**XFillRectangles** *(display, d, gc, rectangles, nrectangles)*

```c
Display *display;
Drawable d;
GC gc;
XRectangle *rectangles;
int nrectangles;
```

- **display** Specifies the connection to the XWIN server.
- **d** Specifies the drawable.
- **gc** Specifies the GC.
- **rectangles** Specifies a pointer to an array of rectangles.
- **nrectangles** Specifies the number of rectangles in the array.

The **XFillRectangle** and **XFillRectangles** functions fill the specified rectangle or rectangles as if a four-point FillPolygon protocol request were specified for each rectangle:

```
[x, y] [x+width, y] [x+width, y+height] [x, y+height]
```

Each function uses the x and y coordinates, width and height dimensions, and GC you specify.

**XFillRectangles** fills the rectangles in the order listed in the array. For any given rectangle, **XFillRectangle** and **XFillRectangles** do not draw a pixel more than once. If rectangles intersect, the intersecting pixels are drawn multiple times.

Both functions use these GC components: function, plane-mask, fill-style, subwindow-mode, clip-x-origin, clip-y-origin, and clip-mask. They also use these GC mode-dependent components: foreground, background, tile, stipple, tile-stipple-x-origin, and tile-stipple-y-origin.

**XFillRectangle** and **XFillRectangles** can generate BadDrawable, BadGC, and BadMatch errors.
Filling a Single Polygon

To fill a polygon area in a given drawable, use XFillPolygon.

```c
XFillPolygon(display, d, gc, points, npoints, shape, mode)
    Display *display;
    Drawable d;
    GC gc;
    XPoint *points;
    int npoints;
    int shape;
    int mode;
```

- `display`: Specifies the connection to the XWIN server.
- `d`: Specifies the drawable.
- `gc`: Specifies the GC.
- `points`: Specifies a pointer to an array of points.
- `npoints`: Specifies the number of points in the array.
- `shape`: Specifies a shape that helps the server to improve performance. You can pass Complex, Convex, or Nonconvex.
- `mode`: Specifies the coordinate mode. You can pass CoordModeOrigin or CoordModePrevious.

XFillPolygon fills the region closed by the specified path. The path is closed automatically if the last point in the list does not coincide with the first point. XFillPolygon does not draw a pixel of the region more than once. CoordModeOrigin treats all coordinates as relative to the origin, and CoordModePrevious treats all coordinates after the first as relative to the previous point.

Depending on the specified shape, the following occurs:

- If shape is Complex, the path may self-intersect.
- If shape is Convex, the path is wholly convex. If known by the client, specifying Convex can improve performance. If you specify Convex for a path that is not convex, the graphics results are undefined.
If shape is Nonconvex, the path does not self-intersect, but the shape is
not wholly convex. If known by the client, specifying Nonconvex instead
of Complex may improve performance. If you specify Nonconvex for a
self-intersecting path, the graphics results are undefined.

The fill-rule of the GC controls the filling behavior of self-intersecting polygons.

This function uses these GC components: function, plane-mask, fill-style, fill-
rule, subwindow-mode, clip-x-origin, clip-y-origin, and clip-mask. It also uses
these GC mode-dependent components: foreground, background, tile, stipple,
tile-stipple-x-origin, and tile-stipple-y-origin.

XFillPolygon can generate BadDrawable, BadGC, BadMatch, and BadValue
errors.

Filling Single and Multiple Arcs

To fill a single arc in a given drawable, use XFillArc.

```
XFillArc(display, d, gc, x, y, width, height, angle1, angle2)
```

- `display` Specifies the connection to the XWIN server.
- `d` Specifies the drawable.
- `gc` Specifies the GC.
- `x` `y` Specify the x and y coordinates, which are relative to the origin
  of the drawable and specify the upper-left corner of the bound-
  ing rectangle.
- `width` `height` Specify the width and height, which are the major and minor
  axes of the arc.
angle1  Specifies the start of the arc relative to the three-o’clock position from the center, in units of degrees * 64.

angle2  Specifies the path and extent of the arc relative to the start of the arc, in units of degrees * 64.

To fill multiple arcs in a given drawable, use XFillArcs.

```
XFillArcs (display, d, gc, arcs, narcs)
Display *display;
Drawable d;
GC gc;
XArc *arcs;
int narcs;
```

- **display**: Specifies the connection to the XWin server.
- **d**: Specifies the drawable.
- **gc**: Specifies the GC.
- **arcs**: Specifies a pointer to an array of arcs.
- **narcs**: Specifies the number of arcs in the array.

For each arc, XFillArc or XFillArcs fills the region closed by the infinitely thin path described by the specified arc and, depending on the arc-mode specified in the GC, one or two line segments. For ArcChord, the single line segment joining the endpoints of the arc is used. For ArcPieSlice, the two line segments joining the endpoints of the arc with the center point are used. XFillArcs fills the arcs in the order listed in the array. For any given arc, XFillArc and XFillArcs do not draw a pixel more than once. If regions intersect, the intersecting pixels are drawn multiple times.

Both functions use these GC components: function, plane-mask, fill-style, arc-mode, subwindow-mode, clip-x-origin, clip-y-origin, and clip-mask. They also use these GC mode-dependent components: foreground, background, tile, stipple, tile-stipple-x-origin, and tile-stipple-y-origin.

XFillArc and XFillArcs can generate BadDrawable, BadGC, and BadMatch errors.
Font Metrics

A font is a graphical description of a set of characters that are used to increase efficiency whenever a set of small, similar sized patterns are repeatedly used.

This section discusses how to:

- Load and free fonts
- Obtain and free font names
- Set and retrieve the font search path
- Compute character string sizes
- Return logical extents
- Query character string sizes

The XWIN server loads fonts whenever a program requests a new font. The server can cache fonts for quick lookup. Fonts are global across all screens in a server. Several levels are possible when dealing with fonts. Most applications simply use XLoadQueryFont to load a font and query the font metrics.

Characters in fonts are regarded as masks. Except for image text requests, the only pixels modified are those in which bits are set to 1 in the character. This means that it makes sense to draw text using stipples or tiles (for example, many menus gray-out unusable entries).

The XFontStruct structure contains all of the information for the font and consists of the font-specific information as well as a pointer to an array of XCharStruct structures for the characters contained in the font. The XFontStruct, XFontProp, and XCharStruct structures contain:

typedef struct {
    short lbearing; /* origin to left edge of raster */
    short rbearing; /* origin to right edge of raster */
    short width; /* advance to next char's origin */
    short ascent; /* baseline to top edge of raster */
    short descent; /* baseline to bottom edge of raster */
    unsigned short attributes; /* per char flags (not predefined) */
} XCharStruct;
typedef struct {
    Atom name;
    unsigned long card32;
} XFontProp;

typedef struct {
    unsigned char byte1;
    unsigned char byte2;
} XChar2b;

typedef struct {
    XExtData *ext_data; /* hook for extension to hang data */
    Font fid; /* Font id for this font */
    unsigned direction; /* hint about the direction font is painted */
    unsigned min_char_or_byte2; /* first character */
    unsigned max_char_or_byte2; /* last character */
    unsigned min_byte1; /* first row that exists */
    unsigned max_byte1; /* last row that exists */
    Bool all_chars_exist; /* flag if all characters have nonzero size */
    unsigned default_char; /* char to print for undefined character */
    int n_properties; /* how many properties there are */
    XFontProp *properties; /* pointer to array of additional properties */
    XCharStruct min_bounds; /* minimum bounds over all existing char */
    XCharStruct max_bounds; /* maximum bounds over all existing char */
    XCharStruct *per_char; /* first_char to last_char information */
    int ascent; /* logical extent above baseline for spacing */
    int descent; /* logical decent below baseline for spacing */
} XFontStruct;

X supports single byte/character, two bytes/character matrix, and 16-bit character text operations. Note that any of these forms can be used with a font, but a single byte/character text request can only specify a single byte (that is, the first row of a 2-byte font). You should view 2-byte fonts as a two-dimensional matrix of defined characters: byte1 specifies the range of defined rows and byte2 defines the range of defined columns of the font. Single byte/character fonts have one row defined, and the byte2 range specified in the structure defines a range of characters.
The bounding box of a character is defined by the `XCharStruct` of that character. When characters are absent from a font, the default_char is used. When fonts have all characters of the same size, only the information in the `XFontStruct` min and max bounds are used.

The members of the `XFontStruct` have the following semantics:

- The direction member can be either `FontLeftToRight` or `FontRightToLeft`. It is just a hint as to whether most `XCharStruct` elements have a positive (`FontLeftToRight`) or a negative (`FontRightToLeft`) character width metric. The core protocol defines no support for vertical text.

- If the `min_byte1` and `max_byte1` members are both zero, `min_char_or_byte2` specifies the linear character index corresponding to the first element of the `per_char` array, and `max_char_or_byte2` specifies the linear character index of the last element.

If either `min_byte1` or `max_byte1` are nonzero, both `min_char_or_byte2` and `max_char_or_byte2` are less than 256, and the 2-byte character index values corresponding to the `per_char` array element N (counting from 0) are:

```plaintext
byte1 = N/D + min_byte1
byte2 = N\D + min_char_or_byte2
```

where:

```plaintext
D = max_char_or_byte2 - min_char_or_byte2 + 1
/ = integer division
\ = integer modulus
```

- If the `per_char` pointer is NULL, all glyphs between the first and last character indexes inclusive have the same information, as given by both `min_bounds` and `max_bounds`.

- If `all_chars_exist` is `true`, all characters in the `per_char` array have nonzero bounding boxes.

- The default_char member specifies the character that will be used when an undefined or nonexistent character is printed. The default_char is a 16-bit character (not a 2-byte character). For a font using 2-byte matrix format, the default_char has `byte1` in the most-significant byte and `byte2` in the least-significant byte. If the default_char itself specifies an undefined or nonexistent character, no printing is performed for an undefined or nonexistent character.
The min_bounds and max_bounds members contain the most extreme values of each individual XCharStruct component over all elements of this array (and ignore nonexistent characters). The bounding box of the font (the smallest rectangle enclosing the shape obtained by superimposing all of the characters at the same origin \([x,y]\)) has its upper-left coordinate at:

\[ [x + \text{min_bounds.lbearing}, y - \text{max_bounds.ascent}] \]

Its width is:

\[ \text{max_bounds.rbearing} - \text{min_bounds.ibmearing} \]

Its height is:

\[ \text{max_bounds.ascent} + \text{max_bounds.descent} \]

- The ascent member is the logical extent of the font above the baseline that is used for determining line spacing. Specific characters may extend beyond this.

- The descent member is the logical extent of the font at or below the baseline that is used for determining line spacing. Specific characters may extend beyond this.

- If the baseline is at \(Y\)-coordinate \(y\), the logical extent of the font is inclusive between the \(Y\)-coordinate values \((y - \text{font.ascent})\) and \((y + \text{font.descent} - 1)\). Typically, the minimum interline spacing between rows of text is given by ascent + descent.

For a character origin at \([x,y]\), the bounding box of a character (that is, the smallest rectangle that encloses the character’s shape) described in terms of XCharStruct components is a rectangle with its upper-left corner at:

\[ [x + \text{lbearing}, y - \text{ascent}] \]

Its width is:

\[ \text{rbearing} - \text{lbearing} \]
Its height is:

\[ \text{ascent} + \text{descent} \]

The origin for the next character is defined to be:

\[ [x + \text{width}, y] \]

The lbearing member defines the extent of the left edge of the character ink from the origin. The rbearing member defines the extent of the right edge of the character ink from the origin. The ascent member defines the extent of the top edge of the character ink from the origin. The descent member defines the extent of the bottom edge of the character ink from the origin. The width member defines the logical width of the character.

Note that the baseline (the y position of the character origin) is logically viewed as being the scanline just below nondescending characters. When descent is zero, only pixels with Y-coordinates less than y are drawn, and the origin is logically viewed as being coincident with the left edge of a nonkerned character. When lbearing is zero, no pixels with X-coordinate less than x are drawn. Any of the XCharStruct metric members could be negative. If the width is negative, the next character will be placed to the left of the current origin.

The X protocol does not define the interpretation of the attributes member in the XCharStruct structure. A nonexistent character is represented with all members of its XCharStruct set to zero.

A font is not guaranteed to have any properties. The interpretation of the property value (for example, long or unsigned long) must be derived from a priori knowledge of the property. When possible, fonts should have at least the properties listed in the table. With atom names, uppercase and lowercase matter. The following built-in property atoms can be found in < X11/Xatom.h >:
<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MIN_SPACE</td>
<td>unsigned</td>
<td>The minimum interword spacing, in pixels.</td>
</tr>
<tr>
<td>NORM_SPACE</td>
<td>unsigned</td>
<td>The normal interword spacing, in pixels.</td>
</tr>
<tr>
<td>MAX_SPACE</td>
<td>unsigned</td>
<td>The maximum interword spacing, in pixels.</td>
</tr>
<tr>
<td>END_SPACE</td>
<td>unsigned</td>
<td>The additional spacing at the end of sentences, in pixels.</td>
</tr>
<tr>
<td>SUPERSCRIPT_X</td>
<td>int</td>
<td>Offset from the character origin where superscripts should begin, in pixels.</td>
</tr>
<tr>
<td>SUPERSCRIPT_Y</td>
<td>int</td>
<td>If the origin is at ([x,y]), then superscripts should begin at ([x + SUPERSCRIPT_X, y - SUPERSCRIPT_Y]).</td>
</tr>
<tr>
<td>SUBSCRIPT_X</td>
<td>int</td>
<td>Offset from the character origin where subscripts should begin, in pixels.</td>
</tr>
<tr>
<td>SUBSCRIPT_Y</td>
<td>int</td>
<td>If the origin is at ([x,y]), then subscripts should begin at ([x + SUPERSCRIPT_X, y + SUPERSCRIPT_Y]).</td>
</tr>
<tr>
<td>UNDERLINE_POSITION</td>
<td>int</td>
<td>Y offset from the baseline to the top of an underline, in pixels.</td>
</tr>
<tr>
<td>UNDERLINE_THICKNESS</td>
<td>unsigned</td>
<td>Thickness of the underline, in pixels.</td>
</tr>
<tr>
<td>STRIKEOUT_ASCENT</td>
<td>int</td>
<td>Vertical extents for boxing or voiding characters, in pixels.</td>
</tr>
<tr>
<td>STRIKEOUT_DESCENT</td>
<td>int</td>
<td>If the baseline is at Y-coordinate (y), then the top of the strikeout box is at ((y - STRIKEOUT_ASCENT)), and the height of the box is ((\text{STRIKEOUT_ASCENT} + \text{STRIKEOUT_DESCENT})).</td>
</tr>
<tr>
<td>ITALIC_ANGLE</td>
<td>int</td>
<td>The angle of the dominant staffs of characters in the font, in degrees scaled by 64.</td>
</tr>
<tr>
<td>X_HEIGHT</td>
<td>int</td>
<td>1 ex as in TeX, but expressed in units of pixels.</td>
</tr>
<tr>
<td>QUAD_WIDTH</td>
<td>int</td>
<td>1 em as in TeX, but expressed in units of pixels.</td>
</tr>
</tbody>
</table>
## Font Metrics

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CAP_HEIGHT</td>
<td>int</td>
<td>Y offset from the baseline to the top of the capital letters, ignoring accents, in pixels. If the baseline is at Y-coordinate y, then the top of the capitals is at (y - CAP_HEIGHT).</td>
</tr>
<tr>
<td>WEIGHT</td>
<td>unsigned</td>
<td>The weight or boldness of the font, expressed as a value between 0 and 1000.</td>
</tr>
<tr>
<td>POINT_SIZE</td>
<td>unsigned</td>
<td>The point size of this font at the ideal resolution, expressed in 1/10 points.</td>
</tr>
<tr>
<td>RESOLUTION</td>
<td>unsigned</td>
<td>The number of pixels per point, expressed in 1/100, at which this font was created.</td>
</tr>
</tbody>
</table>

## Loading and Freeing Fonts

Xlib provides functions that you can use to load fonts, get font information, unload fonts, and free font information. A few font functions use a GContext resource ID or a font ID interchangeably.

To load a given font, use `XLoadFont`.

```c
Font XLoadFont (display, name)
Display *display;
char *name;
```

*display* Specifies the connection to the XWIN server.

*name* Specifies the name of the font, which is a null-terminated string.

The `XLoadFont` function loads the specified font and returns its associated font ID. The name should be ISO Latin-1 encoding; uppercase and lowercase do not matter. If `XLoadFont` was unsuccessful at loading the specified font, a BadName error results. Fonts are not associated with a particular screen and can be stored as a component of any GC. When the font is no longer needed, call `XUnloadFont`.

`XLoadFont` can generate BadAlloc and BadName errors.
To return information about an available font, use XQueryFont.

\[
\text{XFontStruct } \ast \text{XQueryFont} \left( \text{display, font\_ID} \right)
\]
\[
\text{Display } \ast \text{display};
\]
\[
\text{XID font\_ID};
\]

\text{display} \quad \text{Specifies the connection to the XWIN server.}

\text{font\_ID} \quad \text{Specifies the font ID or the GContext ID.}

The \text{XQueryFont} function returns a pointer to the \text{XFontStruct} structure, which contains information associated with the font. You can query a font or the font stored in a GC. The font ID stored in the \text{XFontStruct} structure will be the GContext ID, and you need to be careful when using this ID in other functions (see \text{XGContextFromGC}). To free this data, use XFreeFontInfo.

To perform a \text{XLoadFont} and \text{XQueryFont} in a single operation, use \text{XLoadQueryFont}.

\[
\text{XFontStruct } \ast \text{XLoadQueryFont} \left( \text{display, name} \right)
\]
\[
\text{Display } \ast \text{display};
\]
\[
\text{char } \ast \text{name};
\]

\text{display} \quad \text{Specifies the connection to the XWIN server.}

\text{name} \quad \text{Specifies the name of the font, which is a null-terminated string.}

The \text{XLoadQueryFont} function provides the most common way for accessing a font. \text{XLoadQueryFont} both opens (loads) the specified font and returns a pointer to the appropriate \text{XFontStruct} structure. If the font does not exist, \text{XLoadQueryFont} returns NULL.

\text{XLoadQueryFont} can generate a BadAlloc error.

To unload the font and free the storage used by the font structure that was allocated by \text{XQueryFont} or \text{XLoadQueryFont}, use \text{XFreeFont}.

\[
\text{XFreeFont} \left( \text{display, font\_struct} \right)
\]
\[
\text{Display } \ast \text{display};
\]
\[
\text{XFontStruct } \ast \text{font\_struct};
\]

\text{display} \quad \text{Specifies the connection to the XWIN server.}
font_struct  Specifies the storage associated with the font.

The \texttt{XFreeFont} function deletes the association between the font resource ID and the specified font and frees the \texttt{XFontStruct} structure. The font itself will be freed when no other resource references it. The data and the font should not be referenced again.

\texttt{XFreeFont} can generate a \texttt{BadFont} error.

To return a given font property, use \texttt{XGetFontProperty}.

\begin{verbatim}
Bool XGetFontProperty (font_struct, atom, value_return)
    XFontStruct *font_struct;
    Atom atom;
    unsigned long *value_return;
\end{verbatim}

\texttt{font_struct}  Specifies the storage associated with the font.
\texttt{atom}  Specifies the atom for the property name you want returned.
\texttt{value_return}  Returns the value of the font property.

Given the atom for that property, the \texttt{XGetFontProperty} function returns the value of the specified font property. \texttt{XGetFontProperty} also returns \texttt{False} if the property was not defined or \texttt{True} if it was defined. A set of predefined atoms exists for font properties, which can be found in \texttt{<X11/Atom.h>}. This set contains the standard properties associated with a font. Although it is not guaranteed, it is likely that the predefined font properties will be present.

To unload a font that was loaded by \texttt{XLoadFont}, use \texttt{XUnloadFont}.

\begin{verbatim}
XUnloadFont (display, font)
    Display *display;
    Font font;
\end{verbatim}

\texttt{display}  Specifies the connection to the XWIN server.
\texttt{font}  Specifies the font.

The \texttt{XUnloadFont} function deletes the association between the font resource ID and the specified font. The font itself will be freed when no other resource references it. The font should not be referenced again.
XUnloadFont can generate a BadFont error.

## Obtaining and Freeing Font Names and Information

You obtain font names and information by matching a wildcard specification when querying a font type for a list of available sizes and so on.

To return a list of the available font names, use XListFonts.

```c
char **XListFonts (display, pattern, maxnames, actual_count_return)

Display *display;
char *pattern;
int maxnames;
int *actual_count_return;
```

- **display** Specifies the connection to the XWIN server.
- **pattern** Specifies the null-terminated pattern string that can contain wildcard characters.
- **maxnames** Specifies the maximum number of names to be returned.
- **actual_count_return** Returns the actual number of font names.

The XListFonts function returns an array of available font names (as controlled by the font search path; see XSetFontPath) that match the string you passed to the pattern argument. The string should be ISO Latin-1; uppercase and lowercase do not matter. Each string is terminated by an ASCII null. The pattern string can contain any characters, but each asterisk (*) is a wildcard for any number of characters, and each question mark (?) is a wildcard for a single character. The client should call XFreeFontNames when finished with the result to free the memory.

To free a font name array, use XFreeFontNames.

```c
XFreeFontNames (list)
char *list[];
```
list  Specifies the array of strings you want to free.

The XFreeFontNames function frees the array and strings returned by XListFonts or XListFontsWithInfo.

To obtain the names and information about available fonts, use XListFontsWithInfo.

```c
char **XListFontsWithInfo (display, pattern, maxnames, count_return, info_return)
Display *display;
char *pattern;
int maxnames;
int *count_return;
XFontStruct **info_return;
```

display  Specifies the connection to the XWIN server.

pattern  Specifies the null-terminated pattern string that can contain wildcard characters.

maxnames  Specifies the maximum number of names to be returned.

count_return  Returns the actual number of matched font names.

info_return  Returns a pointer to the font information.

The XListFontsWithInfo function returns a list of font names that match the specified pattern and their associated font information. The list of names is limited to size specified by maxnames. The information returned for each font is identical to what XLoadQueryFont would return except that the per-character metrics are not returned. The pattern string can contain any characters, but each asterisk (*) is a wildcard for any number of characters, and each question mark (?) is a wildcard for a single character. To free the allocated name array, the client should call XFreeFontNames. To free the the font information array, the client should call XFreeFontInfo.

To free the the font information array, use XFreeFontInfo.

```c
XFreeFontInfo (names, free_info, actual_count)
char **names;
XFontStruct *free_info;
int actual_count;
```
names Specifies the list of font names returned by XListFontsWithInfo.

free_info Specifies the pointer to the font information returned by XListFontsWithInfo.

actual_count Specifies the actual number of matched font names returned by XListFontsWithInfo.

### Setting and Retrieving the Font Search Path

To set the font search path, use XSetFontPath.

```c
XSetFontPath (display, directories, ndirs)
Display *display;
char **directories;
int ndirs;
```

display Specifies the connection to the XWIN server.

directories Specifies the directory path used to look for a font. Setting the path to the empty list restores the default path defined for the XWIN server.

ndirs Specifies the number of directories in the path.

The XSetFontPath function defines the directory search path for font lookup. There is only one search path per XWIN server, not one per client. The interpretation of the strings is operating system dependent, but they are intended to specify directories to be searched in the order listed. Also, the contents of these strings are operating system dependent and are not intended to be used by client applications. Usually, the XWIN server is free to cache font information internally rather than having to read fonts from files. In addition, the XWIN server is guaranteed to flush all cached information about fonts for which there currently are no explicit resource IDs allocated. The meaning of an error from this request is operating system dependent.

XSetFontPath can generate a BadValue error.
To get the current font search path, use XGetFontPath.

```c
char **XGetFontPath (display, npaths_return)
    Display *display;
    int *npaths_return;
```

display specifies the connection to the XWIN server.

npaths_return returns the number of strings in the font path array.

The XGetFontPath function allocates and returns an array of strings containing the search path. When it is no longer needed, the data in the font path should be freed by using XFreeFontPath.

To free data returned by XGetFontPath, use XFreeFontPath.

```c
XFreeFontPath (list)
    char **list;
```

list specifies the array of strings you want to free.

The XFreeFontPath function frees the data allocated by XGetFontPath.

## Computing Character String Sizes

Xlib provides functions that you can use to compute the width, the logical extents, and the server information about 8-bit and 2-byte text strings. The width is computed by adding the character widths of all the characters. It does not matter if the font is an 8-bit or 2-byte font. These functions return the sum of the character metrics, in pixels.

To determine the width of an 8-bit character string, use XTextWidth.

```c
int XTextWidth (font_struct, string, count)
    XFontStruct *font_struct;
    char *string;
    int count;
```

font_struct specifies the font used for the width computation.
string
Specifies the character string.

count
Specifies the character count in the specified string.

To determine the width of a 2-byte character string, use XTextWidth16.

```c
int XTextWidth16 (font_struct, string, count)
    XFontStruct *font_struct;
    XChar2b *string;
    int count;
```

font_struct
Specifies the font used for the width computation.

string
Specifies the character string.

count
Specifies the character count in the specified string.

Computing Logical Extents

To compute the bounding box of an 8-bit character string in a given font, use XTextExtents.

```c
XTextExtents (font_struct, string, nchars, direction_return, font_ascent_return,
    font_descent_return, overall_return)
    XFontStruct *font_struct;
    char *string;
    int nchars;
    int *direction_return;
    int *font_ascent_return, *font_descent_return;
    XCharStruct *overall_return;
```

font_struct
Specifies a pointer to the XFontStruct structure.

string
Specifies the character string.

nchars
Specifies the number of characters in the character string.

direction_return
Returns the value of the direction hint (FontLeftToRight or FontRightToLeft).
Font Metrics

`font_ascent_return`  
Returns the font ascent.

`font_descent_return`  
Returns the font descent.

`overall_return`  
Returns the overall size in the specified XCharStruct structure.

To compute the bounding box of a 2-byte character string in a given font, use XTextExtents16.

```c
XTextExtents16 (font_struct, string, nchars, direction_return, font_ascent_return,
                font_descent_return, overall_return)
```

- `font_struct` Specifies a pointer to the XFontStruct structure.
- `string` Specifies the character string.
- `nchars` Specifies the number of characters in the character string.
- `direction_return` Returns the value of the direction hint (FontLeftToRight or FontRightToLeft).
- `font_ascent_return` Returns the font ascent.
- `font_descent_return` Returns the font descent.
- `overall_return` Returns the overall size in the specified XCharStruct structure.

The XTextExtents and XTextExtents16 functions perform the size computation locally and, thereby, avoid the round-trip overhead of XQueryTextExtents and XQueryTextExtents16. Both functions return an XCharStruct structure, whose members are set to the values as follows.
The ascent member is set to the maximum of the ascent metrics of all characters in the string. The descent member is set to the maximum of the descent metrics. The width member is set to the sum of the character-width metrics of all characters in the string. For each character in the string, let \( W \) be the sum of the character-width metrics of all characters preceding it in the string. Let \( L \) be the left-side-bearing metric of the character plus \( W \). Let \( R \) be the right-side-bearing metric of the character plus \( W \). The lbearing member is set to the minimum \( L \) of all characters in the string. The rbearing member is set to the maximum \( R \).

For fonts defined with linear indexing rather than 2-byte matrix indexing, each XChar2b structure is interpreted as a 16-bit number with byte1 as the most-significant byte. If the font has no defined default character, undefined characters in the string are taken to have all zero metrics.

**Querying Character String Sizes**

To query the server for the bounding box of an 8-bit character string in a given font, use `XQueryTextExtents`.

```c
XQueryTextExtents (display, font_ID, string, nchars, direction_return, font_ascent_return,
                   font_descent_return, overall_return)
```

- `display` Specifies the connection to the XWIN server.
- `font_ID` Specifies either the font ID or the GContext ID that contains the font.
- `string` Specifies the character string.
- `nchars` Specifies the number of characters in the character string.
**Font Metrics**

`direction_return`
Returns the value of the direction hint (FontLeftToRight or FontRightToLeft).

`font_ascent_return`
Returns the font ascent.

`font_descent_return`
Returns the font descent.

`overall_return`
Returns the overall size in the specified XCharStruct structure.

To query the server for the bounding box of a 2-byte character string in a given font, use `XQueryTextExtents16`.

```
XQueryTextExtents16 (display, font_ID, string, nchars, direction_return, font_ascent_return, font_descent_return, overall_return)
```

- `display` Specifies the connection to the XWIN server.
- `font_ID` Specifies either the font ID or the GContext ID that contains the font.
- `string` Specifies the character string.
- `nchars` Specifies the number of characters in the character string.
- `direction_return` Returns the value of the direction hint (FontLeftToRight or FontRightToLeft).
- `font_ascent_return` Returns the font ascent.
- `font_descent_return` Returns the font descent.
overall_return  Returns the overall size in the specified XCharStruct structure.

The XQueryTextExtents and XQueryTextExtents16 functions return the bounding box of the specified 8-bit and 16-bit character string in the specified font or the font contained in the specified GC. These functions query the XWIN server and, therefore, suffer the round-trip overhead that is avoided by XTextExtents and XTextExtents16. Both functions return a XCharStruct structure, whose members are set to the values as follows.

The ascent member is set to the maximum of the ascent metrics of all characters in the string. The descent member is set to the maximum of the descent metrics. The width member is set to the sum of the character-width metrics of all characters in the string. For each character in the string, let W be the sum of the character-width metrics of all characters preceding it in the string. Let L be the left-side-bearing metric of the character plus W. Let R be the right-side-bearing metric of the character plus W. The lbearing member is set to the minimum L of all characters in the string. The rbearing member is set to the maximum R.

For fonts defined with linear indexing rather than 2-byte matrix indexing, each XChar2b structure is interpreted as a 16-bit number with byte1 as the most-significant byte. If the font has no defined default character, undefined characters in the string are taken to have all zero metrics.

XQueryTextExtents and XQueryTextExtents16 can generate BadFont and BadGC errors.
Drawing Text

This section discusses how to draw:

- Complex text
- Text characters
- Image text characters

The fundamental text functions XDrawText and XDrawText16 use the following structures.

```c
typedef struct {
    char *chars;  /* pointer to string */
    int nchars;  /* number of characters */
    int delta;   /* delta between strings */
    Font font;   /* Font to print it in, None don't change */
} XTextItem;

typedef struct {
    XChar2b *chars;  /* pointer to two-byte characters */
    int nchars;     /* number of characters */
    int delta;      /* delta between strings */
    Font font;      /* font to print it in, None don't change */
} XTextItem16;
```

If the font member is not None, the font is changed before printing and also is stored in the GC. If an error was generated during text drawing, the previous items may have been drawn. The baseline of the characters are drawn starting at the x and y coordinates that you pass in the text drawing functions.

For example, consider the background rectangle drawn by XDrawImageString. If you want the upper-left corner of the background rectangle to be at pixel coordinate (x,y), pass the (x,y + ascent) as the baseline origin coordinates to the text functions. The ascent is the font ascent, as given in the XFontStruct structure. If you want the lower-left corner of the background rectangle to be at pixel coordinate (x,y), pass the (x,y - descent + 1) as the baseline origin coordinates to the text functions. The descent is the font descent, as given in the XFontStruct structure.
Drawing Complex Text

To draw 8-bit characters in a given drawable, use XDrawText.

XDrawText (display, d, gc, x, y, items, nitems)

Display *display;
Drawable d;
GC gc;
int x, y;
XTextItem *items;
int nitems;

display    Specifies the connection to the XWIN server.
d    Specifies the drawable.
gc    Specifies the GC.
x
y    Specify the x and y coordinates, which are relative to the origin of the specified drawable and define the origin of the first character.
items    Specifies a pointer to an array of text items.
nitems    Specifies the number of text items in the array.

To draw 2-byte characters in a given drawable, use XDrawText16.

XDrawText16 (display, d, gc, x, y, items, nitems)

Display *display;
Drawable d;
GC gc;
int x, y;
XTextItem16 *items;
int nitems;

display    Specifies the connection to the XWIN server.
d    Specifies the drawable.
gc    Specifies the GC.
x
y
items
nitems

Specify the x and y coordinates, which are relative to the origin of the specified drawable and define the origin of the first character.

Specifies a pointer to an array of text items.

Specifies the number of text items in the array.

The XDrawText16 function is similar to XDrawText except that it uses 2-byte or 16-bit characters. Both functions allow complex spacing and font shifts between counted strings.

Each text item is processed in turn. A font member other than None in an item causes the font to be stored in the GC and used for subsequent text. A text element delta specifies an additional change in the position along the x axis before the string is drawn. The delta is always added to the character origin and is not dependent on any characteristics of the font. Each character image, as defined by the font in the GC, is treated as an additional mask for a fill operation on the drawable. The drawable is modified only where the font character has a bit set to 1. If a text item generates a BadFont error, the previous text items may have been drawn.

For fonts defined with linear indexing rather than 2-byte matrix indexing, each XChar2b structure is interpreted as a 16-bit number with byte1 as the most-significant byte.

Both functions use these GC components: function, plane-mask, fill-style, font, subwindow-mode, clip-x-origin, clip-y-origin, and clip-mask. They also use these GC mode-dependent components: foreground, background, tile, stipple, tile-stipple-x-origin, and tile-stipple-y-origin.

XDrawText and XDrawText16 can generate BadDrawable, BadFont, BadGC, and BadMatch errors.
Drawing Text Characters

To draw 8-bit characters in a given drawable, use XDrawString.

\[
\text{XDrawString}(\text{display}, \ d, \ gc, \ x, \ y, \ string, \ length) \\
\text{Display} \ *\text{display}; \\
\text{Drawable} \ d; \\
\text{GC} \ gc; \\
\text{int} \ x, \ y; \\
\text{char} \ *\text{string}; \\
\text{int} \ length;
\]

display\hspace{1cm} \text{Specifies the connection to the XWIN server.} \\
\text{d}\hspace{1cm} \text{Specifies the drawable.} \\
gc\hspace{1cm} \text{Specifies the GC.} \\
x\hspace{1cm} \text{Specify the x and y coordinates, which are relative to the origin of the specified drawable and define the origin of the first character.} \\
y\hspace{1cm} \text{string}\hspace{1cm} \text{Specifies the character string.} \\
length\hspace{1cm} \text{Specifies the number of characters in the string argument.}

To draw 2-byte characters in a given drawable, use XDrawString16.

\[
\text{XDrawString16}(\text{display}, \ d, \ gc, \ x, \ y, \ string, \ length) \\
\text{Display} \ *\text{display}; \\
\text{Drawable} \ d; \\
\text{GC} \ gc; \\
\text{int} \ x, \ y; \\
\text{XChar2b} \ *\text{string}; \\
\text{int} \ length;
\]

display\hspace{1cm} \text{Specifies the connection to the XWIN server.} \\
\text{d}\hspace{1cm} \text{Specifies the drawable.}
**Drawing Text**

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gc</td>
<td>Specifies the GC.</td>
</tr>
<tr>
<td>x</td>
<td>Specify the x and y coordinates, which are relative to the origin of the specified drawable and define the origin of the first character.</td>
</tr>
<tr>
<td>y</td>
<td></td>
</tr>
<tr>
<td>string</td>
<td>Specifies the character string.</td>
</tr>
<tr>
<td>length</td>
<td>Specifies the number of characters in the string argument.</td>
</tr>
</tbody>
</table>

Each character image, as defined by the font in the GC, is treated as an additional mask for a fill operation on the drawable. The drawable is modified only where the font character has a bit set to 1. For fonts defined with 2-byte matrix indexing and used with `XDrawString16`, each byte is used as a byte2 with a byte1 of zero.

Both functions use these GC components: function, plane-mask, fill-style, font, subwindow-mode, clip-x-origin, clip-y-origin, and clip-mask. They also use these GC mode-dependent components: foreground, background, tile, stipple, tile-stipple-x-origin, and tile-stipple-y-origin.

`XDrawString` and `XDrawString16` can generate BadDrawable, BadGC, and BadMatch errors.

**Drawing Image Text Characters**

Some applications, in particular terminal emulators, need to print image text in which both the foreground and background bits of each character are painted. This prevents annoying flicker on many displays.

To draw 8-bit image text characters in a given drawable, use `XDrawImageString`.

```c
XDrawImageString (display, d, gc, x, y, string, length)
Display *display;
Drawable d;
GC gc;
int x, y;
char *string;
int length;
```
Specifies the connection to the XWIN server.

Specifies the drawable.

Specifies the GC.

Specify the x and y coordinates, which are relative to the origin of the specified drawable and define the origin of the first character.

Specifies the character string.

Specifies the number of characters in the string argument.

To draw 2-byte image text characters in a given drawable, use `XDrawImageString16`.

\[
\text{XDrawImageString16(} \text{display, } \text{drawable, } \text{gc, } \text{x, y, string, length})
\]

Display *display;
Drawable drawable;
GC gc;
int x, y;
XChar2b *string;
int length;

Specifies the connection to the XWIN server.

Specifies the drawable.

Specifies the GC.

Specify the x and y coordinates, which are relative to the origin of the specified drawable and define the origin of the first character.

Specifies the character string.

Specifies the number of characters in the string argument.

The `XDrawImageString16` function is similar to `XDrawImageString` except that it uses 2-byte or 16-bit characters. Both functions also use both the foreground and background pixels of the GC in the destination.
The effect is first to fill a destination rectangle with the background pixel defined in the GC and then to paint the text with the foreground pixel. The upper-left corner of the filled rectangle is at:

\[ x, \ y - \text{font-ascent} \]

The width is:

\[ \text{overall-width} \]

The height is:

\[ \text{font-ascent} + \text{font-descent} \]

The overall-width, font-ascent, and font-descent are as would be returned by XQueryTextExtents using gc and string. The function and fill-style defined in the GC are ignored for these functions. The effective function is GXcopy, and the effective fill-style is FillSolid.

For fonts defined with 2-byte matrix indexing and used with XDrawImageString, each byte is used as a byte2 with a byte1 of zero.

Both functions use these GC components: plane-mask, foreground, background, font, subwindow-mode, clip-x-origin, clip-y-origin, and clip-mask.

XDrawImageString and XDrawImageString16 can generate BadDrawable, BadGC, and BadMatch errors.
Transferring Images between Client and Server

Xlib provides functions that you can use to transfer images between a client and the server. Because the server may require diverse data formats, Xlib provides an image object that fully describes the data in memory and that provides for basic operations on that data. You should reference the data through the image object rather than referencing the data directly. However, some implementations of the Xlib library may efficiently deal with frequently used data formats by replacing functions in the procedure vector with special case functions. Supported operations include destroying the image, getting a pixel, storing a pixel, extracting a subimage of an image, and adding a constant to an image (see Chapter 10).

All the image manipulation functions discussed in this section make use of the XImage data structure, which describes an image as it exists in the client’s memory.
typedef struct _XImage {
    int width, height;             /* size of image */
    int xoffset;                   /* number of pixels offset in X direction */
    int format;                    /* XYBitmap, XPIXmap, ZPixmap */
    char *data;                    /* pointer to image data */
    int byte_order;                /* data byte order, LSBFirst, MSBFirst */
    int bitmap_unit;               /* quant. of scanline 8, 16, 32 */
    int bitmap_bit_order;          /* LSBFirst, MSBFirst */
    int bitmap_pad;                /* 8, 16, 32 either XY or ZPixmap */
    int depth;                     /* depth of image */
    int bytes_per_line;            /* accelerator to next scanline */
    int bits_per_pixel;            /* bits per pixel (ZPixmap) */
    unsigned long long red_mask;   /* bits in z arrangement */
    unsigned long long green_mask;
    unsigned long long blue_mask;
    char *objdata;                 /* hook for the object routines to hang on */
    struct funcs {                 /* image manipulation routines */
        struct _XImage *(*create_image)();
        int (*destroy_image)();
        unsigned long long (*get_pixel)();
        int (*put_pixel)();
        struct _XImage *(*sub_image)();
        int (*add_pixel)();
    } f;
} XImage;

You may request that some of the members (for example, height, width, and xoffset) be changed when the image is sent to the server. That is, you may send a subset of the image. Other members (for example, byte_order, bitmap_unit, and so forth) are characteristics of both the image and the server. If these members differ between the image and the server, XPutImage makes the appropriate conversions. The first byte of the first scanline of plane n is located at the address (data + (n * height * bytes_per_line)).

To combine an image in memory with a rectangle of a drawable on the display, use XPutImage.
Transferring Images between Client and Server

XPutImage (display, d, gc, image, src_x, src_y, dest_x, dest_y, width, height)

Display *display;
Drawable d;
GC gc;
XImage *image;
int src_x, src_y;
int dest_x, dest_y;
unsigned int width, height;

display Specifies the connection to the XWIN server.
d Specifies the drawable.
 gc Specifies the GC.
image Specifies the image you want combined with the rectangle.
src_x Specifies the offset in X from the left edge of the image defined by the XImage data structure.
src_y Specifies the offset in Y from the top edge of the image defined by the XImage data structure.
dest_x Specify the x and y coordinates, which are relative to the origin of the drawable and are the coordinates of the subimage.
dest_y
width Specify the width and height of the subimage, which define the dimensions of the rectangle.
height

The XPutImage function combines an image in memory with a rectangle of the specified drawable. If XYBitmap format is used, the depth must be one, or a BadMatch error results. The foreground pixel in the GC defines the source for the one bits in the image, and the background pixel defines the source for the zero bits. For XYPixmap and ZPixmap, the depth must match the depth of the drawable, or a BadMatch error results. The section of the image defined by the src_x, src_y, width, and height arguments is drawn on the specified part of the drawable.

This function uses these GC components: function, plane-mask, subwindow-mode, clip-x-origin, clip-y-origin, and clip-mask. It also uses these GC mode-dependent components: foreground and background.
XPutImage can generate BadDrawable, BadGC, BadMatch, and BadValue errors.

To return the contents of a rectangle in a given drawable on the display, use XGetImage. This function specifically supports rudimentary screen dumps.

```c
XImage *XGetImage (display, d, x, y, width, height, plane_mask, format)
  Display *display;
  Drawable d;
  int x, y;
  unsigned int width, height;
  long plane_mask;
  int format;
```

- **display**: Specifies the connection to the XWIN server.
- **d**: Specifies the drawable.
- **x**: Specifies the x and y coordinates, which are relative to the origin of the drawable and define the upper-left corner of the rectangle.
- **y**: Specify the y coordinate.
- **width**: Specify the width and height of the subimage, which define the dimensions of the rectangle.
- **height**: Specify the height of the subimage.
- **plane_mask**: Specifies the plane mask.
- **format**: Specifies the format for the image. You can pass XYPixmap, XYBitmap, or ZPixmap.

The XGetImage function returns a pointer to an XImage structure. This structure provides you with the contents of the specified rectangle of the drawable in the format you specify. If the format argument is XYPixmap, the image contains only the bit planes you passed to the plane_mask argument. If the plane_mask argument only requests a subset of the planes of the display, the depth of the returned image will be the number of planes requested. If the format argument is ZPixmap, XGetImage returns as zero the bits in all planes not specified in the plane_mask argument. The function performs no range checking on the values in plane_mask and ignores extraneous bits.
XGetImage returns the depth of the image to the depth member of the XImage structure. The depth of the image is as specified when the drawable was created, except when getting a subset of the planes in XYPixmap format, when the depth is given by the number of bits set to 1 in plane_mask.

If the drawable is a pixmap, the given rectangle must be wholly contained within the pixmap, or a BadMatch error results. If the drawable is a window, the window must be viewable, and it must be the case that if there were no inferiors or overlapping windows, the specified rectangle of the window would be fully visible on the screen and wholly contained within the outside edges of the window, or a BadMatch error results. Note that the borders of the window can be included and read with this request. If the window has backing-store, the backing-store contents are returned for regions of the window that are obscured by noninferior windows. If the window does not have backing-store, the returned contents of such obscured regions are undefined. The returned contents of visible regions of inferiors of a different depth than the specified window's depth are also undefined. The pointer cursor image is not included in the returned contents.

XGetImage can generate BadDrawable, BadMatch, and BadValue errors.

To copy the contents of a rectangle on the display to a location within a preexisting image structure, use XGetSubImage.

```c
XImage *XGetSubImage (display, d, x, y, width, height, plane_mask, format, dest_image, dest_x, dest_y)
...
```

- **display** Specifies the connection to the XWIN server.
- **d** Specifies the drawable.
Transferring Images between Client and Server

\[ x \]
\[ y \]

Specify the \( x \) and \( y \) coordinates, which are relative to the origin of the drawable and define the upper-left corner of the rectangle.

\[ width \]
\[ height \]

Specify the width and height of the subimage, which define the dimensions of the rectangle.

\[ plane\_mask \]

Specifies the plane mask.

\[ format \]

Specifies the format for the image. You can pass \texttt{XYBitmap}, \texttt{XYPixmap}, or \texttt{ZPixmap}.

\[ dest\_image \]

Specify the destination image.

\[ dest\_x \] \[ dest\_y \]

Specify the \( x \) and \( y \) coordinates, which are relative to the origin of the destination rectangle, specify its upper-left corner, and determine where the subimage is placed in the destination image.

The \texttt{XGetSubImage} function updates \texttt{dest\_image} with the specified subimage in the same manner as \texttt{XGetImage}. If the \texttt{format} argument is \texttt{XYPixmap}, the image contains only the bit planes you passed to the \texttt{plane\_mask} argument. If the \texttt{format} argument is \texttt{ZPixmap}, \texttt{XGetSubImage} returns as zero the bits in all planes not specified in the \texttt{plane\_mask} argument. The function performs no range checking on the values in \texttt{plane\_mask} and ignores extraneous bits. As a convenience, \texttt{XGetSubImage} returns a pointer to the same \texttt{XImage} structure specified by \texttt{dest\_image}.

The depth of the destination \texttt{XImage} structure must be the same as that of the drawable. If the specified subimage does not fit at the specified location on the destination image, the right and bottom edges are clipped. If the drawable is a pixmap, the given rectangle must be wholly contained within the pixmap, or a \texttt{BadMatch} error results. If the drawable is a window, the window must be viewable, and it must be the case that if there were no inferiors or overlapping windows, the specified rectangle of the window would be fully visible on the screen and wholly contained within the outside edges of the window, or a \texttt{BadMatch} error results. If the window has backing-store, then the backing-store contents are returned for regions of the window that are obscured by noninferior windows. If the window does not have backing-store, the returned contents of such obscured regions are undefined. The returned contents of visible
regions of inferiors of a different depth than the specified window’s depth are also undefined.

XGetSubImage can generate BadDrawable, BadGC, BadMatch, and BadValue errors.
Cursors

This section discusses how to:

- Create a cursor
- Change or destroy a cursor
- Define the cursor for a window

Each window can have a different cursor defined for it. Whenever the pointer is in a visible window, it is set to the cursor defined for that window. If no cursor was defined for that window, the cursor is the one defined for the parent window.

From X’s perspective, a cursor consists of a cursor source, mask, colors, and a hotspot. The mask pixmap determines the shape of the cursor and must be a depth of one. The source pixmap must have a depth of one, and the colors determine the colors of the source. The hotspot defines the point on the cursor that is reported when a pointer event occurs. There may be limitations imposed by the hardware on cursors as to size and whether a mask is implemented. XQueryBestCursor can be used to find out what sizes are possible. It is intended that most standard cursors will be stored as a special font.

Creating a Cursor

Xlib provides functions that you can use to create a font, bitmap, or glyph cursor.

To create a cursor from a standard font, use XCreateFontCursor.

```
#include <X11/cursorfont.h>

Cursor XCreateFontCursor(display, shape)
    Display *display;
    unsigned int shape;

display    Specifies the connection to the XWIN server.
shape      Specifies the shape of the cursor.
```
X provides a set of standard cursor shapes in a special font named cursor. Applications are encouraged to use this interface for their cursors because the font can be customized for the individual display type. The shape argument specifies which glyph of the standard fonts to use.

The hotspot comes from the information stored in the cursor font. The initial colors of a cursor are a black foreground and a white background (see XRecolorCursor). For further information about cursor shapes, see appendix B.

XCreateFontCursor can generate BadAlloc and BadValue errors.

To create a cursor from two bitmaps, use XCreatePixmapCursor.

```c
Cursor XCreatePixmapCursor(display, source, mask, foreground_color, background_color, x, y)
```

- **display**: Specifies the connection to the XWIN server.
- **source**: Specifies the shape of the source cursor.
- **mask**: Specifies the cursor's source bits to be displayed or None.
- **foreground_color**: Specifies the RGB values for the foreground of the source.
- **background_color**: Specifies the RGB values for the background of the source.
- **x**, **y**: Specify the x and y coordinates, which indicate the hotspot relative to the source's origin.

The XCreatePixmapCursor function creates a cursor and returns the cursor ID associated with it. The foreground and background RGB values must be specified using foreground_color and background_color, even if the XWIN server only has a StaticGray or GrayScale screen. The foreground color is used for the pixels set to 1 in the source, and the background color is used for the pixels set to 0. Both source and mask, if specified, must have depth one (or a
BadMatch error results) but can have any root. The mask argument defines the shape of the cursor. The pixels set to 1 in the mask define which source pixels are displayed, and the pixels set to 0 define which pixels are ignored. If no mask is given, all pixels of the source are displayed. The mask, if present, must be the same size as the pixmap defined by the source argument, or a BadMatch error results. The hotspot must be a point within the source, or a BadMatch error results.

The components of the cursor can be transformed arbitrarily to meet display limitations. The pixmaps can be freed immediately if no further explicit references to them are to be made. Subsequent drawing in the source or mask pixmap has an undefined effect on the cursor. The XWIN server might or might not make a copy of the pixmap.

XCreatePixmapCursor can generate BadAlloc and BadPixmap errors.

To create a cursor from font glyphs, use XCreateGlyphCursor.

```c
Cursor XCreateGlyphCursor(display, source_font, mask_font, source_char, mask_char,
                           foreground_color, background_color)
```

- `display` Specifies the connection to the XWIN server.
- `source_font` Specifies the font for the source glyph.
- `mask_font` Specifies the font for the mask glyph or None.
- `source_char` Specifies the character glyph for the source.
- `mask_char` Specifies the glyph character for the mask.
- `foreground_color` Specifies the RGB values for the foreground of the source.
- `background_color` Specifies the RGB values for the background of the source.
The XCreateGlyphCursor function is similar to XCreatePixmapCursor except that the source and mask bitmaps are obtained from the specified font glyphs. The source_char must be a defined glyph in source_font, or a BadValue error results. If mask_font is given, mask_char must be a defined glyph in mask_font, or a BadValue error results. The mask_font and character are optional. The origins of the source_char and mask_char (if defined) glyphs are positioned coincidently and define the hotspot. The source_char and mask_char need not have the same bounding box metrics, and there is no restriction on the placement of the hotspot relative to the bounding boxes. If no mask_char is given, all pixels of the source are displayed. You can free the fonts immediately by calling XFreeFont if no further explicit references to them are to be made.

For 2-byte matrix fonts, the 16-bit value should be formed with the bytel member in the most-significant byte and the byte2 member in the least-significant byte.

XCreateGlyphCursor can generate BadAlloc, BadFont, and BadValue errors.

### Changing and Destroying Cursors

Xlib provides functions that you can use to change the cursor color, destroy the cursor, and determine the best cursor size.

To change the color of a given cursor, use XRecolorCursor.

```
XRecolorCursor (display, cursor, foreground_color, background_color)
    Display *display;
    Cursor cursor;
    XColor *foreground_color, *background_color;
```

display Specifies the connection to the XWIN server.
cursor Specifies the cursor.
foreground_color Specifies the RGB values for the foreground of the source.
background_color Specifies the RGB values for the background of the source.
The `XRecolorCursor` function changes the color of the specified cursor, and if the cursor is being displayed on a screen, the change is visible immediately.

`XRecolorCursor` can generate a BadCursor error.

To free (destroy) a given cursor, use `XFreeCursor`.

```c
XFreeCursor(display, cursor)
Display *display;
Cursor cursor;
```

- `display`: Specifies the connection to the XWIN server.
- `cursor`: Specifies the cursor.

The `XFreeCursor` function deletes the association between the cursor resource ID and the specified cursor. The cursor storage is freed when no other resource references it. The specified cursor ID should not be referred to again.

`XFreeCursor` can generate a BadCursor error.

To determine useful cursor sizes, use `XQueryBestCursor`.

```c
Status XQueryBestCursor(display, d, width, height, width_return, height_return)
Display *display;
Drawable d;
unsigned int width, height;
unsigned int *width_return, *height_return;
```

- `display`: Specifies the connection to the XWIN server.
- `d`: Specifies the drawable, which indicates the screen.
- `width`: Specify the width and height of the cursor that you want the size information for.
- `height`: Specify the width and height of the cursor that you want the size information for.
- `width_return`: Return the best width and height that is closest to the specified width and height.
- `height_return`: Return the best width and height that is closest to the specified width and height.

Some displays allow larger cursors than other displays. The `XQueryBestCursor` function provides a way to find out what size cursors are actually possible on the display.
It returns the largest size that can be displayed. Applications should be prepared to use smaller cursors on displays that cannot support large ones. 

XQueryBestCursor can generate a BadDrawable error.

Defining the Cursor

Xlib provides functions that you can use to define or undefine the cursor that should be displayed in a window.

To define which cursor will be used in a window, use XDefineCursor.

XDefineCursor(display, w, cursor)

Display *display;
Window w;
Cursor cursor;

display Specifies the connection to the XWIN server.
w Specifies the window.
cursor Specifies the cursor that is to be displayed or None.

If a cursor is set, it will be used when the pointer is in the window. If the cursor is None, it is equivalent to XUndefineCursor.

XDefineCursor can generate BadCursor and BadWindow errors.

To undefine the cursor in a given window, use XUndefineCursor.

XUndefineCursor(display, w)

Display *display;
Window w;

display Specifies the connection to the XWIN server.
w Specifies the window.
The `XUndefineCursor` undoes the effect of a previous `XDefineCursor` for this window. When the pointer is in the window, the parent's cursor will now be used. On the root window, the default cursor is restored.

`XUndefineCursor` can generate a `BadWindow` error.
7 Window Manager Functions

Introduction 7-1

Changing the Parent of a Window 7-2

Controlling the Lifetime of a Window 7-4

Determining Resident Colormaps 7-6

Pointer Grabbing 7-8

Keyboard Grabbing 7-16

Server Grabbing 7-24

Miscellaneous Control Functions 7-25
  Controlling Input Focus 7-25
  Killing Clients 7-28

Introduction

Although it is difficult to categorize functions as application only or window manager only, the functions in this chapter are most often used by window managers. It is not expected that these functions will be used by most application programs. You can use the Xlib window manager functions to:

- Change the parent of a window
- Control the lifetime of a window
- Determine resident colormaps
- Grab the pointer
- Grab the keyboard
- Grab the server
- Control event processing
- Manipulate the keyboard and pointer settings
- Control the screen saver
- Control host access
Changing the Parent of a Window

To change a window’s parent to another window on the same screen, use XReparentWindow. There is no way to move a window between screens.

\[
\text{XReparentWindow}(\text{display}, \ w, \ \text{parent}, \ x, \ y)
\]

\[
\begin{align*}
\text{Display *display;} \\
\text{Window w;} \\
\text{Window parent;} \\
\text{int x, y;}
\end{align*}
\]

\[
\begin{align*}
\text{display} & \quad \text{Specifies the connection to the XWIN server.} \\
\text{w} & \quad \text{Specifies the window.} \\
\text{parent} & \quad \text{Specifies the parent window.} \\
x & \quad \text{Specify the x and y coordinates of the position in the new parent window.}
\end{align*}
\]

If the specified window is mapped, XReparentWindow automatically performs an UnmapWindow request on it, removes it from its current position in the hierarchy, and inserts it as the child of the specified parent. The window is placed in the stacking order on top with respect to sibling windows.

After reparenting the specified window, XReparentWindow causes the XWIN server to generate a ReparentNotify event. The override_redirect member returned in this event is set to the window’s corresponding attribute. Window manager clients usually should ignore this window if this member is set to True. Finally, if the specified window was originally mapped, the XWIN server automatically performs a MapWindow request on it.

The XWIN server performs normal exposure processing on formerly obscured windows. The XWIN server might not generate Expose events for regions from the initial UnmapWindow request that are immediately obscured by the final MapWindow request. A BadMatch error results if:

- The new parent window is not on the same screen as the old parent window.
- The new parent window is the specified window or an inferior of the specified window.
Changing the Parent of a Window

- The specified window has a ParentRelative background, and the new parent window is not the same depth as the specified window.

XReparentWindow can generate BadMatch and BadWindow errors.
Controlling the Lifetime of a Window

The save-set of a client is a list of other clients’ windows that, if they are inferiors of one of the client’s windows at connection close, should not be destroyed and should be remapped if they are unmapped. For further information about close-connection processing, see "X Server Connection Close Operations" in Chapter 2. To allow an application’s window to survive when a window manager that has reparented a window fails, Xlib provides the save-set functions that you can use to control the longevity of subwindows that are normally destroyed when the parent is destroyed. For example, a window manager that wants to add decoration to a window by adding a frame might reparent an application’s window. When the frame is destroyed, the application’s window should not be destroyed but be returned to its previous place in the window hierarchy.

The XWIN server automatically removes windows from the save-set when they are destroyed.

To add or remove a window from the client’s save-set, use XChangeSaveSet.

\[
\text{XChangeSaveSet (display, w, change\_mode)}
\]
\[
\text{Display *display;}
\]
\[
\text{Window w;}
\]
\[
\text{int change\_mode;}
\]

- **display**: Specifies the connection to the XWIN server.
- **w**: Specifies the window that you want to add to or delete from the client’s save-set.
- **change\_mode**: Specifies the mode. You can pass SetModeInsert or SetModeDelete.

Depending on the specified mode, XChangeSaveSet either inserts or deletes the specified window from the client’s save-set. The specified window must have been created by some other client, or a BadMatch error results.

XChangeSaveSet can generate BadMatch, BadValue, and BadWindow errors.

To add a window to the client’s save-set, use XAddToSaveSet.

\[
\text{XAddToSaveSet (display, w)}
\]
\[
\text{Display *display;}
\]
\[
\text{Window w;}
\]
Controlling the Lifetime of a Window

display Specifies the connection to the XWIN server.

w Specifies the window that you want to add to the client’s save-set.

The XAddToSaveSet function adds the specified window to the client’s save-set. The specified window must have been created by some other client, or a BadMatch error results.

XAddToSaveSet can generate BadMatch and BadWindow errors.

To remove a window from the client’s save-set, use XRemoveFromSaveSet.

XRemoveFromSaveSet (display, w)
Display *display;
Window w;

display Specifies the connection to the XWIN server.

w Specifies the window that you want to delete from the client’s save-set.

The XRemoveFromSaveSet function removes the specified window from the client’s save-set. The specified window must have been created by some other client, or a BadMatch error results.

XRemoveFromSaveSet can generate BadMatch and BadWindow errors.
Determining Resident Colormaps

Xlib provides functions that you can use to install a colormap, uninstall a colormap, and obtain a list of installed colormaps.

At any time, there is a subset of the installed maps that is viewed as an ordered list and is called the required list. The length of the required list is at most $M$, where $M$ is the minimum number of installed colormaps specified for the screen in the connection setup. The required list is maintained as follows. When a colormap is specified to `XInstallColormap`, it is added to the head of the list; the list is truncated at the tail, if necessary, to keep its length to at most $M$. When a colormap is specified to `XUninstallColormap` and it is in the required list, it is removed from the list. A colormap is not added to the required list when it is implicitly installed by the XWIN server, and the XWIN server cannot implicitly uninstall a colormap that is in the required list.

To install a colormap, use `XInstallColormap`.

```
XInstallColormap (display, colormap)
  Display *display;
  Colormap colormap;
```

- `display` specifies the connection to the XWIN server.
- `colormap` specifies the colormap.

The `XInstallColormap` function installs the specified colormap for its associated screen. All windows associated with this colormap immediately display with true colors. You associated the windows with this colormap when you created them by calling `XCreateWindow`, `XCreateSimpleWindow`, `XChangeWindowAttributes`, or `XSetWindowColormap`.

If the specified colormap is not already an installed colormap, the XWIN server generates a `ColormapNotify` event on each window that has that colormap. In addition, for every other colormap that is installed as a result of a call to `XInstallColormap`, the XWIN server generates a `ColormapNotify` event on each window that has that colormap.

`XInstallColormap` can generate a `BadColor` error.

To uninstall a colormap, use `XUninstallColormap`.

XUninstallColormap(display, colormap)

Display *display;
Colormap colormap;

display Specifies the connection to the XWIN server.
colormap Specifies the colormap.

The XUninstallColormap function removes the specified colormap from the required list for its screen. As a result, the specified colormap might be uninstalled, and the XWIN server might implicitly install or uninstall additional colormaps. Which colormaps get installed or uninstalled is server-dependent except that the required list must remain installed.

If the specified colormap becomes uninstalled, the XWIN server generates a ColormapNotify event on each window that has that colormap. In addition, for every other colormap that is installed or uninstalled as a result of a call to XUninstallColormap, the XWIN server generates a ColormapNotify event on each window that has that colormap.

XUninstallColormap can generate a BadColor error.

To obtain a list of the currently installed colormaps for a given screen, use XListInstalledColormaps.

Colormap *XListInstalledColormaps(display, w, num_return)

Display *display;
Window w;
int *num_return;

display Specifies the connection to the XWIN server.
w Specifies the window that determines the screen.
num_return Returns the number of currently installed colormaps.

The XListInstalledColormaps function returns a list of the currently installed colormaps for the screen of the specified window. The order of the colormaps in the list is not significant and is no explicit indication of the required list. When the allocated list is no longer needed, free it by using XFree.

XListInstalledColormaps can generate a BadWindow error.
Pointer Grabbing

Xlib provides functions that you can use to control input from the pointer, which usually is a mouse. Window managers most often use these facilities to implement certain styles of user interfaces. Some toolkits also need to use these facilities for special purposes.

Usually, as soon as keyboard and mouse events occur, the XWIN server delivers them to the appropriate client, which is determined by the window and input focus. The XWIN server provides sufficient control over event delivery to allow window managers to support mouse ahead and various other styles of user interface. Many of these user interfaces depend upon synchronous delivery of events. The delivery of pointer and keyboard events can be controlled independently.

When mouse buttons or keyboard keys are grabbed, events will be sent to the grabbing client rather than the normal client who would have received the event. If the keyboard or pointer is in asynchronous mode, further mouse and keyboard events will continue to be processed. If the keyboard or pointer is in synchronous mode, no further events are processed until the grabbing client allows them (see XAllowEvents). The keyboard or pointer is considered frozen during this interval. The event that triggered the grab can also be replayed.

Note that the logical state of a device (as seen by client applications) may lag the physical state if device event processing is frozen.

There are two kinds of grabs: active and passive. An active grab occurs when a single client grabs the keyboard and/or pointer explicitly (see XGrabPointer and XGrabKeyboard). A passive grab occurs when clients grab a particular keyboard key or pointer button in a window, and the grab will activate when the key or button is actually pressed. Passive grabs are convenient for implementing reliable pop-up menus. For example, you can guarantee that the pop-up is mapped before the up pointer button event occurs by grabbing a button requesting synchronous behavior. The down event will trigger the grab and freeze further processing of pointer events until you have the chance to map the pop-up window. You can then allow further event processing. The up event will then be correctly processed relative to the pop-up window.

For many operations, there are functions that take a time argument. The XWIN server includes a timestamp in various events. One special time, called CurrentTime, represents the current server time. The XWIN server maintains the time when the input focus was last changed, when the keyboard was last grabbed, when the pointer was last grabbed, or when a selection was last changed. Your application may be slow reacting to an event. You often need
some way to specify that your request should not occur if another application has in the meanwhile taken control of the keyboard, pointer, or selection. By providing the timestamp from the event in the request, you can arrange that the operation not take effect if someone else has performed an operation in the meanwhile.

A timestamp is a time value, expressed in milliseconds. It typically is the time since the last server reset. Timestamp values wrap around (after about 49.7 days). The server, given its current time is represented by timestamp $T$, always interprets timestamps from clients by treating half of the timestamp space as being later in time than $T$. One timestamp value, named `currentTime`, is never generated by the server. This value is reserved for use in requests to represent the current server time.

For many functions in this section, you pass pointer event mask bits. The valid pointer event mask bits are: `ButtonPressMask`, `ButtonReleaseMask`, `EnterWindowMask`, `LeaveWindowMask`, `PointerMotionMask`, `PointerMotionHintMask`, `Button1MotionMask`, `Button2MotionMask`, `Button3MotionMask`, `Button4MotionMask`, `Button5MotionMask`, `ButtonMotionMask`, and `KeyMapStateMask`. For other functions in this section, you pass keymask bits. The valid keymask bits are: `ShiftMask`, `LockMask`, `ControlMask`, `Mod1Mask`, `Mod2Mask`, `Mod3Mask`, `Mod4Mask`, and `Mod5Mask`.

To grab the pointer, use `XGrabPointer`.

```c
int XGrabPointer (display, grab_window, owner_events, event_mask, pointer_mode,
                  keyboard_mode, confine_to, cursor, time)

Display *display;
Window grab_window;
Bool owner_events;
unsigned int event_mask;
int pointer_mode, keyboard_mode;
Window confine_to;
Cursor cursor;
Time time;
```

`display` specifies the connection to the XWIN server.
**Pointer Grabbing**

- **grab_window** Specifies the grab window.

- **owner_events** Specifies a Boolean value that indicates whether the pointer events are to be reported as usual or reported with respect to the grab window if selected by the event mask.

- **event_mask** Specifies which pointer events are reported to the client. The mask is the bitwise inclusive OR of the valid pointer event mask bits.

- **pointer_mode** Specifies further processing of pointer events. You can pass `GrabModeSync` or `GrabModeAsync`.

- **keyboard_mode** Specifies further processing of keyboard events. You can pass `GrabModeSync` or `GrabModeAsync`.

- **confine_to** Specifies the window to confine the pointer in or `None`.

- **cursor** Specifies the cursor that is to be displayed during the grab or `None`.

- **time** Specifies the time. You can pass either a timestamp or `CurrentTime`.

The `XGrabPointer` function actively grabs control of the pointer and returns `GrabSuccess` if the grab was successful. Further pointer events are reported only to the grabbing client. `XGrabPointer` overrides any active pointer grab by this client. If `owner_events` is `False`, all generated pointer events are reported with respect to `grab_window` and are reported only if selected by `event_mask`. If `owner_events` is `True` and if a generated pointer event would normally be reported to this client, it is reported as usual. Otherwise, the event is reported with respect to the `grab_window` and is reported only if selected by `event_mask`. For either value of `owner_events`, unreported events are discarded.

If the `pointer_mode` is `GrabModeAsync`, pointer event processing continues as usual. If the pointer is currently frozen by this client, the processing of events for the pointer is resumed. If the `pointer_mode` is `GrabModeSync`, the state of the pointer, as seen by client applications, appears to freeze, and the XWIN server generates no further pointer events until the grabbing client calls `XAllowEvents` or until the pointer grab is released. Actual pointer changes are not lost while the pointer is frozen; they are simply queued in the server for later processing.
If the keyboard_mode is `GrabModeAsync`, keyboard event processing is unaffected by activation of the grab. If the keyboard_mode is `GrabModeSync`, the state of the keyboard, as seen by client applications, appears to freeze, and the XWIN server generates no further keyboard events until the grabbing client calls `XAllowEvents` or until the pointer grab is released. Actual keyboard changes are not lost while the pointer is frozen; they are simply queued in the server for later processing.

If a cursor is specified, it is displayed regardless of what window the pointer is in. If `None` is specified, the normal cursor for that window is displayed when the pointer is in grab_window or one of its subwindows; otherwise, the cursor for grab_window is displayed.

If a confine_to window is specified, the pointer is restricted to stay contained in that window. The confine_to window need have no relationship to the grab_window. If the pointer is not initially in the confine_to window, it is warped automatically to the closest edge just before the grab activates and enter/leave events are generated as usual. If the confine_to window is subsequently reconfigured, the pointer is warped automatically, as necessary, to keep it contained in the window.

The time argument allows you to avoid certain circumstances that come up if applications take a long time to respond or if there are long network delays. Consider a situation where you have two applications, both of which normally grab the pointer when clicked on. If both applications specify the timestamp from the event, the second application may wake up faster and successfully grab the pointer before the first application. The first application then will get an indication that the other application grabbed the pointer before its request was processed.

`XGrabPointer` generates `EnterNotify` and `LeaveNotify` events.

Either if grab_window or confine_to_window is not viewable or if the confine_to_window lies completely outside the boundaries of the root window, `XGrabPointer` fails and returns `GrabNotViewable`. If the pointer is actively grabbed by some other client, it fails and returns `AlreadyGrabbed`. If the pointer is frozen by an active grab of another client, it fails and returns `GrabFrozen`. If the specified time is earlier than the last-pointer-grab time or later than the current XWIN server time, it fails and returns `GrabInvalidTime`. Otherwise, the last-pointer-grab time is set to the specified time (`CurrentTime` is replaced by the current XWIN server time).
Pointer Grabbing

XGrabPointer can generate BadCursor, BadValue, and BadWindow errors.

To ungrab the pointer, use XUngrabPointer.

```
XUngrabPointer (display, time)
    Display *display;
    Time time;

display       Specifies the connection to the XWIN server.
time          Specifies the time. You can pass either a timestamp or Current-Time.
```

The XUngrabPointer function releases the pointer and any queued events if this client has actively grabbed the pointer from XGrabPointer, XGrabButton, or from a normal button press. XUngrabPointer does not release the pointer if the specified time is earlier than the last-pointer-grab time or is later than the current XWIN server time. It also generates EnterNotify and LeaveNotify events. The XWIN server performs an UngrabPointer request automatically if the event window or confine_to window for an active pointer grab becomes not viewable or if window reconfiguration causes the confine_to window to lie completely outside the boundaries of the root window.

To change an active pointer grab, use XChangeActivePointerGrab.

```
XChangeActivePointerGrab (display, event_mask, cursor, time)
    Display *display;
    unsigned int event_mask;
    Cursor cursor;
    Time time;

display       Specifies the connection to the XWIN server.
event_mask     Specifies which pointer events are reported to the client. The mask is the bitwise inclusive OR of the valid pointer event mask bits.
```
cursor Specifies the cursor that is to be displayed or None.

time Specifies the time. You can pass either a timestamp or Current-Time.

The XChangeActivePointerGrab function changes the specified dynamic parameters if the pointer is actively grabbed by the client and if the specified time is no earlier than the last-pointer-grab time and no later than the current XWIN server time. This function has no effect on the passive parameters of a XGrabButton. The interpretation of event_mask and cursor is the same as described in XGrabPointer.

XChangeActivePointerGrab can generate BadCursor and BadValue errors.

To grab a pointer button, use XGrabButton.

XGrabButton (display, button, modifiers, grab_window, owner_events, event_mask,
pointer_mode, keyboard_mode, confine_to, cursor)

Display *display;
unsigned int button;
unsigned int modifiers;
Window grab_window;
Bool owner_events;
unsigned int event_mask;
int pointer_mode, keyboard_mode;
Window confine_to;
Cursor cursor;

display Specifies the connection to the XWIN server.
button Specifies the pointer button that is to be grabbed or AnyButton.
modifiers Specifies the set of keymasks or AnyModifier. The mask is the bitwise inclusive OR of the valid keymask bits.
grab_window Specifies the grab window.
owner_events Specifies a Boolean value that indicates whether the pointer events are to be reported as usual or reported with respect to the grab window if selected by the event mask.
event_mask  Specifies which pointer events are reported to the client. The mask is the bitwise inclusive OR of the valid pointer event mask bits.

pointer_mode  Specifies further processing of pointer events. You can pass GrabModeSync or GrabModeAsync.

keyboard_mode  Specifies further processing of keyboard events. You can pass GrabModeSync or GrabModeAsync.

confine_to  Specifies the window to confine the pointer in or None.

cursor  Specifies the cursor that is to be displayed or None.

The XGrabButton function establishes a passive grab. In the future, the pointer is actively grabbed (as for XGrabPointer), the last-pointer-grab time is set to the time at which the button was pressed (as transmitted in the ButtonPress event), and the ButtonPress event is reported if all of the following conditions are true:

- The pointer is not grabbed, and the specified button is logically pressed when the specified modifier keys are logically down, and no other buttons or modifier keys are logically down.
- The grab_window contains the pointer.
- The confine_to window (if any) is viewable.
- A passive grab on the same button/key combination does not exist on any ancestor of grab_window.

The interpretation of the remaining arguments is as for XGrabPointer. The active grab is terminated automatically when the logical state of the pointer has all buttons released (independent of the state of the logical modifier keys).

Note that the logical state of a device (as seen by client applications) may lag the physical state if device event processing is frozen.

This request overrides all previous grabs by the same client on the same button/key combinations on the same window. A modifiers of AnyModifier is equivalent to issuing the grab request for all possible modifier combinations (including the combination of no modifiers). It is not required that all modifiers specified have currently assigned KeyCodes. A button of AnyButton is equivalent to issuing the request for all possible buttons. Otherwise, it is not required that the specified button currently be assigned to a physical button.
If some other client has already issued a XGrabButton with the same button/key combination on the same window, a BadAccess error results. When using AnyModifier or AnyButton, the request fails completely, and a BadAccess error results (no grabs are established) if there is a conflicting grab for any combination. XGrabButton has no effect on an active grab.

XGrabButton can generate BadCursor, BadValue, and BadWindow errors.

To ungrab a pointer button, use XUngrabButton.

\[
\text{XUngrabButton (display, button, modifiers, grab\_window)}
\]

Display *display;
unsigned int button;
unsigned int modifiers;
Window grab_window;

- **display**: Specifies the connection to the XWIN server.
- **button**: Specifies the pointer button that is to be released or AnyButton.
- **modifiers**: Specifies the set of keymasks or AnyModifier. The mask is the bitwise inclusive OR of the valid keymask bits.
- **grab_window**: Specifies the grab window.

The XUngrabButton function releases the passive button/key combination on the specified window if it was grabbed by this client. A modifiers of AnyModifier is equivalent to issuing the ungrab request for all possible modifier combinations, including the combination of no modifiers. A button of AnyButton is equivalent to issuing the request for all possible buttons. XUngrabButton has no effect on an active grab.

XUngrabButton can generate BadValue and BadWindow errors.
Keyboard Grabbing

Xlib provides functions that you can use to grab or ungrab the keyboard as well as allow events.

For many functions in this section, you pass keymask bits. The valid keymask bits are: ShiftMask, LockMask, ControlMask, Mod1Mask, Mod2Mask, Mod3Mask, Mod4Mask, and Mod5Mask.

To grab the keyboard, use XGrabKeyboard.

```c
int XGrabKeyboard (display, grab_window, owner_events, pointer_mode, keyboard_mode, time)

Display *display;
Window grab_window;
Bool owner_events;
int pointer_mode, keyboard_mode;
Time time;
```

display Specifies the connection to the XWIN server.

grab_window Specifies the grab window.

owner_events Specifies a Boolean value that indicates whether the pointer events are to be reported as usual or reported with respect to the grab window if selected by the event mask.

pointer_mode Specifies further processing of pointer events. You can pass GrabModeSync or GrabModeAsync.

keyboard_mode Specifies further processing of keyboard events. You can pass GrabModeSync or GrabModeAsync.

time Specifies the time. You can pass either a timestamp or CurrentTime.

The XGrabKeyboard function actively grabs control of the keyboard and generates FocusIn and FocusOut events. Further key events are reported only to the grabbing client. XGrabKeyboard overrides any active keyboard grab by this client. If owner_events is False, all generated key events are reported with respect to grab_window. If owner_events is True and if a generated key event would normally be reported to this client, it is reported normally; otherwise, the event is reported with respect to the grab_window. Both KeyPress and KeyRelease events are always reported, independent of any event selection made by the client.
Keyboard Grabbing

If the keyboard_mode argument is GrabModeAsync, keyboard event processing continues as usual. If the keyboard is currently frozen by this client, then processing of keyboard events is resumed. If the keyboard_mode argument is GrabModeSync, the state of the keyboard (as seen by client applications) appears to freeze, and the XWIN server generates no further keyboard events until the grabbing client issues a releasing XAllowEvents call or until the keyboard grab is released. Actual keyboard changes are not lost while the keyboard is frozen; they are simply queued in the server for later processing.

If pointer_mode is GrabModeAsync, pointer event processing is unaffected by activation of the grab. If pointer_mode is GrabModeSync, the state of the pointer (as seen by client applications) appears to freeze, and the XWIN server generates no further pointer events until the grabbing client issues a releasing XAllowEvents call or until the keyboard grab is released. Actual pointer changes are not lost while the pointer is frozen; they are simply queued in the server for later processing.

If the keyboard is actively grabbed by some other client, XGrabKeyboard fails and returns AlreadyGrabbed. If grab_window is not viewable, it fails and returns GrabNotViewable. If the keyboard is frozen by an active grab of another client, it fails and returns GrabFrozen. If the specified time is earlier than the last-keyboard-grab time or later than the current XWIN server time, it fails and returns GrabInvalidTime. Otherwise, the last-keyboard-grab time is set to the specified time (CurrentTime is replaced by the current XWIN server time).

XGrabKeyboard can generate BadValue and BadWindow errors.

To ungrab the keyboard, use XUngrabKeyboard.

```c
XUngrabKeyboard (display, time)
    Display *display;
    Time time;
```

display Specifies the connection to the XWIN server.
time Specifies the time. You can pass either a timestamp or CurrentTime.

The XUngrabKeyboard function releases the keyboard and any queued events if this client has it actively grabbed from either XGrabKeyboard or XGrabKey. XUngrabKeyboard does not release the keyboard and any queued events if the specified time is earlier than the last-keyboard-grab time or is later than the

Window Manager Functions
current XWIN server time. It also generates FocusIn and FocusOut events. The XWIN server automatically performs an UngrabKeyboard request if the event window for an active keyboard grab becomes not viewable.

To passively grab a single key of the keyboard, use XGrabKey.

\[
X\text{GrabKey}(\text{display, keycode, modifiers, grab\_window, owner\_events, pointer\_mode, keyboard\_mode})
\]

Display *display;
int keycode;
unsigned int modifiers;
Window grab_window;
Bool owner_events;
int pointer_mode, keyboard_mode;

- **display** Specifies the connection to the XWIN server.
- **keycode** Specifies the KeyCode or AnyKey.
- **modifiers** Specifies the set of keymasks or AnyModifier. The mask is the bitwise inclusive OR of the valid keymask bits.
- **grab_window** Specifies the grab window.
- **owner_events** Specifies a Boolean value that indicates whether the pointer events are to be reported as usual or reported with respect to the grab window if selected by the event mask.
- **pointer_mode** Specifies further processing of pointer events. You can pass GrabModeSync or GrabModeAsync.
- **keyboard_mode** Specifies further processing of keyboard events. You can pass GrabModeSync or GrabModeAsync.

The XGrabKey function establishes a passive grab on the keyboard. In the future, the keyboard is actively grabbed (as for XGrabKeyboard), the last-keyboard-grab time is set to the time at which the key was pressed (as transmitted in the KeyPress event), and the KeyPress event is reported if all of the following conditions are true:

- The keyboard is not grabbed and the specified key (which can itself be a modifier key) is logically pressed when the specified modifier keys are logically down, and no other modifier keys are logically down.
Either the grab_window is an ancestor of (or is) the focus window, or the
grab_window is a descendant of the focus window and contains the
pointer.

A passive grab on the same key combination does not exist on any ances-
tor of grab_window.

The interpretation of the remaining arguments is as for XGrabKeyboard. The
active grab is terminated automatically when the logical state of the keyboard
has the specified key released (independent of the logical state of the modifier
keys).

Note that the logical state of a device (as seen by client applications) may lag
the physical state if device event processing is frozen.

A modifiers argument of AnyModifier is equivalent to issuing the request for
all possible modifier combinations (including the combination of no modifiers).
It is not required that all modifiers specified have currently assigned KeyCodes.
A keycode argument of AnyKey is equivalent to issuing the request for all possi-
ble KeyCodes. Otherwise, the specified keycode must be in the range specified
by min_keycode and max_keycode in the connection setup, or a BadValue error
results.

If some other client has issued a XGrabKey with the same key combination on
the same window, a BadAccess error results. When using AnyModifier or
AnyKey, the request fails completely, and a BadAccess error results (no grabs
are established) if there is a conflicting grab for any combination.

XGrabKey can generate BadAccess, BadValue, and BadWindow errors.

To ungrab a key, use XUngrabKey.

XUngrabKey (display, keycode, modifiers, grab_window)
    Display *display;
    int keycode;
    unsigned int modifiers;
    Window grab_window;

display          Specifies the connection to the XWIN server.
Keyboard Grabbing

`keycode` Specifies the KeyCode or AnyKey.

`modifiers` Specifies the set of keymasks or AnyModifier. The mask is the bitwise inclusive OR of the valid keymask bits.

`grab_window` Specifies the grab window.

The `XUngrabKey` function releases the key combination on the specified window if it was grabbed by this client. It has no effect on an active grab. A modifiers of AnyModifier is equivalent to issuing the request for all possible modifier combinations (including the combination of no modifiers). A keycode argument of AnyKey is equivalent to issuing the request for all possible key codes.

`XUngrabKey` can generate BadValue and BadWindow errors.

To allow further events to be processed when the device has been frozen, use `XAllowEvents`.

```c
XAllowEvents (display, event_mode, time)
    Display *display;
    int event_mode;
    Time time;
```

`display` Specifies the connection to the XWIN server.

`event_mode` Specifies the event mode. You can pass AsyncPointer, SyncPointer, AsyncKeyboard, SyncKeyboard, ReplayPointer, ReplayKeyboard, AsyncBoth, or SyncBoth.

`time` Specifies the time. You can pass either a timestamp or Current-Time.

The `XAllowEvents` function releases some queued events if the client has caused a device to freeze. It has no effect if the specified time is earlier than the last-grab time of the most recent active grab for the client or if the specified time is later than the current XWIN server time. Depending on the event_mode argument, the following occurs:
AsyncPointer | If the pointer is frozen by the client, pointer event processing continues as usual. If the pointer is frozen twice by the client on behalf of two separate grabs, AsyncPointer thaws for both. AsyncPointer has no effect if the pointer is not frozen by the client, but the pointer need not be grabbed by the client.

SyncPointer | If the pointer is frozen and actively grabbed by the client, pointer event processing continues as usual until the next ButtonPress or ButtonRelease event is reported to the client. At this time, the pointer again appears to freeze. However, if the reported event causes the pointer grab to be released, the pointer does not freeze. SyncPointer has no effect if the pointer is not frozen by the client or if the pointer is not grabbed by the client.

ReplayPointer | If the pointer is actively grabbed by the client and is frozen as the result of an event having been sent to the client (either from the activation of a XGrabButton or from a previous XAllowEvents with mode SyncPointer but not from a XGrabPointer), the pointer grab is released and that event is completely reprocessed. This time, however, the function ignores any passive grabs at or above (towards the root of) the grab_window of the grab just released. The request has no effect if the pointer is not grabbed by the client or if the pointer is not frozen as the result of an event.

AsyncKeyboard | If the keyboard is frozen by the client, keyboard event processing continues as usual. If the keyboard is frozen twice by the client on behalf of two separate grabs, AsyncKeyboard thaws for both. AsyncKeyboard has no effect if the keyboard is not frozen by the client, but the keyboard need not be grabbed by the client.

SyncKeyboard | If the keyboard is frozen and actively grabbed by the client, keyboard event processing continues as usual
Keyboard Grabbing

until the next KeyPress or KeyRelease event is reported to the client. At this time, the keyboard again appears to freeze. However, if the reported event causes the keyboard grab to be released, the keyboard does not freeze. SyncKeyboard has no effect if the keyboard is not frozen by the client or if the keyboard is not grabbed by the client.

ReplayKeyboard

If the keyboard is actively grabbed by the client and is frozen as the result of an event having been sent to the client (either from the activation of a XGrabKey or from a previous XAllowEvents with mode SyncKeyboard but not from a XGrabKeyboard), the keyboard grab is released and that event is completely reprocessed. This time, however, the function ignores any passive grabs at or above (towards the root of) the grab_window of the grab just released. The request has no effect if the keyboard is not grabbed by the client or if the keyboard is not frozen as the result of an event.

SyncBoth

If both pointer and keyboard are frozen by the client, event processing for both devices continues as usual until the next ButtonPress, ButtonRelease, KeyPress, or KeyRelease event is reported to the client for a grabbed device (button event for the pointer, key event for the keyboard), at which time the devices again appear to freeze. However, if the reported event causes the grab to be released, then the devices do not freeze (but if the other device is still grabbed, then a subsequent event for it will still cause both devices to freeze). SyncBoth has no effect unless both pointer and keyboard are frozen by the client. If the pointer or keyboard is frozen twice by the client on behalf of two separate grabs, SyncBoth thaws for both (but a subsequent freeze for SyncBoth will only freeze each device once).

AsyncBoth

If the pointer and the keyboard are frozen by the client, event processing for both devices continues as
usual. If a device is frozen twice by the client on behalf of two separate grabs, AsyncBoth thaws for both. AsyncBoth has no effect unless both pointer and keyboard are frozen by the client.

AsyncPointer, SyncPointer, and ReplayPointer have no effect on the processing of keyboard events. AsyncKeyboard, SyncKeyboard, and ReplayKeyboard have no effect on the processing of pointer events. It is possible for both a pointer grab and a keyboard grab (by the same or different clients) to be active simultaneously. If a device is frozen on behalf of either grab, no event processing is performed for the device. It is possible for a single device to be frozen because of both grabs. In this case, the freeze must be released on behalf of both grabs before events can again be processed.

XAllowEvents can generate a BadValue error.
Server Grabbing

Xlib provides functions that you can use to grab and ungrab the server. These functions can be used to control processing of output on other connections by the window system server. While the server is grabbed, no processing of requests or close downs on any other connection will occur. A client closing its connection automatically ungrabs the server.

Although grabbing the server is highly discouraged, it is sometimes necessary.

To grab the server, use **XGrabServer**.

\[
\text{XGrabServer(} \text{display} \text{)}
\]
\[
\text{Display *display;}
\]

*display* Specifies the connection to the XWIN server.

The **XGrabServer** function disables processing of requests and close downs on all other connections than the one this request arrived on. You should not grab the XWIN server any more than is absolutely necessary.

To ungrab the server, use **XUngrabServer**.

\[
\text{XUngrabServer(} \text{display} \text{)}
\]
\[
\text{Display *display;}
\]

*display* Specifies the connection to the XWIN server.

The **XUngrabServer** function restarts processing of requests and close downs on other connections. You should avoid grabbing the XWIN server as much as possible.
Miscellaneous Control Functions

This section discusses how to:

- Control the input focus
- Control the pointer
- Kill clients

Controlling Input Focus

Xlib provides functions that you can use to move the pointer position as well as to set and get the input focus.

To move the pointer to an arbitrary point on the screen, use `XWarpPointer`.

```c
XWarpPointer (display, src_w, dest_w, src_x, src_y, src_width, src_height, dest_x,
               dest_y)

Display *display;
Window src_w, dest_w;
int src_x, src_y;
unsigned int src_width, src_height;
int dest_x, dest_y;
```

- `display` Specifies the connection to the XWIN server.
- `src_w` Specifies the source window or `None`.
- `dest_w` Specifies the destination window or `None`.
- `src_x`  
- `src_y`  
- `src_width`  
- `src_height` Specify a rectangle in the source window.
- `dest_x`  
- `dest_y` Specify the x and y coordinates within the destination window.

If `dest_w` is `None`, `XWarpPointer` moves the pointer by the offsets `(dest_x, dest_y)` relative to the current position of the pointer. If `dest_w` is a window, `XWarpPointer` moves the pointer to the offsets `(dest_x, dest_y)` relative to the origin of `dest_w`. However, if `src_w` is a window, the move only takes place if the specified rectangle `src_w` contains the pointer.
The src\_x and src\_y coordinates are relative to the origin of src\_w. If src\_height is zero, it is replaced with the current height of src\_w minus src\_y. If src\_width is zero, it is replaced with the current width of src\_w minus src\_x.

There is seldom any reason for calling this function. The pointer should normally be left to the user. If you do use this function, however, it generates events just as if the user had instantaneously moved the pointer from one position to another. Note that you cannot use XWarpPointer to move the pointer outside the confine\_to window of an active pointer grab. An attempt to do so will only move the pointer as far as the closest edge of the confine\_to window.

XWarpPointer can generate a BadWindow error.

To set the input focus, use XSetInputFocus.

\begin{verbatim}
XSetInputFocus (display, focus, revert\_to, time)
    Display *display;
    Window focus;
    int revert\_to;
    Time time;
\end{verbatim}

- \texttt{display} Specifies the connection to the XWIN server.
- \texttt{focus} Specifies the window, PointerRoot, or None.
- \texttt{revert\_to} Specifies where the input focus reverts to if the window becomes not viewable. You can pass RevertToParent, RevertToPointerRoot, or RevertToNone.
- \texttt{time} Specifies the time. You can pass either a timestamp or CurrentTime.

The XSetInputFocus function changes the input focus and the last-focus-change time. It has no effect if the specified time is earlier than the current last-focus-change time or is later than the current XWIN server time. Otherwise, the last-focus-change time is set to the specified time (CurrentTime is replaced by the current XWIN server time). XSetInputFocus causes the XWIN server to generate FocusIn and FocusOut events.

Depending on the focus argument, the following occurs:
If focus is None, all keyboard events are discarded until a new focus window is set, and the revert_to argument is ignored.

If focus is a window, it becomes the keyboard’s focus window. If a generated keyboard event would normally be reported to this window or one of its inferiors, the event is reported as usual. Otherwise, the event is reported relative to the focus window.

If focus is PointerRoot, the focus window is dynamically taken to be the root window of whatever screen the pointer is on at each keyboard event. In this case, the revert_to argument is ignored.

The specified focus window must be viewable at the time XSetInputFocus is called, or a BadMatch error results. If the focus window later becomes not viewable, the XWIN server evaluates the revert_to argument to determine the new focus window as follows:

If revert_to is RevertToParent, the focus reverts to the parent (or the closest viewable ancestor), and the new revert_to value is taken to be RevertToNone.

If revert_to is RevertToPointerRoot or RevertToNone, the focus reverts to PointerRoot or None, respectively. When the focus reverts, the XWIN server generates FocusIn and FocusOut events, but the last-focus-change time is not affected.

XSetInputFocus can generate BadMatch, BadValue, and BadWindow errors.

To obtain the current input focus, use XGetInputFocus.

XGetInputFocus (display, focus_return, revert_to_return)
Display *display;
Window *focus_return;
int *revert_to_return;

display Specifies the connection to the XWIN server.
focus_return Returns the focus window, PointerRoot, or None.
revert_to_return Returns the current focus state (RevertToParent, RevertToPointerRoot, or RevertToNone).
The XGetInputFocus function returns the focus window and the current focus state.

**Killing Clients**

Xlib provides functions that you can use to control the lifetime of resources owned by a client or to cause the connection to a client to be destroyed.

To change a client's close-down mode, use `XSetCloseDownMode`.

```c
XSetCloseDownMode (display, close_mode)
Display *display;
int close_mode;
```

- `display` Specifies the connection to the XWIN server.
- `close_mode` Specifies the client close-down mode. You can pass DestroyAll, RetainPermanent, or RetainTemporary.

The `XSetCloseDownMode` defines what will happen to the client's resources at connection close. A connection starts in DestroyAll mode. For information on what happens to the client's resources when the `close_mode` argument is RetainPermanent or RetainTemporary, see "X Server Connection Close Operations" in Chapter 2.

`XSetCloseDownMode` can generate a BadValue error.

To destroy a client, use `XKillClient`.

```c
XKillClient (display, resource)
Display *display;
XID resource;
```

- `display` Specifies the connection to the XWIN server.
- `resource` Specifies any resource associated with the client that you want to destroy or AllTemporary.

The `XKillClient` function forces a close-down of the client that created the resource if a valid resource is specified. If the client has already terminated in either RetainPermanent or RetainTemporary mode, all of the client's resources are destroyed. If AllTemporary is specified, the resources of all clients that
Miscellaneous Control Functions

have terminated in `RetainTemporary` are destroyed (see "X Server Connection Close Operations" in Chapter 2). This permits implementation of window manager facilities that aid debugging. A client can set its close-down mode to `RetainTemporary`. If the client then crashes, its windows would not be destroyed. The programmer can then inspect the application's window tree and use the window manager to destroy the zombie windows.

`XKillClient` can generate a `BadValue` error.
Keyboard and Pointer Settings

Xlib provides functions that you can use to change the keyboard control, obtain a list of the auto-repeat keys, turn keyboard auto-repeat on or off, ring the bell, set or obtain the pointer button or keyboard mapping, and obtain a bit vector for the keyboard.

This section discusses the user-preference options of bell, key click, pointer behavior, and so on. The default values for many of these functions are determined by command line arguments to the XWIN server and, on UNIX-based systems, are typically set in the /etc/ttys file.

Not all implementations will actually be able to control all of these parameters.

The XChangeKeyboardControl function changes control of a keyboard and operates on a XKeyboardControl structure:

```c
/* Mask bits for ChangeKeyboardControl */
#define KBKeyClickPercent (1L<<0)
#define KBBellPercent (1L<<1)
#define KBBellPitch (1L<<2)
#define KBBellDuration (1L<<3)
#define KBLed (1L<<4)
#define KBLedMode (1L<<5)
#define KBKey (1L<<6)
#define KBAutoRepeatMode (1L<<7)

/* Values */

typedef struct {
    int key_click_percent;
    int bell_percent;
    int bell_pitch;
    int bell_duration;
    int led;
    int led_mode; /* LedModeOn, LedModeOff */
    int key;
    int auto_repeat_mode; /* AutoRepeatModeOff, AutoRepeatModeOn, AutoRepeatModeDefault */
} XKeyboardControl;
```
The key_click_percent member sets the volume for key clicks between 0 (off) and 100 (loud) inclusive, if possible. A setting of -1 restores the default. Other negative values generate a BadValue error.

The bell_percent sets the base volume for the bell between 0 (off) and 100 (loud) inclusive, if possible. A setting of -1 restores the default. Other negative values generate a BadValue error. The bell_pitch member sets the pitch (specified in Hz) of the bell, if possible. A setting of -1 restores the default. Other negative values generate a BadValue error. The bell_duration member sets the duration of the bell specified in milliseconds, if possible. A setting of -1 restores the default. Other negative values generate a BadValue error.

If both the led_mode and led members are specified, the state of that LED is changed, if possible. The led_mode member can be set to LedModeOn or LedModeOff. If only led_mode is specified, the state of all LEDs are changed, if possible. At most 32 LEDs numbered from one are supported. No standard interpretation of LEDs is defined. If led is specified without led_mode, a BadMatch error results.

If both the auto_repeat_mode and key members are specified, the auto_repeat_mode of that key is changed (according to AutoRepeatModeOn, AutoRepeatModeOff, or AutoRepeatModeDefault), if possible. If only auto_repeat_mode is specified, the global auto_repeat_mode for the entire keyboard is changed, if possible, and does not affect the per key settings. If a key is specified without an auto_repeat_mode, a BadMatch error results. Each key has an individual mode of whether or not it should auto-repeat and a default setting for the mode. In addition, there is a global mode of whether auto-repeat should be enabled or not and a default setting for that mode. When global mode is AutoRepeatModeOn, keys should obey their individual auto-repeat modes. When global mode is AutoRepeatModeOff, no keys should auto-repeat. An auto-repeating key generates alternating KeyPress and KeyRelease events. When a key is used as a modifier, it is desirable for the key not to auto-repeat, regardless of its auto-repeat setting.

A bell generator connected with the console but not directly on a keyboard is treated as if it were part of the keyboard. The order in which controls are verified and altered is server-dependent. If an error is generated, a subset of the controls may have been altered.
Keyboard and Pointer Settings

XChangeKeyboardControl (display, value_mask, values)
Display *display;
unsigned long value_mask;
XKeyboardControl *values;

display Specifies the connection to the XWIN server.
value_mask Specifies one value for each bit set to 1 in the mask.
values Specifies which controls to change. This mask is the bitwise inclusive OR of the valid control mask bits.

The XChangeKeyboardControl function controls the keyboard characteristics defined by the XKeyboardControl structure. The value_mask argument specifies which values are to be changed.

XChangeKeyboardControl can generate BadMatch and BadValue errors.

To obtain the current control values for the keyboard, use XGetKeyboardControl.

XGetKeyboardControl (display, values_return)
Display *display;
XKeyboardState *values_return;

display Specifies the connection to the XWIN server.
values_return Returns the current keyboard controls in the specified XKeyboardState structure.

The XGetKeyboardControl function returns the current control values for the keyboard to the XKeyboardState structure.

typedef struct {
    int key_click_percent;
    int bell_percent;
    unsigned int bell_pitch, bell_duration;
    unsigned long led_mask;
    int global_auto_repeat;
    char auto_repeats[32];
} XKeyboardState;

For the LEDs, the least-significant bit of led_mask corresponds to LED one, and each bit set to 1 in led_mask indicates an LED that is lit. The
global_auto_repeat member can be set to AutoRepeatModeOn or AutoRepeatModeOff. The auto_repeats member is a bit vector. Each bit set to 1 indicates that auto-repeat is enabled for the corresponding key. The vector is represented as 32 bytes. Byte N (from 0) contains the bits for keys 8N to 8N + 7 with the least-significant bit in the byte representing key 8N.

To turn on keyboard auto-repeat, use XAutoRepeatOn.

```c
XAutoRepeatOn (display)
Display *display;
```

display Specifies the connection to the XWIN server.

The XAutoRepeatOn function turns on auto-repeat for the keyboard on the specified display.

To turn off keyboard auto-repeat, use XAutoRepeatOff.

```c
XAutoRepeatOff (display)
Display *display;
```

display Specifies the connection to the XWIN server.

The XAutoRepeatOff function turns off auto-repeat for the keyboard on the specified display.

To ring the bell, use XBell.

```c
XBell (display, percent)
Display *display;
int percent;
```

display Specifies the connection to the XWIN server.

percent Specifies the volume for the bell, which can range from −100 to 100 inclusive.

The XBell function rings the bell on the keyboard on the specified display, if possible. The specified volume is relative to the base volume for the keyboard. If the value for the percent argument is not in the range −100 to 100 inclusive, a BadValue error results. The volume at which the bell rings when the percent argument is nonnegative is:
Keyboard and Pointer Settings

base - [(base * percent) / 100] + percent

The volume at which the bell rings when the percent argument is negative is:

base + [(base * percent) / 100]

To change the base volume of the bell, use XChangeKeyboardControl.

XBell can generate a BadValue error.

To obtain a bit vector that describes the state of the keyboard, use XQueryKeymap.

XQueryKeymap(display, keys_return)

Display *display;
char keys_return[32];

display Specifies the connection to the XWIN server.

keys_return Returns an array of bytes that identifies which keys are pressed down. Each bit represents one key of the keyboard.

The XQueryKeymap function returns a bit vector for the logical state of the keyboard, where each bit set to 1 indicates that the corresponding key is currently pressed down. The vector is represented as 32 bytes. Byte N (from 0) contains the bits for keys 8N to 8N + 7 with the least-significant bit in the byte representing key 8N.

Note that the logical state of a device (as seen by client applications) may lag the physical state if device event processing is frozen.

To set the mapping of the pointer buttons, use XSetPointerMapping.

int XSetPointerMapping(display, map, nmap)

Display *display;
unsigned char map[];
int nmap;

display Specifies the connection to the XWIN server.

map Specifies the mapping list.
Specifies the number of items in the mapping list.

The XSetPointerMapping function sets the mapping of the pointer. If it succeeds, the XWIN server generates a MappingNotify event, and XSetPointerMapping returns MappingSuccess. Elements of the list are indexed starting from one. The length of the list must be the same as XGetPointerMapping would return, or a BadValue error results. The index is a core button number, and the element of the list defines the effective number. A zero element disables a button, and elements are not restricted in value by the number of physical buttons. However, no two elements can have the same nonzero value, or a BadValue error results. If any of the buttons to be altered are logically in the down state, XSetPointerMapping returns MappingBusy, and the mapping is not changed.

XSetPointerMapping can generate a BadValue error.

To get the pointer mapping, use XGetPointerMapping.

```c
int XGetPointerMapping(display, map_return, nmap)
    Display *display;
    unsigned char map_return[];
    int nmap;
```

- **display** Specifies the connection to the XWIN server.
- **map_return** Returns the mapping list.
- **nmap** Specifies the number of items in the mapping list.

The XGetPointerMapping function returns the current mapping of the pointer. Elements of the list are indexed starting from one. XGetPointerMapping returns the number of physical buttons actually on the pointer. The nominal mapping for a pointer is the identity mapping: map[i]=i. The nmap argument specifies the length of the array where the pointer mapping is returned, and only the first nmap elements are returned in map_return.

To control the pointer's interactive feel, use XChangePointerControl.
Keyboard and Pointer Settings

XChangePointerControl (display, do_accel, do_threshold, accel_numerator,
accel_denominator, threshold)

Display *display;
Bool do_accel, do_threshold;
int accel_numerator, accel_denominator;
int threshold;

display Specifies the connection to the XWIN server.
do_accel Specifies a Boolean value that controls whether the values for
the accel_numerator or accel_denominator are used.
do_threshold Specifies a Boolean value that controls whether the value for the
threshold is used.
accel_numerator Specifies the numerator for the acceleration multiplier.
accel_denominator Specifies the denominator for the acceleration multiplier.
threshold Specifies the acceleration threshold.

The XChangePointerControl function defines how the pointing device moves. The acceleration, expressed as a fraction, is a multiplier for movement. For example, specifying 3/1 means the pointer moves three times as fast as normal. The fraction may be rounded arbitrarily by the XWIN server. Acceleration only takes effect if the pointer moves more than threshold pixels at once and only applies to the amount beyond the value in the threshold argument. Setting a value to -1 restores the default. The values of the do_accel and do_threshold arguments must be True for the pointer values to be set, or the parameters are unchanged. Negative values (other than -1) generate a BadValue error, as does a zero value for the accel_denominator argument.

XChangePointerControl can generate a BadValue error.

To get the current pointer parameters, use XGetPointerControl.

XGetPointerControl (display, accel_numerator_return, accel_denominator_return,
threshold_return)

Display *display;
int *accel_numerator_return, *accel_denominator_return;
int *threshold_return;
Keyboard and Pointer Settings

display Specifications the connection to the XWIN server.

accel_numerator_return
Returns the numerator for the acceleration multiplier.

accel_denominator_return
Returns the denominator for the acceleration multiplier.

threshold_return
Returns the acceleration threshold.

The XGetPointerControl function returns the pointer's current acceleration multiplier and acceleration threshold.
Keyboard Encoding

Most applications will find the simple interface XLookupString, which performs simple translation of a key event to an ASCII string, most useful. Keyboard-related utilities are discussed in Chapter 10. The following section explains how to completely control the bindings of symbols to keys and modifiers.

A KeyCode represents a physical (or logical) key. KeyCodes lie in the inclusive range [8,255]. A KeyCode value carries no intrinsic information, although server implementors may attempt to encode geometry (for example, matrix) information in some fashion so that it can be interpreted in a server-dependent fashion. The mapping between keys and KeyCodes cannot be changed.

A KeySym is an encoding of a symbol on the cap of a key. The set of defined KeySyms include the ISO Latin character sets (1–4), Katakana, Arabic, Cyrillic, Greek, Technical, Special, Publishing, APL, Hebrew, and a special miscellany of keys found on keyboards (Return, Help, Tab, and so on). To the extent possible, these sets are derived from international standards. In areas where no standards exist, some of these sets are derived from Digital Equipment Corporation standards. The list of defined symbols can be found in <X11/keysymdef.h>.

Unfortunately, some C preprocessors have limits on the number of defined symbols. If you must use KeySyms not in the Latin 1–4, Greek, and miscellaneous classes, you may have to define a symbol for those sets. Most applications usually only include <X11/keysym.h>, which defines symbols for ISO Latin 1–4, Greek, and miscellaneous.

A list of KeySyms is associated with each KeyCode. The length of the list can vary with each KeyCode. The list is intended to convey the set of symbols on the corresponding key. By convention, if the list contains a single KeySym and if that KeySym is alphabetic and case distinction is relevant for it, then it should be treated as equivalent to a two-element list of the lowercase and uppercase KeySyms. For example, if the list contains the single KeySym for uppercase A, the client should treat it as if it were a pair with lowercase a as the first KeySym and uppercase A as the second KeySym.

For any KeyCode, the first KeySym in the list should be chosen as the interpretation of a KeyPress when no modifier keys are down. The second KeySym in the list normally should be chosen when the Shift modifier is on or when the Lock modifier is on and Lock is interpreted as ShiftLock. When the Lock modifier is on and is interpreted as CapsLock, it is suggested that the Shift modifier first be applied to choose a KeySym. However, if that KeySym is lowercase alphabetic, the corresponding uppercase KeySym should be used instead. Other interpretations of CapsLock are possible; for example, it may be
viewed as equivalent to ShiftLock, but only applying when the first KeySym is lowercase alphabetic and the second KeySym is the corresponding uppercase alphabetic. No interpretation of KeySym beyond the first two in a list is suggested here. No spatial geometry of the symbols on the key is defined by their order in the KeySym list, although a geometry might be defined on a vendor-specific basis. The XWIN server does not use the mapping between KeyCodes and KeySym. Rather, it stores it merely for reading and writing by clients.

To obtain the legal KeyCodes for a display, use XDisplayKeycodes.

```c
XDisplayKeycodes (display, min_keycodes_return, max_keycodes_return)

Display *display;
int *min_keycodes_return, max_keycodes_return;
```

- `display` Specifies the connection to the XWIN server.
- `min_keycodes_return` Returns the minimum number of KeyCodes.
- `max_keycodes_return` Returns the maximum number of KeyCodes.

The XDisplayKeycodes function returns the min-keycodes and max-keycodes supported by the specified display. The minimum number of KeyCodes returned is never less than 8, and the maximum number of KeyCodes returned is never greater than 255. Not all KeyCodes in this range are required to have corresponding keys.

To obtain the symbols for the specified KeyCodes, use XGetKeyboardMapping.

```c
KeySym *XGetKeyboardMapping (display, first_keycode, keycode_count,
                     keysyms_per_keycode_return)

Display *display;
KeyCode first_keycode;
int keycode_count;
int *keysyms_per_keycode_return;
```

- `display` Specifies the connection to the XWIN server.
**Keyboard Encoding**

`first keycode` Specifies the first KeyCode that is to be returned.

`keycode_count` Specifies the number of KeyCodes that are to be returned.

`keysyms_per_keycode_return`

Returns the number of KeySyms per KeyCode.

The `XGetKeyboardMapping` function returns the symbols for the specified number of KeyCodes starting with `first keycode`. The value specified in `first keycode` must be greater than or equal to `min keycode` as returned by `XDisplayKeycodes`, or a `BadValue` error results. In addition, the following expression must be less than or equal to `max keycode` as returned by `XDisplayKeycodes`:

\[
first keycode + keycode_count - 1
\]

If this is not the case, a `BadValue` error results. The number of elements in the KeySyms list is:

\[
keycode_count \times keysyms_per_keycode_return
\]

KeySym number N, counting from zero, for KeyCode K has the following index in the list, counting from zero:

\[
(K - first keycode) \times keysyms_per_keycode_return + N
\]

The XWIN server arbitrarily chooses the `keysyms_per_keycode_return` value to be large enough to report all requested symbols. A special KeySym value of `NoSymbol` is used to fill in unused elements for individual KeyCodes. To free the storage returned by `XGetKeyboardMapping`, use `XFree`.

`XGetKeyboardMapping` can generate a `BadValue` error.

To change the keyboard mapping, use `XChangeKeyboardMapping`.

```c
XChangeKeyboardMapping (display, first keycode, keysyms_per_keycode, keysyms, num_codes)
Display *display;
int first keycode;
int keysyms_per_keycode;
KeySym *keysyms;
int num_codes;
```
display Specifies the connection to the XWIN server.

first_keycode Specifies the first KeyCode that is to be changed.

keysyms_per_keycode Specifies the number of KeySyms per KeyCode.

keysyms Specifies a pointer to an array of KeySyms.

num_codes Specifies the number of KeyCodes that are to be changed.

The XChangeKeyboardMapping function defines the symbols for the specified number of KeyCodes starting with first_keycode. The symbols for KeyCodes outside this range remain unchanged. The number of elements in keysyms must be:

\[ \text{num_codes} \times \text{keysyms\_per\_keycode} \]

The specified first_keycode must be greater than or equal to min_keycode returned by XDisplayKeycodes, or a BadValue error results. In addition, the following expression must be less than or equal to max_keycode as returned by XDisplayKeycodes, or a BadValue error results:

\[ \text{first_keycode} + \text{num_codes} - 1 \]

KeySym number N, counting from zero, for KeyCode K has the following index in keysyms, counting from zero:

\[ (K - \text{first_keycode}) \times \text{keysyms\_per\_keycode} + N \]

The specified keysyms_per_keycode can be chosen arbitrarily by the client to be large enough to hold all desired symbols. A special KeySym value of NoSymbol should be used to fill in unused elements for individual KeyCodes. It is legal for NoSymbol to appear in nontrailing positions of the effective list for a KeyCode. XChangeKeyboardMapping generates a MappingNotify event.

There is no requirement that the XWIN server interpret this mapping. It is merely stored for reading and writing by clients. XChangeKeyboardMapping can generate BadAlloc and BadValue errors.

The next four functions make use of the XModifierKeymap data structure, which contains:

Window Manager Functions
typedef struct {
    int max_keypermod; /* This server's max number of keys per modifier */
    KeyCode *modifiermap; /* An 8 by max_keypermod array of the modifiers */
} XModifierKeymap;

To create an XModifierKeymap structure, use XNewModifiermap.

XModifierKeymap *XNewModifiermap (max_keys_per_mod)
    int max_keys_per_mod;

max_keys_per_mod
    Specifies the number of KeyCode entries preallocated to the
    modifiers in the map.

The XNewModifiermap function returns a pointer to XModifierKeymap structure
for later use.

To add a new entry to an XModifierKeymap structure, use XInsertModifiermapEntry.

XModifierKeymap *XInsertModifiermapEntry (modmap, keycode_entry, modifier)
    XModifierKeymap *modmap;
    KeyCode keycode_entry;
    int modifier;

modmap
    Specifies a pointer to the XModifierKeymap structure.

keycode_entry
    Specifies the KeyCode.

modifier
    Specifies the modifier.

The XInsertModifiermapEntry function adds the specified KeyCode to the set
that controls the specified modifier and returns the resulting XModifierKeymap
structure (expanded as needed).

To delete an entry from an XModifierKeymap structure, use XDeleteModifiermapEntry.

XModifierKeymap *XDeleteModifiermapEntry (modmap, keycode_entry, modifier)
    XModifierKeymap *modmap;
    KeyCode keycode_entry;
    int modifier;
modmap Specifies a pointer to the XModifierKeymap structure.

keycode_entry Specifies the KeyCode.

modifier Specifies the modifier.

The XDeleteModifiermapEntry function deletes the specified KeyCode from the set that controls the specified modifier and returns a pointer to the resulting XModifierKeymap structure.

To destroy an XModifierKeymap structure, use XFreeModifiermap.

\[
\text{XFreeModifiermap} (\text{modmap})
\]
\[
\text{XModifierKeymap} * \text{modmap};
\]

modmap Specifies a pointer to the XModifierKeymap structure.

The XFreeModifiermap function frees the specified XModifierKeymap structure.

To set the KeyCodes to be used as modifiers, use XSetModifierMapping.

\[
\text{int XSetModifierMapping} (\text{display, modmap})
\]
\[
\text{Display} * \text{display};
\]
\[
\text{XModifierKeymap} * \text{modmap};
\]

display Specifies the connection to the XWIN server.

modmap Specifies a pointer to the XModifierKeymap structure.

The XSetModifierMapping function specifies the KeyCodes of the keys (if any) that are to be used as modifiers. If it succeeds, the XWIN server generates a MappingNotify event, and XSetModifierMapping returns MappingSuccess. X permits at most eight modifier keys. If more than eight are specified in the XModifierKeymap structure, a BadLength error results.

The modifiermap member of the XModifierKeymap structure contains eight sets of max_keypermod KeyCodes, one for each modifier in the order Shift, Lock, Control, Mod1, Mod2, Mod3, Mod4, and Mod5. Only nonzero KeyCodes have meaning in each set, and zero KeyCodes are ignored. In addition, all of the nonzero KeyCodes must be in the range specified by min_keycode and max_keycode in the Display structure, or a BadValue error results. No KeyCode may appear twice in the entire map, or a BadValue error results.
An XWIN server can impose restrictions on how modifiers can be changed, for example, if certain keys do not generate up transitions in hardware, if auto-repeat cannot be disabled on certain keys, or if multiple modifier keys are not supported. If some such restriction is violated, the status reply is MappingFailed, and none of the modifiers are changed. If the new KeyCodes specified for a modifier differ from those currently defined and any (current or new) keys for that modifier are in the logically down state, XSetModifierMapping returns MappingBusy, and none of the modifiers is changed.

XSetModifierMapping can generate BadAlloc and BadValue errors.

To obtain the KeyCodes used as modifiers, use XGetModifierMapping.

```c
XModifierKeymap *XGetModifierMapping(display)
    Display *display;
```

display Specifies the connection to the XWIN server.

The XGetModifierMapping function returns a pointer to a newly created XModifierKeymap structure that contains the keys being used as modifiers. The structure should be freed after use by calling XFreeModifierMap. If only zero values appear in the set for any modifier, that modifier is disabled.
Screen Saver Control

Xlib provides functions that you can use to set, force, activate, or reset the screen saver and to obtain the current screen saver values.

To set the screen saver, use XSetScreenSaver.

```c
XSetScreenSaver (display, timeout, interval, prefer_blanking, allow_exposures)
    Display *display;
    int timeout, interval;
    int prefer_blanking;
    int allow_exposures;
```

- `display` Specifies the connection to the XWIN server.
- `timeout` Specifies the timeout, in seconds, until the screen saver turns on.
- `interval` Specifies the interval between screen saver alterations.
- `prefer_blanking` Specifies how to enable screen blanking. You can pass DontPreferBlanking, PreferBlanking, or DefaultBlanking.
- `allow_exposures` Specifies the screen save control values. You can pass DontAllowExposures, AllowExposures, or DefaultExposures.

Timeout and interval are specified in seconds. A timeout of 0 disables the screen saver, and a timeout of -1 restores the default. Other negative values generate a BadValue error. If the timeout value is nonzero, XSetScreenSaver enables the screen saver. An interval of 0 disables the random-pattern motion. If no input from devices (keyboard, mouse, and so on) is generated for the specified number of timeout seconds once the screen saver is enabled, the screen saver is activated.

For each screen, if blanking is preferred and the hardware supports video blanking, the screen simply goes blank. Otherwise, if either exposures are allowed or the screen can be regenerated without sending Expose events to clients, the screen is tiled with the root window background tile randomly re-origined each interval minutes. Otherwise, the screens' state do not change, and the screen saver is not activated. The screen saver is deactivated, and all screen states are restored at the next keyboard or pointer input or at the next call to XForceScreenSaver with mode ScreenSaverReset.
If the server-dependent screen saver method supports periodic change, the interval argument serves as a hint about how long the change period should be, and zero hints that no periodic change should be made. Examples of ways to change the screen include scrambling the colormap periodically, moving an icon image around the screen periodically, or tiling the screen with the root window background tile, randomly re-origined periodically.

`XSetScreenSaver` can generate a BadValue error.

To force the screen saver on or off, use `XForceScreenSaver`.

```c
XForceScreenSaver (display, mode)
    Display *display;
    int mode;
```

- **display** Specifies the connection to the XWIN server.
- **mode** Specifies the mode that is to be applied. You can pass `ScreenSaverActive` or `ScreenSaverReset`.

If the specified mode is `ScreenSaverActive` and the screen saver currently is deactivated, `XForceScreenSaver` activates the screen saver even if the screen saver had been disabled with a timeout of zero. If the specified mode is `ScreenSaverReset` and the screen saver currently is enabled, `XForceScreenSaver` deactivates the screen saver if it was activated, and the activation timer is reset to its initial state (as if device input had been received).

`XForceScreenSaver` can generate a BadValue error.

To activate the screen saver, use `XActivateScreenSaver`.

```c
XActivateScreenSaver (display)
    Display *display;
```

- **display** Specifies the connection to the XWIN server.

To reset the screen saver, use `XResetScreenSaver`.

```c
XResetScreenSaver (display)
    Display *display;
```
display Specifies the connection to the XWIN server.

To get the current screen saver values, use XGetScreenSaver.

\[ \text{XGetScreenSaver} \left( \text{display}, \text{timeout \_return}, \text{interval \_return}, \text{prefer \_blanking \_return}, \text{allow \_exposures \_return} \right) \]

\[ \begin{align*}
\text{Display} & \quad \ast \text{display}; \\
\text{int} & \quad \ast \text{timeout \_return}, \ast \text{interval \_return}; \\
\text{int} & \quad \ast \text{prefer \_blanking \_return}; \\
\text{int} & \quad \ast \text{allow \_exposures \_return};
\end{align*} \]

\[ \text{display} \quad \text{Specifies the connection to the XWIN server.} \]

\[ \text{timeout \_return} \] Returns the timeout, in minutes, until the screen saver turns on.

\[ \text{interval \_return} \] Returns the interval between screen saver invocations.

\[ \text{prefer \_blanking \_return} \] Returns the current screen blanking preference (DontPreferBlanking, PreferBlanking, or DefaultBlanking).

\[ \text{allow \_exposures \_return} \] Returns the current screen save control value (DontAllowExposures, AllowExposures, or DefaultExposures).
Controlling Host Access

This section discusses how to:

- Add, get, or remove hosts from the access control list
- Change, enable, or disable access

X does not provide any protection on a per-window basis. If you find out the resource ID of a resource, you can manipulate it. To provide some minimal level of protection, however, connections are permitted only from machines you trust. This is adequate on single-user workstations but obviously breaks down on timesharing machines. Although provisions exist in the X protocol for proper connection authentication, the lack of a standard authentication server leaves host-level access control as the only common mechanism.

The initial set of hosts allowed to open connections typically consists of:

- The host the window system is running on.
- On UNIX-based systems, each host listed in the /etc/X?.hosts file. The ? indicates the number of the display.

This file should consist of host names separated by newlines.

If a host is not in the access control list when the access control mechanism is enabled and if the host attempts to establish a connection, the server refuses the connection. To change the access list, the client must reside on the same host as the server and/or must have been granted permission in the initial authorization at connection setup.

Servers also can implement other access control policies in addition to or in place of this host access facility. For further information about other access control implementations, see "X Window System Protocol."
Controlling Host Access

Adding, Getting, or Removing Hosts

Xlib provides functions that you can use to add, get, or remove hosts from the access control list. All the host access control functions use the XHostAddress structure, which contains:

```c
typedef struct {
    int family; /* for example FamilyInternet */
    int length; /* length of address, in bytes */
    char *address; /* pointer to where to find the address */
} XHostAddress;
```

The family member specifies which protocol address family to use. The length member specifies the length of the address in bytes. The address member specifies a pointer to the address. For TCP/IP, the address should be in network byte order.

To add a single host, use `XAddHost`.

```c
XAddHost (display, host)
  Display *display;
  XHostAddress *host;
```

- `display` specifies the connection to the XWIN server.
- `host` specifies the host that is to be added.

The `XAddHost` function adds the specified host to the access control list for that display. The server must be on the same host as the client issuing the command, or a BadAccess error results.

`XAddHost` can generate BadAccess and BadValue errors.

To add multiple hosts at one time, use `XAddHosts`.

```c
XAddHosts (display, hosts, num_hosts)
  Display *display;
  XHostAddress *hosts;
  int num_hosts;
```
Controlling Host Access

display  Specifies the connection to the XWIN server.
hosts  Specifies each host that is to be added.
um_hosts  Specifies the number of hosts.

The XAddHosts function adds each specified host to the access control list for that display. The server must be on the same host as the client issuing the command, or a BadAccess error results.

XAddHosts can generate BadAccess and BadValue errors.

To obtain a host list, use XListHosts.

    XHostAddress *XListHosts (display, nhosts_return, state_return)
    Display *display;
    int *nhosts_return;
    Bool *state_return;

display  Specifies the connection to the XWIN server.
nhosts_return  Returns the number of hosts currently in the access control list.
state_return  Returns the state of the access control.

The XListHosts function returns the current access control list as well as whether the use of the list at connection setup was enabled or disabled.

XListHosts allows a program to find out what machines can make connections. It also returns a pointer to a list of host structures that were allocated by the function. When no longer needed, this memory should be freed by calling XFree.

To remove a single host, use XRemoveHost.

    XRemoveHost (display, host)
    Display *display;
    XHostAddress *host;

display  Specifies the connection to the XWIN server.
host  Specifies the host that is to be removed.
The `XRemoveHost` function removes the specified host from the access control list for that display. The server must be on the same host as the client process, or a BadAccess error results. If you remove your machine from the access list, you can no longer connect to that server, and this operation cannot be reversed unless you reset the server.

`XRemoveHost` can generate BadAccess and BadValue errors.

To remove multiple hosts at one time, use `XRemoveHosts`.

```c
XRemoveHosts (display, hosts, num_hosts)
Display *display;
XHostAddress *hosts;
int num_hosts;
```

display Specifies the connection to the XWIN server.
hosts Specifies each host that is to be removed.
num_hosts Specifies the number of hosts.

The `XRemoveHosts` function removes each specified host from the access control list for that display. The XWIN server must be on the same host as the client process, or a BadAccess error results. If you remove your machine from the access list, you can no longer connect to that server, and this operation cannot be reversed unless you reset the server.

`XRemoveHosts` can generate BadAccess and BadValue errors.

**Changing, Enabling, or Disabling Access Control**

Xlib provides functions that you can use to enable, disable, or change access control.

For these functions to execute successfully, the client application must reside on the same host as the XWIN server and/or have been given permission in the initial authorization at connection setup.

To change access control, use `XSetAccessControl`. 
Controlling Host Access

\[ \texttt{XSetAccessControl}(\textit{display, mode}) \]
\[
\begin{align*}
\text{Display } & \textit{display}; \\
\text{int } & \textit{mode}; \\
\end{align*}
\]

\textit{display} \hspace{1em} \text{Specifies the connection to the XWIN server.} \\
\textit{mode} \hspace{1em} \text{Specifies the mode. You can pass EnableAccess or DisableAccess.}

The \texttt{XSetAccessControl} function either enables or disables the use of the access control list at each connection setup.

\texttt{XSetAccessControl} can generate BadAccess and BadValue errors.

To enable access control, use \texttt{XEnableAccessControl}.

\[ \texttt{XEnableAccessControl}(\textit{display}) \]
\[
\begin{align*}
\text{Display } & \textit{display}; \\
\end{align*}
\]

\textit{display} \hspace{1em} \text{Specifies the connection to the XWIN server.}

The \texttt{XEnableAccessControl} function enables the use of the access control list at each connection setup.

\texttt{XEnableAccessControl} can generate a BadAccess error.

To disable access control, use \texttt{XDisableAccessControl}.

\[ \texttt{XDisableAccessControl}(\textit{display}) \]
\[
\begin{align*}
\text{Display } & \textit{display}; \\
\end{align*}
\]

\textit{display} \hspace{1em} \text{Specifies the connection to the XWIN server.}

The \texttt{XDisableAccessControl} function disables the use of the access control list at each connection setup.

\texttt{XDisableAccessControl} can generate a BadAccess error.
8 Events and Event-Handling Functions

Introduction

A client application communicates with the XWIN server through the connection you establish with the XOpenDisplay function. A client application sends requests to the XWIN server over this connection. These requests are made by the Xlib functions that are called in the client application. Many Xlib functions cause the XWIN server to generate events, and the user's typing or moving the pointer can generate events asynchronously. The XWIN server returns events to the client on the same connection.

This chapter begins with a discussion of the following topics associated with events:

- Event types
- Event structures
- Event mask
- Event processing

It then discusses the Xlib functions you can use to:

- Select events
- Handle the output buffer and the event queue
- Select events from the event queue
- Send and get events
- Handle error events

Some toolkits use their own event-handling functions and do not allow you to interchange these event-handling functions with those in Xlib. For further information, see the documentation supplied with the toolkit.

Most applications simply are event loops: they wait for an event, decide what to do with it, execute some amount of code that results in changes to the display, and then wait for the next event.
Event Types

An event is data generated asynchronously by the XWIN server as a result of some device activity or as side effects of a request sent by an Xlib function. Device-related events propagate from the source window to ancestor windows until some client application has selected that event type or until the event is explicitly discarded. The XWIN server generally sends an event to a client application only if the client has specifically asked to be informed of that event type, typically by setting the event-mask attribute of the window. The mask can also be set when you create a window or by changing the window’s event-mask. You can also mask out events that would propagate to ancestor windows by manipulating the do-not-propagate mask of the window’s attributes. However, MappingNotify events are always sent to all clients.

An event type describes a specific event generated by the XWIN server. For each event type, a corresponding constant name is defined in <X11/X.h>, which is used when referring to an event type.

The following table lists the event category and its associated event type or types. The processing associated with these events is discussed in "Event Processing" in this chapter.

</tr>
</tbody>
</table>
Event Structures

For each event type, a corresponding structure is declared in `<x11/Xlib.h>`. All the event structures have the following common members:

```c
typedef struct {
    int type;
    unsigned long serial; /* # of last request processed by server */
    Bool send_event; /* true if this came from a SendEvent request */
    Display *display; /* Display the event was read from */
    Window window;
} XAnyEvent;
```

The type member is set to the event type constant name that uniquely identifies it. For example, when the XWIN server reports a GraphicsExpose event to a client application, it sends an `XGraphicsExposeEvent` structure with the type member set to `GraphicsExpose`. The display member is set to a pointer to the display the event was read on. The send_event member is set to `True` if the event came from a `SendEvent` protocol request. The serial member is set from the serial number reported in the protocol but expanded from the 16-bit least-significant bits to a full 32-bit value. The window member is set to the window that is most useful to toolkit dispatchers.

The XWIN server can send events at any time in the input stream. Xlib stores any events received while waiting for a reply in an event queue for later use. Xlib also provides functions that allow you to check events in the event queue (see "Event Queue Management" in this chapter).

In addition to the individual structures declared for each event type, the `XEvent` structure is a union of the individual structures declared for each event type. Depending on the type, you should access members of each event by using the `XEvent` union.
An _XEvent_ structure’s first entry always is the type member, which is set to the event type. The second member always is the serial number of the protocol request that generated the event. The third member always is send_event, which is a `bool` that indicates if the event was sent by a different client. The
fourth member always is a display, which is the display that the event was read from. Except for keymap events, the fifth member always is a window, which has been carefully selected to be useful to toolkit dispatchers. To avoid breaking toolkits, the order of these first five entries is not to change. Most events also contain a time member, which is the time at which an event occurred. In addition, a pointer to the generic event must be cast before it is used to access any other information in the structure.
Event Masks

Clients select event reporting of most events relative to a window. To do this, pass an event mask to an Xlib event-handling function that takes an event_mask argument. The bits of the event mask are defined in `<X11/X.h>`. Each bit in the event mask maps to an event mask name, which describes the event or events you want the XWIN server to return to a client application.

Unless the client has specifically asked for them, most events are not reported to clients when they are generated. Unless the client suppresses them by setting graphics-exposures in the GC to False, GraphicsExpose and NoExpose are reported by default as a result of XCopyPlane and XCopyArea. SelectionClear, SelectionRequest, SelectionNotify, or ClientMessage cannot be masked. Selection related events are only sent to clients cooperating with selections (see "Selections" in Chapter 4). When the keyboard or pointer mapping is changed, MappingNotify is always sent to clients.

The following table lists the event mask constants you can pass to the event_mask argument and the circumstances in which you would want to specify the event mask:

<table>

</tbody>
</table>
Event Processing

The event reported to a client application during event processing depends on which event masks you provide as the event-mask attribute for a window. For some event masks, there is a one-to-one correspondence between the event mask constant and the event type constant. For example, if you pass the event mask ButtonPressMask, the XWIN server sends back only ButtonPress events. Most events contain a time member, which is the time at which an event occurred.

In other cases, one event mask constant can map to several event type constants. For example, if you pass the event mask SubstructureNotifyMask, the XWIN server can send back CirculateNotify, ConfigureNotify, CreateNotify, DestroyNotify, GravityNotify, MapNotify, ReparentNotify, or UnmapNotify events.

In another case, two event masks can map to one event type. For example, if you pass either PointerMotionMask or ButtonMotionMask, the XWIN server sends back a MotionNotify event.

The following table lists the event mask, its associated event type or types, and the structure name associated with the event type. Some of these structures actually are typedefs to a generic structure that is shared between two event types. Note that N.A. appears in columns for which the information is not applicable.

The sections that follow describe the processing that occurs when you select the different event masks. The sections are organized according to these processing categories:

- Keyboard and pointer events
- Window crossing events
- Input focus events
- Keymap state notification events
- Exposure events
- Window state notification events
- Structure control events
- Colormap state notification events
- Client communication events
Keyboard and Pointer Events

This section discusses:

- Pointer button events
- Keyboard and pointer events

Pointer Button Events

The following describes the event processing that occurs when a pointer button press is processed with the pointer in some window \( w \) and when no active pointer grab is in progress.

The \texttt{XWIN} server searches the ancestors of \( w \) from the root down, looking for a passive grab to activate. If no matching passive grab on the button exists, the \texttt{XWIN} server automatically starts an active grab for the client receiving the event and sets the last-pointer-grab time to the current server time. The effect is essentially equivalent to an \texttt{XGrabButton} with these client passed arguments:

<table>
<thead>
<tr>
<th>Argument</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>( w )</td>
<td>The event window</td>
</tr>
<tr>
<td>\texttt{event_mask}</td>
<td>The client's selected pointer events on the event window</td>
</tr>
<tr>
<td>\texttt{pointer_mode}</td>
<td>\texttt{GrabModeAsync}</td>
</tr>
<tr>
<td>\texttt{keyboard_mode}</td>
<td>\texttt{GrabModeAsync}</td>
</tr>
<tr>
<td>\texttt{owner_events}</td>
<td>True, if the client has selected \texttt{OwnerGrabButtonMask} on the event window, otherwise False</td>
</tr>
<tr>
<td>\texttt{confine_to}</td>
<td>None</td>
</tr>
<tr>
<td>\texttt{cursor}</td>
<td>None</td>
</tr>
</tbody>
</table>

The active grab is automatically terminated when the logical state of the pointer has all buttons released. Clients can modify the active grab by calling \texttt{XUngrabPointer} and \texttt{XChangeActivePointerGrab}.
Keyboard and Pointer Events

This section discusses the processing that occurs for the keyboard events KeyPress and KeyRelease and the pointer events ButtonPress, ButtonRelease, and MotionNotify. For information about the keyboard event-handling utilities, see Chapter 10.

The XWIN server reports KeyPress or KeyRelease events to clients wanting information about keys that logically change state. Note that these events are generated for all keys, even those mapped to modifier bits. The XWIN server reports ButtonPress or ButtonRelease events to clients wanting information about buttons that logically change state.

The XWIN server reports MotionNotify events to clients wanting information about when the pointer logically moves. The XWIN server generates this event whenever the pointer is moved and the pointer motion begins and ends in the window. The granularity of MotionNotify events is not guaranteed, but a client that selects this event type is guaranteed to receive at least one event when the pointer moves and then rests.

The generation of the logical changes lags the physical changes if device event processing is frozen.

To receive KeyPress, KeyRelease, ButtonPress, and ButtonRelease events, set KeyPressMask, KeyReleaseMask, ButtonPressMask, and ButtonReleaseMask bits in the event-mask attribute of the window.

To receive MotionNotify events, set one or more of the following event masks bits in the event-mask attribute of the window:

- ButtonlMotionMask–Button5MotionMask The client application receives MotionNotify events only when one or more of the specified buttons is pressed.
- ButtonMotionMask The client application receives MotionNotify events only when at least one button is pressed.
- PointerMotionMask The client application receives MotionNotify events independent of the state of the pointer buttons.
- PointerMotionHint If PointerMotionHintMask is selected, the XWIN server is free to send only one MotionNotify event (with the is_hint member of the XPointerMovedEvent structure set to NotifyHint) to the client for the event window, until either the key or button state changes, the pointer leaves the event window, or the client calls XQueryPointer or
XGetMotionEvents. The server still may send MotionNotify events without is_hint set to NotifyHint.

The source of the event is the viewable window that the pointer is in. The window used by the XWIN server to report these events depends on the window's position in the window hierarchy and whether any intervening window prohibits the generation of these events. Starting with the source window, the XWIN server searches up the window hierarchy until it locates the first window specified by a client as having an interest in these events. If one of the intervening windows has its do-not-propagate-mask set to prohibit generation of the event type, the events of those types will be suppressed. Clients can modify the actual window used for reporting by performing active grabs and, in the case of keyboard events, by using the focus window.

The structures for these event types contain:

```c
typedef struct {
    int type;          /* ButtonPress or ButtonRelease */
    unsigned long serial;  /* $ of last request processed by server */
    Bool send_event;    /* true if this came from a SendEvent request */
    Display *display;   /* Display the event was read from */
    Window window;      /* 'event' window it is reported relative to */
    Window root;        /* root window that the event occurred on */
    Window subwindow;   /* child window */
    Time time;          /* milliseconds */
    int x, y;           /* pointer x, y coordinates in event window */
    int x_root, y_root;  /* coordinates relative to root */
    unsigned int state; /* key or button mask */
    unsigned int button; /* detail */
    Bool same_screen;   /* same screen flag */
} XButtonEvent;
```

```c
typedef XButtonEvent XButtonPressedEvent;
typedef XButtonEvent XButtonReleasedEvent;
```
typedef struct {
    int type; /* KeyPress or KeyRelease */
    unsigned long serial; /* $ of last request processed by server */
    Bool send_event; /* true if this came from a SendEvent request */
    Display *display; /* Display the event was read from */
    Window window; /* 'event' window it is reported relative to */
    Window root; /* root window that the event occurred on */
    Window subwindow; /* child window */
    Time time; /* milliseconds */
    int x, y; /* pointer x, y coordinates in event window */
    int x_root, y_root; /* coordinates relative to root */
    unsigned int state; /* key or button mask */
    unsigned int keycode; /* detail */
    Bool same_screen; /* same screen flag */
} XKeyEvent;

typedef XKeyEvent XKeyPressedEvent;

typedef XKeyEvent XKeyReleasedEvent;

typedef struct {
    int type; /* MotionNotify */
    unsigned long serial; /* $ of last request processed by server */
    Bool send_event; /* true if this came from a SendEvent request */
    Display *display; /* Display the event was read from */
    Window window; /* 'event' window reported relative to */
    Window root; /* root window that the event occurred on */
    Window subwindow; /* child window */
    Time time; /* milliseconds */
    int x, y; /* pointer x, y coordinates in event window */
    int x_root, y_root; /* coordinates relative to root */
    unsigned int state; /* key or button mask */
    char is_hint; /* detail */
    Bool same_screen; /* same screen flag */
} XMotionEvent;

typedef XMotionEvent XPointerMovedEvent;

These structures have the following common members: window, root, subwindow, time, x, y, x_root, y_root, state, and same_screen. The window member is set to the window on which the event was generated and is referred to as the event window. As long as the conditions previously discussed are met, this is the window used by the XWIN server to report the event. The root member is
set to the source window’s root window. The x_root and y_root members are
set to the pointer’s coordinates relative to the root window’s origin at the time
of the event.

The same_screen member is set to indicate whether the event window is on the
same screen as the root window and can be either True or False. If True, the
event and root windows are on the same screen. If False, the event and root
windows are not on the same screen.

If the source window is an inferior of the event window, the subwindow
member of the structure is set to the child of the event window that is the
source member or an ancestor of it. Otherwise, the XWIN server sets the
subwindow member to None. The time member is set to the time when the
event was generated and is expressed in milliseconds.

If the event window is on the same screen as the root window, the x and y
members are set to the coordinates relative to the event window’s origin. Oth­
erwise, these members are set to zero.

The state member is set to indicate the logical state of the pointer buttons and
modifier keys just prior to the event, which is the bitwise inclusive OR of one or
more of the button or modifier key masks: Button1Mask, Button2Mask,
Button3Mask, Button4Mask, Button5Mask, ShiftMask, LockMask, Control-
Mask, ModlMask, Mod2Mask, Mod3Mask, Mod4Mask, and Mod5Mask.

Each of these structures also has a member that indicates the detail. For the
XKeyPressedEvent and XKeyReleasedEvent structures, this member is called
keycode. It is set to a number that represents a physical key on the keyboard.
The keycode is an arbitrary representation for any key on the keyboard (see
Chapter 7).

For the XButtonPressedEvent and XButtonReleasedEvent structures, this
member is called button. It represents the pointer button that changed state and
can be the Button1, Button2, Button3, Button4, or Button5 value. For the
XPointerMovedEvent structure, this member is called is_hint. It can be set to
NotifyNormal or NotifyHint.
Window Entry/Exit Events

This section describes the processing that occurs for the window crossing events EnterNotify and LeaveNotify. If a pointer motion or a window hierarchy change causes the pointer to be in a different window than before, the XWIN server reports EnterNotify or LeaveNotify events to clients who have selected for these events. All EnterNotify and LeaveNotify events caused by a hierarchy change are generated after any hierarchy event (UnmapNotify, MapNotify, ConfigureNotify, GravityNotify, CirculateNotify) caused by that change; however, the X protocol does not constrain the ordering of EnterNotify and LeaveNotify events with respect to FocusOut, VisibilityNotify, and Expose events.

This contrasts with MotionNotify events, which are also generated when the pointer moves but only when the pointer motion begins and ends in a single window. An EnterNotify or LeaveNotify event also can be generated when some client application calls XGrabPointer and XUngrabPointer.

To receive EnterNotify or LeaveNotify events, set the EnterWindowMask or LeaveWindowMask bits of the event-mask attribute of the window.

The structure for these event types contains:
typedef struct {
    int type;       /* EnterNotify or LeaveNotify */
    unsigned long serial; /* # of last request processed by server */
    Bool send_event; /* true if this came from a SendEvent request */
    Display *display; /* Display the event was read from */
    Window window;    /* "event" window reported relative to */
    Window root;      /* root window that the event occurred on */
    Window subwindow; /* child window */
    Time time;        /* milliseconds */
    int x, y;         /* pointer x, y coordinates in event window */
    int x_root, y_root; /* coordinates relative to root */
    int mode;         /* NotifyNormal, NotifyGrab, NotifyUngrab */
    int detail;
    /*
     * NotifyAncestor, NotifyVirtual, NotifyInferior,
     * NotifyNonlinear, NotifyNonlinearVirtual
     */
    Bool same_screen; /* same screen flag */
    Bool focus;       /* boolean focus */
    unsigned int state; /* key or button mask */
} XCrossingEvent;

typedef XCrossingEvent XEnterWindowEvent;

typedef XCrossingEvent XLeaveWindowEvent;

The window member is set to the window on which the EnterNotify or LeaveNotify event was generated and is referred to as the event window. This is the window used by the XWIN server to report the event, and is relative to the root window on which the event occurred. The root member is set to the root window of the screen on which the event occurred.

For a LeaveNotify event, if a child of the event window contains the initial position of the pointer, the subwindow component is set to that child. Otherwise, the XWIN server sets the subwindow member to None. For an EnterNotify event, if a child of the event window contains the final pointer position, the subwindow component is set to that child or None.

The time member is set to the time when the event was generated and is expressed in milliseconds. The x and y members are set to the coordinates of the pointer position in the event window. This position is always the pointer's final position, not its initial position. If the event window is on the same screen as the root window, x and y are the pointer coordinates relative to the event
window's origin. Otherwise, x and y are set to zero. The \texttt{x\_root} and \texttt{y\_root} members are set to the pointer's coordinates relative to the root window's origin at the time of the event.

The \texttt{same\_screen} member is set to indicate whether the event window is on the same screen as the root window and can be either \texttt{True} or \texttt{False}. If \texttt{True}, the event and root windows are on the same screen. If \texttt{False}, the event and root windows are not on the same screen.

The \texttt{focus} member is set to indicate whether the event window is the focus window or an inferior of the focus window. The \texttt{XWIN} server can set this member to either \texttt{True} or \texttt{False}. If \texttt{True}, the event window is the focus window or an inferior of the focus window. If \texttt{False}, the event window is not the focus window or an inferior of the focus window.

The \texttt{state} member is set to indicate the state of the pointer buttons and modifier keys just prior to the event. The \texttt{XWIN} server can set this member to the bitwise inclusive OR of one or more of the button or modifier key masks: \texttt{Button1Mask}, \texttt{Button2Mask}, \texttt{Button3Mask}, \texttt{Button4Mask}, \texttt{Button5Mask}, \texttt{ShiftMask}, \texttt{LockMask}, \texttt{ControlMask}, \texttt{Mod1Mask}, \texttt{Mod2Mask}, \texttt{Mod3Mask}, \texttt{Mod4Mask}, \texttt{Mod5Mask}.

The \texttt{mode} member is set to indicate whether the events are normal events, pseudo-motion events when a grab activates, or pseudo-motion events when a grab deactivates. The \texttt{XWIN} server can set this member to \texttt{NotifyNormal}, \texttt{NotifyGrab}, or \texttt{NotifyUngrab}.

The \texttt{detail} member is set to indicate the notify detail and can be \texttt{NotifyAncestor}, \texttt{NotifyVirtual}, \texttt{NotifyInferior}, \texttt{NotifyNonlinear}, or \texttt{NotifyNonlinearVirtual}.

**Normal Entry/Exit Events**

\texttt{EnterNotify} and \texttt{LeaveNotify} events are generated when the pointer moves from one window to another window. Normal events are identified by \texttt{XEnterWindowEvent} or \texttt{XLeaveWindowEvent} structures whose mode member is set to \texttt{NotifyNormal}.

- When the pointer moves from window A to window B and A is an inferior of B, the \texttt{XWIN} server does the following:
Event Processing

- It generates a LeaveNotify event on window A, with the detail member of the XLeaveWindowEvent structure set to NotifyAncestor.

- It generates a LeaveNotify event on each window between window A and window B, exclusive, with the detail member of each XLeaveWindowEvent structure set to NotifyVirtual.

- It generates an EnterNotify event on window B, with the detail member of the XEnterWindowEvent structure set to NotifyInferior.

When the pointer moves from window A to window B and B is an inferior of A, the XWIN server does the following:

- It generates a LeaveNotify event on window A, with the detail member of the XLeaveWindowEvent structure set to NotifyInferior.

- It generates an EnterNotify event on each window between window A and window B, exclusive, with the detail member of each XEnterWindowEvent structure set to NotifyVirtual.

- It generates an EnterNotify event on window B, with the detail member of the XEnterWindowEvent structure set to NotifyAncestor.

When the pointer moves from window A to window B and window C is their least common ancestor, the XWIN server does the following:

- It generates a LeaveNotify event on window A, with the detail member of the XLeaveWindowEvent structure set to NotifyNonlinear.

- It generates a LeaveNotify event on each window between window A and window C, exclusive, with the detail member of each XLeaveWindowEvent structure set to NotifyNonlinearVirtual.

- It generates an EnterNotify event on each window between window C and window B, exclusive, with the detail member of each XEnterWindowEvent structure set to NotifyNonlinearVirtual.
- It generates an EnterNotify event on window B, with the detail member of the XEnterWindowEvent structure set to NotifyNonlinear.

When the pointer moves from window A to window B on different screens, the XWIN server does the following:

- It generates a LeaveNotify event on window A, with the detail member of the XLeaveWindowEvent structure set to NotifyNonlinear.

- If window A is not a root window, it generates a LeaveNotify event on each window above window A up to and including its root, with the detail member of each XLeaveWindowEvent structure set to NotifyNonlinearVirtual.

- If window B is not a root window, it generates an EnterNotify event on each window from window B's root down to but not including window B, with the detail member of each XEnterWindowEvent structure set to NotifyNonlinearVirtual.

- It generates an EnterNotify event on window B, with the detail member of the XEnterWindowEvent structure set to NotifyNonlinear.

**Grab and Ungrab Entry/Exit Events**

Pseudo-motion mode EnterNotify and LeaveNotify events are generated when a pointer grab activates or deactivates. Events in which the pointer grab activates are identified by XEnterWindowEvent or XLeaveWindowEvent structures whose mode member is set to NotifyGrab. Events in which the pointer grab deactivates are identified by XEnterWindowEvent or XLeaveWindowEvent structures whose mode member is set to NotifyUngrab (see XGrabPointer).

- When a pointer grab activates after any initial warp into a confine_to_window and before generating any actual ButtonPress event that activates the grab, G is the grab_window for the grab, and P is the window the pointer is in, the XWIN server does the following:
  - It generates EnterNotify and LeaveNotify events (see "Normal Entry/Exit Events" in this chapter), with the mode members of the XEnterWindowEvent and XLeaveWindowEvent structures set to NotifyGrab. These events are generated as if the pointer
were to suddenly warp from its current position in \( P \) to some position in \( G \). However, the pointer does not warp, and the XWIN server uses the pointer position as both the initial and final positions for the events.

When a pointer grab deactivates after generating any actual ButtonRelease event that deactivates the grab, \( G \) is the grab_window for the grab, and \( P \) is the window the pointer is in, the XWIN server does the following:

- It generates EnterNotify and LeaveNotify events (see "Normal Entry/Exit Events" in this chapter), with the mode members of the XEnterWindowEvent and XLeaveWindowEvent structures set to NotifyUngrab. These events are generated as if the pointer were to suddenly warp from some position in \( G \) to its current position in \( P \). However, the pointer does not warp, and the XWIN server uses the current pointer position as both the initial and final positions for the events.

**Input Focus Events**

This section describes the processing that occurs for the input focus events FocusIn and FocusOut. The XWIN server can report FocusIn or FocusOut events to clients wanting information about when the input focus changes. The keyboard is always attached to some window (typically, the root window or a top-level window), which is called the focus window. The focus window and the position of the pointer determine the window that receives keyboard input. Clients may need to know when the input focus changes to control highlighting of areas on the screen.

To receive FocusIn or FocusOut events, set the FocusChangeMask bit in the event-mask attribute of the window.

The structure for these event types contains:
typedef struct {
    int type;     /* FocusIn or FocusOut */
    unsigned long serial; /* # of last request processed by server */
    Bool send_event; /* true if this came from a SendEvent request */
    Display *display; /* Display the event was read from */
    Window window; /* window of event */
    int mode;      /* NotifyNormal, NotifyGrab, NotifyUngrab */
    int detail;    
        /**< NotifyAncestor, NotifyVirtual, NotifyInferior,
         * NotifyNonlinear, NotifyNonlinearVirtual, NotifyPointer,
         * NotifyPointerRoot, NotifyDetailNone */
} XFocusChangeEvent;

typedef XFocusChangeEvent XFocusInEvent;

typedef XFocusChangeEvent XFocusOutEvent;

The window member is set to the window on which the FocusIn or FocusOut event was generated. This is the window used by the XWIN server to report the event. The mode member is set to indicate whether the focus events are normal focus events, focus events while grabbed, focus events when a grab activates, or focus events when a grab deactivates. The XWIN server can set the mode member to NotifyNormal, NotifyWhileGrabbed, NotifyGrab, or NotifyUngrab.

All FocusOut events caused by a window unmap are generated after any UnmapNotify event; however, the X protocol does not constrain the ordering of FocusOut events with respect to generated EnterNotify, LeaveNotify, VisibilityNotify, and Expose events.

Depending on the event mode, the detail member is set to indicate the notify detail and can be NotifyAncestor, NotifyVirtual, NotifyInferior, NotifyNonlinear, NotifyNonlinearVirtual, NotifyPointer, NotifyPointerRoot, or NotifyDetailNone.
Normal Focus Events and Focus Events While Grabbed

Normal focus events are identified by XFocusInEvent or XFocusOutEvent structures whose mode member is set to NotifyNormal. Focus events while grabbed are identified by XFocusInEvent or XFocusOutEvent structures whose mode member is set to NotifyWhileGrabbed. The XWIN server processes normal focus and focus events while grabbed according to the following:

- When the focus moves from window A to window B, A is an inferior of B, and the pointer is in window P, the XWIN server does the following:
  - It generates a FocusOut event on window A, with the detail member of the XFocusOutEvent structure set to NotifyAncestor.
  - It generates a FocusOut event on each window between window A and window B, exclusive, with the detail member of each XFocusOutEvent structure set to NotifyVirtual.
  - It generates a FocusIn event on window B, with the detail member of the XFocusOutEvent structure set to NotifyInferior.
  - If window P is an inferior of window B but window P is not window A or an inferior or ancestor of window A, it generates a FocusIn event on each window below window B, down to and including window P, with the detail member of each XFocusInEvent structure set to NotifyPointer.

- When the focus moves from window A to window B, B is an inferior of A, and the pointer is in window P, the XWIN server does the following:
  - If window P is an inferior of window A but P is not an inferior of window B or an ancestor of B, it generates a FocusOut event on each window from window P up to but not including window A, with the detail member of each XFocusOutEvent structure set to NotifyPointer.
  - It generates a FocusOut event on window A, with the detail member of the XFocusOutEvent structure set to NotifyInferior.
- It generates a FocusIn event on each window between window A and window B, exclusive, with the detail member of each XFocusInEvent structure set to NotifyVirtual.

- It generates a FocusIn event on window B, with the detail member of the XFocusInEvent structure set to NotifyAncestor.

When the focus moves from window A to window B, window C is their least common ancestor, and the pointer is in window P, the XWIN server does the following:

- If window P is an inferior of window A, it generates a FocusOut event on each window from window P up to but not including window A, with the detail member of the XFocusOutEvent structure set to NotifyPointer.

- It generates a FocusOut event on window A, with the detail member of the XFocusOutEvent structure set to NotifyNonlinear.

- It generates a FocusOut event on each window between window A and window C, exclusive, with the detail member of each XFocusOutEvent structure set to NotifyNonlinearVirtual.

- It generates a FocusIn event on each window between C and B, exclusive, with the detail member of each XFocusInEvent structure set to NotifyNonlinearVirtual.

- It generates a FocusIn event on window B, with the detail member of the XFocusInEvent structure set to NotifyNonlinear.

- If window P is an inferior of window B, it generates a FocusIn event on each window below window B down to and including window P, with the detail member of the XFocusInEvent structure set to NotifyPointer.

When the focus moves from window A to window B on different screens and the pointer is in window P, the XWIN server does the following:

- If window P is an inferior of window A, it generates a FocusOut event on each window from window P up to but not including window A, with the detail member of each XFocusOutEvent structure set to NotifyPointer.
- It generates a FocusOut event on window A, with the detail member of the XFocusOutEvent structure set to NotifyNonlinear.

- If window A is not a root window, it generates a FocusOut event on each window above window A up to and including its root, with the detail member of each XFocusOutEvent structure set to NotifyNonlinearVirtual.

- If window B is not a root window, it generates a FocusIn event on each window from window B’s root down to but not including window B, with the detail member of each XFocusInEvent structure set to NotifyNonlinearVirtual.

- It generates a FocusIn event on window B, with the detail member of each XFocusInEvent structure set to NotifyNonlinear.

- If window P is an inferior of window B, it generates a FocusIn event on each window below window B down to and including window P, with the detail member of each XFocusInEvent structure set to NotifyPointer.

When the focus moves from window A to PointerRoot (events sent to the window under the pointer) or None (discard), and the pointer is in window P, the XWIN server does the following:

- If window P is an inferior of window A, it generates a FocusOut event on each window from window P up to but not including window A, with the detail member of each XFocusOutEvent structure set to NotifyPointer.

- It generates a FocusOut event on window A, with the detail member of the XFocusOutEvent structure set to NotifyNonlinear.

- If window A is not a root window, it generates a FocusOut event on each window above window A up to and including its root, with the detail member of each XFocusOutEvent structure set to NotifyNonlinearVirtual.
- It generates a FocusIn event on the root window of all screens, with the detail member of each XFocusInEvent structure set to NotifyPointerRoot (or NotifyDetailNone).

- If the new focus is PointerRoot, it generates a FocusIn event on each window from window P's root down to and including window P, with the detail member of each XFocusInEvent structure set to NotifyPointer.

When the focus moves from PointerRoot (events sent to the window under the pointer) or None to window A, and the pointer is in window P, the XWIN server does the following:

- If the old focus is PointerRoot, it generates a FocusOut event on each window from window P up to and including window P's root, with the detail member of each XFocusOutEvent structure set to NotifyPointer.

- It generates a FocusOut event on all root windows, with the detail member of each XFocusOutEvent structure set to NotifyPointerRoot (or NotifyDetailNone).

- If window A is not a root window, it generates a FocusIn event on each window from window A's root down to but not including window A, with the detail member of each XFocusInEvent structure set to NotifyNonlinearVirtual.

- It generates a FocusIn event on window A, with the detail member of the XFocusInEvent structure set to NotifyNonlinear.

- If window P is an inferior of window A, it generates a FocusIn event on each window below window A down to and including window P, with the detail member of each XFocusInEvent structure set to NotifyPointer.

When the focus moves from PointerRoot (events sent to the window under the pointer) to None (or vice versa), and the pointer is in window P, the XWIN server does the following:
- If the old focus is PointerRoot, it generates a FocusOut event on each window from window P up to and including window P’s root, with the detail member of each XFocusOutEvent structure set to NotifyPointer.

- It generates a FocusOut event on all root windows, with the detail member of each XFocusOutEvent structure set to either NotifyPointerRoot or NotifyDetailNone.

- It generates a FocusIn event on all root windows, with the detail member of each XFocusInEvent structure set to NotifyDetailNone or NotifyPointerRoot.

- If the new focus is PointerRoot, it generates a FocusIn event on each window from window P’s root down to and including window P, with the detail member of each XFocusInEvent structure set to NotifyPointer.

**Focus Events Generated by Grabs**

Focus events in which the keyboard grab activates are identified by XFocusInEvent or XFocusOutEvent structures whose mode member is set to NotifyGrab. Focus events in which the keyboard grab deactivates are identified by XFocusInEvent or XFocusOutEvent structures whose mode member is set to NotifyUngrab (see XGrabKeyboard).

- When a keyboard grab activates before generating any actual KeyPress event that activates the grab, G is the grab_window, and F is the current focus, the XWIN server does the following:

  - It generates FocusIn and FocusOut events, with the mode members of the XFocusInEvent and XFocusOutEvent structures set to NotifyGrab. These events are generated as if the focus were to change from F to G.

- When a keyboard grab deactivates after generating any actual KeyRelease event that deactivates the grab, G is the grab_window, and F is the current focus, the XWIN server does the following:

  - It generates FocusIn and FocusOut events, with the mode members of the XFocusInEvent and XFocusOutEvent structures set to NotifyUngrab. These events are generated as if the focus were to change from G to F.
Key Map State Notification Events

The XWIN server can report KeymapNotify events to clients that want information about changes in their keyboard state.

To receive KeymapNotify events, set the KeymapStateMask bit in the event-mask attribute of the window. The XWIN server generates this event immediately after every EnterNotify and FocusIn event.

The structure for this event type contains:

```c
typedef struct {
    int type;          /* KeymapNotify */
    unsigned long serial; /* # of last request processed by server */
    Bool send_event;   /* true if this came from a SendEvent request */
    Display *display;  /* Display the event was read from */
    Window window;
    char key_vector[32];
} XKeymapEvent;
```

The window member is not used but is present to aid some toolkits. The key_vector member is set to the bit vector of the keyboard. Each bit set to 1 indicates that the corresponding key is currently pressed. The vector is represented as 32 bytes. Byte N (from 0) contains the bits for keys 8N to 8N + 7 with the least-significant bit in the byte representing key 8N.

Exposure Events

The X protocol does not guarantee to preserve the contents of window regions when the windows are obscured or reconfigured. Some implementations may preserve the contents of windows. Other implementations are free to destroy the contents of windows when exposed. X expects client applications to assume the responsibility for restoring the contents of an exposed window region. (An exposed window region describes a formerly obscured window whose region becomes visible.) Therefore, the XWIN server sends Expose events describing the window and the region of the window that has been exposed. A naive client application usually redraws the entire window. A more sophisticated client application redraws only the exposed region.
Expose Events

The XWIN server can report Expose events to clients wanting information about when the contents of window regions have been lost. The circumstances in which the XWIN server generates Expose events are not as definite as those for other events. However, the XWIN server never generates Expose events on windows whose class you specified as InputOnly. The XWIN server can generate Expose events when no valid contents are available for regions of a window and either the regions are visible, the regions are viewable and the server is (perhaps newly) maintaining backing store on the window, or the window is not viewable but the server is (perhaps newly) honoring the window's backing-store attribute of Always or WhenMapped. The regions decompose into an (arbitrary) set of rectangles, and an Expose event is generated for each rectangle. For any given window, the XWIN server guarantees to report contiguously all of the regions exposed by some action that causes Expose events, such as raising a window.

To receive Expose events, set the ExposureMask bit in the event-mask attribute of the window.

The structure for this event type contains:

```c
typedef struct {
    int type;     /* Expose */
    unsigned long serial; /* # of last request processed by server */
    Bool send_event; /* true if this came from a SendEvent request */
    Display *display; /* Display the event was read from */
    Window window;
    int x, y;
    int width, height;
    int count;     /* if nonzero, at least this many more */
} XExposeEvent;
```

The window member is set to the exposed (damaged) window. The x and y members are set to the coordinates relative to the window's origin and indicate the upper-left corner of the rectangle. The width and height members are set to the size (extent) of the rectangle. The count member is set to the number of Expose events that are to follow. If count is zero, no more Expose events follow for this window. However, if count is nonzero, at least that number of Expose events (and possibly more) follow for this window. Simple applications that do not want to optimize redisplay by distinguishing between subareas of its
window can just ignore all Expose events with nonzero counts and perform full redispays on events with zero counts.

**GraphicsExpose and NoExpose Events**

The XWIN server can report GraphicsExpose events to clients wanting information about when a destination region could not be computed during certain graphics requests: XCopyArea or XCopyPlane. The XWIN server generates this event whenever a destination region could not be computed due to an obscured or out-of-bounds source region. In addition, the XWIN server guarantees to report contiguously all of the regions exposed by some graphics request (for example, copying an area of a drawable to a destination drawable).

The XWIN server generates a NoExpose event whenever a graphics request that might produce a GraphicsExpose event does not produce any. In other words, the client is really asking for a GraphicsExpose event but instead receives a NoExpose event.

To receive GraphicsExpose or NoExpose events, you must first set the graphics-exposure attribute of the graphics context to True. You also can set the graphics-expose attribute when creating a graphics context using XCreateGC or by calling XSetGraphicsExposures.

The structures for these event types contain:

```c
typedef struct {
    int type; /* GraphicsExpose */
    unsigned long serial; /* # of last request processed by server */
    Bool send_event; /* true if this came from a SendEvent request */
    Display *display; /* Display the event was read from */
    Drawable drawable;
    int x, y;
    int width, height;
    int count; /* if nonzero, at least this many more */
    int major_code; /* Core is CopyArea or CopyPlane */
    int minor_code; /* not defined in the core */
} XGraphicsExposeEvent;
```
typedef struct {
    int type;          /* NoExpose */
    unsigned long serial; /* # of last request processed by server */
    Bool send_event;   /* true if this came from a SendEvent request */
    Display *display;  /* Display the event was read from */
    Drawable drawable;
    int major_code;    /* core is CopyArea or CopyPlane */
    int minor_code;    /* not defined in the core */
} XNoExposeEvent;

Both structures have these common members: drawable, major_code, and minor_code. The drawable member is set to the drawable of the destination region on which the graphics request was to be performed. The major_code member is set to the graphics request initiated by the client and can be either X_CopyArea or X_CopyPlane. If it is X_CopyArea, a call to XCopyArea initiated the request. If it is X_CopyPlane, a call to XCopyPlane initiated the request. These constants are defined in <X11/Xproto.h>. The minor_code member, like the major_code member, indicates which graphics request was initiated by the client. However, the minor_code member is not defined by the core X protocol and will be zero in these cases, although it may be used by an extension.

The XGraphicsExposeEvent structure has these additional members: x, y, width, height, and count. The x and y members are set to the coordinates relative to the drawable’s origin and indicate the upper-left corner of the rectangle. The width and height members are set to the size (extent) of the rectangle. The count member is set to the number of GraphicsExpose events to follow. If count is zero, no more GraphicsExpose events follow for this window. However, if count is nonzero, at least that number of GraphicsExpose events (and possibly more) are to follow for this window.

Window State Change Events

The following sections discuss:

- CirculateNotify events
- ConfigureNotify events
CirculateNotify Events

The XWIN server can report CirculateNotify events to clients wanting information about when a window changes its position in the stack. The XWIN server generates this event type whenever a window is actually restacked as a result of a client application calling 

\[ \text{XCirculateSubwindows,} \]
\[ \text{XCirculateSubwindowsUp, or XCirculateSubwindowsDown.} \]

To receive CirculateNotify events, set the StructureNotifyMask bit in the event-mask attribute of the window or the SubstructureNotifyMask bit in the event-mask attribute of the parent window (in which case, circulating any child generates an event).

The structure for this event type contains:

```c
typedef struct {
    int type;             /* CirculateNotify */
    unsigned long serial; /* # of last request processed by server */
    Bool send_event;      /* true if this came from a SendEvent request */
    Display *display;     /* Display the event was read from */
    Window event;
    Window window;
    int place;            /* PlaceOnTop, PlaceOnBottom */
} XCirculateEvent;
```
The event member is set either to the restacked window or to its parent, depending on whether StructureNotify or SubstructureNotify was selected. The window member is set to the window that was restacked. The place member is set to the window's position after the restack occurs and is either PlaceOnTop or PlaceOnBottom. If it is PlaceOnTop, the window is now on top of all siblings. If it is PlaceOnBottom, the window is now below all siblings.

ConfigureNotify Events

The XWIN server can report ConfigureNotify events to clients wanting information about actual changes to a window's state, such as size, position, border, and stacking order. The XWIN server generates this event type whenever one of the following configure window requests made by a client application actually completes:

- A window's size, position, border, and/or stacking order is reconfigured by calling XConfigureWindow.
- The window's position in the stacking order is changed by calling XLowerWindow, XRaiseWindow, or XRestackWindows.
- A window is moved by calling XMoveWindow.
- A window's size is changed by calling XResizeWindow.
- A window's size and location is changed by calling XMoveResizeWindow.
- A window is mapped and its position in the stacking order is changed by calling XMapRaised.
- A window's border width is changed by calling XSetWindowBorderWidth.

To receive ConfigureNotify events, set the StructureNotifyMask bit in the event-mask attribute of the window or the SubstructureNotifyMask bit in the event-mask attribute of the parent window (in which case, configuring any child generates an event).

The structure for this event type contains:
typedef struct {
    int type;            /* ConfigureNotify */
    unsigned long serial; /* # of last request processed by server */
    Bool send_event;     /* true if this came from a SendEvent request */
    Display *display;    /* Display the event was read from */
    Window event;
    Window window;
    int x, y;
    int width, height;
    int border_width;
    Window above;
    Bool override_redirect;
} XConfigureEvent;

The event member is set either to the reconfigured window or to its parent, depending on whether StructureNotify or SubstructureNotify was selected. The window member is set to the window whose size, position, border, and/or stacking order was changed.

The x and y members are set to the coordinates relative to the parent window’s origin and indicate the position of the upper-left outside corner of the window. The width and height members are set to the inside size of the window, not including the border. The border_width member is set to the width of the window’s border, in pixels.

The above member is set to the sibling window and is used for stacking operations. If the XWIN server sets this member to None, the window whose state was changed is on the bottom of the stack with respect to sibling windows. However, if this member is set to a sibling window, the window whose state was changed is placed on top of this sibling window.

The override_redirect member is set to the override-redirect attribute of the window. Window manager clients normally should ignore this window if the override_redirect member is True.
CreateNotify Events

The XWIN server can report CreateNotify events to clients wanting information about creation of windows. The XWIN server generates this event whenever a client application creates a window by calling XCreateWindow or XCreateSimpleWindow.

To receive CreateNotify events, set the SubstructureNotifyMask bit in the event-mask attribute of the window. Creating any children then generates an event.

The structure for the event type contains:

```c
typedef struct {
    int type;  /* CreateNotify */
    unsigned long serial; /* # of last request processed by server */
    Bool send_event; /* true if this came from a SendEvent request */
    Display *display; /* Display the event was read from */
    Window parent; /* parent of the window */
    Window window; /* window id of window created */
    int x, y; /* window location */
    int width, height; /* size of window */
    int border_width; /* border width */
    Bool override_redirect; /* creation should be overridden */
} XCreateWindowEvent;
```

The parent member is set to the created window's parent. The window member specifies the created window. The x and y members are set to the created window's coordinates relative to the parent window's origin and indicate the position of the upper-left outside corner of the created window. The width and height members are set to the inside size of the created window (not including the border) and are always nonzero. The border_width member is set to the width of the created window's border, in pixels. The override_redirect member is set to the override-redirect attribute of the window. Window manager clients normally should ignore this window if the override_redirect member is True.
DestroyNotify Events

The XWIN server can report DestroyNotify events to clients wanting information about which windows are destroyed. The XWIN server generates this event whenever a client application destroys a window by calling XDestroyWindow or XDestroySubwindows.

The ordering of the DestroyNotify events is such that for any given window, DestroyNotify is generated on all inferiors of the window before being generated on the window itself. The X protocol does not constrain the ordering among siblings and across subhierarchies.

To receive DestroyNotify events, set the StructureNotifyMask bit in the event-mask attribute of the window or the SubstructureNotifyMask bit in the event-mask attribute of the parent window (in which case, destroying any child generates an event).

The structure for this event type contains:

```c
typedef struct {
    int type;            /* DestroyNotify */
    unsigned long serial; /* $ of last request processed by server */
    Bool send_event;     /* true if this came from a SendEvent request */
    Display *display;    /* Display the event was read from */
    Window event;
    Window window;
} XDestroyWindowEvent;
```

The event member is set either to the destroyed window or to its parent, depending on whether StructureNotify or SubstructureNotify was selected. The window member is set to the window that is destroyed.

GravityNotify Events

The XWIN server can report GravityNotify events to clients wanting information about when a window is moved because of a change in the size of its parent. The XWIN server generates this event whenever a client application actually moves a child window as a result of resizing its parent by calling XConfigureWindow, XMoveResizeWindow, or XResizeWindow.
To receive GravityNotify events, set the StructureNotifyMask bit in the event-mask attribute of the window or the SubstructureNotifyMask bit in the event-mask attribute of the parent window (in which case, any child that is moved because its parent has been resized generates an event).

The structure for this event type contains:

```c
typedef struct {
    int type;    /* GravityNotify */
    unsigned long serial; /* $ of last request processed by server */
    Bool send_event; /* true if this came from a SendEvent request */
    Display *display; /* Display the event was read from */
    Window event;
    Window window;
    int x, y;
} XGravityEvent;
```

The event member is set either to the window that was moved or to its parent, depending on whether StructureNotify or SubstructureNotify was selected. The window member is set to the child window that was moved. The x and y members are set to the coordinates relative to the new parent window's origin and indicate the position of the upper-left outside corner of the window.

MapNotify Events

The XWIN server can report MapNotify events to clients wanting information about which windows are mapped. The XWIN server generates this event type whenever a client application changes the window's state from unmapped to mapped by calling XMapWindow, XMapRaised, XMapSubwindows, XReparentWindow, or as a result of save-set processing.

To receive MapNotify events, set the StructureNotifyMask bit in the event-mask attribute of the window or the SubstructureNotifyMask bit in the event-mask attribute of the parent window (in which case, mapping any child generates an event).

The structure for this event type contains:
typedef struct {
    int type;  /* MapNotify */
    unsigned long serial;  /* # of last request processed by server */
    Bool send_event;  /* true if this came from a SendEvent request */
    Display *display;  /* Display the event was read from */
    Window event;
    Window window;
    Bool override_redirect;  /* boolean, is override set... */
} XMapEvent;

The event member is set either to the window that was mapped or to its parent, depending on whether StructureNotify or SubstructureNotify was selected. The window member is set to the window that was mapped. The override_redirect member is set to the window that was mapped. The override_redirect attribute of the window. Window manager clients normally should ignore this window if the override-redirect attribute is True, because these events usually are generated from pop-ups, which override structure control.

MappingNotify Events

The XWIN server reports MappingNotify events to all clients. There is no mechanism to express disinterest in this event. The XWIN server generates this event type whenever a client application successfully calls:

- XSetModifierMapping to indicate which KeyCodes are to be used as modifiers
- XChangeKeyboardMapping to change the keyboard mapping
- XSetPointerMapping to set the pointer mapping

The structure for this event type contains:
typedef struct {
  int type;          /* MappingNotify */
  unsigned long serial; /* # of last request processed by server */
  Bool send_event;   /* true if this came from a SendEvent request */
  Display *display;  /* Display the event was read from */
  Window window;     /* unused */
  int request;       /* one of MappingModifier, MappingKeyboard,
                         MappingPointer */
  int first_keycode; /* first keycode */
  int count;         /* defines range of change w. first_keycode*/
} XMappingEvent;

The request member is set to indicate the kind of mapping change that occurred
and can be MappingModifier, MappingKeyboard, MappingPointer. If it is
MappingModifier, the modifier mapping was changed. If it is MappingKey-
board, the keyboard mapping was changed. If it is MappingPointer, the
pointer button mapping was changed. The first_keycode and count members are
set only if the request member was set to MappingKeyboard. The number in
first_keycode represents the first number in the range of the altered mapping,
and count represents the number of keycodes altered.

To update the client application's knowledge of the keyboard, you should call
XRefreshKeyboardMapping.

**ReparentNotify Events**

The XWIN server can report ReparentNotify events to clients wanting informa-
tion about changing a window's parent. The XWIN server generates this event
whenever a client application calls XReparentWindow and the window is actu-
ally reparented.

To receive ReparentNotify events, set the StructureNotifyMask bit in the
event-mask attribute of the window or the SubstructureNotifyMask bit in the
event-mask attribute of either the old or the new parent window (in which case,
reparenting any child generates an event).

The structure for this event type contains:
typedef struct {
    int type;    /* ReparentNotify */
    unsigned long serial; /* 0 of last request processed by server */
    Bool send_event; /* true if this came form a SendEvent request */
    Display *display; /* Display the event was read from */
    Window event;
    Window window;
    Window parent;
    int x, y;
    Bool override_redirect;
} XRparentEvent;

The event member is set either to the reparented window or to the old or the new parent, depending on whether StructureNotify or SubstructureNotify was selected. The window member is set to the window that was reparented. The parent member is set to the new parent window. The x and y members are set to the reparented window's coordinates relative to the new parent window's origin and define the upper-left outer corner of the reparented window. The override_redirect member is set to the override-redirect attribute of the window specified by the window member. Window manager clients normally should ignore this window if the override_redirect member is True.

UnmapNotify Events

The XWIN server can report UnmapNotify events to clients wanting information about which windows are unmapped. The XWIN server generates this event type whenever a client application changes the window's state from mapped to unmapped.

To receive UnmapNotify events, set the StructureNotifyMask bit in the event-mask attribute of the window or the SubstructureNotifyMask bit in the event-mask attribute of the parent window (in which case, unmapping any child window generates an event).

The structure for this event type contains:
typedef struct {
    int type; /* UnmapNotify */
    unsigned long serial; /* # of last request processed by server */
    Bool send_event; /* true if this came from a SendEvent request */
    Display *display; /* Display the event was read from */
    Window event;
    Window window;
    Bool from_configure;
} XUnmapEvent;

The event member is set either to the unmapped window or to its parent, depending on whether StructureNotify or SubstructureNotify was selected. This is the window used by the XWIN server to report the event. The window member is set to the window that was unmapped. The from_configure member is set to True if the event was generated as a result of a resizing of the window's parent when the window itself had a win_gravity of UnmapGravity.

VisibilityNotify Events

The XWIN server can report VisibilityNotify events to clients wanting any change in the visibility of the specified window. A region of a window is visible if someone looking at the screen can actually see it. The XWIN server generates this event whenever the visibility changes state. However, this event is never generated for windows whose class is InputOnly.

All VisibilityNotify events caused by a hierarchy change are generated after any hierarchy event (UnmapNotify, MapNotify, ConfigureNotify, GravityNotify, CirculateNotify) caused by that change. Any VisibilityNotify event on a given window is generated before any Expose events on that window, but it is not required that all VisibilityNotify events on all windows be generated before all Expose events on all windows. The X protocol does not constrain the ordering of VisibilityNotify events with respect to FocusOut, EnterNotify, and LeaveNotify events.

To receive VisibilityNotify events, set the VisibilityChangeMask bit in the event-mask attribute of the window.

The structure for this event type contains:
typedef struct {
    int type;            /* VisibilityNotify */
    unsigned long serial; /* $ of last request processed by server */
    Bool send_event;     /* true if this came from a SendEvent request */
    Display *display;    /* Display the event was read from */
    Window *window;
    int state;
} XVisibilityEvent;

The window member is set to the window whose visibility state changes. The
state member is set to the state of the window's visibility and can be Visibili-
tyUnobscured, VisibilityPartiallyObscured, or VisibilityFullyObscured. The XWIN server ignores all of a window's subwindows when deter-
mining the visibility state of the window and processes VisibilityNotify
events according to the following:

- When the window changes state from partially obscured, fully obscured,
or not viewable to viewable and completely unobscured, the XWIN server
generates the event with the state member of the XVisibilityEvent
structure set to VisibilityUnobscured.

- When the window changes state from viewable and completely unob-
sured or not viewable to viewable and partially obscured, the XWIN
server generates the event with the state member of the XVisibilityEvent
structure set to VisibilityPartiallyObscured.

- When the window changes state from viewable and completely unob-
sured, viewable and partially obscured, or not viewable to viewable and
fully obscured, the XWIN server generates the event with the state member
of the XVisibilityEvent structure set to VisibilityFullyObscured.

Structure Control Events

This section discusses:

- CirculateRequest events
Event Processing

- ConfigureRequest events
- MapRequest events
- ResizeRequest events

CirculateRequest Events

The XWIN server can report CirculateRequest events to clients wanting information about when another client initiates a circulate window request on a specified window. The XWIN server generates this event type whenever a client initiates a circulate window request on a window and a subwindow actually needs to be restacked. The client initiates a circulate window request on the window by calling XCirculateSubwindows, XCirculateSubwindowsUp, or XCirculateSubwindowsDown.

To receive CirculateRequest events, set the SubstructureRedirectMask in the event-mask attribute of the window. Then, in the future, the circulate window request for the specified window is not executed, and thus, any subwindow’s position in the stack is not changed. For example, suppose a client application calls XCirculateSubwindowsUp to raise a subwindow to the top of the stack. If you had selected SubstructureRedirectMask on the window, the XWIN server reports to you a CirculateRequest event and does not raise the subwindow to the top of the stack.

The structure for this event type contains:

typedef struct {
    int type;            /* CirculateRequest */
    unsigned long serial; /* # of last request processed by server */
    Bool send_event;     /* true if this came from a SendEvent request */
    Display *display;    /* Display the event was read from */
    Window parent;
    Window window;
    int place;            /* PlaceOnTop, PlaceOnBottom */
} XCirculateRequestEvent;

The parent member is set to the parent window. The window member is set to the subwindow to be restacked. The place member is set to what the new position in the stacking order should be and is either PlaceOnTop or PlaceOnBottom. If it is PlaceOnTop, the subwindow should be on top of all siblings. If it is PlaceOnBottom, the subwindow should be below all siblings.
ConfigureRequest Events

The XWIN server can report ConfigureRequest events to clients wanting information about when a different client initiates a configure window request on any child of a specified window. The configure window request attempts to reconfigure a window’s size, position, border, and stacking order. The XWIN server generates this event whenever a different client initiates a configure window request on a window by calling XConfigureWindow, XLowerWindow, XRaiseWindow, XMapRaised, XMoveResizeWindow, XMoveWindow, XResizeWindow, XRestackWindows, or XSetWindowBorderWidth.

To receive ConfigureRequest events, set the SubstructureRedirectMask bit in the event-mask attribute of the window. ConfigureRequest events are generated when a ConfigureWindow protocol request is issued on a child window by another client. For example, suppose a client application calls XLowerWindow to lower a window. If you had selected SubstructureRedirectMask on the parent window and if the override-redirect attribute of the window is set to False, the XWIN server reports a ConfigureRequest event to you and does not lower the specified window.

The structure for this event type contains:

```c
typedef struct {
    int type;       /* ConfigureRequest */
    unsigned long serial;  /* # of last request processed by server */
    Bool send_event;     /* true if this came from a SendEvent request */
    Display *display;    /* Display the event was read from */
    Window parent;
    Window window;
    int x, y;
    int width, height;
    int border_width;
    Window above;
    int detail;          /* Above, Below, TopIf, BottomIf, Opposite */
    unsigned long value_mask;
} XConfigureRequestEvent;
```

The parent member is set to the parent window. The window member is set to the window whose size, position, border width, and/or stacking order is to be reconfigured. The value_mask member indicates which components were specified in the ConfigureWindow protocol request. The corresponding values are reported as given in the request. The remaining values are filled in from the
current geometry of the window, except in the case of above (sibling) and detail (stack-mode), which are reported as Above and None, respectively, if they are not given in the request.

**MapRequest Events**

The XWIN server can report MapRequest events to clients wanting information about a different client's desire to map windows. A window is considered mapped when a map window request completes. The XWIN server generates this event whenever a different client initiates a map window request on an unmapped window whose override_redirect member is set to False. Clients initiate map window requests by calling XMapWindow, XMapRaised, or XMapSubwindows.

To receive MapRequest events, set the SubstructureRedirectMask bit in the event-mask attribute of the window. This means another client's attempts to map a child window by calling one of the map window request functions is intercepted, and you are sent a MapRequest instead. For example, suppose a client application calls XMapWindow to map a window. If you (usually a window manager) had selected SubstructureRedirectMask on the parent window and if the override-redirect attribute of the window is set to False, the XWIN server reports a MapRequest event to you and does not map the specified window. Thus, this event gives your window manager client the ability to control the placement of subwindows.

The structure for this event type contains:

```c
typedef struct {
    int type;         /* MapRequest */
    unsigned long serial; /* # of last request processed by server */
    Bool send_event; /* true if this came from a SendEvent request */
    Display *display; /* Display the event was read from */
    Window parent;
    Window window;
} XMapRequestEvent;
```

The parent member is set to the parent window. The window member is set to the window to be mapped.
ResizeRequest Events

The XWIN server can report ResizeRequest events to clients wanting information about another client’s attempts to change the size of a window. The XWIN server generates this event whenever some other client attempts to change the size of the specified window by calling XConfigureWindow, XResizeWindow, or XMoveResizeWindow.

To receive ResizeRequest events, set the ResizeRedirect bit in the event-mask attribute of the window. Any attempts to change the size by other clients are then redirected.

The structure for this event type contains:

typedef struct {
    int type;          /* ResizeRequest */
    unsigned long serial; /* # of last request processed by server */
    Bool send_event;   /* true if this came from a SendEvent request */
    Display *display;  /* Display the event was read from */
    Window window;
    int width, height;
} XResizeRequestEvent;

The window member is set to the window whose size another client attempted to change. The width and height members are set to the inside size of the window, excluding the border.

Colormap State Change Events

The XWIN server can report ColormapNotify events to clients wanting information about when the colormap changes and when a colormap is installed or uninstalled. The XWIN server generates this event type whenever a client application:

- Changes the colormap member of the XSetWindowAttributes structure by calling XChangeWindowAttributes, XFreeColormap, or XSetWindowColormap
Installs or uninstalls the colormap by calling XInstallColormap or XUninstallColormap.

To receive ColormapNotify events, set the ColormapChangeMask bit in the event-mask attribute of the window.

The structure for this event type contains:

```c
typedef struct {
    int type;      /* ColormapNotify */
    unsigned long serial;   /* # of last request processed by server */
    Bool send_event;  /* true if this came from a SendEvent request */
    Display *display; /* Display the event was read from */
    Window window;
    Colormap colormap; /* colormap or None */
    Bool new;
    int state;       /* ColormapInstalled, ColormapUninstalled */
} XColormapEvent;
```

The window member is set to the window whose associated colormap is changed, installed, or uninstalled. For a colormap that is changed, installed, or uninstalled, the colormap member is set to the colormap associated with the window. For a colormap that is changed by a call to XFreeColormap, the colormap member is set to None. The new member is set to indicate whether the colormap for the specified window was changed or installed or uninstalled and can be True or False. If it is True, the colormap was changed. If it is False, the colormap was installed or uninstalled. The state member is always set to indicate whether the colormap is installed or uninstalled and can be ColormapInstalled or ColormapUninstalled.

Client Communication Events

This section discusses:

- ClientMessage events
- PropertyNotify events
Event Processing

- SelectionClear events
- SelectionNotify events
- SelectionRequest events

ClientMessage Events

The XWIN server generates ClientMessage events only when a client calls the function XSendEvent.

The structure for this event type contains:

```c
typedef struct {
    int type;    /* ClientMessage */
    unsigned long serial; /* # of last request processed by server */
    Bool send_event;     /* true if this came from a SendEvent request */
    Display *display;    /* Display the event was read from */
    Window window;
    Atom message_type;
    int format;
    union {
        char b[20];
        short s[10];
        long l[5];
    } data;
} XClientMessageEvent;
```

The window member is set to the window to which the event was sent. The message_type member is set to an atom that indicates how the data should be interpreted by the receiving client. The format member is set to 8, 16, or 32 and specifies whether the data should be viewed as a list of bytes, shorts, or longs. The data member is a union that contains the members b, s, and l. The b, s, and l members represent data of 20 8-bit values, 10 16-bit values, and 5 32-bit values. Particular message types might not make use of all these values. The XWIN server places no interpretation on the values in the message_type or data members.
PropertyNotify Events

The XWIN server can report PropertyNotify events to clients wanting information about property changes for a specified window.

To receive PropertyNotify events, set the PropertyChangeMask bit in the event-mask attribute of the window.

The structure for this event type contains:

```c
typedef struct {
    int type;            /* PropertyNotify */
    unsigned long serial; /* # of last request processed by server */
    Bool send_event;     /* true if this came from a SendEvent request */
    Display *display;    /* Display the event was read from */
    Window window;
    Atom atom;
    Time time;
    int state;           /* PropertyNewValue or PropertyDeleted */
} XPropertyEvent;
```

The window member is set to the window whose associated property was changed. The atom member is set to the property’s atom and indicates which property was changed or desired. The time member is set to the server time when the property was changed. The state member is set to indicate whether the property was changed to a new value or deleted and can be PropertyNewValue or PropertyDeleted. The state member is set to PropertyNewValue when a property of the window is changed using XChangeProperty or XRotateWindowProperties (even when adding zero-length data using XChangeProperty) and when replacing all or part of a property with identical data using XChangeProperty or XRotateWindowProperties. The state member is set to PropertyDeleted when a property of the window is deleted using XDeleteProperty or, if the delete argument is True, XGetWindowProperty.
SelectionClear Events

The XWIN server reports SelectionClear events to the current owner of a selection. The XWIN server generates this event type on the window losing ownership of the selection to a new owner. This sequence of events could occur whenever a client calls XSetSelectionOwner.

The structure for this event type contains:

```c
typedef struct {
    int type;            /* SelectionClear */
    unsigned long serial; /* # of last request processed by server */
    Bool send_event;     /* true if this came from a SendEvent request */
    Display *display;    /* Display the event was read from */
    Window window;
    Atom selection;
    Time time;
} XSelectionClearEvent;
```

The window member is set to the window losing ownership of the selection. The selection member is set to the selection atom. The time member is set to the last change time recorded for the selection. The owner member is the window that was specified by the current owner in its XSetSelectionOwner call.

SelectionRequest Events

The XWIN server reports SelectionRequest events to the owner of a selection. The XWIN server generates this event whenever a client requests a selection conversion by calling XConvertSelection and the specified selection is owned by a window.

The structure for this event type contains:
Event Processing

typedef struct {
    int type;            /* SelectionRequest */
    unsigned long serial; /* # of last request processed by server */
    Bool send_event;     /* true if this came from a SendEvent request */
    Display *display;    /* Display the event was read from */
    Window owner;
    Window requestor;
    Atom selection;
    Atom target;
    Atom property;
    Time time;
} XSelectionRequestEvent;

The owner member is set to the window owning the selection and is the window that was specified by the current owner in its XSetSelectionOwner call. The requestor member is set to the window requesting the selection. The selection member is set to the atom that names the selection. For example, PRIMARY is used to indicate the primary selection. The target member is set to the atom that indicates the type the selection is desired in. The property member can be a property name or None. The time member is set to the time and is a timestamp or CurrentTime from the ConvertSelection request.

The client who owns the selection should do the following:

■ The owner client should convert the selection based on the atom contained in the target member.

■ If a property was specified (that is, the property member is set), the owner client should store the result as that property on the requestor window and then send a SelectionNotify event to the requestor by calling XSendEvent with an empty event-mask; that is, the event should be sent to the creator of the requestor window.

■ If None is specified as the property, the owner client should choose a property name on the requestor window and then send a SelectionNotify event giving the actual name.

■ If the selection cannot be converted as requested, the owner client should send a SelectionNotify event with the property set to None.
SelectionNotify Events

This event is generated by the XWIN server in response to a ConvertSelection protocol request when there is no owner for the selection. When there is an owner, it should be generated by the owner of the selection by using XSendEvent. The owner of a selection should send this event to a requestor when a selection has been converted and stored as a property or when a selection conversion could not be performed (which is indicated by setting the property member to None).

If None is specified as the property in the ConvertSelection protocol request, the owner should choose a property name, store the result as that property on the requestor window, and then send a SelectionNotify giving that actual property name.

The structure for this event type contains:

```c
typedef struct {
    int type; /* SelectionNotify */
    unsigned long serial; /* # of last request processed by server */
    Bool send_event; /* true if this came from a SendEvent request */
    Display *display; /* Display the event was read from */
    Window requestor;
    Atom selection;
    Atom target;
    Atom property; /* atom or None */
    Time time;
} XSelectionEvent;
```

The requestor member is set to the window associated with the requestor of the selection. The selection member is set to the atom that indicates the selection. For example, PRIMARY is used for the primary selection. The target member is set to the atom that indicates the converted type. For example, PIXMAP is used for a pixmap. The property member is set to the atom that indicates which property the result was stored on. If the conversion failed, the property member is set to None. The time member is set to the time the conversion took place and can be a timestamp or CurrentTime.
Selecting Events

There are two ways to select the events you want reported to your client application. One way is to set the event_mask member of the XSetWindowAttributes structure when you call XCreateWindow and XChangeWindowAttributes. Another way is to use XSelectInput.

XSelectInput (display, w, event_mask)
   Display *display;
   Window w;
   long event_mask;

**display** Specifies the connection to the XWIN server.

**w** Specifies the window whose events you are interested in.

**event_mask** Specifies the event mask.

The XSelectInput function requests that the XWIN server report the events associated with the specified event mask. Initially, X will not report any of these events. Events are reported relative to a window. If a window is not interested in a device event, it usually propagates to the closest ancestor that is interested, unless the do_not_propagate mask prohibits it.

Setting the event-mask attribute of a window overrides any previous call for the same window but not for other clients. Multiple clients can select for the same events on the same window with the following restrictions:

- Multiple clients can select events on the same window because their event masks are disjoint. When the XWIN server generates an event, it reports it to all interested clients.

- Only one client at a time can select CirculateRequest, ConfigureRequest, or MapRequest events, which are associated with the event mask SubstructureRedirectMask.

- Only one client at a time can select a ResizeRequest event, which is associated with the event mask ResizeRedirectMask.

- Only one client at a time can select a ButtonPress event, which is associated with the event mask ButtonPressMask.

The server reports the event to all interested clients.

XSelectInput can generate a BadWindow error.
Handling the Output Buffer

The output buffer is an area used by Xlib to store requests. The functions described in this section flush the output buffer if the function would block or not return an event. That is, all requests residing in the output buffer that have not yet been sent are transmitted to the XWIN server. These functions differ in the additional tasks they might perform.

To flush the output buffer, use XFlush.

\[
\text{XFlush}(\text{display})
\]
\[
\text{Display } \ast \text{display};
\]

\textit{display} \quad \text{Specifies the connection to the XWIN server.}

The XFlush function flushes the output buffer. Most client applications need not use this function because the output buffer is automatically flushed as needed by calls to XPending, XNextEvent, and XWindowEvent. Events generated by the server may be enqueued into the library’s event queue.

To flush the output buffer and then wait until all requests have been processed, use XSync.

\[
\text{XSync}(\text{display}, \text{discard})
\]
\[
\text{Display } \ast \text{display};
\]
\[
\text{Bool discard};
\]

\textit{display} \quad \text{Specifies the connection to the XWIN server.}

\textit{discard} \quad \text{Specifies a Boolean value that indicates whether XSync discards all events on the event queue.}

The XSync function flushes the output buffer and then waits until all requests have been received and processed by the XWIN server. Any errors generated must be handled by the error handler. For each error event received by Xlib, XSync calls the client application’s error handling routine (see "Using the Default Error Handlers" in this chapter). Any events generated by the server are enqueued into the library’s event queue.

Finally, if you passed False, XSync does not discard the events in the queue. If you passed True, XSync discards all events in the queue, including those events that were on the queue before XSync was called. Client applications seldom need to call XSync.
Event Queue Management

Xlib maintains an event queue. However, the operating system also may be buffering data in its network connection that is not yet read into the event queue.

To check the number of events in the event queue, use XEventsQueued.

```c
int XEventsQueued (display, mode)
Display *display;
int mode;
```

display Specifies the connection to the XWIN server.

mode Specifies the mode. You can pass QueuedAlready, QueuedAfterFlush, or QueuedAfterReading.

If mode is QueuedAlready, XEventsQueued returns the number of events already in the event queue (and never performs a system call). If mode is QueuedAfterFlush, XEventsQueued returns the number of events already in the queue if the number is nonzero. If there are no events in the queue, XEventsQueued flushes the output buffer, attempts to read more events out of the application’s connection, and returns the number read. If mode is QueuedAfterReading, XEventsQueued returns the number of events already in the queue if the number is nonzero. If there are no events in the queue, XEventsQueued attempts to read more events out of the application’s connection without flushing the output buffer and returns the number read.

XEventsQueued always returns immediately without I/O if there are events already in the queue. XEventsQueued with mode QueuedAfterFlush is identical in behavior to XPending. XEventsQueued with mode QueuedAlready is identical to the XQLength function.

To return the number of events that are pending, use XPending.

```c
int XPending (display)
Display *display;
```

display Specifies the connection to the XWIN server.

The XPending function returns the number of events that have been received from the XWIN server but have not been removed from the event queue. XPending is identical to XEventsQueued with the mode QueuedAfterFlush specified.
Manipulating the Event Queue

Xlib provides functions that let you manipulate the event queue. The next three sections discuss how to:

- Obtain events, in order, and remove them from the queue
- Peek at events in the queue without removing them
- Obtain events that match the event mask or the arbitrary predicate procedures that you provide

Returning the Next Event

To get the next event and remove it from the queue, use XNextEvent.

\[
\text{XNextEvent} \left( \text{display, event\_return} \right)
\]

- \text{Display *display;}
- \text{XEvent *event\_return;}

\text{display} \quad \text{Specifies the connection to the XWIN server.}

\text{event\_return} \quad \text{Returns the next event in the queue.}

The \text{XNextEvent} function copies the first event from the event queue into the specified \text{XEvent} structure and then removes it from the queue. If the event queue is empty, \text{XNextEvent} flushes the output buffer and blocks until an event is received.

To peek at the event queue, use XPeekEvent.

\[
\text{XPeekEvent} \left( \text{display, event\_return} \right)
\]

- \text{Display *display;}
- \text{XEvent *event\_return;}

\text{display} \quad \text{Specifies the connection to the XWIN server.}

\text{event\_return} \quad \text{Returns a copy of the matched event's associated structure.}

The \text{XPeekEvent} function returns the first event from the event queue, but it does not remove the event from the queue. If the queue is empty, \text{XPeekEvent} flushes the output buffer and blocks until an event is received. It then copies the event into the client-supplied \text{XEvent} structure without removing it from the event queue.
Selecting Events Using a Predicate Procedure

Each of the functions discussed in this section requires you to pass a predicate procedure that determines if an event matches what you want. Your predicate procedure must decide only if the event is useful and must not call Xlib functions. In particular, a predicate is called from inside the event routine, which must lock data structures so that the event queue is consistent in a multi-threaded environment.

The predicate procedure and its associated arguments are:

```c
Bool (*predicate)(display, event, arg)
Display *display;
XEvent *event;
char *arg;
```

- **display**: Specifies the connection to the XWIN server.
- **event**: Specifies a pointer to the XEvent structure.
- **arg**: Specifies the argument passed in from the XIfEvent, XCheckIfEvent, or XPeekIfEvent function.

The predicate procedure is called once for each event in the queue until it finds a match. After finding a match, the predicate procedure must return `True`. If it did not find a match, it must return `False`.

To check the event queue for a matching event and, if found, remove the event from the queue, use XIfEvent:

```c
XIfEvent (display, event_return, predicate, arg)
Display *display;
XEvent *event_return;
Bool (*predicate)();
char *arg;
```

- **display**: Specifies the connection to the XWIN server.
- **event_return**: Returns the matched event’s associated structure.
**Manipulating the Event Queue**

- **predicate**: Specifies the procedure that is to be called to determine if the next event in the queue matches what you want.
- **arg**: Specifies the user-supplied argument that will be passed to the predicate procedure.

The `XIfEvent` function completes only when the specified predicate procedure returns `True` for an event, which indicates an event in the queue matches. `XIfEvent` flushes the output buffer if it blocks waiting for additional events. `XIfEvent` removes the matching event from the queue and copies the structure into the client-supplied `XEvent` structure.

To check the event queue for a matching event without blocking, use `XCheckIfEvent`.

```c
Bool XCheckIfEvent (display, event_return, predicate, arg)
    Display *display;
    XEvent *event_return;
    Bool (*predicate)();
    char *arg;
```

- **display**: Specifies the connection to the XWIN server.
- **event_return**: Returns a copy of the matched event's associated structure.
- **predicate**: Specifies the procedure that is to be called to determine if the next event in the queue matches what you want.
- **arg**: Specifies the user-supplied argument that will be passed to the predicate procedure.

When the predicate procedure finds a match, `XCheckIfEvent` copies the matched event into the client-supplied `XEvent` structure and returns `True`. (This event is removed from the queue.) If the predicate procedure finds no match, `XCheckIfEvent` returns `False`, and the output buffer will have been flushed. All earlier events stored in the queue are not discarded.

To check the event queue for a matching event without removing the event from the queue, use `XPeekIfEvent`. 
Manipulating the Event Queue

`XPeekIfEvent (display, event_return, predicate, arg)`

Display *display;
XEvent *event_return;
Bool (*predicate)();
char *arg;

display Specifies the connection to the XWIN server.
event_return Returns a copy of the matched event's associated structure.
predicate Specifies the procedure that is to be called to determine if the next event in the queue matches what you want.
arg Specifies the user-supplied argument that will be passed to the predicate procedure.

The `XPeekIfEvent` function returns only when the specified predicate procedure returns `True` for an event. After the predicate procedure finds a match, `XPeekIfEvent` copies the matched event into the client-supplied `XEvent` structure without removing the event from the queue. `XPeekIfEvent` flushes the output buffer if it blocks waiting for additional events.

Selecting Events Using a Window or Event Mask

The functions discussed in this section let you select events by window or event types, allowing you to process events out of order.

To remove the next event that matches both a window and an event mask, use `XWindowEvent`.

`XWindowEvent (display, w, event_mask, event_return)`

Display *display;
Window w;
long event_mask;
XEvent *event_return;

display Specifies the connection to the XWIN server.
Manipulating the Event Queue

The XWindowEvent function searches the event queue for an event that matches both the specified window and event mask. When it finds a match, XWindowEvent removes that event from the queue and copies it into the specified XEvent structure. The other events stored in the queue are not discarded. If a matching event is not in the queue, XWindowEvent flushes the output buffer and blocks until one is received.

To remove the next event that matches both a window and an event mask (if any), use XCheckWindowEvent. This function is similar to XWindowEvent except that it never blocks and it returns a Bool indicating if the event was returned.

```c
Bool XCheckWindowEvent (display, w, event_mask, event_return)
    Display *display;
    Window w;
    long event_mask;
    XEvent *event_return;
```

- **display**: Specifies the connection to the XWIN server.
- **w**: Specifies the window whose events you are interested in.
- **event_mask**: Specifies the event mask.
- **event_return**: Returns the matched event’s associated structure.

The XCheckWindowEvent function searches the event queue and then the events available on the server connection for the first event that matches the specified window and event mask. If it finds a match, XCheckWindowEvent removes that event, copies it into the specified XEvent structure, and returns True. The other events stored in the queue are not discarded. If the event you requested is not available, XCheckWindowEvent returns False, and the output buffer will have been flushed.

To remove the next event that matches an event mask, use XMaskEvent.
Manipulating the Event Queue

XMaskEvent (display, event_mask, event_return)
    Display *display;
    long event_mask;
    XEvent *event_return;

display Specifies the connection to the XWIN server.
event_mask Specifies the event mask.
event_return Returns the matched event's associated structure.

The XMaskEvent function searches the event queue for the events associated with the specified mask. When it finds a match, XMaskEvent removes that event and copies it into the specified XEvent structure. The other events stored in the queue are not discarded. If the event you requested is not in the queue, XMaskEvent flushes the output buffer and blocks until one is received.

To return and remove the next event that matches an event mask (if any), use XCheckMaskEvent. This function is similar to XMaskEvent except that it never blocks and it returns a Bool indicating if the event was returned.

Bool XCheckMaskEvent (display, event_mask, event_return)
    Display *display;
    long event_mask;
    XEvent *event_return;

display Specifies the connection to the XWIN server.
event_mask Specifies the event mask.
event_return Returns the matched event's associated structure.

The XCheckMaskEvent function searches the event queue and then any events available on the server connection for the first event that matches the specified mask. If it finds a match, XCheckMaskEvent removes that event, copies it into the specified XEvent structure, and returns True. The other events stored in the queue are not discarded. If the event you requested is not available, XCheckMaskEvent returns False, and the output buffer will have been flushed.

To return and remove the next event in the queue that matches an event type, use XCheckTypedEvent.
Manipulating the Event Queue

Bool XCheckTypedEvent (display, event_type, event_return)
    Display *display;
    int event_type;
    XEvent *event_return;

display    Specifies the connection to the XWIN server.
display

event_type   Specifies the event type to be compared.
event_type

event_return Returns the matched event's associated structure.
event_return

The XCheckTypedEvent function searches the event queue and then any events available on the server connection for the first event that matches the specified type. If it finds a match, XCheckTypedEvent removes that event, copies it into the specified XEvent structure, and returns True. The other events in the queue are not discarded. If the event is not available, XCheckTypedEvent returns False, and the output buffer will have been flushed.

To return and remove the next event in the queue that matches an event type and a window, use XCheckTypedWindowEvent.

Bool XCheckTypedWindowEvent (display, w, event_type, event_return)
    Display *display;
    Window w;
    int event_type;
    XEvent *event_return;

display    Specifies the connection to the XWIN server.
display

w          Specifies the window.
w

event_type   Specifies the event type to be compared.
event_type

event_return Returns the matched event's associated structure.
event_return

The XCheckTypedWindowEvent function searches the event queue and then any events available on the server connection for the first event that matches the specified type and window. If it finds a match, XCheckTypedWindowEvent removes the event from the queue, copies it into the specified XEvent structure, and returns True. The other events in the queue are not discarded. If the event is not available, XCheckTypedWindowEvent returns False, and the output buffer will have been flushed.
Putting an Event Back into the Queue

To push an event back into the event queue, use `XPutBackEvent`.

```
XPutBackEvent (display, event)
Display *display;
XEvent *event;
```

display Specifies the connection to the XWIN server.

event Specifies a pointer to the event.

The `XPutBackEvent` function pushes an event back onto the head of the display's event queue by copying the event into the queue. This can be useful if you read an event and then decide that you would rather deal with it later. There is no limit to the number of times in succession that you can call `XPutBackEvent`. 
Sending Events to Other Applications

To send an event to a specified window, use XSendEvent. This function is often used in selection processing. For example, the owner of a selection should use XSendEvent to send a SelectionNotify event to a requestor when a selection has been converted and stored as a property.

```
Status XSendEvent (display, w, propagate, event_mask, event_send)
  Display *display;
  Window w;
  Bool propagate;
  long event_mask;
  XEvent *event_send;
```

display Specifies the connection to the XWIN server.
w Specifies the window the event is to be sent to, PointerWindow, or InputFocus.
propagate Specifies a Boolean value.
event_mask Specifies the event mask.
event_send Specifies a pointer to the event that is to be sent.

The XSendEvent function identifies the destination window, determines which clients should receive the specified events, and ignores any active grabs. This function requires you to pass an event mask. For a discussion of the valid event mask names, see "Event Masks" in this chapter. This function uses the w argument to identify the destination window as follows:

- If w is PointerWindow, the destination window is the window that contains the pointer.
- If w is InputFocus and if the focus window contains the pointer, the destination window is the window that contains the pointer; otherwise, the destination window is the focus window.

To determine which clients should receive the specified events, XSendEvent uses the propagate argument as follows:

- If event_mask is the empty set, the event is sent to the client that created the destination window. If that client no longer exists, no event is sent.
Sending Events to Other Applications

- If propagate is False, the event is sent to every client selecting on destination any of the event types in the event_mask argument.

- If propagate is True and no clients have selected on destination any of the event types in event-mask, the destination is replaced with the closest ancestor of destination for which some client has selected a type in event-mask and for which no intervening window has that type in its do-not-propagate-mask. If no such window exists or if the window is an ancestor of the focus window and InputFocus was originally specified as the destination, the event is not sent to any clients. Otherwise, the event is reported to every client selecting on the final destination any of the types specified in event_mask.

The event in the XEvent structure must be one of the core events or one of the events defined by an extension (or a BadValue error results) so that the XWIN server can correctly byte-swap the contents as necessary. The contents of the event are otherwise unaltered and unchecked by the XWIN server except to force send_event to True in the forwarded event and to set the serial number in the event correctly.

XSendEvent returns zero if the conversion to wire protocol format failed and returns nonzero otherwise.

XSendEvent can generate BadValue and BadWindow errors.
Getting Pointer Motion History

Some XWIN server implementations will maintain a more complete history of pointer motion than is reported by event notification. The pointer position at each pointer hardware interrupt may be stored in a buffer for later retrieval. This buffer is called the motion history buffer. For example, a few applications, such as paint programs, want to have a precise history of where the pointer traveled. However, this historical information is highly excessive for most applications.

To determine the size of the motion buffer, use XDisplayMotionBufferSize.

```c
unsigned long XDisplayMotionBufferSize(display)
    Display *display;
```

display Specifies the connection to the XWIN server.

The server may retain the recent history of the pointer motion and do so to a finer granularity than is reported by MotionNotify events. The XGetMotionEvents function makes this history available.

To get the motion history for a specified window and time, use XGetMotionEvents.

```c
XTimeCoord *XGetMotionEvents(display, w, start, stop, nevents_return)
    Display *display;
    Window w;
    Time start, stop;
    int *nevents_return;
```

display Specifies the connection to the XWIN server.
w Specifies the window.
start Specify the time interval in which the events are returned from the motion history buffer. You can pass a timestamp or CurrentTime.
stop

nevents_return Returns the number of events from the motion history buffer.
The `XGetMotionEvents` function returns all events in the motion history buffer that fall between the specified start and stop times, inclusive, and that have coordinates that lie within the specified window (including its borders) at its present placement. If the start time is later than the stop time or if the start time is in the future, no events are returned. If the stop time is in the future, it is equivalent to specifying `CurrentTime`. The return type for this function is a structure defined as follows:

```c
typedef struct {
    Time time;
    short x, y;
} XTimeCoord;
```

The time member is set to the time, in milliseconds. The x and y members are set to the coordinates of the pointer and are reported relative to the origin of the specified window. To free the data returned from this call, use `XFree`.

`XGetMotionEvents` can generate a BadWindow error.
Handling Error Events

Xlib provides functions that you can use to enable or disable synchronization and to use the default error handlers.

Enabling or Disabling Synchronization

When debugging X applications, it often is very convenient to require Xlib to behave synchronously so that errors are reported as they occur. The following function lets you disable or enable synchronous behavior. Note that graphics may occur 30 or more times more slowly when synchronization is enabled. On UNIX-based systems, there is also a global variable _Xdebug that, if set to nonzero before starting a program under a debugger, will force synchronous library behavior.

After completing their work, all Xlib functions that generate protocol requests call what is known as an after function. XSetAfterFunction sets which function is to be called.

```c
int (*XSetAfterFunction)(display, procedure)

Display *display;
int (*procedure)();
```

*display*: Specifies the connection to the XWIN server.

*procedure*: Specifies the function to be called after an Xlib function that generates a protocol request completes its work.

The specified procedure is called with only a display pointer. XSetAfterFunction returns the previous after function.

To enable or disable synchronization, use XSynchronize.

```c
int (*XSynchronize)(display, onoff)

Display *display;
Bool onoff;
```

*display*: Specifies the connection to the XWIN server.
Handling Error Events

Onoff

Specifies a Boolean value that indicates whether to enable or disable synchronization.

The `XSync` function returns the previous after function. If `onoff` is True, `XSync` turns on synchronous behavior. If `onoff` is False, `XSync` turns off synchronous behavior.

Using the Default Error Handlers

There are two default error handlers in Xlib: one to handle typically fatal conditions (for example, the connection to a display server dying because a machine crashed) and one to handle error events from the XWIN server. These error handlers can be changed to user-supplied routines if you prefer your own error handling and can be changed as often as you like. If either function is passed a NULL pointer, it will reinvoke the default handler. The action of the default handlers is to print an explanatory message and exit.

To set the error handler, use `XSetErrorHandler`.

`XSetErrorHandler (handler)`

`int (*handler)(Display *, XErrorEvent *)`

`handler` specifies the program’s supplied error handler.

Xlib generally calls the program’s supplied error handler whenever an error is received. It is not called on BadName errors from OpenFont, LookupColor, or AllocNamedColor protocol requests or on BadFont errors from a QueryFont protocol request. These errors generally are reflected back to the program through the procedural interface. Because this condition is not assumed to be fatal, it is acceptable for your error handler to return. However, the error handler should not call any functions (directly or indirectly) on the display that will generate protocol requests or that will look for input events.

The `XErrorEvent` structure contains:
typedef struct {
    int type;
    Display *display; /* Display the event was read from */
    unsigned long serial; /* serial number of failed request */
    unsigned char error_code; /* error code of failed request */
    unsigned char request_code; /* Major op-code of failed request */
    unsigned char minor_code; /* Minor op-code of failed request */
    XID resourcesid; /* resource id */
} XErrorEvent;

The serial member is the number of requests, starting from one, sent over the network connection since it was opened. It is the number that was the value of NextRequest immediately before the failing call was made. The request_code member is a protocol request of the procedure that failed, as defined in <X11/Xproto.h>. The following error codes can be returned by the functions described in this chapter:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BadAccess</td>
<td>A client attempts to grab a key/button combination already grabbed by another client.</td>
</tr>
<tr>
<td></td>
<td>A client attempts to free a colormap entry that it had not already allocated.</td>
</tr>
<tr>
<td></td>
<td>A client attempts to store into a read-only or unallocated colormap entry.</td>
</tr>
<tr>
<td></td>
<td>A client attempts to modify the access control list from other than the local (or otherwise authorized) host.</td>
</tr>
<tr>
<td></td>
<td>A client attempts to select an event type that another client has already selected.</td>
</tr>
<tr>
<td>BadAlloc</td>
<td>The server fails to allocate the requested resource. Note that the explicit listing of</td>
</tr>
</tbody>
</table>
## Handling Error Events

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BadAlloc</td>
<td>BadAlloc errors in requests only covers allocation errors at a very coarse level and is not intended to (nor can it in practice hope to) cover all cases of a server running out of allocation space in the middle of service. The semantics when a server runs out of allocation space are left unspecified, but a server may generate a BadAlloc error on any request for this reason, and clients should be prepared to receive such errors and handle or discard them.</td>
</tr>
<tr>
<td>BadAtom</td>
<td>A value for an atom argument does not name a defined atom.</td>
</tr>
<tr>
<td>BadColor</td>
<td>A value for a colormap argument does not name a defined colormap.</td>
</tr>
<tr>
<td>BadCursor</td>
<td>A value for a cursor argument does not name a defined cursor.</td>
</tr>
<tr>
<td>BadDrawable</td>
<td>A value for a drawable argument does not name a defined window or pixmap.</td>
</tr>
<tr>
<td>BadFont</td>
<td>A value for a font argument does not name a defined font (or, in some cases, GContext).</td>
</tr>
<tr>
<td>BadGC</td>
<td>A value for a GContext argument does not name a defined GContext.</td>
</tr>
<tr>
<td>BadIDChoice</td>
<td>The value chosen for a resource identifier either is not included in the range assigned to the client or is already in use. Under normal circumstances, this cannot occur and should be considered a server or Xlib error.</td>
</tr>
<tr>
<td>BadImplementation</td>
<td>The server does not implement some aspect of the request. A server that generates this error</td>
</tr>
<tr>
<td>Error Code</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>for a core request is deficient. As such, this error is not listed for any of the requests, but clients should be prepared to receive such errors and handle or discard them.</td>
<td></td>
</tr>
<tr>
<td>BadLength</td>
<td>The length of a request is shorter or longer than that required to contain the arguments. This is an internal Xlib or server error.</td>
</tr>
<tr>
<td></td>
<td>The length of a request exceeds the maximum length accepted by the server.</td>
</tr>
<tr>
<td>BadMatch</td>
<td>In a graphics request, the root and depth of the graphics context does not match that of the drawable.</td>
</tr>
<tr>
<td></td>
<td>An InputOnly window is used as a drawable.</td>
</tr>
<tr>
<td></td>
<td>Some argument or pair of arguments has the correct type and range, but it fails to match in some other way required by the request.</td>
</tr>
<tr>
<td></td>
<td>An InputOnly window lacks this attribute.</td>
</tr>
<tr>
<td>BadName</td>
<td>A font or color of the specified name does not exist.</td>
</tr>
<tr>
<td>BadPixmap</td>
<td>A value for a pixmap argument does not name a defined pixmap.</td>
</tr>
<tr>
<td>BadRequest</td>
<td>The major or minor opcode does not specify a valid request. This usually is an Xlib or server error.</td>
</tr>
<tr>
<td>BadValue</td>
<td>Some numeric value falls outside of the range of values accepted by the request. Unless a specific range is specified for an argument, the full range defined by the argument’s type is accepted. Any argument defined as a set of</td>
</tr>
</tbody>
</table>
Handling Error Events

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>alternatives</td>
<td>typically can generate this error (due to the encoding).</td>
</tr>
<tr>
<td>BadWindow</td>
<td>A value for a window argument does not name a defined window.</td>
</tr>
</tbody>
</table>

The BadAtom, BadColor, BadCursor, BadDrawable, BadFont, BadGC, BadPixmap, and BadWindow errors are also used when the argument type is extended by a set of fixed alternatives.

To obtain textual descriptions of the specified error code, use XGetErrorText.

```c
XGetErrorText(display, code, buffer_return, length)
```

- `display`: Specifies the connection to the XWIN server.
- `code`: Specifies the error code for which you want to obtain a description.
- `buffer_return`: Returns the error description.
- `length`: Specifies the size of the buffer.

The `XGetErrorText` function copies a null-terminated string describing the specified error code into the specified buffer. It is recommended that you use this function to obtain an error description because extensions to Xlib may define their own error codes and error strings.

To obtain error messages from the error database, use `XGetErrorDatabaseText`.
**XGetErrorDatabaseText**

```c
XGetErrorDatabaseText (display, name, message, default_string, buffer_return, length)
```

- **display**
  - Specifies the connection to the XWIN server.
- **name**
  - Specifies the name of the application.
- **message**
  - Specifies the type of the error message.
- **default_string**
  - Specifies the default error message if none is found in the database.
- **buffer_return**
  - Returns the error description.
- **length**
  - Specifies the size of the buffer.

The `XGetErrorDatabaseText` function returns a message (or the default message) from the error message database. `Xlib` uses this function internally to look up its error messages. On a UNIX-based system, the error message database is `/usr/X/lib/XErrorDB`.

The **name** argument should generally be the name of your application. The **message** argument should indicate which type of error message you want. `Xlib` uses three predefined message types to report errors (uppercase and lowercase matter):

- **XProtoError**
  - The protocol error number is used as a string for the message argument.
- **XlibMessage**
  - These are the message strings that are used internally by the library.
- **XRequest**
  - The major request protocol number is used for the message argument. If no string is found in the error database, the default_string is returned to the buffer argument.

To report an error to the user when the requested display does not exist, use `XDisplayName`.
The `XDisplayName` function returns the name of the display that `XOpenDisplay` would attempt to use. If a NULL string is specified, `XDisplayName` looks in the environment for the display and returns the display name that `XOpenDisplay` would attempt to use. This makes it easier to report to the user precisely which display the program attempted to open when the initial connection attempt failed.

To handle fatal I/O errors, use `XSetIOErrorHandler`.

```c
int (*handler)(Display *);
```

The `XSetIOErrorHandler` sets the fatal I/O error handler. `Xlib` calls the program's supplied error handler if any sort of system call error occurs (for example, the connection to the server was lost). This is assumed to be a fatal condition, and the called routine should not return. If the I/O error handler does return, the client process exits.

Introduction

There are a number of predefined properties for information commonly associated with windows. The atoms for these predefined properties can be found in `<X11/Xatom.h>`, where the prefix `XA_` is added to each atom name.

Xlib provides functions that you can use to perform operations on predefined properties. This chapter discusses how to:

- Communicate with window managers
- Manipulate standard colormaps
Communicating with Window Managers

This section discusses a set of properties and functions that are necessary for clients to communicate effectively with window managers. Some of these properties have complex structures. Because all the data in a single property on the server has to be of the same format (8-bit, 16-bit, or 32-bit) and because the C structures representing property types cannot be guaranteed to be uniform in the same way, Set and Get functions are provided for properties with complex structures.

These functions define but do not enforce minimal policy among window managers. Writers of window managers are urged to use the information in these properties rather than invent their own properties and types. A window manager writer, however, can define additional properties beyond this least common denominator.

In addition to Set and Get functions for individual properties, Xlib includes one function, XSetStandardProperties, that sets all or portions of several properties. Applications are encouraged to provide the window manager more information than is possible with XSetStandardProperties. To do so, they should call the Set functions for the additional or specific properties that they need.

To work well with most window managers, every application should specify the following information:

- Name of the application
- Name to be used in the icon
- Command used to invoke the application
- Size and window manager hints

Xlib does not set defaults for the properties described in this section. Thus, the default behavior is determined by the window manager and may be based on the presence or absence of certain properties. All the properties are considered to be hints to a window manager. When implementing window management policy, a window manager determines what to do with this information and can ignore it.
Communicating with Window Managers

The supplied properties are:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>WM_NAME</td>
<td>STRING</td>
<td>8</td>
<td>Name of the application.</td>
</tr>
<tr>
<td>WM_ICON_NAME</td>
<td>STRING</td>
<td>8</td>
<td>Name to be used in icon.</td>
</tr>
<tr>
<td>WM_NORMAL_HINTS</td>
<td>WM_SIZE_HINTS</td>
<td>32</td>
<td>Size hints for a window in its normal state. The C type of this property is XSizeHints.</td>
</tr>
<tr>
<td>WM_ZOOM_HINTS</td>
<td>WM_SIZE_HINTS</td>
<td>32</td>
<td>Size hints for a zoomed window. The C type of this property is XSizeHints.</td>
</tr>
<tr>
<td>WM_HINTS</td>
<td>WM_HINTS</td>
<td>32</td>
<td>Additional hints set by client for use by the window manager. The C type of this property is XWMHints.</td>
</tr>
<tr>
<td>WM_COMMAND</td>
<td>STRING</td>
<td>8</td>
<td>The command and arguments, separated by ASCII nulls, used to invoke the application.</td>
</tr>
<tr>
<td>WM_ICON_SIZE</td>
<td>WM_ICON_SIZE</td>
<td>32</td>
<td>The window manager may set this property on the root window to specify the icon sizes it supports. The C type of this property is XIconSize.</td>
</tr>
<tr>
<td>WM_CLASS</td>
<td>STRING</td>
<td>32</td>
<td>Set by application programs to allow window and session managers to obtain the application's resources from the resource database.</td>
</tr>
<tr>
<td>WM_TRANSIENT_FOR</td>
<td>WINDOW</td>
<td>32</td>
<td>Set by application programs to indicate to the window manager that a transient top-level window, such as a dialog box, is not really a normal application window.</td>
</tr>
</tbody>
</table>
Communicating with Window Managers

The atom names stored in `<x11/Xatom.h>` are named `XAPROPERTY_NAME`. Xlib provides functions that you can use to set and get predefined properties. Note that calling the Set function for a property with complex structure redefines all members in that property, even though only some of those members may have a specified new value. Simple properties for which Xlib does not provide a Set or Get function can be set by using `XChangeProperty`, and their values can be retrieved using `XGetWindowProperty`. The remainder of this section discusses how to:

- Set standard properties
- Set and get the name of a window
- Set and get the icon name of a window
- Set the command and arguments of the application
- Set and get window manager hints
- Set and get window size hints
- Set and get icon size hints
- Set and get the class of a window
- Set and get the transient property for a window

Setting Standard Properties

To specify a minimum set of properties describing the "quickie" application, use `XSetStandardProperties`. This function sets all or portions of the `WM_NAME`, `WM_ICON_NAME`, `WM_HINTS`, `WM_COMMAND`, and `WM_NORMAL_HINTS` properties.
Communicating with Window Managers

\[ \text{XSetStandardProperties} \left( \text{display, w, window\_name, icon\_name, icon\_pixmap, argv, argc, hints} \right) \]

- \text{Display *display;}
- \text{Window w;}
- \text{char *window\_name;}
- \text{char *icon\_name;}
- \text{Pixmap icon\_pixmap;}
- \text{char **argv;}
- \text{int argc;}
- \text{XSizeHints *hints;}

<table>
<thead>
<tr>
<th>display</th>
<th>Specifies the connection to the XWIN server.</th>
</tr>
</thead>
<tbody>
<tr>
<td>w</td>
<td>Specifies the window.</td>
</tr>
<tr>
<td>window_name</td>
<td>Specifies the window name, which should be a null-terminated string.</td>
</tr>
<tr>
<td>icon_name</td>
<td>Specifies the icon name, which should be a null-terminated string.</td>
</tr>
<tr>
<td>icon_pixmap</td>
<td>Specifies the bitmap that is to be used for the icon or None.</td>
</tr>
<tr>
<td>argv</td>
<td>Specifies the application’s argument list.</td>
</tr>
<tr>
<td>argc</td>
<td>Specifies the number of arguments.</td>
</tr>
<tr>
<td>hints</td>
<td>Specifies a pointer to the size hints for the window in its normal state.</td>
</tr>
</tbody>
</table>

The \text{XSetStandardProperties} function provides a means by which simple applications set the most essential properties with a single call. \text{XSetStandardProperties} should be used to give a window manager some information about your program’s preferences. It should not be used by applications that need to communicate more information than is possible with \text{XSetStandardProperties}. (Typically, argv is the argv array of your main program.)

\text{XSetStandardProperties} can generate BadAlloc and BadWindow errors.

\[ \text{Predefined Property Functions} \]
Setting and Getting Window Names

Xlib provides functions that you can use to set and read the name of a window. These functions set and read the WM_NAME property.

To assign a name to a window, use XStoreName.

```c
XStoreName (display, w, window_name)
Display *display;
Window w;
char *window_name;
```

- `display` Specifies the connection to the XWIN server.
- `w` Specifies the window.
- `window_name` Specifies the window name, which should be a null-terminated string.

The XStoreName function assigns the name passed to `window_name` to the specified window. A window manager can display the window name in some prominent place, such as the title bar, to allow users to identify windows easily. Some window managers may display a window’s name in the window’s icon, although they are encouraged to use the window’s icon name if one is provided by the application.

XStoreName can generate BadAlloc and BadWindow errors.

To get the name of a window, use XFetchName.

```c
Status XFetchName (display, w, window_name_return)
Display *display;
Window w;
char **window_name_return;
```

- `display` Specifies the connection to the XWIN server.
- `w` Specifies the window.
- `window_name_return` Returns a pointer to the window name, which is a null-terminated string.
The XFetchName function returns the name of the specified window. If it succeeds, it returns nonzero; otherwise, if no name has been set for the window, it returns zero. If the WM_NAME property has not been set for this window, XFetchName sets window_name_return to NULL. When finished with it, a client must free the window name string using XFree.

XFetchName can generate a BadWindow error.

**Setting and Getting Icon Names**

Xlib provides functions that you can use to set and read the name to be displayed in a window's icon. These functions set and read the WM_ICON_NAME property.

To set the name to be displayed in a window's icon, use XSetIconName.

```c
XSetIconName (display, w, icon_name)
Display *display;
Window w;
char *icon_name;
```

*display* Specifies the connection to the XWIN server.

*w* Specifies the window.

*icon_name* Specifies the icon name, which should be a null-terminated string.

XSetIconName can generate BadAlloc and BadWindow errors.

To get the name a window wants displayed in its icon, use XGetIconName.

```c
Status XGetIconName (display, w, icon_name_return)
Display *display;
Window w;
char *icon_name_return;
```

*display* Specifies the connection to the XWIN server.
Communicating with Window Managers

\[ w \] Specifies the window.

\[ \text{icon\_name\_return} \]
Returns a pointer to the window’s icon name, which is a null-terminated string.

The \text{XGetIconName} function returns the name to be displayed in the specified window’s icon. If it succeeds, it returns nonzero; otherwise, if no icon name has been set for the window, it returns zero. If you never assigned a name to the window, \text{XGetIconName} sets \text{icon\_name\_return} to NULL. When finished with it, a client must free the icon name string using \text{XFree}.

\text{XGetIconName} can generate a \text{BadWindow} error.

\section*{Setting the Command}

To set the command property, use \text{XSetCommand}. This function sets the \text{WM\_COMMAND} property.

\begin{verbatim}
\text{XSetCommand (display, w, argv, argc)}
\end{verbatim}

\text{Display \textit{display};}
\text{Window \textit{w};}
\text{char *\textit{argv};}
\text{int \textit{argc};}

\text{display} Specifies the connection to the XWIN server.
\text{w} Specifies the window.
\text{argv} Specifies the application’s argument list.
\text{argc} Specifies the number of arguments.

The \text{XSetCommand} function sets the command and arguments used to invoke the application. (Typically, \text{argv} is the argv array of your main program.)

\text{XSetCommand} can generate \text{BadAlloc} and \text{BadWindow} errors.
Communicating with Window Managers

Setting and Getting Window Manager Hints

The functions discussed in this section set and read the WM_HINTS property and use the flags and the XWMHints structure, as defined in the <X11/Xutil.h> header file:

/* Window manager hints mask bits */

#define InputHint (1L << 0)
#define StateHint (1L << 1)
#define IconPixmapHint (1L << 2)
#define IconWindowHint (1L << 3)
#define IconPositionHint (1L << 4)
#define IconMaskHint (1L << 5)
#define WindowGroupHint (1L << 6)
#define AllHints (InputHint|StateHint|IconPixmapHint|
                IconWindowHint|IconPositionHint|
                IconMaskHint|WindowGroupHint)

/* Values */

typedef struct {
    long flags; /* marks which fields in this structure are defined */
    Bool input; /* does this application rely on the window manager to get keyboard input? */
    int initial_state; /* see below */
    Pixmap icon pixmap; /* pixmap to be used as icon */
    Window icon_window; /* window to be used as icon */
    int icon_x, icon_y; /* initial position of icon */
    Pixmap icon_mask; /* pixmap to be used as mask for icon pixmap */
    XID window_group; /* id of related window group */
    /* this structure may be extended in the future */
} XWMHints;

The input member is used to communicate to the window manager the input focus model used by the application. Applications that expect input but never explicitly set focus to any of their subwindows (that is, use the push model of focus management), such as X11-style applications that use real-estate driven focus, should set this member to True. Similarly, applications that set input...
focus to their subwindows only when it is given to their top-level window by a
window manager should also set this member to True. Applications that
manage their own input focus by explicitly setting focus to one of their subwin-
dows whenever they want keyboard input (that is, use the pull model of focus
management) should set this member to False. Applications that never expect
any keyboard input also should set this member to False.

Pull model window managers should make it possible for push model applica-
tions to get input by setting input focus to the top-level windows of applications
whose input member is True. Push model window managers should make sure
that pull model applications do not break them by resetting input focus to Poin-
terRoot when it is appropriate (for example, whenever an application whose
input member is False sets input focus to one of its subwindows).

The definitions for the initial_state flag are:

```c
#define DontCareState 0 /* don't know or care */
#define NormalState 1 /* most applications start this way */
#define ZoomState 2 /* application wants to start zoomed */
#define IconicState 3 /* application wants to start as an icon */
#define InactiveState 4 /* application believes it is seldom
                     used;
                   some wm's may put it on inactive
                   menu */
```

The icon_mask specifies which pixels of the icon_pixmap should be used as the
icon. This allows for nonrectangular icons. Both the icon_pixmap and
icon_mask must be bitmaps. The icon_window lets an application provide a
window for use as an icon for window managers that support such use. The
window_group lets you specify that this window belongs to a group of other
windows. For example, if a single application manipulates multiple top-level
windows, this allows you to provide enough information that a window
manager can iconify all of the windows rather than just the one window.

To set the window manager hints for a window, use XSetWMHints.
Communicating with Window Managers

XSetWMHints (display, w, wmhints)
  Display *display;
  Window w;
  XWMHints *wmhints;

display Specifies the connection to the XWIN server.

w Specifies the window.

wmhints Specifies a pointer to the window manager hints.

The XSetWMHints function sets the window manager hints that include icon information and location, the initial state of the window, and whether the application relies on the window manager to get keyboard input.

XSetWMHints can generate BadAlloc and BadWindow errors.

To read the window manager hints for a window, use XGetWMHints.

XWMHints *XGetWMHints (display, w)
  Display *display;
  Window w;

display Specifies the connection to the XWIN server.

w Specifies the window.

The XGetWMHints function reads the window manager hints and returns NULL if no WM_HINTS property was set on the window or a pointer to a XWMHints structure if it succeeds. When finished with the data, free the space used for it by calling XFree.

XGetWMHints can generate a BadWindow error.
Setting and Getting Window Sizing Hints

Xlib provides functions that you can use to set or get window sizing hints.

The functions discussed in this section use the flags and the XSizeHints structure, as defined in the `<X11/Xutil.h>` header file:

/* Size hints mask bits */

```c
#define USPosition (1L << 0)     /* user specified x, y */
#define USSize    (1L << 1)     /* user specified width, height */
#define PPosition (1L << 2)     /* program specified position */
#define PSize     (1L << 3)     /* program specified size */
#define PMinSize  (1L << 4)     /* program specified minimum size */
#define PMaxSize  (1L << 5)     /* program specified maximum size */
#define PResizeInc (1L << 6)    /* program specified resize increments */
#define PAspect   (1L << 7)     /* program specified min and max aspect ratios */
#define PAllHints (PPosition|PSize|PMinSize|PMaxSize|PResizeInc|PAspect)
```

/* Values */

typedef struct {
    long flags;                  /* marks which fields in this structure are defined */
    int x, y;
    int width, height;
    int min_width, min_height;
    int max_width, max_height;
    int width_inc, height_inc;
    struct {
        int x;                     /* numerator */
        int y;                     /* denominator */
    } min_aspect, max_aspect;
} XSizeHints;

9-12 Xwin GWS: Xlib – C Language Interface
Communicating with Window Managers

The x, y, width, and height members describe a desired position and size for the window. To indicate that this information was specified by the user, set the USPosition and USSize flags. To indicate that it was specified by the application without any user involvement, set PPosition and PSize. This lets a window manager know that the user specifically asked where the window should be placed or how the window should be sized and that the window manager does not have to rely on the program’s opinion.

The min_width and min_height members specify the minimum window size that still allows the application to be useful. The max_width and max_height members specify the maximum window size. The width_inc and height_inc members define an arithmetic progression of sizes (minimum to maximum) into which the window prefers to be resized. The min_aspect and max_aspect members are expressed as ratios of x and y, and they allow an application to specify the range of aspect ratios it prefers.

The next two functions set and read the WM_NORMAL_HINTS property.

To set the size hints for a given window in its normal state, use XSetNormalHints.

\[
\text{XSetNormalHints}(\text{display}, \text{w}, \text{hints})
\]

\[
\text{Display *display;}
\]

\[
\text{Window w;}
\]

\[
\text{XSizeHints *hints;}
\]

\[
\text{display} \quad \text{Specifies the connection to the XWIN server.}
\]

\[
\text{w} \quad \text{Specifies the window.}
\]

\[
\text{hints} \quad \text{Specifies a pointer to the size hints for the window in its normal state.}
\]

The XSetNormalHints function sets the size hints structure for the specified window. Applications use XSetNormalHints to inform the window manager of the size or position desirable for that window. In addition, an application that wants to move or resize itself should call XSetNormalHints and specify its new desired location and size as well as making direct Xlib calls to move or resize. This is because window managers may ignore redirected configure requests, but they pay attention to property changes.

Predefined Property Functions
Communicating with Window Managers

To set size hints, an application not only must assign values to the appropriate members in the hints structure but also must set the flags member of the structure to indicate which information is present and where it came from. A call to `XSetNormalHints` is meaningless, unless the flags member is set to indicate which members of the structure have been assigned values.

`XSetNormalHints` can generate BadAlloc and BadWindow errors.

To return the size hints for a window in its normal state, use `XGetNormalHints`.

```c
Status XGetNormalHints (display, w, hints_return)
    Display *display;
    Window w;
    XSizeHints *hints_return;
```

display Specifications the connection to the XWIN server.
w Specifies the window.
hints_return Returns the size hints for the window in its normal state.

The `XGetNormalHints` function returns the size hints for a window in its normal state. It returns a nonzero status if it succeeds or zero if the application specified no normal size hints for this window.

`XGetNormalHints` can generate a BadWindow error.

The next two functions set and read the WM_ZOOM_HINTS property.

To set the zoom hints for a window, use `XSetZoomHints`.

```c
XSetZoomHints (display, w, zhints)
    Display *display;
    Window w;
    XSizeHints *zhints;
```

display Specifies the connection to the XWIN server.
w Specifies the window.
zhints Specifies a pointer to the zoom hints.
Communicating with Window Managers

Many window managers think of windows in one of three states: iconic, normal, or zoomed. The XSetZoomHints function provides the window manager with information for the window in the zoomed state.

XSetZoomHints can generate BadAlloc and BadWindow errors.

To read the zoom hints for a window, use XGetZoomHints.

```c
Status XGetZoomHnts(display, w, zhints_return)
    Display *display;
    Window w;
    XSizeHints *zhints_return;
```

- `display` Specifies the connection to the XWIN server.
- `w` Specifies the window.
- `zhints_return` Returns the zoom hints.

The XGetZoomHints function returns the size hints for a window in its zoomed state. It returns a nonzero status if it succeeds or zero if the application specified no zoom size hints for this window.

XGetZoomHints can generate a BadWindow error.

To set the value of any property of type WM_SIZE_HINTS, use XSetSizeHints.

```c
XSetSizeHints(display, w, hints, property)
    Display *display;
    Window w;
    XSizeHints *hints;
    Atom property;
```

- `display` Specifies the connection to the XWIN server.
- `w` Specifies the window.
- `hints` Specifies a pointer to the size hints.
- `property` Specifies the property name.

Predefined Property Functions

9-15
Communicating with Window Managers

The \texttt{XSetSizeHints} function sets the \texttt{XSizeHints} structure for the named property and the specified window. This is used by \texttt{XSetNormalHints} and \texttt{XSetZoomHints}, and can be used to set the value of any property of type \texttt{WM\_SIZE\_HINTS}. Thus, it may be useful if other properties of that type get defined.

\texttt{XSetSizeHints} can generate \texttt{BadAlloc}, \texttt{BadAtom}, and \texttt{BadWindow} errors.

To read the value of any property of type \texttt{WM\_SIZE\_HINTS}, use \texttt{XGetSizeHints}.

\begin{verbatim}
Status XGetSizeHints(display, w, hints_return, property)
    Display *display;
    Window w;
    XSizeHints *hints_return;
    Atom property;

    display Specifies the connection to the XWIN server.
    w Specifies the window.
    hints_return Returns the size hints.
    property Specifies the property name.
\end{verbatim}

\texttt{XGetSizeHints} returns the \texttt{XSizeHints} structure for the named property and the specified window. This is used by \texttt{XGetNormalHints} and \texttt{XGetZoomHints}. It also can be used to retrieve the value of any property of type \texttt{WM\_SIZE\_HINTS}. Thus, it may be useful if other properties of that type get defined. \texttt{XGetSizeHints} returns a nonzero status if a size hint was defined or zero otherwise.

\texttt{XGetSizeHints} can generate \texttt{BadAtom} and \texttt{BadWindow} errors.
Setting and Getting Icon Size Hints

Applications can cooperate with window managers by providing icons in sizes supported by a window manager. To communicate the supported icon sizes to the applications, a window manager should set the icon size property on the root window of the screen. To find out what icon sizes a window manager supports, applications should read the icon size property from the root window of the screen.

The functions discussed in this section set or read the WM_ICON_SIZE property. In addition, they use the XIconSize structure, which is defined in `<X11/Xutil.h>` and contains:

```c
typedef struct {
    int min_width, min_height;
    int max_width, max_height;
    int width_inc, height_inc;
} XIconSize;
```

The width_inc and height_inc members define an arithmetic progression of sizes (minimum to maximum) that represent the supported icon sizes.

To set the icon size hints for a window, use XSetIconSizes.

```c
XSetIconSizes(display, w, size_list, count)
Display *display;
Window w;
XIconSize *size_list;
int count;
```

- `display` Specifies the connection to the XWIN server.
- `w` Specifies the window.
- `size_list` Specifies a pointer to the size list.
- `count` Specifies the number of items in the size list.

The XSetIconSizes function is used only by window managers to set the supported icon sizes.
Communicating with Window Managers

XSetIconSizes can generate BadAlloc and BadWindow errors.

To return the icon sizes hints for a window, use XGetIconSizes.

```c
Status XGetIconSizes (display, w, size_list_return, count_return)
    Display *display;
    Window w;
    XIconSize **size_list_return;
    int *count_return;

display Specifies the connection to the XWIN server.
w Specifies the window.
size_list_return Returns a pointer to the size list.
count_return Returns the number of items in the size list.
```

The XGetIconSizes function returns zero if a window manager has not set icon sizes or nonzero otherwise. XGetIconSizes should be called by an application that wants to find out what icon sizes would be most appreciated by the window manager under which the application is running. The application should then use XSetWMHints to supply the window manager with an icon pixmap or window in one of the supported sizes. To free the data allocated in size_list_return, use XFree.

XGetIconSizes can generate a BadWindow error.

Setting and Getting the Class of a Window

Xlib provides functions to set and get the class of a window. These functions set and read the WM_CLASS property. In addition, they use the XClassHint structure, which is defined in `<X11/Xutil.h>` and contains:

```c
typedef struct {
    char *res_name;
    char *res_class;
} XClassHint;
```
The res_name member contains the application name, and the res_class member contains the application class. Note that the name set in this property may differ from the name set as WM_NAME. That is, WM_NAME specifies what should be displayed in the title bar and, therefore, can contain temporal information (for example, the name of a file currently in an editor’s buffer). On the other hand, the name specified as part of WM_CLASS is the formal name of the application that should be used when retrieving the application’s resources from the resource database.

To set the class of a window, use XSetClassHint.

\[
\text{XSetClassHint} \ (\text{display}, \ w, \ \text{class\_hints})
\]
\[
\text{Display} \ *\text{display};
\]
\[
\text{Window} \ w;
\]
\[
\text{XClassHint} \ *\text{class\_hints};
\]

- \text{display} \quad \text{Specifies the connection to the XWIN server.}
- \ w \quad \text{Specifies the window.}
- \text{class\_hints} \quad \text{Specifies a pointer to a XClassHint structure that is to be used.}

The XSetClassHint function sets the class hint for the specified window. XSetClassHint can generate BadAlloc and BadWindow errors.

To get the class of a window, use XGetClassHint.

\[
\text{Status} \ \text{XGetClassHint} \ (\text{display}, \ w, \ \text{class\_hints\_return})
\]
\[
\text{Display} \ *\text{display};
\]
\[
\text{Window} \ w;
\]
\[
\text{XClassHint} \ *\text{class\_hints\_return};
\]

- \text{display} \quad \text{Specifies the connection to the XWIN server.}
- \ w \quad \text{Specifies the window.}
- \text{class\_hints\_return} \quad \text{Returns the XClassHint structure.}

The XGetClassHint function returns the class of the specified window. To free res_name and res_class when finished with the strings, use XFree.
Communicating with Window Managers

XGetClassHint can generate a BadWindow error.

Setting and Getting the Transient Property

An application may want to indicate to the window manager that a transient, top-level window (for example, a dialog box) is operating on behalf of (or is transient for) another window. To do so, the application would set the WM_TRANSIENT_FOR property of the dialog box to be the window ID of its main window. Some window managers use this information to unmap an application's dialog boxes (for example, when the main application window gets iconified).

The functions discussed in this section set and read the WM_TRANSIENT_FOR property.

To set the WM_TRANSIENT_FOR property for a window, use XSetTransientForHint.

\[
\text{XSetTransientForHint}(\text{display}, \text{w}, \text{prop\_window})
\]

- \text{display} Specifies the connection to the XWIN server.
- \text{w} Specifies the window.
- \text{prop\_window} Specifies the window that the WM_TRANSIENT_FOR property is to be set to.

The XSetTransientForHint function sets the WM_TRANSIENT_FOR property of the specified window to the specified prop_window.

XSetTransientForHint can generate BadAlloc and BadWindow errors.

To get the WM_TRANSIENT_FOR value for a window, use XGetTransientForHint.
Communicating with Window Managers

Status XGetTransientForHint (display, w, prop_window_return)

Display *display;
Window w;
Window *prop_window_return;

display Specifies the connection to the XWIN server.
w Specifies the window.

prop_window_return Returns the WM_TRANSIENT_FOR property of the specified window.

The XGetTransientForHint function returns the WM_TRANSIENT_FOR property for the specified window.

XGetTransientForHint can generate a BadWindow error.
Manipulating Standard Colormaps

Applications with color palettes, smooth-shaded drawings, or digitized images demand large numbers of colors. In addition, these applications often require an efficient mapping from color triples to pixel values that display the appropriate colors.

As an example, consider a 3D display program that wants to draw a smoothly shaded sphere. At each pixel in the image of the sphere, the program computes the intensity and color of light reflected back to the viewer. The result of each computation is a triple of RGB coefficients in the range 0.0 to 1.0. To draw the sphere, the program needs a colormap that provides a large range of uniformly distributed colors. The colormap should be arranged so that the program can convert its RGB triples into pixel values very quickly, because drawing the entire sphere requires many such conversions.

On many current workstations, the display is limited to 256 or fewer colors. Applications must allocate colors carefully, not only to make sure they cover the entire range they need but also to make use of as many of the available colors as possible. On a typical X display, many applications are active at once. Most workstations have only one hardware look-up table for colors, so only one application colormap can be installed at a given time. The application using the installed colormap is displayed correctly, and the other applications "go technicolor" and are displayed with false colors.

As another example, consider a user who is running an image processing program to display earth-resources data. The image processing program needs a colormap set up with 8 reds, 8 greens, and 4 blues (a total of 256 colors). Because some colors are already in use in the default colormap, the image processing program allocates and installs a new colormap.

The user decides to alter some of the colors in the image. He invokes a color palette program to mix and choose colors. The color palette program also needs a colormap with 8 reds, 8 greens, and 4 blues, so just as the image-processing program, it must allocate and install a new colormap.

Because only one colormap can be installed at a time, the color palette may be displayed incorrectly whenever the image-processing program is active. Conversely, whenever the palette program is active, the image may be displayed incorrectly. The user can never match or compare colors in the palette and image. Contention for colormap resources can be reduced if applications with similar color needs share colormaps.
As another example, the image processing program and the color palette program could share the same colormap if there existed a convention that described how the colormap was set up. Whenever either program was active, both would be displayed correctly.

The standard colormap properties define a set of commonly used colormaps. Applications that share these colormaps and conventions display true colors more often and provide a better interface to the user.

**Standard Colormaps**

Standard colormaps allow applications to share commonly used color resources. This allows many applications to be displayed in true colors simultaneously, even when each application needs an entirely filled colormap.

Several standard colormaps are described in this section. Usually, a window manager creates these colormaps. Applications should use the standard colormaps if they already exist. If the standard colormaps do not exist, you should create them by opening a new connection, creating the properties, and setting the close-down mode of the connection to RetainPermanent.

The `XStandardColormap` structure contains:

```c
typedef struct {
    Colormap colormap;
    unsigned long red_max;
    unsigned long red_mult;
    unsigned long green_max;
    unsigned long green_mult;
    unsigned long blue_max;
    unsigned long blue_mult;
    unsigned long base_pixel;
} XStandardColormap;
```

The colormap member is the colormap created by the `XCreateColormap` function. The `red_max`, `green_max`, and `blue_max` members give the maximum red, green, and blue values, respectively. Each color coefficient ranges from zero to its max, inclusive. For example, a common colormap allocation is 3/3/2 (3 planes for red, 3 planes for green, and 2 planes for blue). This colormap would have `red_max = 7`, `green_max = 7`, and `blue_max = 3`. An alternate allocation that uses only 216 colors is `red_max = 5`, `green_max = 5`, and `blue_max = 5`. 
The red_mult, green_mult, and blue_mult members give the scale factors used to compose a full pixel value. (See the discussion of the base_pixel members for further information.) For a 3/3/2 allocation, red_mult might be 32, green_mult might be 4, and blue_mult might be 1. For a 6-colors-each allocation, red_mult might be 36, green_mult might be 6, and blue_mult might be 1.

The base_pixel member gives the base pixel value used to compose a full pixel value. Usually, the base_pixel is obtained from a call to the XAllocColorPlanes function. Given integer red, green, and blue coefficients in their appropriate ranges, one then can compute a corresponding pixel value by using the following expression:

\[ r \times \text{red} \_\text{Mult} + g \times \text{green} \_\text{Mult} + b \times \text{blue} \_\text{Mult} + \text{base} \_\text{Pixel} \]

For GrayScale colormaps, only the colormap, red_max, red_mult, and base_pixel members are defined. The other members are ignored.

To compute a GrayScale pixel value, use the following expression:

\[ \text{gray} \times \text{red} \_\text{Mult} + \text{base} \_\text{Pixel} \]

The properties containing the XStandardColormap information have the type RGB_COLOR_MAP.

**Standard Colormap Properties and Atoms**

Several standard colormaps are available. Each standard colormap is defined by a property, and each such property is identified by an atom. The following list names the atoms and describes the colormap associated with each one. The `<X11/Xatom.h>` header file contains the definitions for each of the following atoms, which are prefixed with `XA_`.

**RGB_DEFAULT_MAP**

This atom names a property. The value of the property is an XStandardColormap.

The property defines an RGB subset of the default colormap of the screen. Some applications only need a few RGB colors and may be able to allocate them from the system default colormap. This is the ideal situation because the fewer colormaps that are active in the system the more applications are displayed with correct colors at all times.
Manipulating Standard Colormaps

A typical allocation for the RGB_DEFAULT_MAP on 8-plane displays is 6 reds, 6 greens, and 6 blues. This gives 216 uniformly distributed colors (6 intensities of 36 different hues) and still leaves 40 elements of a 256-element colormap available for special-purpose colors for text, borders, and so on.

RGB_BEST_MAP

This atom names a property. The value of the property is an XStandardColormap.

The property defines the best RGB colormap available on the screen. (Of course, this is a subjective evaluation.) Many image processing and 3D applications need to use all available colormap cells and to distribute as many perceptually distinct colors as possible over those cells. This implies that there may be more green values available than red, as well as more green or red than blue.

On an 8-plane pseudoColor display, RGB_BEST_MAP should be a 3/3/2 allocation. On a 24-plane DirectColor display, RGB_BEST_MAP should be an 8/8/8 allocation. On other displays, the RGB_BEST_MAP allocation is purely up to the implementor of the display.

RGB_RED_MAP
RGB_GREEN_MAP
RGB_BLUE_MAP

These atoms name properties. The value of each property is an XStandardColormap.

The properties define all-red, all-green, and all-blue colormaps, respectively. These maps are used by applications that want to make color-separated images. For example, a user might generate a full-color image on an 8-plane display both by rendering an image three times (once with high color resolution in red, once with green, and once with blue) and by multiply-exposing a single frame in a camera.
Manipulating Standard Colormaps

RGB_GRAY_MAP

This atom names a property. The value of the property is an XStandardColormap.

The property describes the best GrayScale colormap available on the screen. As previously mentioned, only the colormap, red_max, red_mult, and base_pixel members of the XStandardColormap structure are used for GrayScale colormaps.

Getting and Setting an XStandardColormap Structure

To get the XStandardColormap structure associated with one of the described atoms, use XGetStandardColormap.

```c
Status XGetStandardColormap(display, w, colormap_return, property)
    Display *display;
    Window w;
    XStandardColormap *colormap_return;
    Atom property; /* RGB_BEST_MAP, etc. */
```

- `display` Specifies the connection to the XWIN server.
- `w` Specifies the window.
- `colormap_return` Returns the colormap associated with the specified atom.
- `property` Specifies the property name.

The XGetStandardColormap function returns the colormap definition associated with the atom supplied as the property argument. For example, to fetch the standard GrayScale colormap for a display, you use XGetStandardColormap with the following syntax:

```c
XGetStandardColormap(dpy, DefaultRootWindow(dpy), &cmap, XA_RGB_GRAY_MAP);
```

Once you have fetched a standard colormap, you can use it to convert RGB values into pixel values. For example, given an XStandardColormap structure and floating-point RGB coefficients in the range 0.0 to 1.0, you can compose pixel values with the following C expression:
Manipulating Standard Colormaps

\[
pixel = \text{base\_pixel} \\
\quad + ((\text{unsigned long} \ (0.5 + r \times \text{red\_max})) \times \text{red\_mult}) \\
\quad + ((\text{unsigned long} \ (0.5 + g \times \text{green\_max})) \times \text{green\_mult}) \\
\quad + ((\text{unsigned long} \ (0.5 + b \times \text{blue\_max})) \times \text{blue\_mult});
\]

The use of addition rather than logical OR for composing pixel values permits allocations where the RGB value is not aligned to bit boundaries.

\text{XGetStandardColormap} can generate BadAtom and BadWindow errors.

To set a standard colormap, use \text{XSetStandardColormap}.

\text{xsetstandardcolormap(\text{display}, \text{w}, \text{colormap}, \text{property})}

\text{Display *display;}
\text{Window w;}
\text{XStandardColormap *colormap;}
\text{Atom property; /* RGB\_BEST\_MAP, etc. */}

\text{display} \quad \text{Specifies the connection to the XWIN server.}
\text{w} \quad \text{Specifies the window.}
\text{colormap} \quad \text{ Specifies the colormap.}
\text{property} \quad \text{Specifies the property name.}

The \text{XSetStandardColormap} function usually is only used by window managers. To create a standard colormap, follow this procedure:

- Open a new connection to the same server.
- Grab the server.
- See if the property is on the property list of the root window for the screen.
- If the desired property is not present:
  - Create a colormap (not required for RGB\_DEFAULT\_MAP)
  - Determine the color capabilities of the display.
  - Call \text{XAllocColorPlanes} or \text{XAllocColorCells} to allocate cells in the colormap.
Manipulating Standard Colormaps

- Call XStoreColors to store appropriate color values in the colormap.
- Fill in the descriptive members in the XStandardColormap structure.
- Attach the property to the root window.
- Use XSetCloseDownMode to make the resource permanent.
- Ungrab the server.

XSetStandardColormap can generate BadAlloc, BadAtom, and BadWindow errors.

### Using the Context Manager

10-52
Introduction

Once you have initialized the X system, you can use the Xlib utility functions to:

- Handle keyboard events
- Obtain the X environment defaults
- Parse window geometry strings
- Parse hardware colors strings
- Generate regions
- Manipulate regions
- Use cut and paste buffers
- Determine the appropriate visual
- Manipulate images
- Manipulate bitmaps
- Use the resource manager
- Use the context manager

As a group, the functions discussed in this chapter provide the functionality that is frequently needed and that spans toolkits. Many of these functions do not generate actual protocol requests to the server.
Keyboard Utility Functions

This section discusses keyboard event functions and KeySym classification macros.

Keyboard Event Functions

The XWIN server does not predefine the keyboard to be ASCII characters. It is often useful to know that the a key was just pressed or that it was just released. When a key is pressed or released, the XWIN server sends keyboard events to client programs. The structures associated with keyboard events contain a keycode member that assigns a number to each physical key on the keyboard. For a discussion of keyboard event processing, see "Keyboard and Pointer Events" in Chapter 8. For information on how to manipulate the keyboard encoding, see "Keyboard Encoding" in Chapter 7.

Because KeyCodes are completely arbitrary and may differ from server to server, client programs wanting to deal with ASCII text, for example, must explicitly convert the KeyCode value into ASCII. Therefore, Xlib provides functions to help you customize the keyboard layout. Keyboards differ dramatically, so writing code that presumes the existence of a particular key on the main keyboard creates portability problems.

Keyboard events are usually sent to the deepest viewable window underneath the pointer's position that is interested in that type of event. It is also possible to assign the keyboard input focus to a specific window. When the input focus is attached to a window, keyboard events go to the client that has selected input on that window rather than the window under the pointer.

The functions in this section handle the shift modifier computations suggested by the protocol. The KeySym table is internally modified to define the lowercase transformation of a–z by adding the lowercase KeySym to the first element of the KeySym list (used internally) defined for the KeyCode, when the list is of length 1. If you want the untransformed KeySyms defined for a key, you should only use the functions described under "Keyboard Encoding" in Chapter 7.

To look up the KeySyms, use XLookupKeysym.

```c
KeySym XLookupKeysym(key_event, index)
    XKeyEvent *key_event;
    int index;
```
Keyboard Utility Functions

`key_event` Specifies the `KeyPress` or `KeyRelease` event.

`index` Specifies the index into the KeySym list for the event’s KeyCode.

The `XLookupKeysym` function uses a given keyboard event and the index you specified to return the KeySym from the list that corresponds to the KeyCode member in the `XKeyPressedEvent` or `XKeyReleasedEvent` structure. If no KeySym is defined for the KeyCode of the event, `XLookupKeysym` returns `NoSymbol`.

To refresh the stored modifier and keymap information, use `XRefreshKeyboardMapping`.

```
XRefreshKeyboardMapping(event_map)
```

`event_map` Specifies the mapping event that is to be used.

The `XRefreshKeyboardMapping` function refreshes the stored modifier and keymap information. You usually call this function when a `MappingNotify` event with a request member of `MappingKeyboard` or `MappingModifier` occurs. The result is to update XLib’s knowledge of the keyboard.

To map a key event to an ISO Latin-1 string, use `XLookupString`.

```
int XLookupString(event_struct, buffer_return, bytes_buffer, keysym_return, status_in_out)
```

`event_struct` Specifies the key event structure to be used. You can pass `XKeyPressedEvent` or `XKeyReleasedEvent`.

`buffer_return` Returns the translated characters.

`bytes_buffer` Specifies the length of the buffer. No more than `bytes_buffer` of translation are returned.
**Keyboard Utility Functions**

**keysym_return**  Returns the KeySym computed from the event if this argument is not NULL.

**status_in_out**  Specifies or returns the XComposeStatus structure or NULL.

The XLookupString function is a convenience routine that maps a key event to an ISO Latin-1 string, using the modifier bits in the key event to deal with shift, lock, and control. It returns the translated string into the user’s buffer. It also detects any rebound KeySyms (see XRebindKeysym) and returns the specified bytes. XLookupString returns the length of the string stored in the tag buffer. If the lock modifier has the caps lock KeySym associated with it, XLookupString interprets the lock modifier to perform caps lock processing.

If present (non-NULL), the XComposeStatus structure records the state, which is private to Xlib, that needs preservation across calls to XLookupString to implement compose processing.

To rebind the meaning of a KeySym for a client, use XRebindKeysym.

\[
\text{XRebindKeysym}(\text{display}, \text{keysym}, \text{list, mod_count, string, bytes_string})
\]

- **display**  Specifies the connection to the XWIN server.
- **keysym**  Specifies the KeySym that is to be rebound.
- **list**  Specifies the KeySyms to be used as modifiers.
- **mod_count**  Specifies the number of modifiers in the modifier list.
- **string**  Specifies a pointer to the string that is copied and will be returned by XLookupString.
- **bytes_string**  Specifies the length of the string.

The XRebindKeysym function can be used to rebind the meaning of a KeySym for the client. It does not redefine any key in the XWIN server but merely provides an easy way for long strings to be attached to keys. XLookupString returns this string when the appropriate set of modifier keys are pressed and...
when the KeySym would have been used for the translation. Note that you can rebind a KeySym that may not exist.

To convert the name of the KeySym to the KeySym code, use XStringToKeysym.

```c
KeySym XStringToKeysym(string)
    char *string;
```

`string` Specifies the name of the KeySym that is to be converted.

Valid KeySym names are listed in `<X11/keysymdef.h>` by removing the XK_prefix from each name. If the specified string does not match a valid KeySym, XStringToKeysym returns NoSymbol.

To convert a KeySym code to the name of the KeySym, use XKeysymToString.

```c
char *XKeysymToString(keysym)
    KeySym keysym;
```

`keysym` Specifies the KeySym that is to be converted.

The returned string is in a static area and must not be modified. If the specified KeySym is not defined, XKeysymToString returns a NULL.

To convert a key code to a defined KeySym, use XKeycodeToKeysym.

```c
KeySym XKeycodeToKeysym(display, keycode, index)
    Display *display;
    KeyCode keycode;
    int index;
```

`display` Specifies the connection to the XWIN server.

`keycode` Specifies the KeyCode.

`index` Specifies the element of KeyCode vector.

The XKeycodeToKeysym function uses internal Xlib tables and returns the KeySym defined for the specified KeyCode and the element of the KeyCode vector. If no symbol is defined, XKeycodeToKeysym returns NoSymbol.
To convert a KeySym to the appropriate KeyCode, use XKeysymToKeyCode.

```c
KeyCode XKeysymToKeyCode (display, keysym)
    Display *display;
    KeySym keysym;
```

- `display` Specifies the connection to the XWIN server.
- `keysym` Specifies the KeySym that is to be searched for.

If the specified KeySym is not defined for any KeyCode, XKeysymToKeyCode returns zero.

**Keysym Classification Macros**

You may want to test if a KeySym is, for example, on the keypad or on one of the function keys. You can use the KeySym macros to perform the following tests.

- `IsCursorKey(keysym)`
  Returns True if the specified KeySym is a cursor key.

- `IsFunctionKey(keysym)`
  Returns True if the specified KeySym is a function key.

- `IsKeypadKey(keysym)`
  Returns True if the specified KeySym is a keypad key.

- `IsMiscFunctionKey(keysym)`
  Returns True if the specified KeySym is a miscellaneous function key.

- `IsModifierKey(keysym)`
  Returns True if the specified KeySym is a modifier key.

- `IsPFKey(keysym)`
  Returns True if the specified KeySym is a PF key.
Obtaining the X Environment Defaults

A program often needs a variety of options in the X environment (for example, fonts, colors, mouse, background, text, and cursor). Specifying these options on the command line is inefficient and unmanageable because individual users have a variety of tastes with regard to window appearance. XGetDefault makes it easy to find out the fonts, colors, and other environment defaults favored by a particular user. Defaults are usually loaded into the RESOURCE_MANAGER property on the root window at login. If no such property exists, a resource file in the user’s home directory is loaded. On a XWIN System system, this file is $HOME/.Xdefaults.

After loading these defaults, XGetDefault merges additional defaults specified by the XENVIRONMENT environment variable. If XENVIRONMENT is defined, it contains a full path name for the additional resource file. If XENVIRONMENT is not defined, XGetDefault looks for $HOME/.Xdefaults-name, where name specifies the name of the machine on which the application is running. For details of the format of these files, see "Using the Resource Manager" in this chapter.

The XGetDefault function provides a simple interface for clients not wishing to use the X toolkit or the more elaborate interfaces provided by the resource manager discussed in "Using the Resource Manager" in this chapter.

```c
char *XGetDefault (display, program, option)
    Display *display;
    char *program;
    char *option;

display Specifies the connection to the XWIN server.
program Specifies the program name for the Xlib defaults (usually argv[0]
of the main program).
option Specifies the option name.
```

The XGetDefault function returns the value NULL if the option name specified in this argument does not exist for the program. The strings returned by XGetDefault are owned by Xlib and should not be modified or freed by the client.

To obtain a pointer to the resource manager string of a display, use XResourceManagerString.
Obtaining the X Environment Defaults

char *XResourceManagerString(display)
   Display *display;

(display) Specifies the connection to the XWIN server.
The XResourceManagerString returns the RESOURCE_MANAGER property from the server’s root window of screen zero, which was returned when the connection was opened using XOpenDisplay.
Parsing the Window Geometry

To parse standard window geometry strings, use XParseGeometry.

```c
int XParseGeometry (parsestring, x_return, y_return, width_return, height_return)
    char *parsestring;
    int *x_return, *y_return;
    int *width_return, *height_return;
```

- **parsestring** Specifies the string you want to parse.
- **x_return** Return the x and y offsets.
- **y_return** Return the width and height determined.

By convention, X applications use a standard string to indicate window size and placement. XParseGeometry makes it easier to conform to this standard because it allows you to parse the standard window geometry. Specifically, this function lets you parse strings of the form:

```
<width>x<height>{+-}<xoffset>{+-}<yoffset>
```

The items in this form map into the arguments associated with this function. (Items enclosed in <> are integers, items in [] are optional, and items enclosed in {} indicate "choose one of". Note that the brackets should not appear in the actual string.)

The XParseGeometry function returns a bitmask that indicates which of the four values (width, height, xoffset, and yoffset) were actually found in the string and whether the x and y values are negative. By convention, -0 is not equal to +0, because the user needs to be able to say "position the window relative to the right or bottom edge." For each value found, the corresponding argument is updated. For each value not found, the argument is left unchanged. The bits are represented by XValue, YValue, WidthValue, HeightValue, XNegative, or YNegative and are defined in <XI1l/Xutil.h>. They will be set whenever one of the values is defined or one of the signs is set.

If the function returns either the XValue or YValue flag, you should place the window at the requested position.
To parse window geometry given a user-specified position and a default position, use `XGeometry`.

```c
int XGeometry (display, screen, position, default_position, bwidth, fwidth, fheight, xadder,
                yadder, x_return, y_return, width_return, height_return)
```

- `display`: Specifies the connection to the XWIN server.
- `screen`: Specifies the screen.
- `position`: Specify the geometry specifications.
- `default_position`: Specify the geometry specifications.
- `bwidth`: Specifies the border width.
- `fheight`: Specify the font height and width in pixels (increment size).
- `fwidth`: Specify the font height and width in pixels (increment size).
- `xadder`: Specify additional interior padding needed in the window.
- `yadder`: Specify additional interior padding needed in the window.
- `x_return`: Return the x and y offsets.
- `y_return`: Return the x and y offsets.
- `width_return`: Return the width determined.
- `height_return`: Return the height determined.

You pass in the border width (`bwidth`), size of the increments `fwidth` and `fheight` (typically font width and height), and any additional interior space (`xadder` and `yadder`) to make it easy to compute the resulting size. The `XGeometry` function returns the position the window should be placed given a position and a default position. `XGeometry` determines the placement of a window using a geometry specification as specified by `XParseGeometry` and the additional information about the window. Given a fully qualified default
geometry specification and an incomplete geometry specification, XParseGeometry returns a bitmask value as defined above in the XParseGeometry call, by using the position argument.

The returned width and height will be the width and height specified by default position as overridden by any user-specified position. They are not affected by fwidth, fheight, xadder, or yadder. The x and y coordinates are computed by using the border width, the screen width and height, padding as specified by xadder and yadder, and the fheight and fwidth times the width and height from the geometry specifications.
Parsing the Color Specifications

To parse color values, use XParseColor.

```
Status XParseColor (display, colormap, spec, exact_def_return)
    Display *display;
    Colormap colormap;
    char *spec;
    XColor *exact_def_return;
```

display Specifies the connection to the XWIN server.
colormap Specifies the colormap.
spec Specifies the color name string; case is ignored.
exact_def_return Returns the exact color value for later use and sets the
DoRed, DoGreen, and DoBlue flags.

The XParseColor function provides a simple way to create a standard user
interface to color. It takes a string specification of a color, typically from a com-
mand line or XGetDefault option, and returns the corresponding red, green,
and blue values that are suitable for a subsequent call to XAllocColor or
XStoreColor. The color can be specified either as a color name (as in XAlloc-
NamedColor) or as an initial sharp sign character followed by a numeric
specification, in one of the following formats:

- #RGB
- #RRGGBB
- #RRRGGGGBBB
- #RRRRGGGGBBBB

(4 bits each)
(8 bits each)
(12 bits each)
(16 bits each)

The R, G, and B represent single hexadecimal digits (both uppercase and lower-
case). When fewer than 16 bits each are specified, they represent the most-
significant bits of the value. For example, #3a7 is the same as #3000a0007000.
The colormap is used only to determine which screen to look up the color on.
For example, you can use the screen’s default colormap.

If the initial character is a sharp sign but the string otherwise fails to fit the
above formats or if the initial character is not a sharp sign and the named color
does not exist in the server’s database, XParseColor fails and returns zero.

XParseColor can generate a BadColor error.
Generating Regions

Regions are arbitrary sets of pixel locations. Xlib provides functions for manipulating regions. The opaque type Region is defined in `<X11/Xutil.h`.

To generate a region from a polygon, use XPolygonRegion.

```c
Region XPolygonRegion(points, n, fill_rule)
XPoint points[n];
int n;
int fill_rule;
```

- `points` Specifies an array of points.
- `n` Specifies the number of points in the polygon.
- `fill_rule` Specifies the fill-rule you want to set for the specified GC. You can pass EvenOddRule or WindingRule.

The XPolygonRegion function returns a region for the polygon defined by the points array. For an explanation of fill_rule, see XCreateGC.

To generate the smallest rectangle enclosing the region, use XClipBox.

```c
XClipBox(r, rect_return)
Region r;
XRectangle *rect_return;
```

- `r` Specifies the region.
- `rect_return` Returns the smallest enclosing rectangle.

The XClipBox function returns the smallest rectangle enclosing the specified region.
Manipulating Regions

Xlib provides functions that you can use to manipulate regions. This section discusses how to:

- Create, copy, or destroy regions
- Move or shrink regions
- Compute with regions
- Determine if regions are empty or equal
- Locate a point or rectangle in a region

Creating, Copying, or Destroying Regions

To create a new empty region, use XCreateRegion.

```c
Region XCreateRegion()
```

To set the clip-mask of a GC to a region, use XSetRegion.

```c
XSetRegion(display, gc, r)
    Display *display;
    GC gc;
    Region r;
```

declares the connection to the XWIN server.

dclares the GC.

dclares the region.

The XSetRegion function sets the clip-mask in the GC to the specified region. Once it is set in the GC, the region can be destroyed.

To deallocate the storage associated with a specified region, use XDestroyRegion.

```c
XDestroyRegion(r)
    Region r;
```

dclares the region.

Moving or Shrinking Regions

To move a region by a specified amount, use XOffsetRegion.

```
XOffsetRegion(r, dx, dy)
    Region r;
    int dx, dy;
```

- `r` Specifies the region.
- `dx` Specify the x and y coordinates, which define the amount you want to move the specified region.
- `dy` Specify the x and y coordinates, which define the amount you want to move the specified region.

To reduce a region by a specified amount, use XShrinkRegion.

```
XShrinkRegion(r, dx, dy)
    Region r;
    int dx, dy;
```

- `r` Specifies the region.
- `dx` Specify the x and y coordinates, which define the amount you want to shrink the specified region.
- `dy` Specify the x and y coordinates, which define the amount you want to shrink the specified region.

Positive values shrink the size of the region, and negative values expand the region.

Computing with Regions

To compute the intersection of two regions, use XIntersectRegion.

```
XIntersectRegion(sra, srb, dr_return)
    Region sra, srb, dr_return;
```

- `sra` Specify the two regions with which you want to perform the computation.
- `srb` Specify the two regions with which you want to perform the computation.
Manipulating Regions

\[ dr\_return \] Returns the result of the computation.

To compute the union of two regions, use \texttt{XUnionRegion}.

\begin{verbatim}
XUnionRegion (sra, srb, dr_return)
Region sra, srb, dr_return;
\end{verbatim}

\texttt{sra} \hspace{1cm} \text{Specify the two regions with which you want to perform the computation.}

\texttt{dr\_return} \hspace{1cm} Returns the result of the computation.

To create a union of a source region and a rectangle, use \texttt{XUnionRectWithRegion}.

\begin{verbatim}
XUnionRectWithRegion (rectangle, src_region, dest_region_return)
XRectangle *rectangle;
Region src_region;
Region dest_region_return;
\end{verbatim}

\texttt{rectangle} \hspace{1cm} Specifies the rectangle.

\texttt{src\_region} \hspace{1cm} Specifies the source region to be used.

\texttt{dest\_region\_return} \hspace{1cm} Returns the destination region.

The \texttt{XUnionRectWithRegion} function updates the destination region from a union of the specified rectangle and the specified source region.

To subtract two regions, use \texttt{XSubtractRegion}.

\begin{verbatim}
XSubtractRegion (sra, srb, dr_return)
Region sra, srb, dr_return;
\end{verbatim}

\texttt{sra} \hspace{1cm} Specify the two regions with which you want to perform the computation.

\texttt{dr\_return} \hspace{1cm} Returns the result of the computation.
The **XSubtractRegion** function subtracts *srb* from *sra* and stores the results in *dr_return*.

To calculate the difference between the union and intersection of two regions, use **XXorRegion**.

```
XXorRegion(sra, srb, dr_return)
Region sra, srb, dr_return;
```

- *sra* Specify the two regions with which you want to perform the computation.
- *srb* Returns the result of the computation.

**Determining if Regions Are Empty or Equal**

To determine if the specified region is empty, use **XEmptyRegion**.

```
Bool XEmptyRegion(r)
Region r;
```

- *r* Specifies the region.

The **XEmptyRegion** function returns True if the region is empty.

To determine if two regions have the same offset, size, and shape, use **XEqualRegion**.

```
Bool XEqualRegion(r1, r2)
Region r1, r2;
```

- *r1* Specify the two regions.
- *r2* Returns True if the two regions have the same offset, size, and shape.
Locating a Point or a Rectangle in a Region

To determine if a specified point resides in a specified region, use `XPointInRegion`.

```c
Bool XPointInRegion(r, x, y)
    Region r;
    int x, y;

    r Specifies the region.
    x
    y Specify the x and y coordinates, which define the point.
```

The `XPointInRegion` function returns `True` if the point `(x, y)` is contained in the region `r`.

To determine if a specified rectangle is inside a region, use `XRectInRegion`.

```c
int XRectInRegion(r, x, y, width, height)
    Region r;
    int x, y;
    unsigned int width, height;

    r Specifies the region.
    x
    y Specify the x and y coordinates, which define the coordinates of the upper-left corner of the rectangle.
    width
    height Specify the width and height, which define the rectangle.
```

The `XRectInRegion` function returns `RectangleIn` if the rectangle is entirely in the specified region, `RectangleOut` if the rectangle is entirely out of the specified region, and `RectanglePart` if the rectangle is partially in the specified region.
Using the Cut and Paste Buffers

Xlib provides functions that you can use to cut and paste buffers for programs using this form of communications. Selections are a more useful mechanism for interchanging data between clients because typed information can be exchanged. X provides property names for properties in which bytes can be stored for implementing cut and paste between windows (implemented by use of properties on the first root window of the display). It is up to applications to agree on how to represent the data in the buffers. The data is most often ISO Latin-1 text. The atoms for eight such buffer names are provided and can be accessed as a ring or as explicit buffers (numbered 0 through 7). New applications are encouraged to share data by using selections (see "Selections" in Chapter 4).

To store data in cut buffer 0, use XStoreBytes.

```c
XStoreBytes (display, bytes, nbytes)
Display *display;
char *bytes;
int nbytes;
```

- `display` Specifies the connection to the XWIN server.
- `bytes` Specifies the bytes, which are not necessarily ASCII or null-terminated.
- `nbytes` Specifies the number of bytes to be stored.

Note that the cut buffer's contents need not be text, so zero bytes are not special. The cut buffer's contents can be retrieved later by any client calling XFetchBytes.

XStoreBytes can generate a BadAlloc error.

To store data in a specified cut buffer, use XStoreBuffer.

```c
XStoreBuffer (display, bytes, nbytes, buffer)
Display *display;
char *bytes;
int nbytes;
int buffer;
```

- `display` Specifies the connection to the XWIN server.
Using the Cut and Paste Buffers

bytes
Specifies the bytes, which are not necessarily ASCII or null-terminated.

nbytes
Specifies the number of bytes to be stored.

buffer
Specifies the buffer in which you want to store the bytes.

If the property for the buffer has never been created, a BadAtom error results.

XStoreBuffer can generate BadAlloc and BadAtom errors.

To return data from cut buffer 0, use XFetchBytes.

```c
char *XFetchBytes (display, nbytes_return)
Display *display;
int *nbytes_return;
```

display
Specifies the connection to the XWIN server.

nbytes_return
Returns the number of bytes in the buffer.

The XFetchBytes function returns the number of bytes in the nbytes_return argument, if the buffer contains data. Otherwise, the function returns NULL and sets nbytes to 0. The appropriate amount of storage is allocated and the pointer returned. The client must free this storage when finished with it by calling XFree. Note that the cut buffer does not necessarily contain text, so it may contain embedded zero bytes and may not terminate with a null byte.

To return data from a specified cut buffer, use XFetchBuffer.

```c
char *XFetchBuffer (display, nbytes_return, buffer)
Display *display;
int *nbytes_return;
int buffer;
```

display
Specifies the connection to the XWIN server.

nbytes_return
Returns the number of bytes in the buffer.

buffer
Specifies the buffer from which you want the stored data returned.
The XFetchBuffer function returns zero to the nbytes_return argument if there is no data in the buffer.

XFetchBuffer can generate a BadValue error.

To rotate the cut buffers, use XRotateBuffers.

```
XRotateBuffers (display, rotate)
    Display *display;
    int rotate;
```

*display* Specifies the connection to the XWIN server.

*rotate* Specifies how much to rotate the cut buffers.

The XRotateBuffers function rotates the cut buffers, such that buffer 0 becomes buffer n, buffer 1 becomes n + 1 mod 8, and so on. This cut buffer numbering is global to the display. Note that XRotateBuffers generates BadMatch errors if any of the eight buffers have not been created.
Determining the Appropriate Visual Type

A single display can support multiple screens. Each screen can have several different visual types supported at different depths. You can use the functions described in this section to determine which visual to use for your application.

The functions in this section use the visual information masks and the XVisualInfo structure, which is defined in `<X11/Xutil.h>` and contains:

/* Visual information mask bits */

```c
#define VisualNoMask 0x0
#define VisualIDMask 0x1
#define VisualScreenMask 0x2
#define VisualDepthMask 0x4
#define VisualClassMask 0x8
#define VisualRedMaskMask 0x10
#define VisualGreenMaskMask 0x20
#define VisualBlueMaskMask 0x40
#define VisualColorMapSizeMask 0x80
#define VisualBitsPerRGBMask 0x100
#define VisualAllMask 0x1FF
```

/* Values */

typedef struct {
    Visual *visual;
    VisualID visualid;
    int screen;
    unsigned int depth;
    int class;
    unsigned long red_mask;
    unsigned long green_mask;
    unsigned long blue_mask;
    int colormap_size;
    int bits_per_rgb;
} XVisualInfo;

To obtain a list of visual information structures that match a specified template, use \texttt{XGetVisualInfo}.

\begin{verbatim}
XVisualInfo *XGetVisualInfo (display, vinfo_mask, vinfo_template, nitems_return)
    Display *display;
    long vinfo_mask;
    XVisualInfo *vinfo_template;
    int *nitems_return;
\end{verbatim}

- \texttt{display} Specifies the connection to the XWin server.
- \texttt{vinfo_mask} Specifies the visual mask value.
- \texttt{vinfo_template} Specifies the visual attributes that are to be used in matching the visual structures.
- \texttt{nitems_return} Returns the number of matching visual structures.

The \texttt{XGetVisualInfo} function returns a list of visual structures that match the attributes specified by \texttt{vinfo_template}. If no visual structures match the template using the specified \texttt{vinfo_mask}, \texttt{XGetVisualInfo} returns a NULL. To free the data returned by this function, use \texttt{XFree}.

To obtain the visual information that matches the specified depth and class of the screen, use \texttt{XMatchVisualInfo}.

\begin{verbatim}
Status XMatchVisualInfo (display, screen, depth, class, vinfo_return)
    Display *display;
    int screen;
    int depth;
    int class;
    XVisualInfo *vinfo_return;
\end{verbatim}

- \texttt{display} Specifies the connection to the XWin server.
- \texttt{screen} Specifies the screen.
- \texttt{depth} Specifies the depth of the screen.
- \texttt{class} Specifies the class of the screen.
- \texttt{vinfo_return} Returns the matched visual information.
The `XMatchVisualInfo` function returns the visual information for a visual that matches the specified depth and class for a screen. Because multiple visuals that match the specified depth and class can exist, the exact visual chosen is undefined. If a visual is found, `XMatchVisualInfo` returns nonzero and the information on the visual to `vinfo_return`. Otherwise, when a visual is not found, `XMatchVisualInfo` returns zero.
Manipulating Images

Xlib provides several functions that perform basic operations on images. All operations on images are defined using an XImage structure, as defined in `<X11/Xlib.h>`. Because the number of different types of image formats can be very large, this hides details of image storage properly from applications.

This section describes the functions for generic operations on images. Manufacturers can provide very fast implementations of these for the formats frequently encountered on their hardware. These functions are neither sufficient nor desirable to use for general image processing. Rather, they are here to provide minimal functions on screen format images. The basic operations for getting and putting images are XGetImage and XPutImage.

Note that no functions have been defined, as yet, to read and write images to and from disk files.

The XImage structure describes an image as it exists in the client's memory. The user can request that some of the members such as height, width, and xoffset be changed when the image is sent to the server. Note that bytes_per_line in concert with offset can be used to extract a subset of the image. Other members (for example, byte order, bitmap_unit, and so forth) are characteristics of both the image and the server. If these members differ between the image and the server, XPutImage makes the appropriate conversions. The first byte of the first line of plane n must be located at the address (data + (n * height * bytes_per_line)). For a description of the XImage structure, see "Transferring Images between Client and Server" in Chapter 6.

To allocate sufficient memory for an XImage structure, use XCreateImage.

```c
XImage *XCreateImage (display, visual, depth, format, offset, data, width, height, bitmap_pad, bytes_per_line)

Display *display;
Visual *visual;
unsigned int depth;
int format;
int offset;
char *data;
unsigned int width;
unsigned int height;
int bitmap_pad;
int bytes_per_line;
```
Manipulating Images

display  Specifies the connection to the XWIN server.

visual   Specifies a pointer to the visual.

depth    Specifies the depth of the image.

format   Specifies the format for the image. You can pass XYBitmap,
          XYPixmap, or ZPixmap.

offset   Specifies the number of pixels to ignore at the beginning of the
          scanline.

data     Specifies a pointer to the image data.

width    Specifies the width of the image, in pixels.

height   Specifies the height of the image, in pixels.

bitmap_pad  Specifies the quantum of a scanline (8, 16, or 32). In other
             words, the start of one scanline is separated in client memory
             from the start of the next scanline by an integer multiple of this
             many bits.

bytes_per_line  Specifies the number of bytes in the client image between the
                 start of one scanline and the start of the next.

The XCreateImage function allocates the memory needed for an XImage struc-
ture for the specified display but does not allocate space for the image itself.
Rather, it initializes the structure byte-order, bit-order, and bitmap-unit values
from the display and returns a pointer to the XImage structure. The red, green,
and blue mask values are defined for Z format images only and are derived
from the Visual structure passed in. Other values also are passed in. The
offset permits the rapid displaying of the image without requiring each scanline
to be shifted into position. If you pass a zero value in bytes_per_line, Xlib
assumes that the scanlines are contiguous in memory and calculates the value of
bytes_per_line itself.

Note that when the image is created using XCreateImage, XGetImage, or
XSubImage, the destroy procedure that the XDestroyImage function calls frees
both the image structure and the data pointed to by the image structure.

The basic functions used to get a pixel, set a pixel, create a subimage, and add a
constant offset to a Z format image are defined in the image object. The func-
tions in this section are really macro invocations of the functions in the image
object and are defined in < X11/Xutil.h >.
To obtain a pixel value in an image, use XGetPixel.

```c
unsigned long XGetPixel(ximage, x, y)
    XImage *ximage;
    int x;
    int y;
```

*ximage* Specifies a pointer to the image.

*x* Specify the x and y coordinates.

*y* Specify the x and y coordinates.

The XGetPixel function returns the specified pixel from the named image. The pixel value is returned in normalized format (that is, the least-significant byte of the long is the least-significant byte of the pixel). The image must contain the x and y coordinates.

To set a pixel value in an image, use XPutPixel.

```c
int XPutPixel(ximage, x, y, pixel)
    XImage *ximage;
    int x;
    int y;
    unsigned long pixel;
```

*ximage* Specifies a pointer to the image.

*x* Specify the x and y coordinates.

*y* Specify the x and y coordinates.

*pixel* Specifies the new pixel value.

The XPutPixel function overwrites the pixel in the named image with the specified pixel value. The input pixel value must be in normalized format (that is, the least-significant byte of the long is the least-significant byte of the pixel). The image must contain the x and y coordinates.

To create a subimage, use XSubImage.
Manipulating Images

XImage *XSubImage (ximage, x, y, subimage_width, subimage_height)
    XImage *ximage;
    int x;
    int y;
    unsigned int subimage_width;
    unsigned int subimage_height;

    ximage Specifies a pointer to the image.
    x
    y Specify the x and y coordinates.
    subimage_width Specifies the width of the new subimage, in pixels.
    subimage_height Specifies the height of the new subimage, in pixels.

The XSubImage function creates a new image that is a subsection of an existing one. It allocates the memory necessary for the new XImage structure and returns a pointer to the new image. The data is copied from the source image, and the image must contain the rectangle defined by x, y, subimage_width, and subimage_height.

To increment each pixel in the pixmap by a constant value, use XAddPixel.

    XAddPixel (ximage, value)
    XImage *ximage;
    long value;

    ximage Specifies a pointer to the image.
    value Specifies the constant value that is to be added.

The XAddPixel function adds a constant value to every pixel in an image. It is useful when you have a base pixel value from allocating color resources and need to manipulate the image to that form.

To deallocate the memory allocated in a previous call to XCreateImage, use XDestroyImage.

    int XDestroyImage (ximage)
    XImage *ximage;
ximage Specifies a pointer to the image.

The XDestroyImage function deallocates the memory associated with the XImage structure.

Note that when the image is created using XCreateImage, XGetImage, or XSubImage, the destroy procedure that this macro calls frees both the image structure and the data pointed to by the image structure.
Manipulating Bitmaps

Xlib provides functions that you can use to read a bitmap from a file, save a bitmap to a file, or create a bitmap. This section describes those functions that transfer bitmaps to and from the client's file system, thus allowing their reuse in a later connection (for example, from an entirely different client or to a different display or server).

The X version 11 bitmap file format is:

```
#define name_width width
#define name_height height
#define name_x_hot x
#define name_y_hot y
static char name_bits[] = { 0xNN,... }
```

The variables ending with _x_hot and _y_hot suffixes are optional because they are present only if a hotspot has been defined for this bitmap. The other variables are required. The_bits array must be large enough to contain the size bitmap. The bitmap unit is eight. The name is derived from the name of the file that you specified on the original command line by deleting the directory path and extension.

To read a bitmap from a file, use XReadBitmapFile.

```c
int XReadBitmapFile(display, d, filename, width_return, height_return, bitmap_return, x_hot_return, y_hot_return)
  Display *display;
  Drawable d;
  char *filename;
  unsigned int *width_return, *height_return;
  Pixmap *bitmap_return;
  int *x_hot_return, *y_hot_return;
```

- **display** Specifies the connection to the XWIN server.
- **d** Specifies the drawable that indicates the screen.
- **filename** Specifies the file name to use. The format of the file name is operating-system dependent.
- **width_return** **height_return** Return the width and height values of the read in bitmap file.
Manipulating Bitmaps

**bitmap_return**  Returns the bitmap that is created.

**x_hot_return**  Returns the hotspot coordinates.

**y_hot_return**  Returns the hotspot coordinates.

The `XReadBitmapFile` function reads in a file containing a bitmap. The file can be either in the standard X version 10 format (that is, the format used by X version 10 bitmap program) or in the X version 11 bitmap format. If the file cannot be opened, `XReadBitmapFile` returns `BitmapOpenFailed`. If the file can be opened but does not contain valid bitmap data, it returns `BitmapFileInvalid`. If insufficient working storage is allocated, it returns `BitmapNoMemory`. If the file is readable and valid, it returns `BitmapSuccess`. `XReadBitmapFile` returns the bitmap's height and width, as read from the file, to `width_return` and `height_return`. It then creates a pixmap of the appropriate size, reads the bitmap data from the file into the pixmap, and assigns the pixmap to the caller's variable bitmap. The caller must free the bitmap using `XFreePixmap` when finished. If `name_x_hot` and `name_y_hot` exist, `XReadBitmapFile` returns them to `x_hot_return` and `y_hot_return`; otherwise, it returns `-1,-1`.

`XReadBitmapFile` can generate `BadAlloc` and `BadDrawable` errors.

To write out a bitmap to a file, use `XWriteBitmapFile`.

```c
int XWriteBitmapFile(display, filename, bitmap, width, height, x_hot, y_hot)
    Display *display;
    char *filename;
    Pixmap bitmap;
    unsigned int width, height;
    int x_hot, y_hot;

    display  Specifies the connection to the XWIN server.
    filename Specifies the file name to use. The format of the file name is operating-system dependent.
    bitmap  Specifies the bitmap.
    width
    height  Specify the width and height.
```
Manipulating Bitmaps

Specify where to place the hotspot coordinates (or -1,-1 if none are present) in the file.

The XWriteBitmapFile function writes a bitmap out to a file. While XReadBitmapFile can read in either X version 10 format or X version 11 format, XWriteBitmapFile always writes out X version 11 format. If the file cannot be opened for writing, it returns BitmapOpenFailed. If insufficient memory is allocated, XWriteBitmapFile returns BitmapNoMemory; otherwise, on no error, it returns BitmapSuccess. If x_hot and y_hot are not -1,-1, XWriteBitmapFile writes them out as the hotspot coordinates for the bitmap.

XWriteBitmapFile can generate BadDrawable and BadMatch errors.

To create a pixmap and then store bitmap-format data into it, use XCreatePixmapFromBitmapData.

```c
Pixmap XCreatePixmapFromBitmapData (Display *display, Drawable d, char *data, unsigned int width, unsigned int height, unsigned long fg, unsigned long bg, unsigned int depth)

Display *display;
Drawable d;
char *data;
unsigned int width, height;
unsigned long fg, bg;
unsigned int depth;
```

display Specifies the connection to the XWIN server.
d Specifies the drawable that indicates the screen.
data Specifies the data in bitmap format.
width Specify the width and height.
height

gf Specify the foreground and background pixel values to use.
bg

depth Specifies the depth of the pixmap.

The XCreatePixmapFromBitmapData function creates a pixmap of the given depth and then does a bitmap-format XPutImage of the data into it. The depth must be supported by the screen of the specified drawable, or a BadMatch error results.
XCreatePixmapFromBitmapData can generate BadAlloc and BadMatch errors.

To include a bitmap written out by XWriteBitmapFile in a program directly, as opposed to reading it in every time at run time, use XCreateBitmapFromData.

```
Pixmap XCreateBitmapFromData(display, d, data, width, height)
```

- `display`: Specifies the connection to the XWIN server.
- `d`: Specifies the drawable that indicates the screen.
- `data`: Specifies the location of the bitmap data.
- `width`: Specify the width and height.
- `height`: Specify the width and height.

The XCreateBitmapFromData function allows you to include in your C program (using #include) a bitmap file that was written out by XWriteBitmapFile (X version 11 format only) without reading in the bitmap file. The following example creates a gray bitmap:

```
#include "gray.bitmap"

Pixmap bitmap;
bitmap = XCreateBitmapFromData(display, window, gray_bits, gray_width, gray_height);
```

If insufficient working storage was allocated, XCreateBitmapFromData returns None. It is your responsibility to free the bitmap using XFreePixmap when finished.

XCreateBitmapFromData can generate a BadAlloc error.
Using the Resource Manager

The resource manager is a database manager with a twist. In most database systems, you perform a query using an imprecise specification, and you get back a set of records. The resource manager, however, allows you to specify a large set of values with an imprecise specification, to query the database with a precise specification, and to get back only a single value. This should be used by applications that need to know what the user prefers for colors, fonts, and other resources. It is this use as a database for dealing with X resources that inspired the name “Resource Manager,” although the resource manager can be and is used in other ways.

For example, a user of your application may want to specify that all windows should have a blue background but that all mail-reading windows should have a red background. Presuming that all applications use the resource manager, a user can define this information using only two lines of specifications. Your personal resource database usually is stored in a file and is loaded onto a server property when you log in. This database is retrieved automatically by Xlib when a connection is opened.

As an example of how the resource manager works, consider a mail-reading application called xmh. Assume that it is designed so that it uses a complex window hierarchy all the way down to individual command buttons, which may be actual small subwindows in some toolkits. These are often called objects or widgets. In such toolkit systems, each user interface object can be composed of other objects and can be assigned a name and a class. Fully qualified names or classes can have arbitrary numbers of component names, but a fully qualified name always has the same number of component names as a fully qualified class. This generally reflects the structure of the application as composed of these objects, starting with the application itself.

For example, the xmh mail program has a name “xmh” and is one of a class of “Mail” programs. By convention, the first character of class components is capitalized, and the first letter of name components is in lowercase. Each name and class finally has an attribute (for example “foreground” or “font”). If each window is properly assigned a name and class, it is easy for the user to specify attributes of any portion of the application.

At the top level, the application might consist of a paned window (that is, a window divided into several sections) named “toc”. One pane of the paned window is a button box window named “buttons” and is filled with command buttons. One of these command buttons is used to retrieve (include) new mail and has the name “include”. This window has a fully qualified name,
"xmh.toc.buttons.include", and a fully qualified class, "Xmh.VPaned.Box.Command". Its fully qualified name is the name of its parent, "xmh.toc.buttons", followed by its name, "include". Its class is the class of its parent, "Xmh.VPaned.Box", followed by its particular class, "Command". The fully qualified name of a resource is the attribute’s name appended to the object’s fully qualified name, and the fully qualified class is its class appended to the object’s class.

This include button needs the following resources:

- Title string
- Font
- Foreground color for its inactive state
- Background color for its inactive state
- Foreground color for its active state
- Background color for its active state

Each of the resources that this button needs are considered to be attributes of the button and, as such, have a name and a class. For example, the foreground color for the button in its active state might be named "activeForeground", and its class would be "Foreground."

When an application looks up a resource (for example, a color), it passes the complete name and complete class of the resource to a look-up routine. After look up, the resource manager returns the resource value and the representation type.

The resource manager allows applications to store resources by an incomplete specification of name, class, and a representation type, as well as to retrieve them given a fully qualified name and class.
Resource Manager Matching Rules

The algorithm for determining which resource name or names match a given query is the heart of the database. Resources are stored with only partially specified names and classes, using pattern matching constructs. An asterisk (*) is used to represent any number of intervening components (including none). A period (.) is used to separate immediately adjacent components. All queries fully specify the name and class of the resource needed. A trailing period and asterisk are not removed. The library supports 100 components in a name or class. The look-up algorithm then searches the database for the name that most closely matches (is most specific) this full name and class. The rules for a match in order of precedence are:

1. The attribute of the name and class must match. For example, queries for:
   
   \[
   \begin{align*}
   \text{xterm.scrollbar.background} & \quad \text{(name)} \\
   \text{XTerm.Scrollbar.Background} & \quad \text{(class)}
   \end{align*}
   \]

   will not match the following database entry:

   \[
   \text{xterm.scrollbar:on}
   \]

2. Database entries with name or class prefixed by a period (.) are more specific than those prefixed by an asterisk (*). For example, the entry xterm.geometry is more specific than the entry xterm*geometry.

3. Names are more specific than classes. For example, the entry "*scrollbar.background" is more specific than the entry "Scrollbar.Background".

4. Specifying a name or class is more specific than omitting either. For example, the entry "Scrollbar*Background" is more specific than the entry "Background".

5. Left components are more specific than right components. For example, "*vt100*background" is more specific than the entry "*scrollbar*background" for the query "*.vt100.scrollbar.background".

6. If neither a period (.) nor an asterisk (*) is specified at the beginning, a period (.) is implicit. For example, "xterm.background" is identical to "*.xterm.background".
Names and classes can be mixed. As an example of these rules, assume the following user preference specification:

```
*mh*background: red
*command.font: 8x13
*command.background: blue
*Command.Foreground: green
xmhl toc*Command.activeForeground: black
```

A query for the name "xmhl toc.messagefunctions.include.activeForeground" and class "Xmh.VPaned.Box.Command.Foreground" would match "xmhl toc*Command.activeForeground" and return "black". However, it also matches "*Command.Foreground".

Using the precedence algorithm described above, the resource manager would return the value specified by "xmhl toc*Command.activeForeground".

**Basic Resource Manager Definitions**

The definitions for the resource manager's use are contained in `<X11/Xresource.h>`. Xlib also uses the resource manager internally to allow for non-English language error messages.

Database values consist of a size, an address, and a representation type. The size is specified in bytes. The representation type is a way for you to store data tagged by some application-defined type (for example, "font" or "color"). It has nothing to do with the C data type or with its class. The XrmValue structure contains:

```
typedef struct {
    unsigned int size;
    caddr_t addr;
} XrmValue, *XrmValuePtr;
```

A resource database is an opaque type used by the look-up functions.

```
typedef struct _XrmHashBucketRec *XrmDatabase;
```
Using the Resource Manager

To initialize the resource manager, use XrmInitialize.

```c
void XrmInitialize();
```

Most uses of the resource manager involve defining names, classes, and representation types as string constants. However, always referring to strings in the resource manager can be slow, because it is so heavily used in some toolkits. To solve this problem, a shorthand for a string is used in place of the string in many of the resource manager functions. Simple comparisons can be performed rather than string comparisons. The shorthand name for a string is called a quark and is the type `XrmQuark`. On some occasions, you may want to allocate a quark that has no string equivalent.

A quark is to a string what an atom is to a string in the server, but its use is entirely local to your application.

To allocate a new quark, use XrmUniqueQuark.

```c
XrmQuark XrmUniqueQuark();
```

The `XrmUniqueQuark` function allocates a quark that is guaranteed not to represent any string that is known to the resource manager.

To allocate some memory you will never give back, use Xpermalloc.

```c
char *Xpermalloc(size)
unsigned int size;
```

The `Xpermalloc` function is used by some toolkits for permanently allocated storage and allows some performance and space savings over the completely general memory allocator.

Each name, class, and representation type is typedef’d as an `XrmQuark`.

```c
typedef int XrmQuark, *XrmQuarkList;
typedef XrmQuark XrmName;
typedef XrmQuark XrmClass;
typedef XrmQuark XrmRepresentation;
```

Lists are represented as null-terminated arrays of quarks. The size of the array must be large enough for the number of components used.
typedef XrmQuarkList XrmNameList;
typedef XrmQuarkList XrmClassList;

To convert a string to a quark, use XrmStringToQuark.

#define XrmStringToName(string) XrmStringToQuark(string)
#define XrmStringToClass(string) XrmStringToQuark(string)
#define XrmStringToRepresentation(string) XrmStringToQuark(string)

XrmQuark XrmStringToQuark(string)
    char *string;

string Specifies the string for which a quark is to be allocated.

To convert a quark to a string, use XrmQuarkToString.

#define XrmNameToString(name) XrmQuarkToString(name)
#define XrmClassToString(class) XrmQuarkToString(class)
#define XrmRepresentationToString(type) XrmQuarkToString(type)

c char *XrmQuarkToString(quark)
    XrmQuark quark;

quark Specifies the quark for which the equivalent string is desired.

These functions can be used to convert to and from quark representations. The string pointed to by the return value must not be modified or freed. If no string exists for that quark, XrmQuarkToString returns NULL.

To convert a string with one or more components to a quark list, use XrmStringToQuarkList.

#define XrmStringToNameList(str, name) XrmStringToQuarkList((str), (name))
#define XrmStringToClassList(str, class) XrmStringToQuarkList((str), (class))

void XrmStringToQuarkList(string, quarks_return)
    char *string;
    XrmQuarkList quarks_return;
Using the Resource Manager

string Specifies the string for which a quark is to be allocated.

quarks_return Returns the list of quarks.

The XrmStringToQuarkList function converts the null-terminated string (generally a fully qualified name) to a list of quarks. The components of the string are separated by a period or asterisk character.

A binding list is a list of type XrmBindingList and indicates if components of name or class lists are bound tightly or loosely (that is, if wildcarding of intermediate components is specified).

typedef enum {XrmBindTightly, XrmBindLoosely} XrmBinding, *XrmBindingList;

XrmBindTightly indicates that a period separates the components, and XrmBindLoosely indicates that an asterisk separates the components.

To convert a string with one or more components to a binding list and a quark list, use XrmStringToBindingQuarkList.

XrmStringToBindingQuarkList (string, bindings return, quarks return)
    char *string;
    XrmBindingList bindings return;
    XrmQuarkList quarks return;

string Specifies the string for which a quark is to be allocated.

bindings_return Returns the binding list. The caller must allocate sufficient space for the binding list before calling XrmStringToBindingQuarkList.

quarks_return Returns the list of quarks. The caller must allocate sufficient space for the quarks list before calling XrmStringTo BindingQuarkList.

Component names in the list are separated by a period or an asterisk character. If the string does not start with a period or an asterisk, a period is assumed. For example, "a.b*c" becomes:

<table>
<thead>
<tr>
<th>quarks</th>
<th>a</th>
<th>b</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>bindings</td>
<td>loose</td>
<td>tight</td>
<td>loose</td>
</tr>
</tbody>
</table>
Resource Database Access

Xlib provides resource management functions that you can use to manipulate resource databases. The next sections discuss how to:

- Store and get resources
- Get database levels
- Merge two databases
- Retrieve and store databases

Storing Into a Resource Database

To store resources into the database, use XrmPutResource or XrmQPutResource. Both functions take a partial resource specification, a representation type, and a value. This value is copied into the specified database.

```c
void XrmPutResource (database, specifier, type, value)

XrmDatabase *database;
char *specifier;
char *type;
XrmValue *value;
```

- `database` Specifies a pointer to the resource database.
- `specifier` Specifies a complete or partial specification of the resource.
- `type` Specifies the type of the resource.
- `value` Specifies the value of the resource, which is specified as a string.

If `database` contains NULL, XrmPutResource creates a new database and returns a pointer to it. XrmPutResource is a convenience function that calls XrmStringToBindingQuarkList followed by:

```c
XrmQPutResource (database, bindings, quarks, XrmStringToQuark(type), value)
```
void XrmPutResource (database, bindings, quarks, type, value)
    XrmDatabase *database;
    XrmBindingList bindings;
    XrmQuarkList quarks;
    XrmRepresentation type;
    XrmValue *value;

database Specifies a pointer to the resource database.
bindings Specifies a list of bindings.
quarks Specifies the complete or partial name or the class list of the resource.
type Specifies the type of the resource.
value Specifies the value of the resource, which is specified as a string.

If database contains NULL, XrmPutResource creates a new database and returns a pointer to it.

To add a resource that is specified as a string, use XrmPutStringResource.

void XrmPutStringResource (database, specifier, value)
    XrmDatabase *database;
    char *specifier;
    char *value;

database Specifies a pointer to the resource database.
specifier Specifies a complete or partial specification of the resource.
value Specifies the value of the resource, which is specified as a string.

If database contains NULL, XrmPutStringResource creates a new database and returns a pointer to it. XrmPutStringResource adds a resource with the specified value to the specified database. XrmPutStringResource is a convenience routine that takes both the resource and value as null-terminated strings, converts them to quarks, and then calls XrmPutResource, using a "String" representation type.
To add a string resource using quarks as a specification, use `XrmQPutStringResource`.

```c
void XrmQPutStringResource (database, bindings, quarks, value)
    XrmDatabase *database;
    XrmBindingList bindings;
    XrmQuarkList quarks;
    char *value;
```

- **database**: Specifies a pointer to the resource database.
- **bindings**: Specifies a list of bindings.
- **quarks**: Specifies the complete or partial name or the class list of the resource.
- **value**: Specifies the value of the resource, which is specified as a string.

If `database` contains NULL, `XrmQPutStringResource` creates a new database and returns a pointer to it. `XrmQPutStringResource` is a convenience routine that constructs an `XrmValue` for the value string (by calling `strlen` to compute the size) and then calls `XrmQPutResource`, using a “String” representation type.

To add a single resource entry that is specified as a string that contains both a name and a value, use `XrmPutLineResource`.

```c
void XrmPutLineResource (database, line)
    XrmDatabase *database;
    char *line;
```

- **database**: Specifies a pointer to the resource database.
- **line**: Specifies the resource value pair as a single string. A single colon (:) separates the name from the value.

If `database` contains NULL, `XrmPutLineResource` creates a new database and returns a pointer to it. `XrmPutLineResource` adds a single resource entry to the specified database. Any white space before or after the name or colon in the line argument is ignored. The value is terminated by a new-line or a NULL character. To allow values to contain embedded new-line characters, a “\n” is recognized and replaced by a new-line character. For example, line might have the value “xterm\nbackground:green\n”. Null-terminated strings without a new line are also permitted.
Looking Up from a Resource Database

To retrieve a resource from a resource database, use XrmGetResource or XrmQGetResource.

```c
Bool XrmGetResource (database, str_name, str_class, str_type_return, value_return)
XrmDatabase database;
char *str_name;
char *str_class;
char **str_type_return;
XrmValue *value_return;
```

- `database` Specifies the database that is to be used.
- `str_name` Specifies the fully qualified name of the value being retrieved (as a string).
- `str_class` Specifies the fully qualified class of the value being retrieved (as a string).
- `str_type_return` Returns a pointer to the representation type of the destination (as a string).
- `value_return` Returns the value in the database.

```c
Bool XrmQGetResource (database, quark_name, quark_class, quark_type_return, value_return)
XrmDatabase database;
XrmNameList quark_name;
XrmClassList quark_class;
XrmRepresentation *quark_type_return;
XrmValue *value_return;
```

- `database` Specifies the database that is to be used.
- `quark_name` Specifies the fully qualified name of the value being retrieved (as a quark).
- `quark_class` Specifies the fully qualified class of the value being retrieved (as a quark).
Using the Resource Manager

**quark_type_return**

Returns a pointer to the representation type of the destination (as a quark).

**value_return**

Returns the value in the database.

The XrmGetResource and XrmQGetResource functions retrieve a resource from the specified database. Both take a fully qualified name/class pair, a destination resource representation, and the address of a value (size/address pair). The value and returned type point into database memory; therefore, you must not modify the data.

The database only frees or overwrites entries on XrmPutResource, XrmQPutResource, or XrmMergeDatabases. A client that is not storing new values into the database or is not merging the database should be safe using the address passed back at any time until it exits. If a resource was found, both XrmGetResource and XrmQGetResource return True; otherwise, they return False.

**Database Search Lists**

Most applications and toolkits do not make random probes into a resource database to fetch resources. The X toolkit access pattern for a resource database is quite stylized. A series of from 1 to 20 probes are made with only the last name/class differing in each probe. The XrmGetResource function is at worst a \( 2^n \) algorithm, where \( n \) is the length of the name/class list. This can be improved upon by the application programmer by prefetching a list of database levels that might match the first part of a name/class list.

To return a list of database levels, use XrmQGetSearchList.

```c
typedef XrmHashTable *XrmSearchList;

Bool XrmQGetSearchList (database, names, classes, list_return, list_length)
    XrmDatabase database;
    XrmNameList names;
    XrmClassList classes;
    XrmSearchList list_return;
    int list_length;
```

**Application Utility Functions**

10-45
Using the Resource Manager

database  Specifies the database that is to be used.

names    Specifies a list of resource names.

classes  Specifies a list of resource classes.

list_return  Returns a search list for further use. The caller must allocate sufficient space for the list before calling XrmQGetSearchList.

list_length  Specifies the number of entries (not the byte size) allocated for list_return.

The XrmQGetSearchList function takes a list of names and classes and returns a list of database levels where a match might occur. The returned list is in best-to-worst order and uses the same algorithm as XrmGetResource for determining precedence. If list_return was large enough for the search list, XrmQGetSearchList returns True; otherwise, it returns False.

The size of the search list that the caller must allocate is dependent upon the number of levels and wildcards in the resource specifiers that are stored in the database. The worst case length is $3^2$, where $n$ is the number of name or class components in names or classes.

When using XrmQGetSearchList followed by multiple probes for resources with a common name and class prefix, only the common prefix should be specified in the name and class list to XrmQGetSearchList.

To search resource database levels for a given resource, use XrmQGetSearchResource.

```c
Bool XrmQGetSearchResource(list, name, class, type_return, value_return)
    XrmSearchList list;
    XrmName name;
    XrmClass class;
    XrmRepresentation *type_return;
    XrmValue *value_return;
```

list  Specifies the search list returned by XrmQGetSearchList.

name  Specifies the resource name.

class  Specifies the resource class.
type_return  Returns data representation type.
value_return  Returns the value in the database.

The XrmQGetSearchResource function searches the specified database levels for the resource that is fully identified by the specified name and class. The search stops with the first match. XrmQGetSearchResource returns True if the resource was found; otherwise, it returns False.

A call to XrmQGetSearchList with a name and class list containing all but the last component of a resource name followed by a call to XrmQGetSearchResource with the last component name and class returns the same database entry as XrmGetResource and XrmQGetResource with the fully qualified name and class.

**Merging Resource Databases**

To merge the contents of one database into another database, use XrmMergeDatabases.

```c
void XrmMergeDatabases(source_db, target_db)
   XrmDatabase source_db, *target_db;
```

source_db  Specifies the resource database that is to be merged into the target database.

A call to XrmQGetSearchList with a name and class list containing all but the last component of a resource name followed by a call to XrmQGetSearchResource with the last component name and class returns the same database entry as XrmGetResource and XrmQGetResource with the fully qualified name and class.

**Merging Resource Databases**

To merge the contents of one database into another database, use XrmMergeDatabases.

```c
void XrmMergeDatabases(source_db, target_db)
   XrmDatabase source_db, *target_db;
```

source_db  Specifies the resource database that is to be merged into the target database.

target_db  Specifies a pointer to the resource database into which the source database is to be merged.

The XrmMergeDatabases function merges the contents of one database into another. It may overwrite entries in the destination database. This function is used to combine databases (for example, an application specific database of defaults and a database of user preferences). The merge is destructive; that is, the source database is destroyed.

**Retrieving and Storing Databases**

To retrieve a database from disk, use XrmGetFileDatabase.

```c
XrmDatabase XrmGetFileDatabase(filename)
   char *filename;
```
Using the Resource Manager

filename  
Specifies the resource database file name.

The XrmGetFileDatabase function opens the specified file, creates a new resource database, and loads it with the specifications read in from the specified file. The specified file must contain lines in the format accepted by XrmPutLineResource. If it cannot open the specified file, XrmGetFileDatabase returns NULL.

To store a copy of a database to disk, use XrmPutFileDatabase.

```c
void XrmPutFileDatabase(database, stored_db)
    XrmDatabase database;
    char *stored_db;
```

database  
Specifies the database that is to be used.

stored_db  
Specifies the file name for the stored database.

The XrmPutFileDatabase function stores a copy of the specified database in the specified file. The file is an ASCII text file that contains lines in the format that is accepted by XrmPutLineResource.

To create a database from a string, use XrmGetStringDatabase.

```c
XrmDatabase XrmGetStringDatabase(data)
    char *data;
```

data  
Specifies the database contents using a string.

The XrmGetStringDatabase function creates a new database and stores the resources specified in the specified null-terminated string. XrmGetStringDatabase is similar to XrmGetFileDatabase except that it reads the information out of a string instead of out of a file. Each line is separated by a new-line character in the format accepted by XrmPutLineResource.
Using the Resource Manager

Parsing Command Line Options

The XrmParseCommand function can be used to parse the command line arguments to a program and modify a resource database with selected entries from the command line.

typedef enum {  
    XrmoptionNoArg,    /* Value is specified in OptionDescRec.value */  
    XrmoptionIsArg,    /* Value is the option string itself */  
    XrmoptionStickyArg, /* Value is characters immediately following option */  
    XrmoptionSepArg,   /* Value is next argument in argv */  
    XrmoptionResArg,   /* Resource and value in next argument in argv */  
    XrmoptionSkipArg,  /* Ignore this option and the next argument in argv */  
    XrmoptionSkipLine  /* Ignore this option and the rest of argv */  
} XrmOptionKind;

typedef struct {  
    char *option;        /* Option specification string in argv */  
    char *resourceName;  /* Binding and resource name (sans application name) */  
    XrmOptionKind argKind;  /* Which style of option it is */  
    caddr_t value;       /* Value to provide if XrmoptionNoArg */  
} XrmOptionDescRec, *XrmOptionDescList;

To load a resource database from a C command line, use XrmParseCommand.

```c
void XrmParseCommand (database, table, table_count, name, argc_in_out, argv_in_out,)
    XrmDatabase *database;
    XrmOptionDescList table;
    int table_count;
    char *name;
    int *argc_in_out;
    char **argv_in_out;
```

database        Specifies a pointer to the resource database.
table           Specifies the table of command line arguments to be parsed.
table_count     Specifies the number of entries in the table.
Using the Resource Manager

Specifying the application name.

Specifies the number of arguments and returns the number of remaining arguments.

Specifies a pointer to the command line arguments and returns the remaining arguments.

The `XrmParseCoDln` function parses an (argc, argv) pair according to the specified option table, loads recognized options into the specified database with type "String," and modifies the (argc, argv) pair to remove all recognized options.

The specified table is used to parse the command line. Recognized entries in the table are removed from argv, and entries are made in the specified resource database. The table entries contain information on the option string, the option name, the style of option, and a value to provide if the option kind is `XmoptionNoArg`. The argc argument specifies the number of arguments in argv and is set to the remaining number of arguments that were not parsed. The name argument should be the name of your application for use in building the database entry. The name argument is prefixed to the resourceName in the option table before storing the specification. No separating (binding) character is inserted. The table must contain either a period (.) or an asterisk (*) as the first character in each resourceName entry. To specify a more completely qualified resource name, the resourceName entry can contain multiple components.

For example, the following is part of the standard option table from the X Toolkit `XtInitialize` function:
In this table, if the -background (or -bg) option is used to set background colors, the stored resource specifier matches all resources of attribute background. If the -borderwidth option is used, the stored resource specifier applies only to border width attributes of class TopLevelShell (that is, outer-most windows, including pop-up windows). If the -title option is used to set a window name, only the topmost application windows receive the resource.

When parsing the command line, any unique unambiguous abbreviation for an option name in the table is considered a match for the option. Note that uppercase and lowercase matter.
Using the Context Manager

The context manager provides a way of associating data with a window in your program. Note that this is local to your program; the data is not stored in the server on a property list. Any amount of data in any number of pieces can be associated with a window, and each piece of data has a type associated with it. The context manager requires knowledge of the window and type to store or retrieve data.

Essentially, the context manager can be viewed as a two-dimensional, sparse array: one dimension is subscripted by the window and the other by a context type field. Each entry in the array contains a pointer to the data. Xlib provides context management functions with which you can save data values, get data values, delete entries, and create a unique context type. The symbols used are in < X11/Xutil.h >.

To save a data value that corresponds to a window and context type, use XSaveContext.

```c
int XSaveContext (display, w, context, data)
   Display *display;
   Window w;
   XContext context;
   caddr_t data;
```

- `display` Specifies the connection to the XWIN server.
- `w` Specifies the window with which the data is associated.
- `context` Specifies the context type to which the data belongs.
- `data` Specifies the data to be associated with the window and type.

If an entry with the specified window and type already exists, XSaveContext overrides it with the specified context. The XSaveContext function returns a nonzero error code if an error has occurred and zero otherwise. Possible errors are XCNOMEM (out of memory).

To get the data associated with a window and type, use XFindContext.
Using the Context Manager

```c
int XFindContext (display, w, context, data_return)
   Display *display;
   Window w;
   XContext context;
   caddr_t *data_return;

display       Specifies the connection to the XWIN server.
w             Specifies the window with which the data is associated.
context       Specifies the context type to which the data belongs.
data_return   Returns a pointer to the data.
```

Because it is a return value, the data is a pointer. The XFindContext function returns a nonzero error code if an error has occurred and zero otherwise. Possible errors are XENOENT (context-not-found).

To delete an entry for a given window and type, use XDeleteContext.

```c
int XDeleteContext (display, w, context)
   Display *display;
   Window w;
   XContext context;

display       Specifies the connection to the XWIN server.
w             Specifies the window with which the data is associated.
context       Specifies the context type to which the data belongs.
```

The XDeleteContext function deletes the entry for the given window and type from the data structure. This function returns the same error codes that XFindContext returns if called with the same arguments. XDeleteContext does not free the data whose address was saved.

To create a unique context type that may be used in subsequent calls to XSaveContext and XFindContext, use XUniqueContext.

```c
XContext XUniqueContext()
```
# Xlib Functions and Protocol Requests

This appendix provides two tables that relate to Xlib functions and the X protocol. The following table lists each Xlib function (in alphabetical order) and the corresponding protocol request that it generates.

<table>
<thead>
<tr>
<th>Xlib Function</th>
<th>Protocol Request</th>
</tr>
</thead>
<tbody>
<tr>
<td>XActivateScreenSaver</td>
<td>ForceScreenSaver</td>
</tr>
<tr>
<td>XAddHost</td>
<td>ChangeHosts</td>
</tr>
<tr>
<td>XAddHosts</td>
<td>ChangeHosts</td>
</tr>
<tr>
<td>XAddToSaveSet</td>
<td>ChangeSaveSet</td>
</tr>
<tr>
<td>XAllocColor</td>
<td>AllocColor</td>
</tr>
<tr>
<td>XAllocColorCells</td>
<td>AllocColorCells</td>
</tr>
<tr>
<td>XAllocColorPlanes</td>
<td>AllocColorPlanes</td>
</tr>
<tr>
<td>XAllocNamedColor</td>
<td>AllocNamedColor</td>
</tr>
<tr>
<td>XAllowEvents</td>
<td>AllowEvents</td>
</tr>
<tr>
<td>XAutoRepeatOff</td>
<td>ChangeKeyboardControl</td>
</tr>
<tr>
<td>XAutoRepeatOn</td>
<td>ChangeKeyboardControl</td>
</tr>
<tr>
<td>XBell</td>
<td>Bell</td>
</tr>
<tr>
<td>XChangeActivePointerGrab</td>
<td>ChangeActivePointerGrab</td>
</tr>
<tr>
<td>XChangeGC</td>
<td>ChangeGC</td>
</tr>
<tr>
<td>XChangeKeyboardControl</td>
<td>ChangeKeyboardControl</td>
</tr>
<tr>
<td>XChangeKeyboardMapping</td>
<td>ChangeKeyboardMapping</td>
</tr>
<tr>
<td>XChangePointerControl</td>
<td>ChangePointerControl</td>
</tr>
<tr>
<td>XChangeProperty</td>
<td>ChangeProperty</td>
</tr>
<tr>
<td>XChangeSaveSet</td>
<td>ChangeSaveSet</td>
</tr>
<tr>
<td>XChangeWindowAttributes</td>
<td>ChangeWindowAttributes</td>
</tr>
<tr>
<td>XCirculateSubwindows</td>
<td>CirculateWindow</td>
</tr>
<tr>
<td>XCirculateSubwindowsDown</td>
<td>CirculateWindow</td>
</tr>
<tr>
<td>XCirculateSubwindowsUp</td>
<td>CirculateWindow</td>
</tr>
<tr>
<td>XClearArea</td>
<td>ClearArea</td>
</tr>
<tr>
<td>XClearWindow</td>
<td>ClearArea</td>
</tr>
<tr>
<td>XConfigureWindow</td>
<td>ConfigureWindow</td>
</tr>
<tr>
<td>XConvertSelection</td>
<td>ConvertSelection</td>
</tr>
<tr>
<td>XCopyArea</td>
<td>CopyArea</td>
</tr>
<tr>
<td>XCopyColormapAndFree</td>
<td>CopyColormapAndFree</td>
</tr>
<tr>
<td>XCopyGC</td>
<td>CopyGC</td>
</tr>
<tr>
<td>XCopyPlane</td>
<td>CopyPlane</td>
</tr>
</tbody>
</table>

Xlib Functions and Protocol Requests

Extensions

Introduction

Because X can evolve by extensions to the core protocol, it is important that extensions not be perceived as second class citizens. At some point, your favorite extensions may be adopted as additional parts of the X Standard.

Therefore, there should be little to distinguish the use of an extension from that of the core protocol. To avoid having to initialize extensions explicitly in application programs, it is also important that extensions perform "lazy evaluations" and automatically initialize themselves when called for the first time.

This appendix describes techniques for writing extensions to Xlib that will run at essentially the same performance as the core protocol requests.

NOTE: It is expected that a given extension to X consists of multiple requests. Defining ten new features as ten separate extensions is a bad practice. Rather, they should be packaged into a single extension and should use minor opcodes to distinguish the requests.

The symbols and macros used for writing stubs to Xlib are listed in

< X11/Xlibint.h >.
Basic Protocol Support Routines

The basic protocol requests for extensions are `XQueryExtension` and `XListExtensions`.

```c
Bool XQueryExtension(display, name, major_opcode_return, first_event_return, first_error_return)
    Display *display;
    char *name;
    int *major_opcode_return;
    int *first_event_return;
    int *first_error_return;
```

`XQueryExtension` determines if the named extension is present. If so, the major opcode for the extension is returned (if it has one); otherwise, `False` is returned. Any minor opcode and the request formats are specific to the extension. If the extension involves additional event types, the base event type code is returned; otherwise, `False` is returned. The format of the events is specific to the extension. If the extension involves additional error codes, the base error code is returned; otherwise, `False` is returned. The format of additional data in the errors is specific to the extension.

The extension name should be in the ISO Latin-1 encoding, and uppercase and lowercase do matter.

```c
char **XListExtensions(display, extensions_return)
    Display *display;
    int *extensions_return;
```

`XListExtensions` returns a list of all extensions supported by the server.

```c
XFreeExtensionList(list)
    char **list;
```

`XFreeExtensionList` frees the memory allocated by `XListExtensions`. 
Hooking into Xlib

These functions allow you to hook into the library. They are not normally used by application programmers but are used by people who need to extend the core X protocol and the X library interface. The functions, which generate protocol requests for X, are typically called stubs.

In extensions, stubs first should check to see if they have initialized themselves on a connection. If they have not, they then should call XInitExtension to attempt to initialize themselves on the connection.

If the extension needs to be informed of GC/font allocation or deallocation or if the extension defines new event types, the functions described here allow the extension to be called when these events occur.

The XExtCodes structure returns the information from XInitExtension and is defined in

\[<\text{Xlib.h}>:\]

```c
typedef struct XExtCodes {
    int extension; /* extension number */
    int major_opcode; /* major op-code assigned by server */
    int first_event; /* first event number for the extension */
    int first_error; /* first error number for the extension */
} XExtCodes;
```

`XExtCodes *XInitExtension(display, name)`
Display *display;
char *name;

XInitExtension determines if the extension exists. Then, it allocates storage for maintaining the information about the extension on the connection, chains this onto the extension list for the connection, and returns the information the stub implementor will need to access the extension. If the extension does not exist, XInitExtension returns NULL.

In particular, the extension number in the XExtCodes structure is needed in the other calls that follow. This extension number is unique only to a single connection.

`XExtCodes *XAddExtension(display)`
Display *display;
For local Xlib extensions, \texttt{XAddExtension} allocates the \texttt{XExtCodes} structure, bumps the extension number count, and chains the extension onto the extension list. (This permits extensions to Xlib without requiring server extensions.)
Hooks into the Library

These functions allow you to define procedures that are to be called when various circumstances occur. The procedures include the creation of a new GC for a connection, the copying of a GC, the freeing a GC, the creating and freeing of fonts, the conversion of events defined by extensions to and from wire format, and the handling of errors.

All of these functions return the previous routine defined for this extension.

```c
int (*XBSetCloseDisplay(display, extension, proc))();
Display *display; /* display */
int extension; /* extension number */
int (*proc)(); /* routine to call when display closed */
```

You use this procedure to define a procedure to be called whenever XCloseDisplay is called. This procedure returns any previously defined procedure, usually NULL.

When XCloseDisplay is called, your routine is called with these arguments:

```c
(*proc)(display, codes)
Display *display;
XExtCodes *codes;
```

```c
int (*XBSetCreateGC(display, extension, proc))();
Display *display; /* display */
int extension; /* extension number */
int (*proc)(); /* routine to call when GC created */
```

You use this procedure to define a procedure to be called whenever a new GC is created. This procedure returns any previously defined procedure, usually NULL.

When a GC is created, your routine is called with these arguments:

```c
(*proc)(display, gc, codes)
Display *display;
GC gc;
XExtCodes *codes;
```
You use this procedure to define a procedure to be called whenever a GC is
copied. This procedure returns any previously defined procedure, usually
NULL.

When a GC is copied, your routine is called with these arguments:

(*proc)(display, gc, codes)
   Display *display;
   GC gc;
   XExtCodes *codes;

You use this procedure to define a procedure to be called whenever a GC is
freed. This procedure returns any previously defined procedure, usually NULL.

When a GC is freed, your routine is called with these arguments:

(*proc)(display, gc, codes)
   Display *display;
   GC gc;
   XExtCodes *codes;

You use this procedure to define a procedure to be called whenever XLoad-
QueryFont and XQueryFont are called. This procedure returns any previously
defined procedure, usually NULL.

When XLoadQueryFont or XQueryFont is called, your routine is called with
these arguments:
Hooks into the Library

(*proc)(display, fs, codes)
    Display *display;
    XFontStruct *fs;
    XExtCodes *codes;

int (*XBSetFreeFont (display, extension, proc))()
    Display *display; /* display */
    int extension; /* extension number */
    int (*proc()); /* routine to call when font freed */

You use this procedure to define a procedure to be called whenever XFreeFont is called. This procedure returns any previously defined procedure, usually NULL.

When XFreeFont is called, your routine is called with these arguments:

(*proc)(display, fs, codes)
    Display *display;
    XFontStruct *fs;
    XExtCodes *codes;

The next two functions allow you to define new events to the library.

NOTE
There is an implementation limit such that your host event structure size cannot be bigger than the size of the XEvent union of structures. There also is no way to guarantee that more than 24 elements or 96 characters in the structure will be fully portable between machines.

int (*XBSetWireToEvent (display, event_number, proc))()
    Display *display; /* display */
    int event_number; /* event routine to replace */
    Bool (*proc()); /* routine to call when converting event */

You use this procedure to define a procedure to be called when an event needs to be converted from wire format (xEvent) to host format (XEvent). The event number defines the protocol event number for which to install a conversion routine. This procedure returns any previously defined procedure.
You can replace a core event conversion routine with one of your own, although this is not encouraged. It would, however, allow you to intercept a core event and modify it before being placed in the queue or otherwise examined.

When Xlib needs to convert an event from wire format to host format, your routine is called with these arguments:

```c
Status (*proc)(display, re, event)
    Display *display;
    XEvent *re;
    xEvent *event;
```

Your routine must return status to indicate if the conversion succeeded. The re argument is a pointer to where the host format event should be stored, and the event argument is the 32-byte wire event structure. In the xEvent structure you are creating, type must be the first member and window must be the second member. You should fill in the type member with the type specified for the xEvent structure. You should copy all other members from the xEvent structure (wire format) to the XEvent structure (host format). Your conversion routine should return True if the event should be placed in the queue or False if it should not be placed in the queue.

```c
Status (*XESetEventToWire(display, event_number, proc))()
    Display *display; /* display */
    int event_number; /* event routine to replace */
    int (*proc); /* routine to call when converting event */
```

You use this procedure to define a procedure to be called when an event needs to be converted from host format (XEvent) to wire format (xEvent) form. The event number defines which protocol event number to install a conversion routine for. This procedure returns any previously defined procedure. It returns zero if the conversion fails or nonzero otherwise.

You can replace a core event conversion routine with one of your own, although this is not encouraged. It would, however, allow you to intercept a core event and modify it before being sent to another client.

When Xlib needs to convert an event from wire format to host format, your routine is called with these arguments:
Hooks Into the Library

(*proc)(display, re, event)
Display *display;
XEvent *re;
xEvent *event;

The re argument is a pointer to the host format event, and the event argument is a pointer to where the 32-byte wire event structure should be stored. In the XEvent structure that you are forming, you must have "type" as the first member and "window" as the second. You then should fill in the type with the type from the xEvent structure. All other members then should be copied from the wire format to the XEvent structure.

int (*XSetErrorHandler(display, extension, proc))()
Display *display; /* display */
int extension; /* extension number */
int (*proc)(); /* routine to call when X error happens */

Inside Xlib, there are times that you may want to suppress the calling of the external error handling when an error occurs. This allows status to be returned on a call at the cost of the call being synchronous (though most such routines are query operations, in any case, and are typically programmed to be synchronous).

When Xlib detects a protocol error in _XReply, it calls your procedure with these arguments:

int (*proc)(display, err, codes, ret_code)
Display *display;
xError *err;
XExtCodes *codes;
int *ret_code;

The err argument is a pointer to the 32-byte wire format error. The codes argument is a pointer to the extension codes structure. The ret_code argument is the return code you may want _XReply returned to.

If your routine returns a zero value, the error is not suppressed, and the client's error handler is called. (For further information, see "Using the Default Error Handlers" in Chapter 8) If your routine returns nonzero, the error is suppressed, and _XReply returns the value of ret_code.
The XGetErrorText function returns a string to the user for an error. XESetErrorString allows you to define a routine to be called that should return a pointer to the error message. The following is an example.

```
(*proc)(display, code, codes, buffer, nbytes)
    Display *display;
    int code;
    XExtCodes *codes;
    char *buffer;
    int nbytes;
```

Your procedure is called with the error code for every error detected. You should copy nbytes of a null-terminated string containing the error message into buffer.

```
int (*XESetFlushGC(display, extension, proc))()
    Display *display;    /* display */
    int extension;      /* extension number */
    char *("proc");    /* routine to call when I/O error happens */
```

The XESetFlushGC procedure is identical to XESetCopyGC except that XESetFlushGC is called when a GC cache needs to be updated in the server.
Hooks onto Xlib Data Structures

Various Xlib data structures have provisions for extension routines to chain extension supplied data onto a list. These structures are GC, Visual, Screen, ScreenFormat, Display, and XFontStruct. Because the list pointer is always the first member in the structure, a single set of routines can be used to manipulate the data on these lists.

The following structure is used in the routines in this section and is defined in `<X11/Xlib.h>`:

```c
typedef struct _XExtData {
    int number;           /* number returned by XInitExtension */
    struct _XExtData *next;  /* next item on list of data for structure */
    int (*free)();      /* if defined, called to free private */
    char *private;      /* data private to this extension. */
} XExtData;
```

When any of the data structures listed above are freed, the list is walked, and the structure's free routine (if any) is called. If free is NULL, then the library frees both the data pointed to by the private member and the structure itself.

```c
union { Display *display;
    GC gc;
    Visual *visual;
    Screen *screen;
    ScreenFormat * pixmap_format;
    XFontStruct *font } XEDataObject;

XExtData **XEHeadOfExtensionList(object)
    XEDataObject object;
```

XEHeadOfExtensionList returns a pointer to the list of extension structures attached to the specified object. In concert with XAddToExtensionList, XEHeadOfExtensionList allows an extension to attach arbitrary data to any of the structures of types contained in XEDataObject.

```c
XAddToExtensionList(structure, ext_data)
    struct _XExtData **structure;  /* pointer to structure to add */
    XExtData *ext_data;            /* extension data structure to add */
```

The structure argument is a pointer to one of the data structures enumerated above. You must initialize ext_data->number with the extension number before calling this routine.
Hook onto Xlib Data Structures

```c
XExtData *XFindObjectExtensionList(structure, number)
    struct XExtData **structure;
    int number;    /* extension number from XInitExtension */
```

`XFindObjectExtensionList` returns the first extension data structure for the extension numbered `number`. It is expected that an extension will add at most one extension data structure to any single data structure's extension data list. There is no way to find additional structures.

The `XAllocID` macro, which allocates and returns a resource ID, is defined in `<X11/Xlib.h>`.

```c
XAllocID(display)
    Display *display;
```

This macro is a call through the `Display` structure to the internal resource ID allocator. It returns a resource ID that you can use when creating new resources.
GC Caching

GCs are cached by the library to allow merging of independent change requests to the same GC into single protocol requests. This is typically called a write-back cache. Any extension routine whose behavior depends on the contents of a GC must flush the GC cache to make sure the server has up-to-date contents in its GC.

The FlushGC macro checks the dirty bits in the library's GC structure and calls _XFlushGCCache if any elements have changed. The FlushGC macro is defined as follows:

```c
FlushGC(display, gc)
Display *display;
GC gc;
```

Note that if you extend the GC to add additional resource ID components, you should ensure that the library stub sends the change request immediately. This is because a client can free a resource immediately after using it, so if you only stored the value in the cache without forcing a protocol request, the resource might be destroyed before being set into the GC. You can use the _XFlushGCCache procedure to force the cache to be flushed. The _XFlushGCCache procedure is defined as follows:

```c
_XFlushGCCache(display, gc)
Display *display;
GC gc;
```
Graphics Batching

If you extend X to add more poly graphics primitives, you may be able to take advantage of facilities in the library to allow back-to-back single calls to be transformed into poly requests. This may dramatically improve performance of programs that are not written using poly requests. A pointer to an xReq, called last_req in the display structure, is the last request being processed. By checking that the last request type, drawable, gc, and other options are the same as the new one and that there is enough space left in the buffer, you may be able to just extend the previous graphics request by extending the length field of the request and appending the data to the buffer. This can improve performance by five times or more in naive programs. For example, here is the source for the XDrawPoint stub. (Writing extension stubs is discussed in the next section.)

```
#include <X11/Xlibint.h>

/* precompute the maximum size of batching request allowed */

static int size = sizeof(xPolyPointReq) + EPERBATCH * sizeof(xPoint);

XDrawPoint(dpy, d, gc, x, y)
    register Display *dpy;
    Drawable d;
    GC gc;
    int x, y; /* INT16 */
{
    xPoint *point;
    LockDisplay(dpy);
    FlushGC(dpy, gc);
    {
    register xPolyPointReq *req = (xPolyPointReq *) dpy->last_req;
    /* if same as previous request, with same drawable, batch requests */
    if ( (req->reqType == X_PolyPoint)
        && (req->drawable == d)
        && (req->gc == gc->gid)
        && (req->coordMode == CoordModeOrigin)
        && ((dpy->bufptr + sizeof (xPoint)) <= dpy->bufmax)
        && (((char *)dpy->bufptr - (char *)req) < size) ) {
        point = (xPoint *) dpy->bufptr;
        req->length += sizeof (xPoint) >> 2;
        dpy->bufptr += sizeof (xPoint);
```
else {
    GetReqExtra(PolyPoint, 4, req); /* 1 point = 4 bytes */
    req->drawable = d;
    req->gc = gc->gid;
    req->coordMode = CoordModeOrigin;
    point = (xPoint *) (req + 1);
}
point->x = x;
point->y = y;
}
UnlockDisplay(dpy);
SyncHandle();
}

To keep clients from generating very long requests that may monopolize the server, there is a symbol defined in <X11/Xlibint.h> of EPERBATCH on the number of requests batched. Most of the performance benefit occurs in the first few merged requests. Note that FlushGC is called before picking up the value of last_req, because it may modify this field.
Writing Extension Stubs

All X requests always contain the length of the request, expressed as a 16-bit quantity of 32 bits. This means that a single request can be no more than 256K bytes in length. Some servers may not support single requests of such a length. The value of dpy->max_request_size contains the maximum length as defined by the server implementation. For further information, see "X Window System Protocol".
Requests, Replies, and Xproto.h

The <X11/Xproto.h> file contains three sets of definitions that are of interest to the stub implementor: request names, request structures, and reply structures.

You need to generate a file equivalent to <X11/Xproto.h> for your extension and need to include it in your stub routine. Each stub routine also must include <X11/Xlibint.h>.

The identifiers are deliberately chosen in such a way that, if the request is called X_DoSomething, then its request structure is xDoSomethingReq, and its reply is xDoSomethingReply. The GetReq family of macros, defined in <X11/Xlibint.h>, takes advantage of this naming scheme.

For each X request, there is a definition in <X11/Xproto.h> that looks similar to this:

```c
#define X_DoSomething 42
```

In your extension header file, this will be a minor opcode, instead of a major opcode.
Request Format

Every request contains an 8-bit major opcode and a 16-bit length field expressed in units of four bytes. Every request consists of four bytes of header (containing the major opcode, the length field, and a data byte) followed by zero or more additional bytes of data. The length field defines the total length of the request, including the header. The length field in a request must equal the minimum length required to contain the request. If the specified length is smaller or larger than the required length, the server should generate a BadLength error. Unused bytes in a request are not required to be zero.

```c
long XMaxRequestSize(display)
    Display *display;
```

XMaxRequestSize returns the maximum request size (in 4-byte units) supported by the server. Single protocol requests to the server can be no longer than this size. Extensions should be designed in such a way that long protocol requests can be split up into smaller requests. The protocol guarantees the size to be no smaller than 4096 unit (16384 bytes).

Major opcodes 128 through 255 are reserved for extensions. Extensions are intended to contain multiple requests, so extension requests typically have an additional minor opcode encoded in the “spare” data byte in the request header, but the placement and interpretation of this minor opcode as well as all other fields in extension requests are not defined by the core protocol. Every request is implicitly assigned a sequence number (starting with one) used in replies, errors, and events.

To help but not cure portability problems to certain machines, the B16 and B32 macros have been defined so that they can become bitfield specifications on some machines. For example, on a Cray, these should be used for all 16-bit and 32-bit quantities, as discussed below.

Most protocol requests have a corresponding structure typedef in `< X11/Xproto.h >`, which looks like:
typedef struct _DoSomethingReq {
    CARD8 reqType;  /* X_DoSomething */
    CARD8 someDatum; /* used differently in different requests */
    CARD16 length B16; /* total # of bytes in request, divided by 4 */

    ... /* request-specific data */
    ...
} xDoSomethingReq;

If a core protocol request has a single 32-bit argument, you need not declare a request structure in your extension header file. Instead, such requests use <X11/Xproto.h>'s xResourceReq structure. This structure is used for any request whose single argument is a Window, Pixmap, Drawable, GContext, Font, Cursor, Colormap, Atom, or VisualID.

typedef struct _ResourceReq {
    CARD8 reqType;  /* the request type, e.g. X_DoSomething */
    BYTE pad; /* not used */
    CARD16 length B16; /* 2 (= total # of bytes in request, divided by 4) */
    CARD32 id B32; /* the Window, Drawable, Font, GContext, etc. */
} xResourceReq;

If convenient, you can do something similar in your extension header file.

In both of these structures, the reqType field identifies the type of the request (for example, X_MapWindow or X_CreatePixmap). The length field tells how long the request is in units of 4-byte longwords. This length includes both the request structure itself and any variable length data, such as strings or lists, that follow the request structure. Request structures come in different sizes, but all requests are padded to be multiples of four bytes long.

A few protocol requests take no arguments at all. Instead, they use <X11/Xproto.h>'s xReq structure, which contains only a reqType and a length (and a pad byte).

If the protocol request requires a reply, then <X11/Xproto.h> also contains a reply structure typedef:
Request Format

typedef struct _DoSomethingReply {
    BYTE type;          /* always X_Reply */
    BYTE someDatum;     /* used differently in different requests */
    CARD16 sequenceNumber B16;  /* # of requests sent so far */
    CARD32 length B32;    /* # of additional bytes, divided by 4 */
    ...
    /* request-specific data */
    ...
} xDoSomethingReply;

Most of these reply structures are 32 bytes long. If there are not that many reply values, then they contain a sufficient number of pad fields to bring them up to 32 bytes. The length field is the total number of bytes in the request minus 32, divided by 4. This length will be nonzero only if:

- The reply structure is followed by variable length data such as a list or string.
- The reply structure is longer than 32 bytes.

Only XGetWindowAttributes, QueryFont, QueryKeymap, and GetKeyboardControl have reply structures longer than 32 bytes in the core protocol.

A few protocol requests return replies that contain no data.

< X11/Xproto.h > does not define reply structures for these. Instead, they use the xGenericReply structure, which contains only a type, length, and sequence number (and sufficient padding to make it 32 bytes long).
Starting to Write a Stub Routine

An Xlib stub routine should always start like this:

```
#include "X11/Xlibint.h"

XDoSomething (arguments, ... )
/* argument declarations */
{

    register XDoSomethingReq *req;

    If the protocol request has a reply, then the variable declarations should include
    the reply structure for the request. The following is an example:

    xDoSomethingReply rep;
```
Locking Data Structures

To lock the display structure for systems that want to support multithreaded access to a single display connection, each stub will need to lock its critical section. Generally, this section is the point from just before the appropriate GetReq call until all arguments to the call have been stored into the buffer. The precise instructions needed for this locking depend upon the machine architecture. Two calls, which are generally implemented as macros, have been provided.

```c
LockDisplay(display)
Display *display;

UnlockDisplay(display)
Display *display;
```
Sending the Protocol Request and Arguments

After the variable declarations, a stub routine should call one of four macros defined in `<X11/Xlibint.h>`: GetReq, GetReqExtra, GetResReq, or GetEmptyReq. All of these macros take, as their first argument, the name of the protocol request as declared in `<X11/Xproto.h>` except with `X_` removed. Each one declares a `Display` structure pointer, called `dpy`, and a pointer to a request structure, called `req`, which is of the appropriate type. The macro then appends the request structure to the output buffer, fills in its type and length field, and sets `req` to point to it.

If the protocol request has no arguments (for instance, `X_GrabServer`), then use `GetEmptyReq`.

```
GetEmptyReq (DoSomething);
```

If the protocol request has a single 32-bit argument (such as a `Pixmap`, `Window`, `Drawable`, `Atom`, and so on), then use `GetResReq`. The second argument to the macro is the 32-bit object. `X_MapWindow` is a good example.

```
GetResReq (DoSomething, rid);
```

The `rid` argument is the `Pixmap`, `Window`, or other resource ID.

If the protocol request takes any other argument list, then call `GetReq`. After the `GetReq`, you need to set all the other fields in the request structure, usually from arguments to the stub routine.

```
GetReq (DoSomething);
/* fill in arguments here */
req->arg1 = arg1;
req->arg2 = arg2;
```

A few stub routines (such as `XCreateGC` and `XCreatePixmap`) return a resource ID to the caller but pass a resource ID as an argument to the protocol request. Such routines use the macro `XAllocID` to allocate a resource ID from the range of IDs that were assigned to this client when it opened the connection.

```
rid = req->rid = XAllocID();
return (rid);
```

Finally, some stub routines transmit a fixed amount of variable length data after the request. Typically, these routines (such as `XMoveWindow` and `XSetBackground`) are special cases of more general functions like `XMoveResizeWindow` and `XChangeGC`. These special case routines use `GetReqExtra`, which is the same as `GetReq` except that it takes an additional...
Sending the Protocol Request and Arguments

argument (the number of extra bytes to allocate in the output buffer after the request structure). This number should always be a multiple of four.
Variable Length Arguments

Some protocol requests take additional variable length data that follow the xDo-SomethingReq structure. The format of this data varies from request to request. Some requests require a sequence of 8-bit bytes, others a sequence of 16-bit or 32-bit entities, and still others a sequence of structures.

It is necessary to add the length of any variable length data to the length field of the request structure. That length field is in units of 32-bit longwords. If the data is a string or other sequence of 8-bit bytes, then you must round the length up and shift it before adding:

\[
\text{req->length} += (\text{nbytes+3})\gg2;
\]

To transmit variable length data, use the Data macros. If the data fits into the output buffer, then this macro copies it to the buffer. If it does not fit, however, the Data macro calls _XSend, which transmits first the contents of the buffer and then your data. The Data macros take three arguments: the Display, a pointer to the beginning of the data, and the number of bytes to be sent.

\[
\text{Data(}\text{display, (char \ast)} \text{data, nbytes)};
\]

\[
\text{Data16(}\text{display, (short \ast)} \text{data, nbytes)};
\]

\[
\text{Data32(}\text{display, (long \ast)} \text{data, nbytes)};
\]

Data, Data16, and Data32 are macros that may use their last argument more than once, so that argument should be a variable rather than an expression such as "nitems*sizeof(item)". You should do that kind of computation in a separate statement before calling them. Use the appropriate macro when sending byte, short, or long data.

If the protocol request requires a reply, then call the procedure _XSend instead of the Data macro. _XSend takes the same arguments, but because it sends your data immediately instead of copying it into the output buffer (which would later be flushed anyway by the following call on _XReply), it is faster.
Replies

If the protocol request has a reply, then call _XReply after you have finished dealing with all the fixed and variable length arguments. _XReply flushes the output buffer and waits for an xReply packet to arrive. If any events arrive in the meantime, _XReply places them in the queue for later use.

    Status _XReply(display, rep, extra, discard)
    Display *display;
    xReply *rep;
    int extra;  /* number of 32-bit words expected after the reply */
    Bool discard;  /* should I discard data following "extra" words */

_XReply waits for a reply packet and copies its contents into the specified rep. _XReply handles error and event packets that occur before the reply is received. _XReply takes four arguments:

- A Display * structure
- A pointer to a reply structure (which must be cast to an xReply *)
- The number of additional bytes (beyond sizeof(xReply) = 32 bytes) in the reply structure
- A Boolean that indicates whether _XReply is to discard any additional bytes beyond those it was told to read

Because most reply structures are 32 bytes long, the third argument is usually 0. The only core protocol exceptions are the replies to GetWindowAttributes, QueryFont, QueryKeymap, and GetKeyboardControl, which have longer replies.

The last argument should be False if the reply structure is followed by additional variable length data (such as a list or string). It should be True if there is not any variable length data.

NOTE: This last argument is provided for upward-compatibility reasons to allow a client to communicate properly with a hypothetical later version of the server that sends more data than the client expected. For example, some later version of GetWindowAttributes might use a larger, but compatible, xGetWindowAttributesReply that contains additional attribute data at the end.

_XReply returns True if it received a reply successfully or False if it received any sort of error.
For a request with a reply that is not followed by variable length data, you write something like:

```c
_XReply(display, (xReply *)&rep, 0, True);
*ret1 = rep.ret1;
*ret2 = rep.ret2;
*ret3 = rep.ret3;
UnlockDisplay(dpy);
SyncHandle0;
return (rep.ret4);
}
```

If there is variable length data after the reply, change the `True` to `False`, and use the appropriate `_XRead` function to read the variable length data.

```c
_XRead(display, data, nbytes)
Display *display;
char *data;
long nbytes;

_XRead reads the specified number of bytes into data.

_XRead16(display, data, nbytes)
Display *display;
short *data;
long nbytes;

_XRead16 reads the specified number of bytes, unpacking them as 16-bit quantities, into the specified array as shorts.

_XRead32(display, data, nbytes)
Display *display;
long *data;
long nbytes;

_XRead32 reads the specified number of bytes, unpacking them as 32-bit quantities, into the specified array as longs.

_XRead16Pad(display, data, nbytes)
Display *display;
short *data;
long nbytes;
```
_XRead16Pad reads the specified number of bytes, unpacking them as 16-bit quantities, into the specified array as shorts. If the number of bytes is not a multiple of four, _XRead16Pad reads up to three additional pad bytes.

```
_XRead16Pad(display, data, nbytes)
    Display *display;
    char *data;
    long nbytes;
```

_XReadPad reads the specified number of bytes into data. If the number of bytes is not a multiple of four, _XReadPad reads up to three additional pad bytes.

Each protocol request is a little different. For further information, see the Xlib sources for examples.
Synchronous Calling

To ease debugging, each routine should have a call, just before returning to the user, to a routine called SyncHandle. This routine generally is implemented as a macro. If synchronous mode is enabled (see Xsynchronize), the request is sent immediately. The library, however, waits until any error the routine could generate at the server has been handled.
Allocating and Deallocation Memory

To support the possible reentry of these routines, you must observe several conventions when allocating and deallocating memory, most often done when returning data to the user from the window system of a size the caller could not know in advance (for example, a list of fonts or a list of extensions). The standard C library routines on many systems are not protected against signals or other multithreaded uses. The following analogies to standard I/O library routines have been defined:

- `Xmalloc()` Replaces `malloc()`
- `Xfree()` Replaces `free()`
- `Xcalloc()` Replaces `calloc()`

These should be used in place of any calls you would make to the normal C library routines.

If you need a single scratch buffer inside a critical section (for example, to pack and unpack data to and from the wire protocol), the general memory allocators may be too expensive to use (particularly in output routines, which are performance critical). The routine below returns a scratch buffer for your use:

```c
char * _XAllocScratch(display, nbytes)
  Display *display;
  unsigned long nbytes;
```

This storage must only be used inside of the critical section of your stub.
Portability Considerations

Many machine architectures, including many of the more recent RISC architectures, do not correctly access data at unaligned locations; their compilers pad out structures to preserve this characteristic. Many other machines capable of unaligned references pad inside of structures as well to preserve alignment, because accessing aligned data is usually much faster. Because the library and the server use structures to access data at arbitrary points in a byte stream, all data in request and reply packets must be naturally aligned; that is, 16-bit data starts on 16-bit boundaries in the request and 32-bit data on 32-bit boundaries. All requests must be a multiple of 32 bits in length to preserve the natural alignment in the data stream. You must pad structures out to 32-bit boundaries. Pad information does not have to be zeroed unless you want to preserve such fields for future use in your protocol requests. Floating point varies radically between machines and should be avoided completely if at all possible.

This code may run on machines with 16-bit ints. So, if any integer argument, variable, or return value either can take only nonnegative values or is declared as a CARD16 in the protocol, be sure to declare it as unsigned int and not as int. (This, of course, does not apply to Booleans or enumerations.)

Similarly, if any integer argument or return value is declared CARD32 in the protocol, declare it as an unsigned long and not as int or long. This also goes for any internal variables that may take on values larger than the maximum 16-bit unsigned int.

The library currently assumes that a char is 8 bits, a short is 16 bits, an int is 16 or 32 bits, and a long is 32 bits. The PackData macro is a half-hearted attempt to deal with the possibility of 32 bit shorts. However, much more work is needed to make this work properly.
Deriving the Correct Extension Opcode

The remaining problem a writer of an extension stub routine faces that the core protocol does not face is to map from the call to the proper major and minor opcodes. While there are a number of strategies, the simplest and fastest is outlined below.

1. Declare an array of pointers, _NFILE long (this is normally found in <stdio.h> and is the number of file descriptors supported on the system) of type XExtCodes. Make sure these are all initialized to NULL.

2. When your stub is entered, your initialization test is just to use the display pointer passed in to access the file descriptor and an index into the array. If the entry is NULL, then this is the first time you are entering the routine for this display. Call your initialization routine and pass it to the display pointer.

3. Once in your initialization routine, call XInitExtension; if it succeeds, store the pointer returned into this array. Make sure to establish a close display handler to allow you to zero the entry. Do whatever other initialization your extension requires. (For example, install event handlers and so on). Your initialization routine would normally return a pointer to the XExtCodes structure for this extension, which is what would normally be found in your array of pointers.

4. After returning from your initialization routine, the stub can now continue normally, because it has its major opcode safely in its hand in the XExtCodes structure.
Version 10 Compatibility Functions

Drawing and Filling Polygons and Curves

Associating User Data with a Value

Table of Contents
Drawing and Filling Polygons and Curves

Xlib provides functions that you can use to draw or fill arbitrary polygons or curves. These functions are provided mainly for compatibility with X10 and have no server support. That is, they call other Xlib functions, not the server directly. Thus, if you just have straight lines to draw, using XDrawLines or XDrawSegments is much faster.

The functions discussed here provide all the functionality of the X10 functions XDraw, XDrawFilled, XDrawPatterned, XDrawDashed, and XDrawTiled. They are as compatible as possible given X11’s new line drawing functions. One thing to note, however, is that VertexDrawLastPoint is no longer supported. Also, the error status returned is the opposite of what it was under X10 (this is the X11 standard error status). XAppendVertex and XClearVertexFlag from X10 also are not supported.

Just how the graphics context you use is set up actually determines whether you get dashes or not, and so on. Lines are properly joined if they connect and include the closing of a closed figure (see XDrawLines). The functions discussed here fail (return zero) only if they run out of memory or are passed a Vertex list that has a Vertex with VertexStartClosed set that is not followed by a Vertex with VertexEndClosed set.

To achieve the effects of the X10 XDraw, XDrawDashed, and XDrawPatterned, use XDraw.

```
#include <X11/X10.h>
Status XDraw (display, d, gc, vlist, vcount)
    Display *display;
    Drawable d;
    GC gc;
    Vertex *vlist;
    int vcount;

display  Specifies the connection to the XWIN server.
d      Specifies the drawable.
gc      Specifies the GC.
vlist   Specifies a pointer to the list of vertices that indicate what to draw.
```
Drawing and Filling Polygons and Curves

\texttt{vcount} \quad \text{Specifies how many vertices are in vlist.}

\texttt{XDraw} draws an arbitrary polygon or curve. The figure drawn is defined by the specified list of vertices (vlist). The points are connected by lines as specified in the flags in the vertex structure.

Each Vertex, as defined in \texttt{<X11/X10.h>}, is a structure with the following members:

\begin{verbatim}
typedef struct _Vertex {
  short x, y;
  unsigned short flags;
} Vertex;
\end{verbatim}

The \texttt{x} and \texttt{y} members are the coordinates of the vertex that are relative to either the upper-left inside corner of the drawable (if \texttt{VertexRelative} is zero) or the previous vertex (if \texttt{VertexRelative} is one).

The flags, as defined in \texttt{<X11/X10.h>}, are as follows:

\begin{verbatim}
VertexRelative 0x0001 /* else absolute */
VertexDontDraw 0x0002 /* else draw */
VertexCurved 0x0004 /* else straight */
VertexStartClosed 0x0008 /* else not */
VertexEndClosed 0x0010 /* else not */
\end{verbatim}

- If \texttt{VertexRelative} is not set, the coordinates are absolute (that is, relative to the drawable's origin). The first vertex must be an absolute vertex.
- If \texttt{VertexDontDraw} is one, no line or curve is drawn from the previous vertex to this one. This is analogous to picking up the pen and moving to another place before drawing another line.
- If \texttt{VertexCurved} is one, a spline algorithm is used to draw a smooth curve from the previous vertex through this one to the next vertex. Otherwise, a straight line is drawn from the previous vertex to this one. It makes sense to set \texttt{VertexCurved} to one only if a previous and next vertex are both defined (either explicitly in the array or through the definition of a closed curve).
- It is permissible for VertexDontDraw bits and VertexCurved bits both to be one. This is useful if you want to define the previous point for the smooth curve but do not want an actual curve drawing to start until this point.

- If VertexStartClosed is one, then this point marks the beginning of a closed curve. This vertex must be followed later in the array by another vertex whose effective coordinates are identical and that has a VertexEndClosed bit of one. The points in between form a cycle to determine predecessor and successor vertices for the spline algorithm.

This function uses these GC components: function, plane-mask, line-width, line-style, cap-style, join-style, fill-style, subwindow-mode, clip-x-origin, clip-y-origin, and clip-mask. It also uses these GC mode-dependent components: foreground, background, tile, stipple, tile-stipple-x-origin, tile-stipple-y-origin, dash-offset, and dash-list.

To achieve the effects of the X10 XDrawTiled and XDrawFilled, use XDrawFilled.

```c
#include <X11/X.h>
Status XDrawFilled(display, d, gc, vlist, vcount)
    Display *display;
    Drawable d;
    GC gc;
    Vertex *vlist;
    int vcount;

display   Specifies the connection to the XWIN server.
d           Specifies the drawable.
gc         Specifies the GC.
vlist      Specifies a pointer to the list of vertices that indicate what to draw.
vcount     Specifies how many vertices are in vlist.
```

XDrawFilled draws arbitrary polygons or curves and then fills them.

This function uses these GC components: function, plane-mask, line-width, line-style, cap-style, join-style, fill-style, subwindow-mode, clip-x-origin, clip-y-origin, and clip-mask. It also uses these GC mode-dependent components: foreground, background, tile, stipple, tile-stipple-x-origin, tile-stipple-y-origin, dash-offset, dash-list, fill-style, and fill-rule.
Associating User Data with a Value

These functions have been superseded by the context management functions (see "Using the Context Manager" in Chapter 10). It is often necessary to associate arbitrary information with resource IDs. Xlib provides the XAssocTable functions that you can use to make such an association. Application programs often need to be able to easily refer to their own data structures when an event arrives. The XAssocTable system provides users of the X library with a method for associating their own data structures with X resources (Pixmaps, Fonts, Windows, and so on).

An XAssocTable can be used to type X resources. For example, the user may want to have three or four types of windows, each with different properties. This can be accomplished by associating each X window ID with a pointer to a window property data structure defined by the user. A generic type has been defined in the X library for resource IDs. It is called an XID.

There are a few guidelines that should be observed when using an XAssocTable:

- All XIDs are relative to the specified display.
- Because of the hashing scheme used by the association mechanism, the following rules for determining the size of a XAssocTable should be followed. Associations will be made and looked up more efficiently if the table size (number of buckets in the hashing system) is a power of two and if there are not more than 8 XIDs per bucket.

To return a pointer to a new XAssocTable, use XCreateAssocTable.

\[
\text{XAssocTable} \ast \text{XCreateAssocTable}(\text{size})
\]

\[
\text{int size;}
\]

\[
\text{size} \quad \text{Specifies the number of buckets in the hash system of XAssocTable.}
\]

The size argument specifies the number of buckets in the hash system of XAssocTable. For reasons of efficiency the number of buckets should be a power of two. Some size suggestions might be: use 32 buckets per 100 objects, and a reasonable maximum number of objects per buckets is 8. If an error allocating memory for the XAssocTable occurs, a NULL pointer is returned.
To create an entry in a given XAssocTable, use XMakeAssoc.

\[
\text{XMakeAssoc (display, table, x_id, data)}
\]

- \( \text{display} \) Specifies the connection to the XWIN server.
- \( \text{table} \) Specifies the assoc table.
- \( \text{x_id} \) Specifies the X resource ID.
- \( \text{data} \) Specifies the data to be associated with the X resource ID.

XMakeAssoc inserts data into an XAssocTable keyed on an XID. Data is inserted into the table only once. Redundant inserts are ignored. The queue in each association bucket is sorted from the lowest XID to the highest XID.

To obtain data from a given XAssocTable, use XLookUpAssoc.

\[
\text{char *XLookUpAssoc (display, table, x_id)}
\]

- \( \text{display} \) Specifies the connection to the XWIN server.
- \( \text{table} \) Specifies the assoc table.
- \( \text{x_id} \) Specifies the X resource ID.

XLookUpAssoc retrieves the data stored in an XAssocTable by its XID. If an appropriately matching XID can be found in the table, XLookUpAssoc returns the data associated with it. If the x_id cannot be found in the table, it returns NULL.

To delete an entry from a given XAssocTable, use XDeleteAssoc.

\[
\text{XDeleteAssoc (display, table, x_id)}
\]

- \( \text{display} \) Specifies the connection to the XWIN server.
- \( \text{table} \) Specifies the assoc table.
- \( \text{x_id} \) Specifies the X resource ID.
**Associating User Data with a Value**

- **display** Specifies the connection to the XWIN server.
- **table** Specifies the assoc table.
- **x_id** Specifies the X resource ID.

`XDeleteAssoc` deletes an association in an `XAssocTable` keyed on its XID. Redundant deletes (and deletes of nonexistent XIDs) are ignored. Deleting associations in no way impairs the performance of an `XAssocTable`.

To free the memory associated with a given `XAssocTable`, use `XDestroyAssocTable`.

```c
XDestroyAssocTable(table)
    XAssocTable *table;
```

- **table** Specifies the assoc table.

Preface

This is an extension to the X11 server and Xlib that provides two capabilities:

- It allows a client to generate user input actions in the server without requiring a user to be present.
- It also allows a client to control the handling of user input actions by the server.

The capability to allow a client to generate user input actions in the server will be used by some of the X Testing Consortium Xlib tests. Both capabilities will be used by the X Testing Consortium client exerciser program. These capabilities may also be useful in other programs.

This extension requires modification to device-dependent code in the server. Therefore it is not a 'portable' extension as defined by the X11 Server Extensions document. However, the majority of the code and functionality of this extension will be implementation-independent.
Conventions Used In This Document

The naming conventions used in the Xlib documentation are followed with these additions:

- The names of all functions defined in this extension begin with 'XTest', with the first letter of each additional word capitalized.
- The names of the protocol request structures follow the Xlib convention of 'x<name>Req'.
- The names of the protocol request minor type codes follow the Xlib convention of 'X<name>'.
- The names of all other constants defined in this extension begin with 'XTest', with the rest of the name in upper case letters.
- All constants and structures defined in this extension will have their values specified in the 'xtestext1.h' file at the end of this document.
Definition Of Terms

Input Actions

Input actions are pointer movements, button presses and releases, and key presses and releases. They can be generated by a user or by a client (using functions in this extension).

User Input Actions

User input actions are input actions that are generated by the user moving a pointing device (typically a mouse), pressing and releasing buttons on the pointing device, and pressing and releasing keys on the keyboard.
What Does This Extension Do?

Without this extension, user input actions are processed by the server, and are converted into normal X events that are sent to the appropriate client or clients.

This extension adds the following capabilities:

- Input actions may be sent from a client to the server to be processed just as if the user had physically performed them. The input actions are provided to the server in the form of X protocol requests defined by this extension. The information provided to the server includes what action should be performed, and how long to delay before processing the action in the server.

- User input actions may be diverted to a client before being processed by the server. The effect on the server is as if the user had performed no input action. The user input actions are provided to the client in the form of X events defined by this extension. The information provided to the client includes what user input action occurred and the delay between this user input action and the previous user input action. The client may then do anything it wishes with this information.

- User input actions may be copied, with one copy going to the server in the normal way, and the other copy being sent to a client as described above.
Functions In This Extension

AT&T Enhancements to this Extension

This section describes two additional Xlib calls added by AT&T Bell Laboratories to allow the testing of clients that "grab" the server. These two calls prevent deadlock. Without these calls to encapsulate the simulated input, it would be possible for the client that "grabbed" the server and the client simulating the input to both deadlock. Take for example, a window manager that "grabs" the server while resizing a window. When the window manager "grabs" the server, the server will ignore all events from other clients, including the client simulating the input. If the simulated button release to finish resizing the window is not already in the server's Input Synthesis Extension input buffer, the server will subsequently ignore the event containing the button release. The final result will be a deadlock; the window manager will be deadlocked waiting for a button release that will never come and the client simulating input will be deadlocked waiting for the server to send an acknowledgement that will never come.

By calling XTestStartSimulation before sending simulated input, the server will continue accepting events from the calling client even if another client should "grab" the server.

```c
int
XTestStartSimulation( display )
    Display *display;
```

`display` Specifies the connection to the X server.

The XTestStartSimulation function must be called before any simulated input is sent to the server. If it is not called, the server will refuse all simulated input. Once called and accepted, only the client making the request will be able to simulate input. If any other client attempts to simulate input or calls XTestSimulateInput, its request will be refused.

The XTestStartSimulation function will return -1 if there is an error or the request is denied, and 0 otherwise.
Functions In This Extension

```c
int
XTestStopSimulation( display )
    Display *display;

display    Specifies the connection to the X server.
```

The `XTestStopSimulation` function should be called after the client has finished simulating input. Once called, other clients will be able to call `XTestStartSimulation`. If a client fails to call `XTestStopSimulation`, other clients attempting to call `XTestStartSimulation` will be denied until the original client terminates.

The `XTestStopSimulation` function will return -1 if there is an error, and 0 otherwise.

**High Level Functions**

These functions are built on top of the low level functions described later.

```c
int
XTestMovePointer(display, device_id, delay, x, y, count)
    Display *display;
    int device_id;
    unsigned long delay[];
    int x[];
    int y[];
    unsigned int count;

display    Specifies the connection to the X server.

device_id  Specifies which pointer device was supposed to have caused the input action. This is a provision for future support of multiple (distinguishable) pointer devices, and should always be set to 0 for now.

delay      Specifies the time (in milliseconds) to wait before each movement of the pointer.

x
y
    Specifies the x and y coordinates to move the pointer to relative to the root window for the specified display.
```
Functions In This Extension

count Specifies the number of ‘delay, x, y’ triplets contained in the delay, x and y arrays.

The XTestMovePointer function creates input actions to be sent to the server. The input actions will be accumulated in a request defined by this extension until the request is full or the XTestFlush function is called. They will then be sent to the server. When the input actions are sent to the server, the input actions will cause the server to think that the pointer was moved to the specified position(s), with the specified delay before each input action.

The XTestMovePointer function will return -1 if there is an error, and 0 otherwise.

XTestPressButton

    int
    XTestPressButton(display, device_id, delay, button_number, button_action)
    Display *display;
    int device_id;
    unsigned long delay;
    unsigned int button_number;
    unsigned int button_action;

display Specifies the connection to the X server.

device_id Specifies which button device was supposed to have caused the input action. This is a provision for future support of multiple (distinguishable) button devices, and should always be set to 0 for now.

delay Specifies the time (in milliseconds) to wait before the input action.

button_number Specifies which button is being acted upon.

button_action Specifies the action to be performed (one of XTestPRESS, XTestRELEASE, or XTestSTROKE).

The XTestPressButton function creates input actions to be sent to the server. The input actions will be accumulated in a request defined by this extension until the request is full or the XTestFlush function is called. They will then be sent to the server. When the input actions are sent to the server, the input
actions will cause the server to think that the specified button was moved as specified.

The XTestPressButton function will return -1 if there is an error, and 0 otherwise.

**XTestPressKey**

```c
int XTestPressKey (display, device_id, delay, keycode, key_action)
  Display *display;
  int device_id;
  unsigned long delay;
  unsigned int keycode;
  unsigned int key_action;
```

- **display** Specifies the connection to the X server.
- **device_id** Specifies which keyboard device was supposed to have caused the input action. This is a provision for future support of multiple (distinguishable) keyboard devices, and should always be set to 0 for now.
- **delay** Specifies the time (in milliseconds) to wait before the input action.
- **keycode** Specifies which keycode is being acted upon.
- **key_action** Specifies the action to be performed (one of XTestPRESS, XTestRELEASE, or XTestSTROKE).

The XTestPressKey function creates input actions to be sent to the server. The input actions will be accumulated in a request defined by this extension until the request is full or the XTestFlush function is called. They will then be sent to the server. When the input actions are sent to the server, the input actions will cause the server to think that the specified key on the keyboard was moved as specified.

The XTestPressKey function will return -1 if there is an error, and 0 otherwise.
Functions In This Extension

XTestFlush

    int
    XTestFlush(display)
    Display *display;

display       Specifies the connection to the X server.

The XTestFlush will send any remaining input actions to the server.
The XTestFlush function will return -1 if there is an error, and 0 otherwise.

Low Level Functions

XTestGetInput

    int
    XTestGetInput(display, action_handling)
    Display *display;
    int action_handling;

display       Specifies the connection to the X server.
action_handling Specifies to the server what to do with the user input actions.
                   (one of 0, XTestPACKED_MOTION or
                   XTestPACKED_ACTIONS; optionally or'ed with
                   XTestEXCLUSIVE).

The XTestGetInput function tells the server to begin putting information about
user input actions into events to be sent to the client that called this function.
These events can be read via the Xlib XNextEvent function.

The server assigns an event type of XTestInputActionType to these events to dis­t

X11 Input Synthesis Extension
An action_handling value of 0 causes the server to send one user input action in each XTestInputActionType event. This can sometimes cause performance problems.

An action_handling value of XTestPACKED_ACTIONS causes the server to pack as many user input actions as possible into a XTestInputActionType event. This is needed if user input actions are happening rapidly (such as when the user moves the pointer) to keep performance at a reasonable level.

An action_handling value of XTestPACKED_MOTION causes the server to pack only user input actions associated with moving the pointer. This allows the client to receive button and key motions as they happen without waiting for the event to fill up, while still keeping performance at a reasonable level.

An action_handling value with XTestEXCLUSIVE 'or'ed in causes the server to send user input actions only to the client. The effect on the server is as if the user had performed no input actions.

An action_handling value without XTestEXCLUSIVE causes the server to copy user input actions, sending one copy to the client, and handling the other copy normally (as it would if this extension were not installed).

There are four types of input actions that are passed from the server to the client. They are:

key/button state change
This type of input action contains the keycode of the key or button that changed state; whether the key or button is up or down, and the time delay between this input action and the previous input action.

pointer motions
This type of input action contains information about the motion of the pointer when the pointer has only moved a short distance. If the pointer has moved a long distance, the pointer jump input action is used.

pointer jumps
This type of input action contains information about the motion of the pointer when the pointer has moved a long distance.

delays
This type of input action is used when the delay between input actions is too large to be held in the other input actions.

The XTestGetInput function will return -1 if there is an error, and 0 otherwise.
An error code of *BadAccess* means that another client has already requested that user input actions be sent to it.

**XTestStopInput**

```c
int
XTestStopInput (display)
Display *display;
```

*display* Specifies the connection to the X server.

The *XTestStopInput* function tells the server to stop putting information about user input actions into events. The server will process user input actions normally (as it would if this extension were not in the server).

The *XTestStopInput* function will return -1 if there is an error, and 0 otherwise.

An error code of *BadAccess* means that a request was made to stop input when input has never been started.

**XTestFakeInput**

```c
int
XTestFakeInput (display, action_list_addr, action_list_size, ack_flag)
Display *display;
char *action_list_addr;
int action_list_size;
int ack_flag;
```

*display* Specifies the connection to the X server.

*action_list_addr* Specifies the address of an list of input actions to be sent to the server.

*action_list_size* Specifies the size (in bytes) of the list of input actions. It may be no larger than *XTemp_MAX_ACTION_LIST_SIZE* bytes.

*ack_flag* Specifies whether the server needs to send an event to indicate that its input action buffer is empty (one of *XTempFAKE_ACK_NOT_NEEDED* or *XTempFAKE_ACK_REQUEST*).
The `XTestFakeInput` function tells the server to take the specified user input actions and process them as if the user had physically performed them.

The server can only accept a limited number of input actions at one time. This limit can be determined by the `XTestQueryInputSize` function in this extension.

The client should set `ack_flag` to `XTестFAKE_ACK_NOT_NEEDED` on calls to `XTestFakeInput` that do not reach this limit.

The client should set `ack_flag` to `XTестFAKE_ACK_REQUEST` on the call to `XTestFakeInput` that reaches this limit.

When the server sees an `ack_flag` value of `XTестFAKE_ACK_REQUEST` it finishes processing its input action buffer, then sends an event with type `XTестFakeAckType` to the client. When the client reads this event, it knows that it is safe to resume sending input actions to the server.

Since the actual value of the event type may vary depending on how many extensions are included with an X11 implementation, `XTестFakeAckType` is a variable that is contained in the Xlib part of this extension. It may be referenced as follows:

```c
extern int XTestFakeAckType;
```

There are four types of input actions that are passed from the client to the server. They are:

- **key/button state change**
  - This type of input action contains the keycode of the key or button that is to change state; whether the key or button is to be up or down, and the time to delay before changing the state of the key or button.

- **pointer motions**
  - This type of input action contains information about the motion of the pointer when the pointer is to be moved a short distance, and the time to delay before moving the pointer. If the pointer is to be moved a long distance, the pointer jump input action must be used.

- **pointer jumps**
  - This type of input action contains information about the motion of the pointer when the pointer is to be moved a long distance, and the time to delay before moving the pointer.
delays  This type of input action is used when the delay between input actions is too large to be held in the other input actions.

The `XTestFakeInput` function will return -1 if there is an error, and 0 otherwise.

An error code of `BadAccess` means that another client has already sent user input actions to the server, and the server has not finished processing the user input actions.

**XTestQueryInputSize**

```c
int XTestQueryInputSize(Display *display, unsigned long *size_return);
```

- `display` Specifies the connection to the X server.
- `size_return` Returns the number of input actions that the server's input action buffer can hold.

The `XTestQueryInputSize` function asks the server to return the number of input actions that it can hold in its input action buffer in the unsigned long pointed to by `size_return`.

The `XTestQueryInputSize` function will return -1 if there is an error, and 0 otherwise.

**XTestReset**

```c
int XTestReset(Display *display);
```

- `display` Specifies the connection to the X server.
The `XTestReset` function tells the server to set everything having to do with this extension back to its initial state. After this call the server will act as if this extension were not installed until one of the extension functions is called by a client. This function is not normally needed, but is included in case a client wishes to clean up the server state, such as after a serious error.

The `XTestReset` function will return -1 if there is an error, and 0 otherwise.

Glossary

Access control list  X maintains a list of hosts from which client programs can be run. By default, only programs on the local host and hosts specified in an initial list read by the server can use the display. This access control list can be changed by clients on the local host. Some server implementations can also implement other authorization mechanisms in addition to or in place of this mechanism. The action of this mechanism can be conditional based on the authorization protocol name and data received by the server at connection setup.

Active grab  A grab is active when the pointer or keyboard is actually owned by the single grabbing client.

Ancestors  If W is an inferior of A, then A is an ancestor of W.

Atom  An atom is a unique ID corresponding to a string name. Atoms are used to identify properties, types, and selections.

Background  An InputOutput window can have a background, which is defined as a pixmap. When regions of the window have their contents lost or invalidated, the server automatically tiles those regions with the background.

Backing store  When a server maintains the contents of a window, the pixels saved off-screen are known as a backing store.

Bit gravity  When a window is resized, the contents of the window are not necessarily discarded. It is possible to request that the server relocate the previous contents to some region of the window (though no guarantees are made). This attraction of window contents for some location of a window is known as bit gravity.

Bit plane  When a pixmap or window is thought of as a stack of bitmaps, each bitmap is called a bit plane or plane.
<table>
<thead>
<tr>
<th>Glossary</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Bitmap</strong></td>
<td>A bitmap is a pixmap of depth one.</td>
</tr>
<tr>
<td><strong>Border</strong></td>
<td>An InputOutput window can have a border of equal thickness on all four sides of the window. The contents of the border are defined by a pixmap, and the server automatically maintains the contents of the border. Exposure events are never generated for border regions.</td>
</tr>
<tr>
<td><strong>Button grabbing</strong></td>
<td>Buttons on the pointer can be passively grabbed by a client. When the button is pressed, the pointer is then actively grabbed by the client.</td>
</tr>
<tr>
<td><strong>Byte order</strong></td>
<td>For image ( pixmap / bitmap ) data, the server defines the byte order, and clients with different native byte ordering must swap bytes as necessary. For all other parts of the protocol, the client defines the byte order, and the server swaps bytes as necessary.</td>
</tr>
<tr>
<td><strong>Children</strong></td>
<td>The children of a window are its first-level subwindows.</td>
</tr>
<tr>
<td><strong>Class</strong></td>
<td>Windows can be of different classes or types. See the entries for InputOnly and InputOutput windows for further information about valid window types.</td>
</tr>
<tr>
<td><strong>Client</strong></td>
<td>An application program connects to the window system server by some interprocess communication (IPC) path, such as a TCP connection or a shared memory buffer. This program is referred to as a client of the window system server. More precisely, the client is the IPC path itself. A program with multiple paths open to the server is viewed as multiple clients by the protocol. Resource lifetimes are controlled by connection lifetimes, not by program lifetimes.</td>
</tr>
<tr>
<td><strong>Clipping region</strong></td>
<td>In a graphics context, a bitmap or list of rectangles can be specified to restrict output to a particular region of the window. The image defined by the bitmap or rectangles is called a clipping region.</td>
</tr>
</tbody>
</table>
Colormap

A colormap consists of a set of entries defining color values. The colormap associated with a window is used to display the contents of the window; each pixel value indexes the colormap to produce RGB values that drive the guns of a monitor. Depending on hardware limitations, one or more colormaps can be installed at one time so that windows associated with those maps display with true colors.

Connection

The IPC path between the server and client program is known as a connection. A client program typically (but not necessarily) has one connection to the server over which requests and events are sent.

Containment

A window contains the pointer if the window is viewable and the hotspot of the cursor is within a visible region of the window or a visible region of one of its inferiors. The border of the window is included as part of the window for containment. The pointer is in a window if the window contains the pointer but no inferior contains the pointer.

Coordinate system

The coordinate system has X horizontal and Y vertical, with the origin \([0, 0]\) at the upper left. Coordinates are discrete and are in terms of pixels. Each window and pixmap has its own coordinate system. For a window, the origin is inside the border at the inside upper-left corner.

Cursor

A cursor is the visible shape of the pointer on a screen. It consists of a hotspot, a source bitmap, a shape bitmap, and a pair of colors. The cursor defined for a window controls the visible appearance when the pointer is in that window.

Depth

The depth of a window or pixmap is the number of bits per pixel it has. The depth of a graphics context is the depth of the drawables it can be used in conjunction with graphics output.
## Glossary

| **Device** | Keyboards, mice, tablets, track-balls, button boxes, and so on are all collectively known as input devices. Pointers can have one or more buttons (the most common number is three). The core protocol only deals with two devices: the keyboard and the pointer. |
| **DirectColor** | DirectColor is a class of colormap in which a pixel value is decomposed into three separate subfields for indexing. The first subfield indexes an array to produce red intensity values. The second subfield indexes a second array to produce blue intensity values. The third subfield indexes a third array to produce green intensity values. The RGB (red, green, and blue) values in the colormap entry can be changed dynamically. |
| **Display** | A server, together with its screens and input devices, is called a display. The Xlib Display structure contains all information about the particular display and its screens as well as the state that Xlib needs to communicate with the display over a particular connection. |
| **Drawable** | Both windows and pixmaps can be used as sources and destinations in graphics operations. These windows and pixmaps are collectively known as drawables. However, an InputOnly window cannot be used as a source or destination in a graphics operation. |
| **Event** | Clients are informed of information asynchronously by means of events. These events can be either asynchronously generated from devices or generated as side effects of client requests. Events are grouped into types. The server never sends an event to a client unless the client has specifically asked to be informed of that type of event. However, clients can force events to be sent to other clients. Events are typically reported relative to a window. |
Event mask
Events are requested relative to a window. The set of event types a client requests relative to a window is described by using an event mask.

Event propagation
Device-related events propagate from the source window to ancestor windows until some client has expressed interest in handling that type of event or until the event is discarded explicitly.

Event synchronization
There are certain race conditions possible when demultiplexing device events to clients (in particular, deciding where pointer and keyboard events should be sent when in the middle of window management operations). The event synchronization mechanism allows synchronous processing of device events.

Event source
The deepest viewable window that the pointer is in is called the source of a device-related event.

Exposure event
Servers do not guarantee to preserve the contents of windows when windows are obscured or reconfigured. Exposure events are sent to clients to inform them when contents of regions of windows have been lost.

Extension
Named extensions to the core protocol can be defined to extend the system. Extensions to output requests, resources, and event types are all possible and expected.

Font
A font is an array of glyphs (typically characters). The protocol does no translation or interpretation of character sets. The client simply indicates values used to index the glyph array. A font contains additional metric information to determine interglyph and interline spacing.

Frozen events
Clients can freeze event processing during keyboard and pointer grabs.

</tr>
<tr>
<td>Occlude</td>
<td>Window A <em>occludes</em> window B if A is higher in the global stacking order, and if the rectangle defined by the outside edges of A intersects the rectangle defined by the outside edges of B. The (fine) distinction between the terms <em>obscures</em> and <em>occludes</em> is that for <em>obscures</em>, the windows have to be mapped, while for <em>occludes</em> they don’t. Also note that window borders are included in the calculation. Note that InputOnly windows never obscure other windows but can occlude other windows.</td>
</tr>
<tr>
<td>Padding</td>
<td>Some padding bytes are inserted in the data stream to maintain alignment of the protocol requests on natural boundaries. This increases ease of portability to some machine architectures.</td>
</tr>
<tr>
<td>Parent window</td>
<td>If C is a child of P, then P is the parent of C.</td>
</tr>
<tr>
<td>Passive grab</td>
<td>Grabbing a key or button is a passive grab. The grab activates when the key or button is actually pressed.</td>
</tr>
<tr>
<td>Pixel value</td>
<td>A pixel is an N-bit value, where N is the number of bit planes used in a particular window or pixmap (that is, is the depth of the window or pixmap). A pixel in a window indexes a colormap to derive an actual color to be displayed.</td>
</tr>
<tr>
<td><strong>Pixmap</strong></td>
<td>A pixmap is a three-dimensional array of bits. A pixmap is normally thought of as a two-dimensional array of pixels, where each pixel can be a value from 0 to $2^N - 1$, and where $N$ is the depth (z axis) of the pixmap. A pixmap can also be thought of as a stack of $N$ bitmaps. A pixmap can only be used on the screen that it was created in.</td>
</tr>
<tr>
<td><strong>Plane</strong></td>
<td>When a pixmap or window is thought of as a stack of bitmaps, each bitmap is called a plane or bit plane.</td>
</tr>
<tr>
<td><strong>Plane mask</strong></td>
<td>Graphics operations can be restricted to only affect a subset of bit planes of a destination. A plane mask is a bit mask describing which planes are to be modified. The plane mask is stored in a graphics context.</td>
</tr>
<tr>
<td><strong>Pointer</strong></td>
<td>The pointer is the pointing device currently attached to the cursor and tracked on the screens.</td>
</tr>
<tr>
<td><strong>Pointer grabbing</strong></td>
<td>A client can actively grab control of the pointer. Then button and motion events will be sent to that client rather than the client the events would normally have been sent to.</td>
</tr>
<tr>
<td><strong>Pointing device</strong></td>
<td>A pointing device is typically a mouse, tablet, or some other device with effective dimensional motion. The core protocol defines only one visible cursor, which tracks whatever pointing device is attached as the pointer.</td>
</tr>
<tr>
<td><strong>Property</strong></td>
<td>Windows can have associated properties that consist of a name, a type, a data format, and some data. The protocol places no interpretation on properties. They are intended as a general-purpose naming mechanism for clients. For example, clients might use properties to share information such as resize hints, program names, and icon formats with a window manager.</td>
</tr>
</tbody>
</table>
The property list of a window is the list of properties that have been defined for the window.

PseudoColor is a class of colormap in which a pixel value indexes the colormap entry to produce independent RGB values; that is, the colormap is viewed as an array of triples (RGB values). The RGB values can be changed dynamically.

A rectangle specified by [x,y,w,h] has an infinitely thin outline path with corners at [x,y], [x+w,y], [x+w,y+h], and [x, y+h]. When a rectangle is filled, the lower-right edges are not drawn. For example, if w=h=0, nothing would be drawn. For w=h=1, a single pixel would be drawn.

Window managers (or client programs) may enforce window layout policy in various ways. When a client attempts to change the size or position of a window, the operation may be redirected to a specified client rather than the operation actually being performed.

Information requested by a client program using the X protocol is sent back to the client with a reply. Both events and replies are multiplexed on the same connection. Most requests do not generate replies, but some requests generate multiple replies.

A command to the server is called a request. It is a single block of data sent over a connection.

Windows, pixmaps, cursors, fonts, graphics contexts, and colormaps are known as resources. They all have unique identifiers associated with them for naming purposes. The lifetime of a resource usually is bounded by the lifetime of the connection over which the resource was created.

RGB values are the red, green, and blue intensity values that are used to define a color. These values are always represented as 16-bit, unsigned numbers, with 0 the minimum intensity and 65535 the
maximum intensity. The XWIN server scales these values to match the display hardware.

Root

The root of a pixmap or graphics context is the same as the root of whatever drawable was used when the pixmap or GC was created. The root of a window is the root window under which the window was created.

Root window

Each screen has a root window covering it. The root window cannot be reconfigured or unmapped, but otherwise it acts as a full-fledged window. A root window has no parent.

Save set

The save set of a client is a list of other clients' windows that, if they are inferiors of one of the client's windows at connection close, should not be destroyed and that should be remapped if currently unmapped. Save sets are typically used by window managers to avoid lost windows if the manager should terminate abnormally.

Scanline

A scanline is a list of pixel or bit values viewed as a horizontal row (all values having the same y coordinate) of an image, with the values ordered by increasing the x coordinate.

Scanline order

An image represented in scanline order contains scanlines ordered by increasing the y coordinate.

Screen

A server can provide several independent screens, which typically have physically independent monitors. This would be the expected configuration when there is only a single keyboard and pointer shared among the screens. A Screen structure contains the information about that screen and is linked to the Display structure.

Selection

A selection can be thought of as an indirect property with dynamic type. That is, rather than having the property stored in the XWIN server, it is maintained by some client (the owner). A selection is global and is thought of as belonging to the user and being
maintained by clients, rather than being private to a particular window subhierarchy or a particular set of clients. When a client asks for the contents of a selection, it specifies a selection target type, which can be used to control the transmitted representation of the contents. For example, if the selection is "the last thing the user clicked on," and that is currently an image, then the target type might specify whether the contents of the image should be sent in XY format or Z format. The target type can also be used to control the class of contents transmitted; for example, asking for the "looks" (fonts, line spacing, indentation, and so forth) of a paragraph selection, rather than the text of the paragraph. The target type can also be used for other purposes. The protocol does not constrain the semantics.

Server

The server, which is also referred to as the XWIN server, provides the basic windowing mechanism. It handles IPC connections from clients, demultiplexes graphics requests onto the screens, and multiplexes input back to the appropriate clients.

Server grabbing

The server can be grabbed by a single client for exclusive use. This prevents processing of any requests from other client connections until the grab is completed. This is typically only a transient state for such things as rubber-banding, pop-up menus, or executing requests indivisibly.

Sibling

Children of the same parent window are known as sibling windows.

Stacking order

Sibling windows, similar to sheets of paper on a desk, can stack on top of each other. Windows above both obscure and occlude lower windows. The relationship between sibling windows is known as the stacking order.
<table>
<thead>
<tr>
<th><strong>StaticColor</strong></th>
<th>StaticColor can be viewed as a degenerate case of PseudoColor in which the RGB values are predefined and read-only.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>StaticGray</strong></td>
<td>StaticGray can be viewed as a degenerate case of GrayScale in which the gray values are predefined and read-only. The values are typically linear or near-linear increasing ramps.</td>
</tr>
<tr>
<td><strong>Status</strong></td>
<td>Many Xlib functions return a success status. If the function does not succeed, however, its arguments are not disturbed.</td>
</tr>
<tr>
<td><strong>Stipple</strong></td>
<td>A stipple pattern is a bitmap that is used to tile a region to serve as an additional clip mask for a fill operation with the foreground color.</td>
</tr>
<tr>
<td><strong>Tile</strong></td>
<td>A pixmap can be replicated in two dimensions to tile a region. The pixmap itself is also known as a tile.</td>
</tr>
<tr>
<td><strong>Timestamp</strong></td>
<td>A timestamp is a time value expressed in milliseconds. It is typically the time since the last server reset. Timestamp values wrap around (after about 49.7 days). The server, given its current time is represented by timestamp T, always interprets timestamps from clients by treating half of the timestamp space as being earlier in time than T and half of the timestamp space as being later in time than T. One timestamp value, represented by the constant CurrentTime, is never generated by the server. This value is reserved for use in requests to represent the current server time.</td>
</tr>
<tr>
<td><strong>TrueColor</strong></td>
<td>TrueColor can be viewed as a degenerate case of DirectColor in which the subfields in the pixel value directly encode the corresponding RGB values. That is, the colormap has predefined read-only RGB values. The values are typically linear or near-linear increasing ramps.</td>
</tr>
</tbody>
</table>
### Glossary

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
<td>A type is an arbitrary atom used to identify the interpretation of property data. Types are completely uninterpreted by the server. They are solely for the benefit of clients. X predefines type atoms for many frequently used types, and clients also can define new types.</td>
</tr>
<tr>
<td><strong>Viewable</strong></td>
<td>A window is viewable if it and all of its ancestors are mapped. This does not imply that any portion of the window is actually visible. Graphics requests can be performed on a window when it is not viewable, but output will not be retained unless the server is maintaining backing store.</td>
</tr>
<tr>
<td><strong>Visible</strong></td>
<td>A region of a window is visible if someone looking at the screen can actually see it; that is, the window is viewable and the region is not occluded by any other window.</td>
</tr>
<tr>
<td><strong>Window gravity</strong></td>
<td>When windows are resized, subwindows may be repositioned automatically relative to some position in the window. This attraction of a subwindow to some part of its parent is known as window gravity.</td>
</tr>
<tr>
<td><strong>Window manager</strong></td>
<td>Manipulation of windows on the screen and much of the user interface (policy) is typically provided by a window manager client.</td>
</tr>
<tr>
<td><strong>XY format</strong></td>
<td>The data for a pixmap is said to be in XY format if it is organized as a set of bitmaps representing individual bit planes with the planes appearing from most-significant to least-significant bit order.</td>
</tr>
<tr>
<td><strong>Z format</strong></td>
<td>The data for a pixmap is said to be in Z format if it is organized as a set of pixel values in scanline order.</td>

ServerVendor(display)

VendorRelease(display)

**ARGUMENTS**

display Specifies the connection to the XWIN server.

screen_number Specifies the appropriate screen number on the host server.
DESCRIPTION

The **AllPlanes** macro returns a value with all bits set to 1 suitable for use in a plane argument to a procedure.

The **BlackPixel** macro returns the black pixel value for the specified screen.

The **WhitePixel** macro returns the white pixel value for the specified screen.

The **ConnectionNumber** macro returns a connection number for the specified display.

The **DefaultColormap** macro returns the default colormap ID for allocation on the specified screen.

The **DefaultDepth** macro returns the depth (number of planes) of the default root window for the specified screen.

The **DefaultGC** macro returns the default GC for the root window of the specified screen.

The **DefaultRootWindow** macro returns the root window for the default screen.

The **DefaultScreenOfDisplay** macro returns the default screen of the specified display.

The **DefaultScreen** macro returns the default screen number referenced in the XOpenDisplay routine.

The **DefaultVisual** macro returns the default visual type for the specified screen.

The **DisplayCells** macro returns the number of entries in the default colormap.

The **DisplayPlanes** macro returns the depth of the root window of the specified screen.

The **DisplayString** macro returns the string that was passed to XOpenDisplay when the current display was opened.

The **LastKnownRequestProcessed** macro extracts the full serial number of the last request known by Xlib to have been processed by the XWIN server.

The **NextRequest** macro extracts the full serial number that is to be used for the next request.

The **ProtocolVersion** macro returns the major version number (11) of the X protocol associated with the connected display.

The **ProtocolRevision** macro returns the minor protocol revision number of the XWIN server.

The **QLength** macro returns the length of the event queue for the connected display.

The **RootWindow** macro returns the root window.

The **ScreenCount** macro returns the number of available screens.

The **ScreenOfDisplay** macro returns a pointer to the screen of the specified display.
The `ServerVendor` macro returns a pointer to a null-terminated string that provides some identification of the owner of the XWIN server implementation.

The `VendorRelease` macro returns a number related to a vendor’s release of the XWIN server.

MinCmapsOfScreen(screen)
PlanesOfScreen(screen)
RootWindowOfScreen(screen)
WidthOfScreen(screen)
WidthMMOfScreen(screen)

ARGUMENTS
screen Specifies a pointer to the appropriate Screen structure.

DESCRIPTION
The BlackPixelOfScreen macro returns the black pixel value of the specified screen.
The WhitePixelOfScreen macro returns the white pixel value of the specified screen.
The CellsOfScreen macro returns the number of colormap cells in the default colormap of the specified screen.
The DefaultColormapOfScreen macro returns the default colormap of the specified screen.
The DefaultDepthOfScreen macro returns the default depth of the root window of the specified screen.

The DefaultGCOfScreen macro returns the default GC of the specified screen, which has the same depth as the root window of the screen.

The DefaultVisualOfScreen macro returns the default visual of the specified screen.

The DoesBackingStore macro returns WhenMapped, NotUseful, or Always, which indicate whether the screen supports backing stores.

The DoesSaveUnders macro returns a Boolean value indicating whether the screen supports save unders.

The DisplayOfScreen macro returns the display of the specified screen.

The EventMaskOfScreen macro returns the root event mask of the root window for the specified screen at connecti setup time.

The HeightOfScreen macro returns the height of the specified screen.

The HeightMMOfScreen macro returns the height of the specified screen in millimeters.

The MaxCmapsOfScreen macro returns the maximum number of installed color maps supported by the specified screen.

The MinCmapsOfScreen macro returns the minimum number of installed color maps supported by the specified screen.

The PlanesOfScreen macro returns the number of planes in the root window of the specified screen.

The RootWindowOfScreen macro returns the root window of the specified screen.

The WidthOfScreen macro returns the width of the specified screen.

The WidthMMOfScreen macro returns the width of the specified screen in millimeters.

NAME
ImageByteOrder, BitmapBitOrder, BitmapPad, BitmapUnit, DisplayHeight, DisplayHeightMM, DisplayWidth, DisplayWidthMM – image format macros

SYNTAX
ImageByteOrder(display)
BitmapBitOrder(display)
BitmapPad(display)
BitmapUnit(display)
DisplayHeight(display, screen_number)
DisplayHeightMM(display, screen_number)
DisplayWidth(display, screen_number)
DisplayWidthMM(display, screen_number)

ARGUMENTS
display Specifies the connection to the XWIN server.
screen_number Specifies the appropriate screen number on the host server.

DESCRIPTION
The ImageByteOrder macro specifies the required byte order for images for each scanline unit in XY format (bitmap) or for each pixel value in Z format.

The BitmapBitOrder macro returns LSBFirst or MSBFirst to indicate whether the leftmost bit in the bitmap as displayed on the screen is the least or most significant bit in the unit.

The BitmapPad macro returns the number of bits that each scanline must be padded.

The BitmapUnit macro returns the size of a bitmap’s scanline unit in bits.

The DisplayHeight macro returns the height of the specified screen in pixels.

The DisplayHeightMM macro returns the height of the specified screen in millimeters.

The DisplayWidth macro returns the width of the screen in pixels.

The DisplayWidthMM macro returns the width of the specified screen in millimeters.

   IsPFKey – keysym classification macros

SYNTAX
   IsCursorKey (keysym)
   IsFunctionKey (keysym)
   IsKeypadKey (keysym)
   IsMiscFunctionKey (keysym)
   IsModifierKey (keysym)
   IsPFKey (keysym)

ARGUMENTS
   keysym  Specifies the KeySym that is to be tested.

DESCRIPTION
   The IsCursorKey macro returns True if the specified KeySym is a cursor key.
   The IsFunctionKey macro returns True if the KeySym is a function key.
   The IsKeypadKey macro returns True if the specified KeySym is a keypad key.
   The IsMiscFunctionKey macro returns True if the specified KeySym is a miscellaneous function key.
   The IsModifierKey macro returns True if the specified KeySym is a modifier key.
   The IsPFKey macro returns True if the specified KeySym is a PF key.

NAME
XAddHost, XAddHosts, XListHosts, XRemoveHost, XRemoveHosts, XSetAccessControl, XEnableAccessControl, XDisableAccessControl – control host access

SYNTAX
XAddHost(display, host)
    Display *display;
    XHostAddress *host;

XAddHosts(display, hosts, num_hosts)
    Display *display;
    XHostAddress *hosts;
    int num_hosts;

XHostAddress *XListHosts(display, nhosts_return, state_return)
    Display *display;
    int *nhosts_return;
    Bool *state_return;

XRemoveHost(display, host)
    Display *display;
    XHostAddress *host;

XRemoveHosts(display, hosts, num_hosts)
    Display *display;
    XHostAddress *hosts;
    int num_hosts;

XSetAccessControl(display, mode)
    Display *display;
    int mode;

XEnableAccessControl(display)
    Display *display;

XDisableAccessControl(display)
    Display *display;

ARGUMENTS
    display    Specifies the connection to the Xwin server.
    host       Specifies the host that is to be added or removed.
    hosts      Specifies each host that is to be added or removed.
    mode       Specifies the mode. You can pass EnableAccess or DisableAccess.
    nhosts_return Returns the number of hosts currently in the access control list.
    num_hosts  Specifies the number of hosts.
    state_return Returns the state of the access control.

DESCRIPTION
The XAddHost function adds the specified host to the access control list for that display. The server must be on the same host as the client issuing the command, or a BadAccess error results.
**XAddHost** can generate **BadAccess** and **BadValue** errors.

The **XAddHost** function adds each specified host to the access control list for that display. The server must be on the same host as the client issuing the command, or a **BadAccess** error results.

**XAddHost**s can generate **BadAccess** and **BadValue** errors.

The **XAddHost** function adds each specified host to the access control list for that display. The server must be on the same host as the client process, or a **BadAccess** error results. If you remove your machine from the access list, you can no longer connect to that server, and this operation cannot be reversed unless you reset the server.

**XRemoveHost** can generate **BadAccess** and **BadValue** errors.

The **XRemoveHost** function removes each specified host from the access control list for that display. The server must be on the same host as the client process, or a **BadAccess** error results. If you remove your machine from the access list, you can no longer connect to that server, and this operation cannot be reversed unless you reset the server.

**XRemoveHost**s can generate **BadAccess** and **BadValue** errors.

The **XSetAccessControl** function either enables or disables the use of the access control list at each connection setup.

**XSetAccessControl** can generate **BadAccess** and **BadValue** errors.

The **XEnableAccessControl** function enables the use of the access control list at each connection setup.

**XEnableAccessControl** can generate a **BadAccess** error.

The **XDisableAccessControl** function disables the use of the access control list at each connection setup.

**XDisableAccessControl** can generate a **BadAccess** error.

**DIAGNOSTICS**

**BadAccess**
A client attempted to modify the access control list from other than the local (or otherwise authorized) host.

**BadValue**
Some numeric value falls outside the range of values accepted by the request. Unless a specific range is specified for an argument, the full range defined by the argument's type is accepted. Any argument defined as a set of alternatives can generate this error.

   XColor *screen_def_return, *exact_def_return;

Status XAllocColorCells (display, colormap, contig, plane_masks_return, nplanes, pixels_return, npixels)
   Display *display;
   Colormap colormap;
   Bool contig;
   unsigned long plane_masks_return[];
   unsigned int nplanes;
   unsigned long pixels_return[];
   unsigned int npixels;

Status XAllocColorPlanes (display, colormap, contig, pixels_return, ncolors, nreds, ngreens, nblues, rmask_return, gmask_return, bmask_return)
   Display *display;
   Colormap colormap;
   Bool contig;
   unsigned long pixels_return[];
   int ncolors;
   int nreds, ngreens, nblues;
   unsigned long *rmask_return, *gmask_return, *bmask_return;

XFreeColors (display, colormap, pixels, npixels, planes)
   Display *display;
   Colormap colormap;
   unsigned long pixels[];
   int npixels;
   unsigned long planes;

**ARGUMENTS**

color_name  Specifies the color name string (for example, red) whose color definition structure you want returned.

colormap   Specifies the colormap.

contig    Specifies a Boolean value that indicates whether the planes must be contiguous.
XAllocColor (3X11)

display Specifies the connection to the XWIN server.
exact_def_return Returns the exact RGB values.
ncolors Specifies the number of pixel values that are to be returned in
the pixels_return array.
npixels Specifies the number of pixels.
nplanes Specifies the number of plane masks that are to be returned in
the plane masks array.
nreds ngreens nblues Specify the number of red, green, and blue planes. The value
you pass must be nonnegative.
pixels Specifies an array of pixel values.
pixels_return Returns an array of pixel values.
plane_mask_return Returns an array of plane masks.
planes Specifies the planes you want to free.
rmask_return gmask_return bmask_return Return bit masks for the red, green, and blue planes.
screen_def_return Returns the closest RGB values provided by the hardware.
screen_in_out Specifies and returns the values actually used in the colormap.

DESCRIPTION
The XAllocColor function allocates a read-only colormap entry corresponding to
the closest RGB values supported by the hardware. XAllocColor returns the
pixel value of the color closest to the specified RGB elements supported by the
hardware and returns the RGB values actually used. The corresponding colormap
cell is read-only. In addition, XAllocColor returns nonzero
if it succeeded or zero if it failed. Read-only colormap cells are shared among clients. When the
last client deallocates a shared cell, it is deallocated. XAllocColor does not use or
affect the flags in the XColor structure.

XAllocColor can generate a BadColor error.

The XAllocNamedColor function looks up the named color with respect to the
screen that is associated with the specified colormap. It returns both the exact
database definition and the closest color supported by the screen. The allocated
color cell is read-only. You should use the ISO Latin-1 encoding; uppercase and
lowercase do not matter.

XAllocNamedColor can generate a BadColor error.

The XAllocColorCells function allocates read/write color cells. The number of
colors must be positive and the number of planes nonnegative, or a BadValue
error results. If ncolors and nplanes are requested, then ncolors pixels and
nplane plane masks are returned. No mask will have any bits set to 1 in common

Page 2 10/89
with any other mask or with any of the pixels. By ORing together each pixel with zero or more masks, ncolors * 2^planes distinct pixels can be produced. All of these are allocated writable by the request. For GrayScale or PseudoColor, each mask has exactly one bit set to 1. For DirectColor, each has exactly three bits set to 1. If contig is True and if all masks are ORed together, a single contiguous set of bits set to 1 will be formed for GrayScale or PseudoColor and three contiguous sets of bits set to 1 (one within each pixel subfield) for DirectColor. The RGB values of the allocated entries are undefined. XAllocColorCells returns nonzero if it succeeded or zero if it failed.

XAllocColorCells can generate BadColor and BadValue errors.

The specified ncolors must be positive; and nreds, ngreens, and nblues must be nonnegative, or a BadValue error results. If ncolors colors, nreds reds, ngreens greens, and nblues blues are requested, ncolors pixels are returned; and the masks have nreds, ngreens, and nblues bits set to 1, respectively. If contig is True, each mask will have a contiguous set of bits set to 1. No mask will have any bits set to 1 in common with any other mask or with any of the pixels. For DirectColor, each mask will lie within the corresponding pixel subfield. By ORing subsets of masks with each pixel value, ncolors * 2^(nreds+ngreens+nblues) distinct pixel values can be produced. All of these are allocated by the request. However, in the colormap, there are only ncolors * 2^nreds independent red entries, ncolors * 2^ngreens independent green entries, and ncolors * 2^nblues independent blue entries. This is true even for PseudoColor. When the colormap entry of a pixel value is changed (using XStoreColors, XStoreColor, or XStoreNamedColor), the pixel is decomposed according to the masks, and the corresponding independent entries are updated. XAllocColorPlanes returns nonzero if it succeeded or zero if it failed.

XAllocColorPlanes can generate BadColor and BadValue errors.

The XFreeColors function frees the cells represented by pixels whose values are in the pixels array. The planes argument should not have any bits set to 1 in common with any of the pixels. The set of all pixels is produced by ORing together subsets of the planes argument with the pixels. The request frees all of these pixels that were allocated by the client (using XAllocColor, XAllocNamedColor, XAllocColorCells, and XAllocColorPlanes). Note that freeing an individual pixel obtained from XAllocColorPlanes may not actually allow it to be reused until all of its related pixels are also freed.

All specified pixels that are allocated by the client in the colormap are freed, even if one or more pixels produce an error. If a specified pixel is not a valid index into the colormap, a BadValue error results. If a specified pixel is not allocated by the client (that is, is unallocated or is only allocated by another client), a BadAccess error results. If more than one pixel is in error, the one that gets reported is arbitrary.

XFreeColors can generate BadAccess, BadColor, and BadValue errors.
XAllocColor (3X11)

DIAGNOSTICS

BadAccess
A client attempted to free a color map entry that it did not already allocate.

BadAccess
A client attempted to store into a read-only color map entry.

BadColor
A value for a Colormap argument does not name a defined Colormap.

BadValue
Some numeric value falls outside the range of values accepted by the request. Unless a specific range is specified for an argument, the full range defined by the argument’s type is accepted. Any argument defined as a set of alternatives can generate this error.

NAME
XAllowEvents – release queued events

SYNTAX
XAllowEvents(display, event_mode, time)
Display *display;
int event_mode;
Time time;

ARGUMENTS

display Specifies the connection to the XWIN server.

event_mode Specifies the event mode. You can pass AsyncPointer, SyncPointer, AsyncKeyboard, SyncKeyboard, ReplayPointer, ReplayKeyboard, AsyncBoth, or SyncBoth.

time Specifies the time. You can pass either a timestamp or CurrentTime.

DESCRIPTION
The XAllowEvents function releases some queued events if the client has caused a device to freeze. It has no effect if the specified time is earlier than the last-grab time of the most recent active grab for the client or if the specified time is later than the current XWIN server time.

XAllowEvents can generate a BadValue error.

DIAGNOSTICS

BadValue Some numeric value falls outside the range of values accepted by the request. Unless a specific range is specified for an argument, the full range defined by the argument’s type is accepted. Any argument defined as a set of alternatives can generate this error.

SEE ALSO

**NAME**

XChangeKeyboardControl, XGetKeyboardControl, XAutoRepeatOn, XAutoRepeatOff, XBell, XQueryKeymap – manipulate keyboard settings

**SYNTAX**

XChangeKeyboardControl(*display, value_mask, values)
  
  Display *display;
  unsigned long value_mask;
  XKeyboardControl *values;

XGetKeyboardControl(*display, values_return)
  
  Display *display;
  XKeyboardState *values_return;

XAutoRepeatOn(*display)
  
  Display *display;

XAutoRepeatOff(*display)
  
  Display *display;

XBell(*display, percent)
  
  Display *display;
  int percent;

XQueryKeymap(*display, keys_return)
  
  Display *display;
  char keys_return[32];

**ARGUMENTS**

*display* Specifies the connection to the XWIN server.

*keys_return* Returns an array of bytes that identifies which keys are pressed down. Each bit represents one key of the keyboard.

*percent* Specifies the volume for the bell, which can range from -100 to 100 inclusive.

*value_mask* Specifies one value for each bit set to 1 in the mask.

*values* Specifies which controls to change. This mask is the bitwise inclusive OR of the valid control mask bits.

*values_return* Returns the current keyboard controls in the specified XKeyboardState structure.

**DESCRIPTION**

The XChangeKeyboardControl function controls the keyboard characteristics defined by the XKeyboardControl structure. The value_mask argument specifies which values are to be changed.

XChangeKeyboardControl can generate BadMatch and BadValue errors.

The XGetKeyboardControl function returns the current control values for the keyboard to the XKeyboardState structure.

The XAutoRepeatOn function turns on auto-repeat for the keyboard on the specified display.
The \texttt{XAutoRepeatOff} function turns off auto-repeat for the keyboard on the specified display.

The \texttt{XBell} function rings the bell on the keyboard on the specified display, if possible. The specified volume is relative to the base volume for the keyboard. If the value for the percent argument is not in the range $-100$ to $100$ inclusive, a \texttt{BadValue} error results. The volume at which the bell rings when the percent argument is nonnegative is:
\[
\text{base} - \left(\frac{\text{base} \times \text{percent}}{100}\right) + \text{percent}
\]

The volume at which the bell rings when the percent argument is negative is:
\[
\text{base} + \left(\frac{\text{base} \times \text{percent}}{100}\right)
\]

To change the base volume of the bell, use \texttt{XChangeKeyboardControl}.

\texttt{XBell} can generate a \texttt{BadValue} error.

The \texttt{XQueryKeymap} function returns a bit vector for the logical state of the keyboard, where each bit set to 1 indicates that the corresponding key is currently pressed down. The vector is represented as 32 bytes. Byte \texttt{N} (from 0) contains the bits for keys \texttt{SN} to \texttt{SN} + 7 with the least-significant bit in the byte representing key \texttt{SN}.

Note that the logical state of a device (as seen by client applications) may lag the physical state if device event processing is frozen.

\textbf{DIAGNOSTICS}

- \texttt{BadMatch} Some argument or pair of arguments has the correct type and range but fails to match in some other way required by the request.

- \texttt{BadValue} Some numeric value falls outside the range of values accepted by the request. Unless a specific range is specified for an argument, the full range defined by the argument's type is accepted. Any argument defined as a set of alternatives can generate this error.

keysyms
keysyms_per_keycode
keysyms_per_keycode_return
max_keys_per_mod
max_keycodes_return
min_keycodes_return
modifier
modmap
num_codes

Specifies the first KeyCode that is to be changed or returned.
Specifies the number of KeyCodes that are to be returned.
Specifies the KeyCode.
Specifies a pointer to an array of KeySyms.
Specifies the number of KeySyms per KeyCode.
Returns the number of KeySyms per KeyCode.
Specifies the number of KeyCode entries preallocated to the modifiers in the map.
Returns the maximum number of KeyCodes.
Returns the minimum number of KeyCodes.
Specifies the modifier.
Specifies a pointer to the XModifierKeymap structure.
Specifies the number of KeyCodes that are to be changed.

DESCRIPTION
The XChangeKeyboardMapping function defines the symbols for the specified number of KeyCodes starting with first_keycode. The symbols for KeyCodes outside this range remain unchanged. The number of elements in keysyms must be:

```
num_codes * keysyms_per_keycode
```

The specified first_keycode must be greater than or equal to min_keycode returned by XDisplayKeycodes, or a BadValue error results. In addition, the following expression must be less than or equal to max_keycode as returned by XDisplayKeycodes, or a BadValue error results:

```
first_keycode + num_codes - 1
```

KeySym number N, counting from zero, for KeyCode K has the following index in keysyms, counting from zero:

```
(K - first_keycode) * keysyms_per_keycode + N
```

The specified keysyms_per_keycode can be chosen arbitrarily by the client to be large enough to hold all desired symbols. A special KeySym value of NoSymbol should be used to fill in unused elements for individual KeyCodes. It is legal for NoSymbol to appear in nontrailing positions of the effective list for a KeyCode. XChangeKeyboardMapping generates a MappingNotify event.
There is no requirement that the XWIN server interpret this mapping. It is merely stored for reading and writing by clients.

XChangeKeyboardMapping can generate BadAlloc and BadValue errors.

The XGetKeyboardMapping function returns the symbols for the specified number of KeyCodes starting with first_keycode. The value specified in first_keycode must be greater than or equal to min_keycode as returned by XDisplayKeycodes, or a BadValue error results. In addition, the following expression must be less than or equal to max_keycode as returned by XDisplayKeycodes:

\[ \text{first_keycode} + \text{keycode\_count} - 1 \]

If this is not the case, a BadValue error results. The number of elements in the KeySym list is:

\[ \text{keycode\_count} \times \text{keysyms\_per\_keycode\_return} \]

KeySym number \( N \), counting from zero, for KeyCode \( K \) has the following index in the list, counting from zero:

\[ (K - \text{first\_code}) \times \text{keysyms\_per\_code\_return} + N \]

The XWIN server arbitrarily chooses the keysyms\_per\_keycode\_return value to be large enough to report all requested symbols. A special KeySym value of NoSymbol is used to fill in unused elements for individual KeyCodes. To free the storage returned by XGetKeyboardMapping, use XFree.

XGetKeyboardMapping can generate a BadValue error.

The XDisplayKeycodes function returns the min-keycodes and max-keycodes supported by the specified display. The minimum number of KeyCodes returned is never less than 8, and the maximum number of KeyCodes returned is never greater than 255. Not all KeyCodes in this range are required to have corresponding keys.

The XSetModifierMapping function specifies the KeyCodes of the keys (if any) that are to be used as modifiers. If it succeeds, the XWIN server generates a MappingNotify event, and XSetModifierMapping returns MappingSuccess. X permits at most eight modifier keys. If more than eight are specified in the XModifierKeymap structure, a BadLength error results.

The modifiermap member of the XModifierKeymap structure contains eight sets of max_keypermod KeyCodes, one for each modifier in the order Shift, Lock, Control, Mod1, Mod2, Mod3, Mod4, and Mod5. Only nonzero KeyCodes have meaning in each set, and zero KeyCodes are ignored. In addition, all of the nonzero KeyCodes must be in the range specified by min_keycode and max_keycode in the Display structure, or a BadValue error results. No KeyCode may appear twice in the entire map, or a BadValue error results.
An XWIN server can impose restrictions on how modifiers can be changed, for example, if certain keys do not generate up transitions in hardware, if auto-repeat cannot be disabled on certain keys, or if multiple modifier keys are not supported. If some such restriction is violated, the status reply is MappingFailed, and none of the modifiers are changed. If the new KeyCodes specified for a modifier differ from those currently defined and any (current or new) keys for that modifier are in the logically down state, XSetModifierMapping returns MappingBusy, and none of the modifiers is changed.

XSetModifierMapping can generate BadAlloc and BadValue errors.

The XGetModifierMapping function returns a pointer to a newly created XModifierKeymap structure that contains the keys being used as modifiers. The structure should be freed after use by calling XFreeModifiermap. If only zero values appear in the set for any modifier, that modifier is disabled.

The XNewModifiermap function returns a pointer to XModifierKeymap structure for later use.

The XInsertModifiermapEntry function adds the specified KeyCode to the set that controls the specified modifier and returns the resulting XModifierKeymap structure (expanded as needed).

The XDeleteModifiermapEntry function deletes the specified KeyCode from the set that controls the specified modifier and returns a pointer to the resulting XModifierKeymap structure.

The XFreeModifiermap function frees the specified XModifierKeymap structure.

**DIAGNOSTICS**

**BadAlloc**
The server failed to allocate the requested resource or server memory.

**BadValue**
Some numeric value falls outside the range of values accepted by the request. Unless a specific range is specified for an argument, the full range defined by the argument's type is accepted. Any argument defined as a set of alternatives can generate this error.

**SEE ALSO**

XSetPointerMapping(3X11)
Xlib — C Language X Interface
NAME
XChangePointerControl, XGetPointerControl - control pointer

SYNTAX
XChangePointerControl(display, do_accel, do_threshold, accel_numerator, accel_denominator, threshold)
  Display *display;
  Bool do_accel, do_threshold;
  int accel_numerator, accel_denominator;
  int threshold;
XGetPointerControl(display, accel_numerator_return, accel_denominator_return, threshold_return)
  Display *display;
  int *accel_numerator_return, *accel_denominator_return;
  int *threshold_return;

ARGUMENTS
  accel_denominator
    Specifies the denominator for the acceleration multiplier.
  accel_denominator_return
    Returns the denominator for the acceleration multiplier.
  accel_numerator
    Specifies the numerator for the acceleration multiplier.
  accel_numerator_return
    Returns the numerator for the acceleration multiplier.
  display
    Specifies the connection to the XWIN server.
  do_accel
    Specifies a Boolean value that controls whether the values for
    the accel_numerator or accel_denominator are used.
  do_threshold
    Specifies a Boolean value that controls whether the value for the
    threshold is used.
  threshold
    Specifies the acceleration threshold.
  threshold_return
    Returns the acceleration threshold.

DESCRIPTION
The XChangePointerControl function defines how the pointing device moves. The acceleration, expressed as a fraction, is a multiplier for movement. For example, specifying 3/1 means the pointer moves three times as fast as normal. The fraction may be rounded arbitrarily by the XWIN server. Acceleration only takes effect if the pointer moves more than threshold pixels at once and only applies to the amount beyond the value in the threshold argument. Setting a value to -1 restores the default. The values of the do_accel and do_threshold arguments must be True for the pointer values to be set, or the parameters are unchanged. Negative values (other than -1) generate a BadValue error, as does a zero value for the accel_denominator argument.

XChangePointerControl can generate a BadValue error.
The `XGetPointerControl` function returns the pointer's current acceleration multiplier and acceleration threshold.

**DIAGNOSTICS**

- **BadValue**: Some numeric value falls outside the range of values accepted by the request. Unless a specific range is specified for an argument, the full range defined by the argument's type is accepted. Any argument defined as a set of alternatives can generate this error.

NAME

XChangeSaveSet, XAddToSaveSet, XRemoveFromSaveSet – change a client’s save set

SYNTAX

XChangeSaveSet(display, w, change_mode)
   Display *display;
   Window w;
   int change_mode;
XAddToSaveSet(display, w)
   Display *display;
   Window w;
XRemoveFromSaveSet(display, w)
   Display *display;
   Window w;

ARGUMENTS

change_mode Specifies the mode. You can pass SetModeInsert or SetModeDelete.
display Specifies the connection to the XWIN server.
w Specifies the window that you want to add or delete from the client’s save-set.

DESCRIPTION

Depending on the specified mode, XChangeSaveSet either inserts or deletes the specified window from the client’s save-set. The specified window must have been created by some other client, or a BadMatch error results.

XChangeSaveSet can generate BadMatch, BadValue, and BadWindow errors.

The XAddToSaveSet function adds the specified window to the client’s save-set. The specified window must have been created by some other client, or a BadMatch error results.

XAddToSaveSet can generate BadMatch and BadWindow errors.

The XRemoveFromSaveSet function removes the specified window from the client’s save-set. The specified window must have been created by some other client, or a BadMatch error results.

XRemoveFromSaveSet can generate BadMatch and BadWindow errors.

DIAGNOSTICS

BadMatch Some argument or pair of arguments has the correct type and range but fails to match in some other way required by the request.

BadValue Some numeric value falls outside the range of values accepted by the request. Unless a specific range is specified for an argument, the full range defined by the argument’s type is accepted. Any argument defined as a set of alternatives can generate this error.
BadWindow  A value for a Window argument does not name a defined Window.

XChangeWindowAttributes, XSetWindowBackground, XSetWindowBackgroundPixmap, XSetWindowBorder, XSetWindowBorderPixmap – change window attributes

SYNTAX

XChangeWindowAttributes(display, w, valuemask, attributes)

Display *display;
Window w;
unsigned long valuemask;
XSetWindowAttributes *attributes;

XSetWindowBackground(display, w, background_pixel)

Display *display;
Window w;
unsigned long background_pixel;

XSetWindowBackgroundPixmap(display, w, background_pixmap)

Display *display;
Window w;
Pixmap background_pixmap;

XSetWindowBorder(display, w, border_pixel)

Display *display;
Window w;
unsigned long border_pixel;

XSetWindowBorderPixmap(display, w, border_pixmap)

Display *display;
Window w;
Pixmap border_pixmap;

ARGUMENTS

attributes Specifies the structure from which the values (as specified by the value mask) are to be taken. The value mask should have the appropriate bits set to indicate which attributes have been set in the structure.

background_pixel Specifies the pixel that is to be used for the background.

background_pixmap Specifies the background pixmap, ParentRelative, or None.

border_pixel Specifies the entry in the colormap.

border_pixmap Specifies the border pixmap or CopyFromParent.

display Specifies the connection to the XWIN server.

valuemask Specifies which window attributes are defined in the attributes argument. This mask is the bitwise inclusive OR of the valid attribute mask bits. If valuemask is zero, the attributes are ignored and are not referenced.
\textbf{XChangeWindowAttributes (3X11)}

\texttt{w} Specifies the window.

\textbf{DESCRIPTION}

Depending on the valuemask, the \texttt{XChangeWindowAttributes} function uses the window attributes in the \texttt{XSetWindowAttributes} structure to change the specified window attributes. Changing the background does not cause the window contents to be changed. To repaint the window and its background, use \texttt{XClearWindow}. Setting the border or changing the background such that the border tile origin changes causes the border to be repainted. Changing the background of a root window to \texttt{None} or \texttt{ParentRelative} restores the default background pixmap. Changing the border of a root window to \texttt{CopyFromParent} restores the default border pixmap. Changing the win-gravity does not affect the current position of the window. Changing the backing-store of an obscured window to \texttt{WhenMapped} or \texttt{Always}, or changing the backing-planes, backing-pixel, or save-under of a mapped window may have no immediate effect. Changing the colormap of a window (that is, defining a new map, not changing the contents of the existing map) generates a \texttt{ColormapNotify} event. Changing the colormap of a visible window may have no immediate effect on the screen because the map may not be installed (see \texttt{XInstallColormap}). Changing the cursor of a root window to \texttt{None} restores the default cursor. Whenever possible, you are encouraged to share colormaps.

Multiple clients can select input on the same window. Their event masks are maintained separately. When an event is generated, it is reported to all interested clients. However, only one client at a time can select for \texttt{SubstructureRedirectMask}, \texttt{ResizeRedirectMask}, and \texttt{ButtonPressMask}. If a client attempts to select any of these event masks and some other client has already selected one, a \texttt{BadAccess} error results. There is only one do-not-propagate-mask for a window, not one per client.

\texttt{XChangeWindowAttributes} can generate \texttt{BadAccess}, \texttt{BadColor}, \texttt{BadCursor}, \texttt{BadMatch}, \texttt{BadPixmap}, \texttt{BadValue}, and \texttt{BadWindow} errors.

The \texttt{XSetWindowBackground} function sets the background of the window to the specified pixel value. Changing the background does not cause the window contents to be changed. \texttt{XSetWindowBackground} uses a pixmap of undefined size filled with the pixel value you passed. If you try to change the background of an \texttt{InputOnly} window, a \texttt{BadMatch} error results.

\texttt{XSetWindowBackground} can generate \texttt{BadMatch} and \texttt{BadWindow} errors.

The \texttt{XSetWindowBackgroundPixmap} function sets the background pixmap of the window to the specified pixmap. The background pixmap can immediately be freed if no further explicit references to it are to be made. If \texttt{ParentRelative} is specified, the background pixmap of the window’s parent is used, or on the root window, the default background is restored. If you try to change the background of an \texttt{InputOnly} window, a \texttt{BadMatch} error results. If the background is set to \texttt{None}, the window has no defined background.

\texttt{XSetWindowBackgroundPixmap} can generate \texttt{BadMatch}, \texttt{BadPixmap}, and \texttt{BadWindow} errors.
The \texttt{XSetWindowBorder} function sets the border of the window to the pixel value you specify. If you attempt to perform this on an \texttt{InputOnly} window, a \texttt{BadMatch} error results.

\texttt{XSetWindowBorder} can generate \texttt{BadMatch} and \texttt{BadWindow} errors.

The \texttt{XSetWindowBorderPixmap} function sets the border pixmap of the window to the pixmap you specify. The border pixmap can be freed immediately if no further explicit references to it are to be made. If you specify \texttt{CopyFromParent}, a copy of the parent window's border pixmap is used. If you attempt to perform this on an \texttt{InputOnly} window, a \texttt{BadMatch} error results.

\texttt{XSetWindowBorderPixmap} can generate \texttt{BadMatch}, \texttt{BadPixmap}, and \texttt{BadWindow} errors.

\textbf{DIAGNOSTICS}

\textbf{BadAccess} A client attempted to free a color map entry that it did not already allocate.

\textbf{BadAccess} A client attempted to store into a read-only color map entry.

\textbf{BadColor} A value for a Colormap argument does not name a defined Colormap.

\textbf{BadCursor} A value for a Cursor argument does not name a defined Cursor.

\textbf{BadMatch} Some argument or pair of arguments has the correct type and range but fails to match in some other way required by the request.

\textbf{BadMatch} An InputOnly window locks this attribute.

\textbf{BadPixmap} A value for a Pixmap argument does not name a defined Pixmap.

\textbf{BadValue} Some numeric value falls outside the range of values accepted by the request. Unless a specific range is specified for an argument, the full range defined by the argument's type is accepted. Any argument defined as a set of alternatives can generate this error.

\textbf{BadWindow} A value for a Window argument does not name a defined Window.

\texttt{XConfigureWindow(3X11)}, \texttt{XCreateWindow(3X11)}, \texttt{XDestroyWindow(3X11)}, \texttt{XMapWindow(3X11)}, \texttt{XRaiseWindow(3X11)}, \texttt{XUnmapWindow(3X11)}

\textit{Xlib - C Language X Interface}
NAME
XClearArea, XClearWindow – clear area or window

SYNTAX
XClearArea(display, w, x, y, width, height, exposures)
Display *display;
Window w;
int x, y;
unsigned int width, height;
Bool exposures;

XClearWindow(display, w)
Display *display;
Window w;

ARGUMENTS

*display     Specifies the connection to the XWIN server.

exposures    Specifies a Boolean value that indicates if Expose events are to
             be generated.

w            Specifies the window.

width        Specify the width and height, which are the dimensions of the
             rectangle.

height

x            Specify the x and y coordinates, which are relative to the origin
             of the window and specify the upper-left corner of the rectan-
             gle.

y

DESCRIPTION

The XClearArea function paints a rectangular area in the specified window
according to the specified dimensions with the window’s background pixel or
 pixmap. The subwindow-mode effectively is ClipByChildren. If width is zero,
it is replaced with the current width of the window minus x. If height is zero, it
is replaced with the current height of the window minus y. If the window has a
defined background tile, the rectangle clipped by any children is filled with this
tile. If the window has background None, the contents of the window are not
changed. In either case, if exposures is True, one or more Expose events are
generated for regions of the rectangle that are either visible or are being retained in a
backing store. If you specify a window whose class is InputOnly, a BadMatch
error results.

XClearArea can generate BadMatch, BadValue, and BadWindow errors.

The XClearWindow function clears the entire area in the specified window and is
equivalent to XClearArea (display, w, 0, 0, 0, 0, False). If the window has a
defined background tile, the rectangle is tiled with a plane-mask of all ones and
GXcopy function. If the window has background None, the contents of the win-
dow are not changed. If you specify a window whose class is InputOnly, a Bad-
Match error results.
XClearWindow can generate BadMatch and BadWindow errors.

**DIAGNOSTICS**

- **BadMatch**
  - An InputOnly window is used as a Drawable.

- **BadValue**
  - Some numeric value falls outside the range of values accepted by the request. Unless a specific range is specified for an argument, the full range defined by the argument's type is accepted. Any argument defined as a set of alternatives can generate this error.

- **BadWindow**
  - A value for a Window argument does not name a defined Window.

**SEE ALSO**

- XCopyArea(3X11)

**NAME**

XConfigureWindow, XMoveWindow, XResizeWindow, XMoveResizeWindow, XSetWindowBorderWidth - configure windows

**SYNTAX**

XConfigureWindow(display, w, value_mask, values)
   Display *display;
   Window w;
   unsigned int value_mask;
   XWindowChanges *values;

XMoveWindow(display, w, x, y)
   Display *display;
   Window w;
   int x, y;

XResizeWindow(display, w, width, height)
   Display *display;
   Window w;
   unsigned int width, height;

XMoveResizeWindow(display, w, x, y, width, height)
   Display *display;
   Window w;
   int x, y;
   unsigned int width, height;

XSetWindowBorderWidth(display, w, width)
   Display *display;
   Window w;
   unsigned int width;

**ARGUMENTS**

*display* Specifies the connection to the XWIN server.

*value_mask* Specifies which values are to be set using information in the values structure. This mask is the bitwise inclusive OR of the valid configure window values bits.

*values* Specifies a pointer to the XWindowChanges structure.

*w* Specifies the window to be reconfigured, moved, or resized.

*width* Specifies the width of the window border.

*height* Specify the width and height, which are the interior dimensions of the window.

*x* Specify the x and y coordinates, which define the new location of the top-left pixel of the window’s border or the window itself if it has no border or define the new position of the window relative to its parent.
DESCRIPTION
The XConfigureWindow function uses the values specified in the XWindowChanges structure to reconfigure a window's size, position, border, and stacking order. Values not specified are taken from the existing geometry of the window.

If a sibling is specified without a stack_mode or if the window is not actually a sibling, a BadMatch error results. Note that the computations for BottomIf, TopIf, and Opposite are performed with respect to the window's final geometry (as controlled by the other arguments passed to XConfigureWindow), not its initial geometry. Any backing store contents of the window, its inferiors, and other newly visible windows are either discarded or changed to reflect the current screen contents (depending on the implementation).

XConfigureWindow can generate BadMatch, BadValue, and BadWindow errors.

The XMoveWindow function moves the specified window to the specified x and y coordinates, but it does not change the window's size, raise the window, or change the mapping state of the window. Moving a mapped window may or may not lose the window's contents depending on if the window is obscured by nonchildren and if no backing store exists. If the contents of the window are lost, the XWIN server generates Expose events. Moving a mapped window generates Expose events on any formerly obscured windows.

If the override-redirect flag of the window is False and some other client has selected SubstructureRedirectMask on the parent, the XWIN server generates a ConfigureRequest event, and no further processing is performed. Otherwise, the window is moved.

XMoveWindow can generate a BadWindow error.

The XResizeWindow function changes the inside dimensions of the specified window, not including its borders. This function does not change the window's upper-left coordinate or the origin and does not restack the window. Changing the size of a mapped window may lose its contents and generate Expose events. If a mapped window is made smaller, changing its size generates Expose events on windows that the mapped window formerly obscured.

If the override-redirect flag of the window is False and some other client has selected SubstructureRedirectMask on the parent, the XWIN server generates a ConfigureRequest event, and no further processing is performed. If either width or height is zero, a BadValue error results.

XResizeWindow can generate BadValue and BadWindow errors.

The XMoveResizeWindow function changes the size and location of the specified window without raising it. Moving and resizing a mapped window may generate an Expose event on the window. Depending on the new size and location parameters, moving and resizing a window may generate Expose events on windows that the window formerly obscured.
If the override-redirect flag of the window is False and some other client has selected SubstructureRedirectMask on the parent, the XWIN server generates a ConfigureRequest event, and no further processing is performed. Otherwise, the window size and location are changed.

XMoveResizeWindow can generate BadValue and BadWindow errors.

The XSetWindowBorderWidth function sets the specified window's border width to the specified width.

XSetWindowBorderWidth can generate a BadWindow error.

**DIAGNOSTICS**

- **BadMatch** An InputOnly window is used as a Drawable.
- **BadMatch** Some argument or pair of arguments has the correct type and range but fails to match in some other way required by the request.
- **BadValue** Some numeric value falls outside the range of values accepted by the request. Unless a specific range is specified for an argument, the full range defined by the argument's type is accepted. Any argument defined as a set of alternatives can generate this error.
- **BadWindow** A value for a Window argument does not name a defined Window.

NAME
XCopyArea, XCopyPlane — copy areas

SYNTAX
XCopyArea(display, src, dest, gc, src_x, src_y, width, height, dest_x, dest_y)
   Display *display;
   Drawable src, dest;
   GC gc;
   int src_x, src_y;
   unsigned int width, height;
   int dest_x, dest_y;

XCopyPlane(display, src, dest, gc, src_x, src_y, width, height, dest_x, dest_y, plane)
   Display *display;
   Drawable src, dest;
   GC gc;
   int src_x, src_y;
   unsigned int width, height;
   int dest_x, dest_y;
   unsigned long plane;

ARGUMENTS
dest_x  dest_y  Specify the x and y coordinates, which are relative to the origin
          of the destination rectangle and specify its upper-left corner.

display  Specifies the connection to the XWIN server.

gc  Specifies the GC.

plane  Specifies the bit plane. You must set exactly one bit to 1.

src  dest  Specify the source and destination rectangles to be combined.

src_x  src_y  Specify the x and y coordinates, which are relative to the origin
              of the source rectangle and specify its upper-left corner.

width  height  Specify the width and height, which are the dimensions of both
              the source and destination rectangles.

DESCRIPTION
The XCopyArea function combines the specified rectangle of src with the
specified rectangle of dest. The drawables must have the same root and depth, or
a BadMatch error results.

If regions of the source rectangle are obscured and have not been retained in
backing store or if regions outside the boundaries of the source drawable are
specified, those regions are not copied. Instead, the following occurs on all
corresponding destination regions that are either visible or are retained in backing
store. If the destination is a window with a background other than None,
corresponding regions of the destination are tiled with that background (with
plane-mask of all ones and GXcopy function). Regardless of tiling or whether
the destination is a window or a pixmap, if graphics-exposures is True, then
GraphicsExpose events for all corresponding destination regions are generated. If graphics-exposures is True but no GraphicsExpose events are generated, a NoExpose event is generated. Note that by default graphics-exposures is True in new GCs.

This function uses these GC components: function, plane-mask, subwindow-mode, graphics-exposures, clip-x-origin, clip-y-origin, and clip-mask. XCopyArea can generate BadDrawable, BadGC, and BadMatch errors.

The XCopyPlane function uses a single bit plane of the specified source rectangle combined with the specified GC to modify the specified rectangle of dest. The drawables must have the same root but need not have the same depth. If the drawables do not have the same root, a BadMatch error results. If plane does not have exactly one bit set to 1 and the values of planes must be less than $2^n$, where $n$ is the depth of src, a BadValue error results.

Effectively, XCopyPlane forms a pixmap of the same depth as the rectangle of dest and with a size specified by the source region. It uses the foreground/background pixels in the GC (foreground everywhere the bit plane in src contains a bit set to 1, background everywhere the bit plane in src contains a bit set to 0) and the equivalent of a CopyArea protocol request is performed with all the same exposure semantics. This can also be thought of as using the specified region of the source bit plane as a stipple with a fill-style of FillOpaqueStippled for filling a rectangular area of the destination.

This function uses these GC components: function, plane-mask, foreground, background, subwindow-mode, graphics-exposures, clip-x-origin, clip-y-origin, and clip-mask. XCopyPlane can generate BadDrawable, BadGC, BadMatch, and BadValue errors.

**DIAGNOSTICS**

**BadDrawable**  A value for a Drawable argument does not name a defined Window or Pixmap.

**BadGC**  A value for a GContext argument does not name a defined GContext.

**BadMatch**  An InputOnly window is used as a Drawable.

**BadMatch**  Some argument or pair of arguments has the correct type and range but fails to match in some other way required by the request.

**BadValue**  Some numeric value falls outside the range of values accepted by the request. Unless a specific range is specified for an argument, the full range defined by the argument's type is accepted. Any argument defined as a set of alternatives can generate this error.

NAME
XCreateColormap, XCopyColormapAndFree, XFreeColormap, XSetWindowColor­map – create, copy, or destroy colormaps

SYNTAX
Colormap XCreateColormap(display, w, visual, alloc)
  Display *display;
  Window w;
  Visual *visual;
  int alloc;
Colormap XCopyColormapAndFree(display, colormap)
  Display *display;
  Colormap colormap;
XFreeColormap(display, colormap)
  Display *display;
  Colormap colormap;
XSetWindowColormap(display, w, colormap)
  Display *display;
  Window w;
  Colormap colormap;

ARGUMENTS
alloc Specifies the colormap entries to be allocated. You can pass AllocNone or AllocAll.
colormap Specifies the colormap that you want to create, copy, set, or destroy.
display Specifies the connection to the XWIN server.
visual Specifies a pointer to a visual type supported on the screen. If the visual type is not one supported by the screen, a BadMatch error results.
w Specifies the window for which you want to create or set a colormap.

DESCRIPTION
The XCreateColormap function creates a colormap of the specified visual type for the screen on which the specified window resides and returns the colormap ID associated with it. Note that the specified window is only used to determine the screen.

The initial values of the colormap entries are undefined for the visual classes GrayScale, PseudoColor, and DirectColor. For StaticGray, StaticColor, and TrueColor, the entries have defined values, but those values are specific to the visual and are not defined by X. For StaticGray, StaticColor, and TrueColor, alloc must be AllocNone, or a BadMatch error results. For the other visual classes, if alloc is AllocNone, the colormap initially has no allocated entries, and clients can allocate them. For information about the visual types, see section 3.1, Xlib—C Language X Interface.
If alloc is AllocAll, the entire colormap is allocated writable. The initial values of all allocated entries are undefined. For GrayScale and PseudoColor, the effect is as if an XAllocColorCells call returned all pixel values from zero to \( N - 1 \), where \( N \) is the colormap entries value in the specified visual. For DirectColor, the effect is as if an XAllocColorPlanes call returned a pixel value of zero and red_mask, green_mask, and blue_mask values containing the same bits as the corresponding masks in the specified visual. However, in all cases, none of these entries can be freed by using XFreeColors.

XCreateColormap can generate BadAlloc, BadMatch, BadValue, and BadWindow errors.

The XCopyColormapAndFree function creates a colormap of the same visual type and for the same screen as the specified colormap and returns the new colormap ID. It also moves all of the client's existing allocation from the specified colormap to the new colormap with their color values intact and their read-only or writable characteristics intact and frees those entries in the specified colormap. Color values in other entries in the new colormap are undefined. If the specified colormap was created by the client with alloc set to AllocAll, the new colormap is also created with AllocAll, all color values for all entries are copied from the specified colormap, and then all entries in the specified colormap are freed. If the specified colormap was not created by the client with AllocAll, the allocations to be moved are all those pixels and planes that have been allocated by the client using XAllocColor, XAllocNamedColor, XAllocColorCells, or XAllocColorPlanes and that have not been freed since they were allocated.

XCopyColormapAndFree can generate BadAlloc and BadColor errors.

The XFreeColormap function deletes the association between the colormap resource ID and the colormap and frees the colormap storage. However, this function has no effect on the default colormap for a screen. If the specified colormap is an installed map for a screen, it is uninstalled (see XUninstallColormap). If the specified colormap is defined as the colormap for a window (by XCreateWindow, XSetWindowColormap, or XChangeWindowAttributes), XFreeColormap changes the colormap associated with the window to None and generates a ColormapNotify event. X does not define the colors displayed for a window with a colormap of None.

XFreeColormap can generate a BadColor error.

The XSetWindowColormap function sets the specified colormap of the specified window. The colormap must have the same visual type as the window, or a BadMatch error results.

XSetWindowColormap can generate BadColor, BadMatch, and BadWindow errors.

**DIAGNOSTICS**

XCreateFontCursor, XCreatePixmapCursor, XCreateGlyphCursor – create cursors

SYNTAX

```c
#include <X11/cursorfont.h>

Cursor XCreateFontCursor(display, shape)
    Display *display;
    unsigned int shape;

Cursor XCreatePixmapCursor(display, source, mask, foreground_color, background_color, x, y)
    Display *display;
    Pixmap source;
    Pixmap mask;
    XColor *foreground_color;
    XColor *background_color;
    unsigned int x, y;

Cursor XCreateGlyphCursor(display, source_font, mask_font, source_char, mask_char, foreground_color, background_color)
    Display *display;
    Font source_font, mask_font;
    unsigned int source_char, mask_char;
    XColor *foreground_color;
    XColor *background_color;
```

ARGUMENTS

- `background_color` Specifies the RGB values for the background of the source.
- `display` Specifies the connection to the XWIN server.
- `foreground_color` Specifies the RGB values for the foreground of the source.
- `mask` Specifies the cursor’s source bits to be displayed or None.
- `mask_char` Specifies the glyph character for the mask.
- `mask_font` Specifies the font for the mask glyph or None.
- `shape` Specifies the shape of the cursor.
- `source` Specifies the shape of the source cursor.
- `source_char` Specifies the character glyph for the source.
- `source_font` Specifies the font for the source glyph.
- `x` Specify the x and y coordinates, which indicate the hotspot relative to the source’s origin.

DESCRIPTION

X provides a set of standard cursor shapes in a special font named cursor. Applications are encouraged to use this interface for their cursors because the font can be customized for the individual display type. The shape argument specifies which glyph of the standard fonts to use.
XCreateFontCursor (3X11)

The hotspot comes from the information stored in the cursor font. The initial colors of a cursor are a black foreground and a white background (see XRecolorCursor).

XCreateFontCursor can generate BadAlloc and BadValue errors.

The XCreatePixmapCursor function creates a cursor and returns the cursor ID associated with it. The foreground and background RGB values must be specified using foreground_color and background_color, even if the XWIN server only has a StaticGray or GrayScale screen. The foreground color is used for the pixels set to 1 in the source, and the background color is used for the pixels set to 0. Both source and mask, if specified, must have depth one (or a BadMatch error results) but can have any root. The mask argument defines the shape of the cursor. The pixels set to 1 in the mask define which source pixels are displayed, and the pixels set to 0 define which pixels are ignored. If no mask is given, all pixels of the source are displayed. The mask, if present, must be the same size as the pixmap defined by the source argument, or a BadMatch error results. The hotspot must be a point within the source, or a BadMatch error results.

The components of the cursor can be transformed arbitrarily to meet display limitations. The pixmaps can be freed immediately if no further explicit references to them are to be made. Subsequent drawing in the source or mask pixmap has an undefined effect on the cursor. The XWIN server might or might not make a copy of the pixmap.

XCreatePixmapCursor can generate BadAlloc and BadPixmap errors.

The XCreateGlyphCursor function is similar to XCreatePixmapCursor except that the source and mask bitmaps are obtained from the specified font glyphs. The source_char must be a defined glyph in source_font, or a BadValue error results. If mask_font is given, mask_char must be a defined glyph in mask_font, or a BadValue error results. The mask_font and character are optional. The origins of the source_char and mask_char (if defined) glyphs are positioned coincidently and define the hotspot. The source_char and mask_char need not have the same bounding box metrics, and there is no restriction on the placement of the hotspot relative to the bounding boxes. If no mask_char is given, all pixels of the source are displayed. You can free the fonts immediately by calling XFreeFont if no further explicit references to them are to be made.

For 2-byte matrix fonts, the 16-bit value should be formed with the byte1 member in the most-significant byte and the byte2 member in the least-significant byte.

XCreateGlyphCursor can generate BadAlloc, BadFont, and BadValue errors.

Xlib – C Language X Interface
NAME

XCreateGC, XCopyGC, XChangeGC, XFreeGC, XGContextFromGC - create or free graphics contexts

SYNTAX

GC XCreateGC(display, d, valuemask, values)
   Display *display;
   Drawable d;
   unsigned long valuemask;
   XGCValues *values;

XCopyGC(display, src, valuemask, dest)
   Display *display;
   GC src, dest;
   unsigned long valuemask;

XChangeGC(display, gc, valuemask, values)
   Display *display;
   GC gc;
   unsigned long valuemask;
   XGCValues *values;

XFreeGC(display, gc)
   Display *display;
   GC gc;

GContext XGContextFromGC(gc)
   GC gc;

ARGUMENTS

\textit{d} \quad \text{Specifies the drawable.}
\textit{dest} \quad \text{Specifies the destination GC.}
\textit{display} \quad \text{Specifies the connection to the XWIN server.}
\textit{gc} \quad \text{Specifies the GC.}
\textit{src} \quad \text{Specifies the components of the source GC.}
\textit{valuemask} \quad \text{Specifies which components in the GC are to be set, copied, or changed. This argument is the bitwise inclusive OR of one or more of the valid GC component mask bits.}
\textit{values} \quad \text{Specifies any values as specified by the valuemask.}

DESCRIPTION

The XCreateGC function creates a graphics context and returns a GC. The GC can be used with any destination drawable having the same root and depth as the specified drawable. Use with other drawables results in a \texttt{BadMatch} error.

XCreateGC can generate \texttt{BadAlloc}, \texttt{BadDrawable}, \texttt{BadFont}, \texttt{BadMatch}, \texttt{BadPixmap}, and \texttt{BadValue} errors.

The XCopyGC function copies the specified components from the source GC to the destination GC. The source and destination GCs must have the same root and depth, or a \texttt{BadMatch} error results. The valuemask specifies which component to copy, as for XCreateGC.
XCopyGC can generate BadAlloc, BadGC, and BadMatch errors.

The XChangeGC function changes the components specified by valuemask for the specified GC. The values argument contains the values to be set. The values and restrictions are the same as for XCreateGC. Changing the clip-mask overrides any previous XSetClipRectangles request on the context. Changing the dash-offset or dash-list overrides any previous XSetDashes request on the context. The order in which components are verified and altered is server-dependent. If an error is generated, a subset of the components may have been altered.

XChangeGC can generate BadAlloc, BadFont, BadGC, BadMatch, BadPixmap, and BadValue errors.

The XFreeGC function destroys the specified GC as well as all the associated storage.

XFreeGC can generate a BadGC error.

**DIAGNOSTICS**

<table>

NAME
XCreateImage, XGetPixel, XPutPixel, XSubImage, XAddPixel, XDestroyImage — image utilities

SYNTAX
XImage *XCreateImage(display, visual, depth, format, offset, data, width, height,
bitmap_pad, bytes_per_line)

Display *display;
Visual *visual;
unsigned int depth;
int format;
int offset;
char *data;
unsigned int width;
unsigned int height;
int bitmap_pad;
int bytes_per_line;

unsigned long XGetPixel(ximage, x, y)

XImage *ximage;
int x;
int y;

int XPutPixel(ximage, x, y, pixel)

XImage *ximage;
int x;
int y;
unsigned long pixel;

XImage *XSubImage(ximage, x, y, subimage_width, subimage_height)

XImage *ximage;
int x;
int y;
unsigned int subimage_width;
unsigned int subimage_height;

XAddPixel(ximage, value)

XImage *ximage;
long value;

int XDestroyImage(ximage)

XImage *ximage;

ARGUMENTS

bitmap_pad Specifies the quantum of a scanline (8, 16, or 32). In other words, the start of one scanline is separated in client memory from the start of the next scanline by an integer multiple of this many bits.

bytes_per_line Specifies the number of bytes in the client image between the start of one scanline and the start of the next.
**XCreateImage**

Specifies a pointer to the image data.

**depth**

Specifies the depth of the image.

**display**

Specifies the connection to the XWIN server.

**format**

Specifies the format for the image. You can pass **XYBitmap**, **XYPixmap**, or **ZPixmap**.

**height**

 Specifies the height of the image, in pixels.

**offset**

Specifies the number of pixels to ignore at the beginning of the scanline.

**pixel**

Specifies the new pixel value.

**subimage_height**

Specifies the height of the new subimage, in pixels.

**subimage_width**

Specifies the width of the new subimage, in pixels.

**value**

Specifies the constant value that is to be added.

**visual**

Specifies a pointer to the visual.

**width**

Specifies the width of the image, in pixels.

**ximage**

Specifies a pointer to the image.

**x**

Specify the x and y coordinates.

**y**

**DESCRIPTION**

The **XCreateImage** function allocates the memory needed for an **XImage** structure for the specified display but does not allocate space for the image itself. Rather, it initializes the structure byte-order, bit-order, and bitmap-unit values from the display and returns a pointer to the **XImage** structure. The red, green, and blue mask values are defined for Z format images only and are derived from the **Visual** structure passed in. Other values also are passed in. The offset permits the rapid displaying of the image without requiring each scanline to be shifted into position. If you pass a zero value in **bytes_per_line**, Xlib assumes that the scanlines are contiguous in memory and calculates the value of **bytes_per_line** itself.

Note that when the image is created using **XCreateImage**, **XGetImage**, or **XSubImage**, the destroy procedure that the **XDestroyImage** function calls frees both the image structure and the data pointed to by the image structure.

The basic functions used to get a pixel, set a pixel, create a subimage, and add a constant offset to a Z format image are defined in the image object. The functions in this section are really macro invocations of the functions in the image object and are defined in `<X11/Xutil.h>`.

The **XGetPixel** function returns the specified pixel from the named image. The pixel value is returned in normalized format (that is, the least-significant byte of the long is the least-significant byte of the pixel). The image must contain the x and y coordinates.
The XPutPixel function overwrites the pixel in the named image with the specified pixel value. The input pixel value must be in normalized format (that is, the least-significant byte of the long is the least-significant byte of the pixel). The image must contain the x and y coordinates.

The XSubImage function creates a new image that is a subsection of an existing one. It allocates the memory necessary for the new XImage structure and returns a pointer to the new image. The data is copied from the source image, and the image must contain the rectangle defined by x, y, subimage_width, and subimage_height.

The XAddPixel function adds a constant value to every pixel in an image. It is useful when you have a base pixel value from allocating color resources and need to manipulate the image to that form.

The XDestroyImage function deallocates the memory associated with the XImage structure.

XPutImage(3X11)

Xlib – C Language X Interface
NAME
XCreatePixmap, XFreePixmap – create or destroy pixmaps

SYNTAX
Pixmap XCreatePixmap(display, d, width, height, depth)
   Display *display;
   Drawable d;
   unsigned int width, height;
   unsigned int depth;
XFreePixmap(display, pixmap)
   Display *display;
  Pixmap pixmap;

ARGUMENTS
   d          Specifies which screen the pixmap is created on.
   depth      Specifies the depth of the pixmap.
   display    Specifies the connection to the XWIN server.
   pixmap     Specifies the pixmap.
   width      Specify the width and height, which define the dimensions of
   height     the pixmap.

DESCRIPTION
The XCreatePixmap function creates a pixmap of the width, height, and depth
you specified and returns a pixmap ID that identifies it. It is valid to pass an
InputOnly window to the drawable argument. The width and height arguments
must be nonzero, or a BadValue error results. The depth argument must be one
of the depths supported by the screen of the specified drawable, or a BadValue
error results.

The server uses the specified drawable to determine on which screen to create the
pixmap. The pixmap can be used only on this screen and only with other draw­
ables of the same depth (see XCopyPlane for an exception to this rule). The ini­
tial contents of the pixmap are undefined.

XCreatePixmap can generate BadAlloc, BadDrawable, and BadValue errors.

The XFreePixmap function first deletes the association between the pix­
map ID and the pixmap. Then, the XWIN server frees the pixmap storage when there are
no references to it. The pixmap should never be referenced again.

XFreePixmap can generate a BadPixmap error.

DIAGNOSTICS
BadAlloc        The server failed to allocate the requested resource or server
                memory.

BadDrawable     A value for a Drawable argument does not name a defined
                Window orPixmap.
BadPixmap

A value for a Pixmap argument does not name a defined Pixmap.

BadValue

Some numeric value falls outside the range of values accepted by the request. Unless a specific range is specified for an argument, the full range defined by the argument's type is accepted. Any argument defined as a set of alternatives can generate this error.

NAME
  XCreateRegion, XSetRegion, XDestroyRegion – create or destroy regions

SYNTAX
  Region XCreateRegion();
  XSetRegion(display, gc, r)
     Display *display;
     GC gc;
     Region r;
  XDestroyRegion(r)
     Region r;

ARGUMENTS
  display   Specifies the connection to the XWIN server.
  gc        Specifies the GC.
  r         Specifies the region.

DESCRIPTION
  The XCreateRegion function creates a new empty region.
  The XSetRegion function sets the clip-mask in the GC to the specified region.
  Once it is set in the GC, the region can be destroyed.
  The XDestroyRegion function deallocates the storage associated with a specified
  region.

NAME

XCreateWindow, XCreateSimpleWindow – create windows

SYNTAX

Window XCreateWindow(display, parent, x, y, width, height, border_width, depth, class, visual, valuemask, attributes)

Display *display;
Window parent;
int x, y;
unsigned int width, height;
unsigned int border_width;
int depth;
unsigned int class;
Visual *visual
unsigned long valuemask;
XSetWindowAttributes *attributes;

Window XCreateSimpleWindow(display, parent, x, y, width, height, border_width, border, background)

Display *display;
Window parent;
int x, y;
unsigned int width, height;
unsigned int border_width;
unsigned long border;
unsigned long background;

ARGUMENTS

attributes Specifies the structure from which the values (as specified by the value mask) are to be taken. The value mask should have the appropriate bits set to indicate which attributes have been set in the structure.

background Specifies the background pixel value of the window.

border Specifies the border pixel value of the window.

border_width Specifies the width of the created window’s border in pixels.

class Specifies the created window’s class. You can pass InputOutput, InputOnly, or CopyFromParent. A class of CopyFromParent means the class is taken from the parent.

depth Specifies the window’s depth. A depth of CopyFromParent means the depth is taken from the parent.

display Specifies the connection to the XWIN server.

parent Specifies the parent window.

valuemask Specifies which window attributes are defined in the attributes argument. This mask is the bitwise inclusive OR of the valid attribute mask bits. If valuemask is zero, the attributes are ignored and are not referenced.
visual

Specifies the visual type. A visual of CopyFromParent means the visual type is taken from the parent.

width
height

Specify the width and height, which are the created window's inside dimensions and do not include the created window's borders.

x
y

Specify the x and y coordinates, which are the top-left outside corner of the window's borders and are relative to the inside of the parent window's borders.

DESCRIPTION

The XCreateWindow function creates an unmapped subwindow for a specified parent window, returns the window ID of the created window, and causes the XWIN server to generate a CreateNotify event. The created window is placed on top in the stacking order with respect to siblings.

The border_width for an InputOnly window must be zero, or a BadMatch error results. For class InputOutput, the visual type and depth must be a combination supported for the screen, or a BadMatch error results. The depth need not be the same as the parent, but the parent must not be a window of class InputOnly, or a BadMatch error results. For an InputOnly window, the depth must be zero, and the visual must be one supported by the screen. If either condition is not met, a BadMatch error results. The parent window, however, may have any depth and class. If you specify any invalid window attribute for a window, a BadMatch error results.

The created window is not yet displayed (mapped) on the user's display. To display the window, call XMapWindow. The new window initially uses the same cursor as its parent. A new cursor can be defined for the new window by calling XCreateFontCursor. The window will not be visible on the screen unless it and all of its ancestors are mapped and it is not obscured by any of its ancestors.

XCreateWindow can generate BadAlloc BadColor, BadCursor, BadMatch, BadPixmap, BadValue, and BadWindow errors.

The XCreateSimpleWindow function creates an unmapped InputOutput subwindow for a specified parent window, returns the window ID of the created window, and causes the XWIN server to generate a CreateNotify event. The created window is placed on top in the stacking order with respect to siblings. Any part of the window that extends outside its parent window is clipped. The border_width for an InputOnly window must be zero, or a BadMatch error results. XCreateSimpleWindow inherits its depth, class, and visual from its parent. All other window attributes, except background and border, have their default values.

XCreateSimpleWindow can generate BadAlloc, BadMatch, BadValue, and BadWindow errors.
DIAGNOSTICS

BadAlloc  The server failed to allocate the requested resource or server memory.

BadColor  A value for a Colormap argument does not name a defined Colormap.

BadCursor A value for a Cursor argument does not name a defined Cursor.

BadMatch  The values do not exist for an InputOnly window.

BadMatch  Some argument or pair of arguments has the correct type and range but fails to match in some other way required by the request.

BadPixmap A value for a Pixmap argument does not name a defined Pixmap.

BadValue  Some numeric value falls outside the range of values accepted by the request. Unless a specific range is specified for an argument, the full range defined by the argument's type is accepted. Any argument defined as a set of alternatives can generate this error.

BadWindow A value for a Window argument does not name a defined Window.

XDefineCursor (3X11)

NAME
XDefineCursor, XUndefineCursor – define cursors

SYNTAX
XDefineCursor(display, w, cursor)
   Display *display;
   Window w;
   Cursor cursor;
XUndefineCursor(display, w)
   Display *display;
   Window w;

ARGUMENTS
   cursor       Specifies the cursor that is to be displayed or None.
   display      Specifies the connection to the XWIN server.
   w            Specifies the window.

DESCRIPTION
If a cursor is set, it will be used when the pointer is in the window. If the cursor
is None, it is equivalent to XUndefineCursor.

XDefineCursor can generate BadCursor and BadWindow errors.
The XUndefineCursor undoes the effect of a previous XDefineCursor for this
window. When the pointer is in the window, the parent’s cursor will now be
used. On the root window, the default cursor is restored.

XUndefineCursor can generate a BadWindow error.

DIAGNOSTICS
   BadAlloc     The server failed to allocate the requested resource or server
                memory.
   BadCursor    A value for a Cursor argument does not name a defined Cursor.
   BadWindow    A value for a Window argument does not name a defined Window.

**NAME**

XDestroyWindow, XDestroySubwindows – destroy windows

**SYNTAX**

XDestroyWindow(display, w)
  
  Display *display;
  Window w;

XDestroySubwindows(display, w)
  
  Display *display;
  Window w;

**ARGUMENTS**

  - **display** Specifies the connection to the XWIN server.
  - **w** Specifies the window.

**DESCRIPTION**

The XDestroyWindow function destroys the specified window as well as all of its subwindows and causes the XWIN server to generate a DestroyNotify event for each window. The window should never be referenced again. If the window specified by the w argument is mapped, it is unmapped automatically. The ordering of the DestroyNotify events is such that for any given window being destroyed, DestroyNotify is generated on any inferiors of the window before being generated on the window itself. The ordering among siblings and across subhierarchies is not otherwise constrained. If the window you specified is a root window, no windows are destroyed. Destroying a mapped window will generate Expose events on other windows that were obscured by the window being destroyed.

XDestroyWindow can generate a BadWindow error.

The XDestroySubwindows function destroys all inferior windows of the specified window, in bottom-to-top stacking order. It causes the XWIN server to generate a DestroyNotify event for each window. If any mapped subwindows were actually destroyed, XDestroySubwindows causes the XWIN server to generate Expose events on the specified window. This is much more efficient than deleting many windows one at a time because much of the work need be performed only once for all of the windows, rather than for each window. The subwindows should never be referenced again.

XDestroySubwindows can generate a BadWindow error.

**DIAGNOSTICS**

- **BadWindow** A value for a Window argument does not name a defined Window.

**SEE ALSO**

Xlib – C Language X Interface
NAME
XDrawArc, XDrawArcs - draw arcs

SYNTAX
XDrawArc(display, d, gc, x, y, width, height, angle1, angle2)
   Display *display;
   Drawable d;
   GC gc;
   int x, y;
   unsigned int width, height;
   int angle1, angle2;

XDrawArcs(display, d, gc, arcs, narcs)
   Display *display;
   Drawable d;
   GC gc;
   XArc *arcs;
   int narcs;

ARGUMENTS
angle1 Specifies the start of the arc relative to the three-o’clock position
from the center, in units of degrees * 64.
angle2 Specifies the path and extent of the arc relative to the start of
the arc, in units of degrees * 64.
arcs Specifies a pointer to an array of arcs.
d Specifies the drawable.
display Specifies the connection to the XWIN server.
 gc Specifies the GC.
narcs Specifies the number of arcs in the array.
width Specify the width and height, which are the major and minor
height axes of the arc.
x y Specify the x and y coordinates, which are relative to the origin
of the drawable and specify the upper-left corner of the bound-
ing rectangle.

DESCRIPTION
XDrawArc draws a single circular or elliptical arc, and XDrawArcs draws multi-
ple circular or elliptical arcs. Each arc is specified by a rectangle and two angles.
The center of the circle or ellipse is the center of the rectangle, and the major and
minor axes are specified by the width and height. Positive angles indicate coun-
terclockwise motion, and negative angles indicate clockwise motion. If the magni-
tude of angle2 is greater than 360 degrees, XDrawArc or XDrawArcs truncates it
to 360 degrees.
For an arc specified as \([x, y, \text{width}, \text{height}, \text{angle1}, \text{angle2}]\), the origin of the major and minor axes is at \([x + \frac{\text{width}}{2}, y + \frac{\text{height}}{2}]\), and the infinitely thin path describing the entire circle or ellipse intersects the horizontal axis at \([x, y + \frac{\text{height}}{2}]\) and \([x + \frac{\text{height}}{2}, y]\) and intersects the vertical axis at \([x + \frac{\text{width}}{2}, y]\) and \([x, y + \frac{\text{width}}{2}]\). These coordinates can be fractional and so are not truncated to discrete coordinates. The path should be defined by the ideal mathematical path. For a wide line with line-width \(lw\), the bounding outlines for filling are given by the two infinitely thin paths consisting of all points whose perpendicular distance from the path of the circle/ellipse is equal to \(lw/2\) (which may be a fractional value). The cap-style and join-style are applied the same as for a line corresponding to the tangent of the circle/ellipse at the endpoint.

For an arc specified as \([x, y, \text{width}, \text{height}, \text{angle1}, \text{angle2}]\), the angles must be specified in the effectively skewed coordinate system of the ellipse (for a circle, the angles and coordinate systems are identical). The relationship between these angles and angles expressed in the normal coordinate system of the screen (as measured with a protractor) is as follows:

\[
\text{skewed-angle} = \tan(\tan(\text{normal-angle}) \cdot \frac{\text{width}}{\text{height}}) + \text{adjust}
\]

The skewed-angle and normal-angle are expressed in radians (rather than in degrees scaled by 64) in the range \([0, 2\pi]\) and where \(\tan\) returns a value in the range \([-\frac{\pi}{2}, \frac{\pi}{2}]\) and \(\text{adjust}\) is:

0 \hspace{1cm} \text{for normal-angle in the range } [0, \frac{\pi}{2}]
\pi \hspace{1cm} \text{for normal-angle in the range } [\frac{\pi}{2}, \frac{3\pi}{2}]
2\pi \hspace{1cm} \text{for normal-angle in the range } [\frac{3\pi}{2}, 2\pi]

For any given arc, \(\text{XDrawArc}\) and \(\text{XDrawArcs}\) do not draw a pixel more than once. If two arcs join correctly and if the line-width is greater than zero and the arcs intersect, \(\text{XDrawArc}\) and \(\text{XDrawArcs}\) do not draw a pixel more than once. Otherwise, the intersecting pixels of intersecting arcs are drawn multiple times. Specifying an arc with one endpoint and a clockwise extent draws the same pixels as specifying the other endpoint and an equivalent counterclockwise extent, except as it affects joins.

If the last point in one arc coincides with the first point in the following arc, the two arcs will join correctly. If the first point in the first arc coincides with the last point in the last arc, the two arcs will join correctly. By specifying one axis to be zero, a horizontal or vertical line can be drawn. Angles are computed based solely on the coordinate system and ignore the aspect ratio.

Both functions use these GC components: function, plane-mask, line-width, linestyle, cap-style, join-style, fill-style, subwindow-mode, clip-x-origin, clip-y-origin,
and clip-mask. They also use these GC mode-dependent components: foreground, background, tile, stipple, tile-stipple-x-origin, tile-stipple-y-origin, dash-offset, and dash-list.

XDrawArc and XDrawArcs can generate BadDrawable, BadGC, and BadMatch errors.

*Xlib – C Language X Interface*
NAME

XDrawImageString, XDrawImageString16 – draw image text

SYNTAX

XDrawImageString(display, d, gc, x, y, string, length)
   Display *display;
   Drawable d;
   GC gc;
   int x, y;
   char *string;
   int length;

XDrawImageString16(display, d, gc, x, y, string, length)
   Display *display;
   Drawable d;
   GC gc;
   int x, y;
   XChar2b *string;
   int length;

ARGUMENTS

d Specifies the drawable.
display Specifies the connection to the XWIN server.
gc Specifies the GC.
length Specifies the number of characters in the string argument.
string Specifies the character string.
x y Specify the x and y coordinates, which are relative to the origin of the specified drawable and define the origin of the first character.

DESCRIPTION

The XDrawImageString16 function is similar to XDrawImageString except that it uses 2-byte or 16-bit characters. Both functions also use both the foreground and background pixels of the GC in the destination.

The effect is first to fill a destination rectangle with the background pixel defined in the GC and then to paint the text with the foreground pixel. The upper-left corner of the filled rectangle is at:

   [x, y - font-ascent]

The width is:

   overall-width

The height is:

   font-ascent + font-descent

The overall-width, font-ascent, and font-descent are as would be returned by XQueryTextExtents using gc and string. The function and fill-style defined in the GC are ignored for these functions. The effective function is GXcopy, and the effective fill-style is FillSolid.
For fonts defined with 2-byte matrix indexing and used with `XDrawImageString`, each byte is used as a byte2 with a byte1 of zero.

Both functions use these GC components: plane-mask, foreground, background, font, subwindow-mode, clip-x-origin, clip-y-origin, and clip-mask.

`XDrawImageString` and `XDrawImageString16` can generate BadDrawable, BadGC, and BadMatch errors.

**DIAGNOSTICS**

**BadDrawable**  A value for a Drawable argument does not name a defined Window orPixmap.

**BadGC**  A value for a GContext argument does not name a defined GContext.

**BadMatch**  An InputOnly window is used as a Drawable.

**BadMatch**  Some argument or pair of arguments has the correct type and range but fails to match in some other way required by the request.

NAME
XDrawLine, XDrawLines, XDrawSegments – draw lines and polygons

SYNTAX
XDrawLine(display, d, gc, x1, y1, x2, y2)
  Display *display;
  Drawable d;
  GC gc;
  int x1, y1, x2, y2;
XDrawLines(display, d, gc, points, npoints, mode)
  Display *display;
  Drawable d;
  GC gc;
  XPoint *points;
  int npoints;
  int mode;
XDrawSegments(display, d, gc, segments, nsegments)
  Display *display;
  Drawable d;
  GC gc;
  XSegment *segments;
  int nsegments;

ARGUMENTS
  d   Specifies the drawable.
  display Specifies the connection to the XWIN server.
  gc   Specifies the GC.
  mode Specifies the coordinate mode. You can pass CoordModeOrigin or CoordModePrevious.
  npoints Specifies the number of points in the array.
  nsegments Specifies the number of segments in the array.
  points Specifies a pointer to an array of points.
  segments Specifies a pointer to an array of segments.
  x1    Specify the points (x1, y1) and (x2, y2) to be connected.
  y1
  x2
  y2

DESCRIPTION
The XDrawLine function uses the components of the specified GC to draw a line between the specified set of points (x1, y1) and (x2, y2). It does not perform joining at coincident endpoints. For any given line, XDrawLine does not draw a pixel more than once. If lines intersect, the intersecting pixels are drawn multiple times.
The \texttt{XDrawLines} function uses the components of the specified GC to draw \(n\) lines between each pair of points \((\text{point}[i], \text{point}[i+1])\) in the array of \texttt{XPoint} structures. It draws the lines in the order listed in the array. The lines join correctly at all intermediate points, and if the first and last points coincide, the first and last lines also join correctly. For any given line, \texttt{XDrawLines} does not draw a pixel more than once. If thin (zero line-width) lines intersect, the intersecting pixels are drawn multiple times. If wide lines intersect, the intersecting pixels are drawn only once, as though the entire \texttt{PolyLine} protocol request were a single, filled shape. \texttt{CoordModeOrigin} treats all coordinates as relative to the origin, and \texttt{CoordModePrevious} treats all coordinates after the first as relative to the previous point.

The \texttt{XDrawSegments} function draws multiple, unconnected lines. For each segment, \texttt{XDrawSegments} draws a line between \((x_1, y_1)\) and \((x_2, y_2)\). It draws the lines in the order listed in the array of \texttt{XSegment} structures and does not perform joining at coincident endpoints. For any given line, \texttt{XDrawSegments} does not draw a pixel more than once. If lines intersect, the intersecting pixels are drawn multiple times.

All three functions use these GC components: function, plane-mask, line-width, line-style, cap-style, fill-style, subwindow-mode, clip-x-origin, clip-y-origin, and clip-mask. The \texttt{XDrawLines} function also uses the join-style GC component. All three functions also use these GC mode-dependent components: foreground, background, tile, stipple, tile-stipple-x-origin, tile-stipple-y-origin, dash-offset, and dash-list.

\texttt{XDrawLine}, \texttt{XDrawLines}, and \texttt{XDrawSegments} can generate \texttt{BadDrawable}, \texttt{BadGC}, and \texttt{BadMatch} errors. \texttt{XDrawLines} can also generate a \texttt{BadValue} error.

**DIAGNOSTICS**

\begin{itemize}
  \item \texttt{BadDrawable} A value for a Drawable argument does not name a defined Window or Pixmap.
  \item \texttt{BadGC} A value for a GContext argument does not name a defined GContext.
  \item \texttt{BadMatch} An InputOnly window is used as a Drawable.
  \item \texttt{BadMatch} Some argument or pair of arguments has the correct type and range but fails to match in some other way required by the request.
  \item \texttt{BadValue} Some numeric value falls outside the range of values accepted by the request. Unless a specific range is specified for an argument, the full range defined by the argument's type is accepted. Any argument defined as a set of alternatives can generate this error.

XDrawPoint (3X11)

NAME
XDrawPoint, XDrawPoints - draw points

SYNTAX
XDrawPoint(display, d, gc, x, y)
  Display *display;
  Drawable d;
  GC gc;
  int x, y;
XDrawPoints(display, d, gc, points, npoints, mode)
  Display *display;
  Drawable d;
  GC gc;
  XPoint *points;
  int npoints;
  int mode;

ARGUMENTS
  d    Specifies the drawable.
  display Specifies the connection to the XWIN server.
  gc   Specifies the GC.
  mode Specifies the coordinate mode. You can pass CoordModeOrigin or CoordModePrevious.
  npoints Specifies the number of points in the array.
  points Specifies a pointer to an array of points.
  x    Specify the x and y coordinates where you want the point drawn.
  y

DESCRIPTION
The XDrawPoint function uses the foreground pixel and function components of the GC to draw a single point into the specified drawable; XDrawPoints draws multiple points this way. CoordModeOrigin treats all coordinates as relative to the origin, and CoordModePrevious treats all coordinates after the first as relative to the previous point. XDrawPoints draws the points in the order listed in the array.

Both functions use these GC components: function, plane-mask, foreground, subwindow-mode, clip-x-origin, clip-y-origin, and clip-mask.

XDrawPoint can generate BadDrawable, BadGC, and BadMatch errors. XDrawPoint can generate BadDrawable, BadGC, BadMatch, and BadValue errors.

DIAGNOSTICS
BadDrawable A value for a Drawable argument does not name a defined Window orPixmap.
BadGC   A value for a GContext argument does not name a defined GContext.
BadMatch  An InputOnly window is used as a Drawable.
BadMatch  Some argument or pair of arguments has the correct type and range but fails to match in some other way required by the request.
BadValue  Some numeric value falls outside the range of values accepted by the request. Unless a specific range is specified for an argument, the full range defined by the argument's type is accepted. Any argument defined as a set of alternatives can generate this error.

NAME
XDrawRectangle, XDrawRectangles – draw rectangles

SYNTAX
XDrawRectangle(display, d, gc, x, y, width, height)
Display *display;
Drawable d;
GC gc;
int x, y;
unsigned int width, height;

XDrawRectangles(display, d, gc, rectangles, nrectangles)
Display *display;
Drawable d;
GC gc;
XRectangle rectangles[];
int nrectangles;

ARGUMENTS
- d Specifies the drawable.
- display Specifies the connection to the XWIN server.
- gc Specifies the GC.
- nrectangles Specifies the number of rectangles in the array.
- rectangles Specifies a pointer to an array of rectangles.
- width Specify the width and height, which specify the dimensions of the rectangle.
- height
- x Specify the x and y coordinates, which specify the upper-left corner of the rectangle.
- y

DESCRIPTION
The XDrawRectangle and XDrawRectangles functions draw the outlines of the specified rectangle or rectangles as if a five-point PolyLine protocol request were specified for each rectangle:

\[[x,y] [x+width,y] [x+width,y+height] [x,y+height] [x,y]\]

For the specified rectangle or rectangles, these functions do not draw a pixel more than once. XDrawRectangles draws the rectangles in the order listed in the array. If rectangles intersect, the intersecting pixels are drawn multiple times.

Both functions use these GC components: function, plane-mask, line-width, line-style, join-style, fill-style, subwindow-mode, clip-x-origin, clip-y-origin, and clip-mask. They also use these GC mode-dependent components: foreground, background, tile, stipple, tile-stipple-x-origin, tile-stipple-y-origin, dash-offset, and dash-list.

XDrawRectangle and XDrawRectangles can generate BadDrawable, BadGC, and BadMatch errors.
DIAGNOSTICS

BadDrawable A value for a Drawable argument does not name a defined Window or Pixmap.

BadGC A value for a GContext argument does not name a defined GContext.

BadMatch An InputOnly window is used as a Drawable.

BadMatch Some argument or pair of arguments has the correct type and range but fails to match in some other way required by the request.

Xlib – C Language X Interface
NAME
XDrawString, XDrawString16 – draw text characters

SYNTAX
XDrawString(display, d, gc, x, y, string, length)
   Display *display;
   Drawable d;
   GC gc;
   int x, y;
   char *string;
   int length;

XDrawString16(display, d, gc, x, y, string, length)
   Display *display;
   Drawable d;
   GC gc;
   int x, y;
   XChar2b *string;
   int length;

ARGUMENTS
   d           Specifies the drawable.
   display     Specifies the connection to the XWIN server.
   gc          Specifies the GC.
   length      Specifies the number of characters in the string argument.
   string      Specifies the character string.
   x           Specify the x and y coordinates, which are relative to the origin
               of the specified drawable and define the origin of the first char­
               acter.
   y

DESCRIPTION
Each character image, as defined by the font in the GC, is treated as an additional
mask for a fill operation on the drawable. The drawable is modified only where
the font character has a bit set to 1. For fonts defined with 2-byte matrix index­
ing and used with XDrawString16, each byte is used as a byte2 with a byte1 of
zero.

Both functions use these GC components: function, plane-mask, fill-style, font, sub­
window-mode, clip-x-origin, clip-y-origin, and clip-mask. They also use these
GC mode-dependent components: foreground, background, tile, stipple, tile­
stipple-x-origin, and tile-stipple-y-origin.

XDrawString and XDrawString16 can generate BadDrawable, BadGC, and
BadMatch errors.

DIAGNOSTICS
   BadDrawable   A value for a Drawable argument does not name a defined
                 Window or Pixmap.
BadGC  A value for a GContext argument does not name a defined GContext.

BadMatch  An InputOnly window is used as a Drawable.

BadMatch  Some argument or pair of arguments has the correct type and range but fails to match in some other way required by the request.

SEE ALSO
XDrawImageString(3X11),
XDrawText(3X11),
Xlib – C Language X Interface
NAME
XDrawText, XDrawText16 — draw polytext text

SYNTAX
XDrawText(display, d, gc, x, y, items, nitems)
   Display *display;
   Drawable d;
   GC gc;
   int x, y;
   XTextItem *items;
   int nitems;

XDrawText16(display, d, gc, x, y, items, nitems)
   Display *display;
   Drawable d;
   GC gc;
   int x, y;
   XTextItem16 *items;
   int nitems;

ARGUMENTS
   d          Specifies the drawable.
   display    Specifies the connection to the XWIN server.
   gc         Specifies the GC.
   items      Specifies a pointer to an array of text items.
   nitems     Specifies the number of text items in the array.
   x          Specify the x and y coordinates, which are relative to the origin of the specified drawable and define the origin of the first character.
   y

DESCRIPTION
The XDrawText16 function is similar to XDrawText except that it uses 2-byte or 16-bit characters. Both functions allow complex spacing and font shifts between counted strings.

Each text item is processed in turn. A font member other than None in an item causes the font to be stored in the GC and used for subsequent text. A text element delta specifies an additional change in the position along the x axis before the string is drawn. The delta is always added to the character origin and is not dependent on any characteristics of the font. Each character image, as defined by the font in the GC, is treated as an additional mask for a fill operation on the drawable. The drawable is modified only where the font character has a bit set to 1. If a text item generates a BadFont error, the previous text items may have been drawn.

For fonts defined with linear indexing rather than 2-byte matrix indexing, each XChar2b structure is interpreted as a 16-bit number with byte1 as the most-significant byte.
Both functions use these GC components: function, plane-mask, fill-style, font, subwindow-mode, clip-x-origin, clip-y-origin, and clip-mask. They also use these GC mode-dependent components: foreground, background, tile, stipple, tile-stipple-x-origin, and tile-stipple-y-origin.

**XDrawText** and **XDrawText16** can generate **BadDrawable**, **BadFont**, **BadGC**, and **BadMatch** errors.

### DIAGNOSTICS

- **BadDrawable**
  
  A value for a Drawable argument does not name a defined Window or Pixmap.

- **BadFont**
  
  A value for a Font or GContext argument does not name a defined Font.

- **BadGC**
  
  A value for a GContext argument does not name a defined GContext.

- **BadMatch**
  
  An InputOnly window is used as a Drawable.

NAME
XEmptyRegion, XEqualRegion, XPointInRegion, XRectInRegion – determine if regions are empty or equal

SYNTAX
Bool XEmptyRegion(r)
    Region r;
Bool XEqualRegion(r1, r2)
    Region r1, r2;
Bool XPointInRegion(r, x, y)
    Region r;
    int x, y;
int XRectInRegion(r, x, y, width, height)
    Region r;
    int x, y;
    unsigned int width, height;

ARGUMENTS
r
    Specifies the region.
r1
r2
    Specify the two regions.
width
height
    Specify the width and height, which define the rectangle.
x
y
    Specify the x and y coordinates, which define the point or the coordinates of the upper-left corner of the rectangle.

DESCRIPTION
The XEmptyRegion function returns True if the region is empty.
The XEqualRegion function returns True if the two regions have the same offset, size, and shape.
The XPointInRegion function returns True if the point (x, y) is contained in the region r.
The XRectInRegion function returns RectangleIn if the rectangle is entirely in the specified region, RectangleOut if the rectangle is entirely out of the specified region, and RectanglePart if the rectangle is partially in the specified region.

NAME
XFillRectangle, XFillRectangles, XFillPolygon, XFillArc, XFillArcs – fill rectangles, polygons, or arcs

SYNTAX
XFillRectangle(display, d, gc, x, y, width, height)
   Display *display;
   Drawable d;
   GC gc;
   int x, y;
   unsigned int width, height;

XFillRectangles(display, d, gc, rectangles, nrectangles)
   Display *display;
   Drawable d;
   GC gc;
   XRectangle *rectangles;
   int nrectangles;

XFillPolygon(display, d, gc, points, npoints, shape, mode)
   Display *display;
   Drawable d;
   GC gc;
   XPoint *points;
   int npoints;
   int shape;
   int mode;

XFillArc(display, d, gc, x, y, width, height, angle1, angle2)
   Display *display;
   Drawable d;
   GC gc;
   int x, y;
   unsigned int width, height;
   int angle1, angle2;

XFillArcs(display, d, gc, arcs, narcs)
   Display *display;
   Drawable d;
   GC gc;
   XArc *arcs;
   int narcs;

ARGUMENTS
angle1 Specifies the start of the arc relative to the three-o’clock position from the center, in units of degrees * 64.

angle2 Specifies the path and extent of the arc relative to the start of the arc, in units of degrees * 64.

arcs Specifies a pointer to an array of arcs.
The XFillRectangle and XFillRectangles functions fill the specified rectangle or rectangles as if a four-point FillPolygon protocol request were specified for each rectangle:
\[(x, y) [x+width, y] [x+width, y+height] [x, y+height]\]
Each function uses the x and y coordinates, width and height dimensions, and GC you specify.

XFillRectangles fills the rectangles in the order listed in the array. For any given rectangle, XFillRectangle and XFillRectangles do not draw a pixel more than once. If rectangles intersect, the intersecting pixels are drawn multiple times.

Both functions use these GC components: function, plane-mask, fill-style, subwindow-mode, clip-x-origin, clip-y-origin, and clip-mask. They also use these GC mode-dependent components: foreground, background, tile, stipple, tile-stipple-x-origin, and tile-stipple-y-origin.

XFillRectangle and XFillRectangles can generate BadDrawable, BadGC, and BadMatch errors.

XFillPolygon fills the region closed by the specified path. The path is closed automatically if the last point in the list does not coincide with the first point. XFillPolygon does not draw a pixel of the region more than once. CoordModeOrigin treats all coordinates as relative to the origin, and CoordModePrevious treats all coordinates after the first as relative to the previous point.
Depending on the specified shape, the following occurs:

- If shape is **Complex**, the path may self-intersect.
- If shape is **Convex**, the path is wholly convex. If known by the client, specifying Convex can improve performance. If you specify Convex for a path that is not convex, the graphics results are undefined.
- If shape is **Nonconvex**, the path does not self-intersect, but the shape is not wholly convex. If known by the client, specifying Nonconvex instead of Complex may improve performance. If you specify Nonconvex for a self-intersecting path, the graphics results are undefined.

The fill-rule of the GC controls the filling behavior of self-intersecting polygons.

This function uses these GC components: function, plane-mask, fill-style, fill-rule, subwindow-mode, clip-x-origin, clip-y-origin, and clip-mask. It also uses these GC mode-dependent components: foreground, background, tile, stipple, tile-stipple-x-origin, and tile-stipple-y-origin.

**XFillPolygon** can generate BadDrawable, BadGC, BadMatch, and BadValue errors.

For each arc, **XFillArc** or **XFillArcs** fills the region closed by the infinitely thin path described by the specified arc and, depending on the arc-mode specified in the GC, one or two line segments. For ArcChord, the single line segment joining the endpoints of the arc is used. For ArcPieSlice, the two line segments joining the endpoints of the arc with the center point are used. **XFillArcs** fills the arcs in the order listed in the array. For any given arc, **XFillArc** and **XFillArcs** do not draw a pixel more than once. If regions intersect, the intersecting pixels are drawn multiple times.

Both functions use these GC components: function, plane-mask, fill-style, arc-mode, subwindow-mode, clip-x-origin, clip-y-origin, and clip-mask. They also use these GC mode-dependent components: foreground, background, tile, stipple, tile-stipple-x-origin, and tile-stipple-y-origin.

**XFillArc** and **XFillArcs** can generate BadDrawable, BadGC, and BadMatch errors.

XDrawArc(3X11),
XDrawRectangle(3X11)
Xlib – C Language X Interface
NAME
XFlush, XSync, XEventsQueued, XPending – handle output buffer or event queue

SYNTAX
XFlush(display)
    Display *display;
XSync(display, discard)
    Display *display;
    Bool discard;
int XEventsQueued(display, mode)
    Display *display;
    int mode;
int XPending(display)
    Display *display;

ARGUMENTS
discard Specifies a Boolean value that indicates whether XSync discards all events on the event queue.
display Specifies the connection to the XWIN server.
mode Specifies the mode. You can pass QueuedAlready, QueuedAfterFlush, or QueuedAfterReading.

DESCRIPTION
The XFlush function flushes the output buffer. Most client applications need not use this function because the output buffer is automatically flushed as needed by calls to XPending, XNextEvent, and XWindowEvent. Events generated by the server may be enqueued into the library's event queue.

The XSync function flushes the output buffer and then waits until all requests have been received and processed by the XWIN server. Any errors generated must be handled by the error handler. For each error event received by Xlib, XSync calls the client application’s error handling routine (see section 8.12.2, Xlib—C Language X Interface). Any events generated by the server are enqueued into the library’s event queue.

Finally, if you passed False, XSync does not discard the events in the queue. If you passed True, XSync discards all events in the queue, including those events that were on the queue before XSync was called. Client applications seldom need to call XSync.

If mode is QueuedAlready, XEventsQueued returns the number of events already in the event queue (and never performs a system call). If mode is QueuedAfterFlush, XEventsQueued returns the number of events already in the queue if the number is nonzero. If there are no events in the queue, XEventsQueued flushes the output buffer, attempts to read more events out of the application’s connection, and returns the number read. If mode is QueuedAfterReading, XEventsQueued returns the number of events already in the queue if the number is nonzero. If there are no events in the queue, XEventsQueued attempts to read more events out of the application’s connection without flushing the output buffer and returns the number read.
XEventsQueued always returns immediately without I/O if there are events already in the queue. XEventsQueued with mode QueuedAfterFlush is identical in behavior to XPending. XEventsQueued with mode QueuedAlready is identical to the XQLength function.

The XPending function returns the number of events that have been received from the XWIN server but have not been removed from the event queue. XPending is identical to XEventsQueued with the mode QueuedAfterFlush specified.

NAME
   XFree, XNoOp – free client data

SYNTAX
   XFree(data)
       char *data;
   XNoOp(display)
       Display *display;

ARGUMENTS
   display    Specifies the connection to the XWIN server.
   data       Specifies a pointer to the data that is to be freed.

DESCRIPTION
   The XFree function is a general-purpose Xlib routine that frees the specified data. You must use it to free any objects that were allocated by Xlib.
   The XNoOp function sends a NoOperation protocol request to the XWIN server, thereby exercising the connection.

SEE ALSO
   Xlib – C Language X Interface
NAME

XGetDefault, XResourceManagerString - get X program defaults

SYNTAX

char *XGetDefault(display, program, option)

Display *display;
char *program;
char *option;

char *XResourceManagerString(display)

Display *display;

ARGUMENTS

display Specifies the connection to the XWIN server.

option Specifies the option name.

program Specifies the program name for the Xlib defaults (usually argv[0] of the main program).

DESCRIPTION

The XGetDefault function returns the value NULL if the option name specified in this argument does not exist for the program. The strings returned by XGetDefault are owned by Xlib and should not be modified or freed by the client.

The XResourceManagerString returns the RESOURCE_MANAGER property from the server's root window of screen zero, which was returned when the connection was opened using XOpenDisplay.

NAME

XrmGetResource, XrmQGetResource, XrmQGetSearchList, XrmQGetSearchResource — retrieve database resources and search lists

SYNTAX

Bool XrmGetResource(database, str_name, str_class, str_type_return, value_return)

XrmDatabase database;
char *str_name;
char *str_class;
char **str_type_return;
XrmValue *value_return;

Bool XrmQGetResource(database, quark_name, quark_class, quark_type_return, value_return)

XrmDatabase database;
XrmNameList quark_name;
XrmClassList quark_class;
XrmRepresentation *quark_type_return;
XrmValue *value_return;

typedef XrmHashTable *XrmSearchList;

Bool XrmQGetSearchList(database, names, classes, list_return, list_length)

XrmDatabase database;
XrmNameList names;
XrmClassList classes;
XrmSearchList list_return;
int list_length;

Bool XrmQGetSearchResource(list, name, class, type_return, value_return)

XrmSearchList list;
XrmName name;
XrmClass class;
XrmRepresentation *type_return;
XrmValue *value_return;

ARGUMENTS

class Specifies the resource class.
classes Specifies a list of resource classes.
database Specifies the database that is to be used.
list Specifies the search list returned by XrmQGetSearchList.
list_length Specifies the number of entries (not the byte size) allocated for list_return.
list_return Returns a search list for further use.
name Specifies the resource name.
names Specifies a list of resource names.
The XrmGetResource and XrmQGetResource functions retrieve a resource from the specified database. Both take a fully qualified name/class pair, a destination resource representation, and the address of a value (size/address pair). The value and returned type point into database memory; therefore, you must not modify the data.

The database only frees or overwrites entries on XrmPutResource, XrmQPutResource, or XrmMergeDatabases. A client that is not storing new values into the database or is not merging the database should be safe using the address passed back at any time until it exits. If a resource was found, both XrmGetResource and XrmQGetResource return True; otherwise, they return False.

The XrmQGetSearchList function takes a list of names and classes and returns a list of database levels where a match might occur. The returned list is in best-to-worst order and uses the same algorithm as XrmGetResource for determining precedence. XrmQGetSearchList returns True if list_return was large enough for the search list, otherwise, it returns False.

The size of the search list that the caller must allocate is dependent upon the number of levels and wildcards in the resource specifiers that are stored in the database. The worst case length is $3^n$, where $n$ is the number of name or class components in names or classes.

When using XrmQGetSearchList followed by multiple probes for resources with a common name and class prefix, only the common prefix should be specified in the name and class list to XrmQGetSearchList.

The XrmQGetSearchResource function searches the specified database levels for the resource that is fully identified by the specified name and class. The search stops with the first match. XrmQGetSearchResource returns True if the resource was found; otherwise, it returns False.
A call to XrmQGetSearchList with a name and class list containing all but the last component of a resource name followed by a call to XrmQGetSearchResource with the last component name and class returns the same database entry as XrmGetResource and XrmQGetResource with the fully qualified name and class.

NAME
XGetVisualInfo, XMatchVisualInfo, XVisualIDFromVisual — obtain visual information

SYNTAX

**XVisualInfo **XGetVisualInfo(**display**, **vinfo_mask**, **vinfo_template**, **nitems_return**)

- Display **display**;
- long **vinfo_mask**;
- XVisualInfo **vinfo_template**;
- int **nitems_return**;

Status XMatchVisualInfo(**display**, **screen**, **depth**, **class**, **vinfo_return**)

- Display **display**;
- int **screen**;
- int **depth**;
- int **class**;
- XVisualInfo **vinfo_return**;

VisualID XVisualIDFromVisual(**visual**)

- Visual **visual**;

ARGUMENTS

- **class** Specifies the class of the screen.
- **depth** Specifies the depth of the screen.
- **display** Specifies the connection to the XWIN server.
- **nitems_return** Returns the number of matching visual structures.
- **screen** Specifies the screen.
- **visual** Specifies the visual type.
- **vinfo_mask** Specifies the visual mask value.
- **vinfo_return** Returns the matched visual information.
- **vinfo_template** Specifies the visual attributes that are to be used in matching the visual structures.

DESCRIPTION

The XGetVisualInfo function returns a list of visual structures that match the attributes specified by vinfo_template. If no visual structures match the template using the specified vinfo_mask, XGetVisualInfo returns a NULL. To free the data returned by this function, use XFree.

The XMatchVisualInfo function returns the visual information for a visual that matches the specified depth and class for a screen. Because multiple visuals that match the specified depth and class can exist, the exact visual chosen is undefined. If a visual is found, XMatchVisualInfo returns nonzero and the information on the visual to vinfo_return. Otherwise, when a visual is not found, XMatchVisualInfo returns zero.

The XVisualIDFromVisual function returns the visual ID for the specified visual type.
SEE ALSO

Xlib – C Language X Interface
NAME

XGetWindowAttributes, XGetGeometry — get current window attribute or geometry

SYNTAX

Status XGetWindowAttributes(display, w, window_attributes_return)
    Display *display;
    Window w;
    XWindowAttributes *window_attributes_return;

Status XGetGeometry(display, d, root_return, x_return, y_return, width_return, 
    height_return, border_width_return, depth_return)
    Display *display;
    Drawable d;
    Window *root_return;
    int *x_return, *y_return;
    unsigned int *width_return, *height_return;
    unsigned int *border_width_return;
    unsigned int *depth_return;

ARGUMENTS

border_width_return
    Returns the border width in pixels.

d
    Specifies the drawable, which can be a window or a pixmap.

depth_return
    Returns the depth of the drawable (bits per pixel for the object).

display
    Specifies the connection to the XWIN server.

root_return
    Returns the root window.

w
    Specifies the window whose current attributes you want to obtain.

width_return
    Return the drawable’s dimensions (width and height).

height_return
    Return the drawable’s dimensions (width and height).

window_attributes_return
    Returns the specified window’s attributes in the XWindowAttributes structure.

x_return
    Return the x and y coordinates that define the location of the drawable. For a window, these coordinates specify the upper-left outer corner relative to its parent’s origin. For pixmaps, these coordinates are always zero.

y_return
    Return the x and y coordinates that define the location of the drawable. For a window, these coordinates specify the upper-left outer corner relative to its parent’s origin. For pixmaps, these coordinates are always zero.

DESCRIPTION

The XGetWindowAttributes function returns the current attributes for the specified window to an XWindowAttributes structure.

XGetWindowAttributes can generate BadDrawable and BadWindow errors.

The XGetGeometry function returns the root window and the current geometry of the drawable. The geometry of the drawable includes the x and y coordinates, width and height, border width, and depth. These are described in the argument list. It is legal to pass to this function a window whose class is InputOnly.
DIAGNOSTICS

BadDrawable  A value for a Drawable argument does not name a defined Window or Pixmap.

BadWindow   A value for a Window argument does not name a defined Window.

NAME
XGetWindowProperty, XListProperties, XChangeProperty, XRotateWindowProperties, XDeleteProperty – obtain and change window properties

SYNTAX
int XGetWindowProperty(display, w, property, long_offset, long_length, delete, 
   req_type, actual_type_return, actual_format_return, nitems_return, 
   bytes_after_return, prop_return)
   Display *display;
   Window w;
   Atom property;
   long long_offset, long_length;
   Bool delete;
   Atom req_type;
   Atom *actual_type_return;
   int *actual_format_return;
   unsigned long *nitems_return;
   unsigned long *bytes_after_return;
   unsigned char **prop_return;

Atom *XListProperties(display, w, num_prop_return)
   Display *display;
   Window w;
   int *num_prop_return;

XChangeProperty(display, w, property, type, format, mode, data, nelements)
   Display *display;
   Window w;
   Atom property, type;
   int format;
   int mode;
   unsigned char *data;
   int nelements;

XRotateWindowProperties(display, w, properties, num_prop, npositions)
   Display *display;
   Window w;
   Atom properties[];
   int num_prop;
   int npositions;

XDeleteProperty(display, w, property)
   Display *display;
   Window w;
   Atom property;

ARGUMENTS
actual_format_return
Returns the actual format of the property.
actual_type_return

Returns the atom identifier that defines the actual type of the property.

bytes_after_return

Returns the number of bytes remaining to be read in the property if a partial read was performed.

data

Specifies the property data.

delete

Specifies a Boolean value that determines whether the property is deleted.

display

Specifies the connection to the XWIN server.

format

Specifies whether the data should be viewed as a list of 8-bit, 16-bit, or 32-bit quantities. Possible values are 8, 16, and 32. This information allows the XWIN server to correctly perform byte-swap operations as necessary. If the format is 16-bit or 32-bit, you must explicitly cast your data pointer to a (char *) in the call to XChangeProperty.

long_length

Specifies the length in 32-bit multiples of the data to be retrieved.

long_offset

Specifies the offset in the specified property (in 32-bit quantities) where the data is to be retrieved.

mode

Specifies the mode of the operation. You can pass PropModeReplace, PropModePrepend, or PropModeAppend.

nelements

Specifies the number of elements of the specified data format.

nitems_return

Returns the actual number of 8-bit, 16-bit, or 32-bit items stored in the prop_return data.

num_prop

Specifies the length of the properties array.

num_prop_return

Returns the length of the properties array.

npositions

Specifies the rotation amount.

prop_return

Returns a pointer to the data in the specified format.

property

Specifies the property name.

properties

Specifies the array of properties that are to be rotated.

req_type

Specifies the atom identifier associated with the property type or AnyPropertyType.

type

Specifies the type of the property. The XWIN server does not interpret the type but simply passes it back to an application that later calls XGetWindowProperty.

w

Specifies the window whose property you want to obtain, change, rotate or delete.
DESCRIPTION

The XGetWindowProperty function returns the actual type of the property; the actual format of the property; the number of 8-bit, 16-bit, or 32-bit items transferred; the number of bytes remaining to be read in the property; and a pointer to the data actually returned. XGetWindowProperty sets the return arguments as follows:

- If the specified property does not exist for the specified window, XGetWindowProperty returns None to actual_type_return and the value zero to actual_format_return and bytes_after_return. The nitems_return argument is empty. In this case, the delete argument is ignored.

- If the specified property exists but its type does not match the specified type, XGetWindowProperty returns the actual property type to actual_type_return, the actual property format (never zero) to actual_format_return, and the property length in bytes (even if the actual_format_return is 16 or 32) to bytes_after_return. It also ignores the delete argument. The nitems_return argument is empty.

- If the specified property exists and either you assign AnyPropertyType to the req_type argument or the specified type matches the actual property type, XGetWindowProperty returns the actual property type to actual_type_return and the actual property format (never zero) to actual_format_return. It also returns a value to bytes_after_return and nitems_return, by defining the following values:

\[N = \text{actual length of the stored property in bytes}\]
\[(\text{even if the format is 16 or 32)}\]
\[I = 4 \times \text{long_offset}\]
\[T = N - I\]
\[L = \text{MINIMUM}(T, 4 \times \text{long_length})\]
\[A = N - (I + L)\]

The returned value starts at byte index I in the property (indexing from zero), and its length in bytes is L. If the value for long_offset causes L to be negative, a BadValue error results. The value of bytes_after_return is A, giving the number of trailing unread bytes in the stored property.

XGetWindowProperty always allocates one extra byte in prop_return (even if the property is zero length) and sets it to ASCII null so that simple properties consisting of characters do not have to be copied into yet another string before use. If delete is True and bytes_after_return is zero, XGetWindowProperty deletes the property from the window and generates a PropertyNotify event on the window.

The function returns Success if it executes successfully. To free the resulting data, use XFree.

XGetWindowProperty can generate BadAtom, BadValue, and BadWindow errors.
The XListProperties function returns a pointer to an array of atom properties that are defined for the specified window or returns NULL if no properties were found. To free the memory allocated by this function, use XFree.

XListProperties can generate a BadWindow error.

The XChangeProperty function alters the property for the specified window and causes the XWIN server to generate a PropertyNotify event on that window. XChangeProperty performs the following:

- If mode is PropModeReplace, XChangeProperty discards the previous property value and stores the new data.
- If mode is PropModePrepend or PropModeAppend, XChangeProperty inserts the specified data before the beginning of the existing data or onto the end of the existing data, respectively. The type and format must match the existing property value, or a BadMatch error results. If the property is undefined, it is treated as defined with the correct type and format with zero-length data.

The lifetime of a property is not tied to the storing client. Properties remain until explicitly deleted, until the window is destroyed, or until the server resets. For a discussion of what happens when the connection to the XWIN server is closed, see section 2.5, Xlib—C Language X Interface. The maximum size of a property is server dependent and can vary dynamically depending on the amount of memory the server has available. (If there is insufficient space, a BadAlloc error results.)

XChangeProperty can generate BadAlloc, BadAtom, BadMatch, BadValue, and BadWindow errors.

The XRotateWindowProperties function allows you to rotate properties on a window and causes the XWIN server to generate a PropertyNotify event for each property in the order that they are listed in the array. If an atom occurs more than once in the list or no property with that name is defined for the window, a BadMatch error results. If a BadAtom or BadMatch error results, no properties are changed.

XRotateWindowProperties can generate BadAtom, BadMatch, and BadWindow errors.

The XDeleteProperty function deletes the specified property only if the property was defined on the specified window and causes the XWIN server to generate a PropertyNotify event on the window unless the property does not exist.

XDeleteProperty can generate BadAtom and BadWindow errors.
XGetWindowProperty (3X11)

DIAGNOSTICS

BadAlloc          The server failed to allocate the requested resource or server memory.

BadAtom           A value for an Atom argument does not name a defined Atom.

BadValue          Some numeric value falls outside the range of values accepted by the request. Unless a specific range is specified for an argument, the full range defined by the argument’s type is accepted. Any argument defined as a set of alternatives can generate this error.

BadWindow         A value for a Window argument does not name a defined Window.

NAME
XGrabButton, XUngrabButton – grab pointer buttons

SYNTAX
XGrabButton(display, button, modifiers, grab_window, owner_events, event_mask,
  pointer_mode, keyboard_mode, confine_to, cursor)
  Display *display;
  unsigned int button;
  unsigned int modifiers;
  Window grab_window;
  Bool owner_events;
  unsigned int event_mask;
  int pointer_mode, keyboard_mode;
  Window confine_to;
  Cursor cursor;
XUngrabButton(display, button, modifiers, grab_window)
  Display *display;
  unsigned int button;
  unsigned int modifiers;
  Window grab_window;

ARGUMENTS
button Specifies the pointer button that is to be grabbed or released or AnyButton.
confine_to Specifies the window to confine the pointer in or None.
cursor Specifies the cursor that is to be displayed or None.
display Specifies the connection to the XWIN server.
event_mask Specifies which pointer events are reported to the client. The mask is the bitwise inclusive OR of the valid pointer event mask bits.
grab_window Specifies the grab window.
keyboard_mode Specifies further processing of keyboard events. You can pass GrabModeSync or GrabModeAsync.
modifiers Specifies the set of keymasks or AnyModifier. The mask is the bitwise inclusive OR of the valid keymask bits.
owner_events Specifies a Boolean value that indicates whether the pointer events are to be reported as usual or reported with respect to the grab window if selected by the event mask.
pointer_mode Specifies further processing of pointer events. You can pass GrabModeSync or GrabModeAsync.

DESCRIPTION
The XGrabButton function establishes a passive grab. In the future, the pointer is actively grabbed (as for XGrabPointer), the last-pointer-grab time is set to the time at which the button was pressed (as transmitted in the ButtonPress event), and the ButtonPress event is reported if all of the following conditions are true:
• The pointer is not grabbed, and the specified button is logically pressed when the specified modifier keys are logically down, and no other buttons or modifier keys are logically down.
• The grab_window contains the pointer.
• The confine_to window (if any) is viewable.
• A passive grab on the same button/key combination does not exist on any ancestor of grab_window.

The interpretation of the remaining arguments is as for XGrabPointer. The active grab is terminated automatically when the logical state of the pointer has all buttons released (independent of the state of the logical modifier keys).

Note that the logical state of a device (as seen by client applications) may lag the physical state if device event processing is frozen.

This request overrides all previous grabs by the same client on the same button/key combinations on the same window. A modifiers of AnyModifier is equivalent to issuing the grab request for all possible modifier combinations (including the combination of no modifiers). It is not required that all modifiers specified have currently assigned KeyCodes. A button of AnyButton is equivalent to issuing the request for all possible buttons. Otherwise, it is not required that the specified button currently be assigned to a physical button.

If some other client has already issued a XGrabButton with the same button/key combination on the same window, a BadAccess error results. When using AnyModifier or AnyButton, the request fails completely, and a BadAccess error results (no grabs are established) if there is a conflicting grab for any combination. XGrabButton has no effect on an active grab.

XGrabButton can generate BadCursor, BadValue, and BadWindow errors.

The XUngrabButton function releases the passive button/key combination on the specified window if it was grabbed by this client. A modifiers of AnyModifier is equivalent to issuing the ungrab request for all possible modifier combinations, including the combination of no modifiers. A button of AnyButton is equivalent to issuing the request for all possible buttons. XUngrabButton has no effect on an active grab.

XUngrabButton can generate BadValue and BadWindow errors.

NAME
XGrabKey, XUngrabKey – grab keyboard keys

SYNTAX
XGrabKey(display, keycode, modifiers, grab_window, owner_events, pointer_mode, keyboard_mode)
  Display *display;
  int keycode;
  unsigned int modifiers;
  Window grab_window;
  Bool owner_events;
  int pointer_mode, keyboard_mode;

XUngrabKey(display, keycode, modifiers, grab_window)
  Display *display;
  int keycode;
  unsigned int modifiers;
  Window grab_window;

ARGUMENTS
  display Specifies the connection to the XWIN server.
  grab_window Specifies the grab window.
  keyboard_mode Specifies further processing of keyboard events. You can pass GrabModeSync or GrabModeAsync.
  keycode Specifies the KeyCode or AnyKey.
  modifiers Specifies the set of keymasks or AnyModifier. The mask is the bitwise inclusive OR of the valid keymask bits.
  owner_events Specifies a Boolean value that indicates whether the pointer events are to be reported as usual or reported with respect to the grab window if selected by the event mask.
  pointer_mode Specifies further processing of pointer events. You can pass GrabModeSync or GrabModeAsync.

DESCRIPTION
The XGrabKey function establishes a passive grab on the keyboard. In the future, the keyboard is actively grabbed (as for XGrabKeyboard), the last-keyboard-grab time is set to the time at which the key was pressed (as transmitted in the KeyPress event), and the KeyPress event is reported if all of the following conditions are true:

- The keyboard is not grabbed and the specified key (which can itself be a modifier key) is logically pressed when the specified modifier keys are logically down, and no other modifier keys are logically down.
- Either the grab_window is an ancestor of (or is) the focus window, or the grab_window is a descendant of the focus window and contains the pointer.
- A passive grab on the same key combination does not exist on any ancestor of grab_window.
The interpretation of the remaining arguments is as for XGrabKeyboard. The active grab is terminated automatically when the logical state of the keyboard has the specified key released (independent of the logical state of the modifier keys).

Note that the logical state of a device (as seen by client applications) may lag the physical state if device event processing is frozen.

A modifiers argument of AnyModifier is equivalent to issuing the request for all possible modifier combinations (including the combination of no modifiers). It is not required that all modifiers specified have currently assigned KeyCodes. A keycode argument of AnyKey is equivalent to issuing the request for all possible KeyCodes. Otherwise, the specified keycode must be in the range specified by min_keycode and max_keycode in the connection setup, or a BadValue error results.

If some other client has issued a XGrabKey with the same key combination on the same window, a BadAccess error results. When using AnyModifier or AnyKey, the request fails completely, and a BadAccess error results (no grabs are established) if there is a conflicting grab for any combination.

XGrabKey can generate BadAccess, BadValue, and BadWindow errors.

The XUngrabKey function releases the key combination on the specified window if it was grabbed by this client. It has no effect on an active grab. A modifiers of AnyModifier is equivalent to issuing the request for all possible modifier combinations (including the combination of no modifiers). A keycode argument of AnyKey is equivalent to issuing the request for all possible key codes.

XUngrabKey can generate BadValue and BadWindow error.

**DIAGNOSTICS**

- **BadAccess**: A client attempted to grab a key/button combination already grabbed by another client.

- **BadValue**: Some numeric value falls outside the range of values accepted by the request. Unless a specific range is specified for an argument, the full range defined by the argument's type is accepted. Any argument defined as a set of alternatives can generate this error.

- **BadWindow**: A value for a Window argument does not name a defined Window.

Xlib – C Language X Interface
NAME
XGrabKeyboard, XUngrabKeyboard – grab the keyboard

SYNTAX
int XGrabKeyboard(display, grab_window, owner_events, pointer_mode,
keyboard_mode, time)
Display *display;
Window grab_window;
Bool owner_events;
int pointer_mode, keyboard_mode;
Time time;

XUngrabKeyboard(display, time)
Display *display;
Time time;

ARGUMENTS

display Specifies the connection to the XWIN server.
grab_window Specifies the grab window.
keyboard_mode Specifies further processing of keyboard events. You can pass
GrabModeSync or GrabModeAsync.
owner_events Specifies a Boolean value that indicates whether the pointer
events are to be reported as usual or reported with respect to
the grab window if selected by the event mask.
pointer_mode Specifies further processing of pointer events. You can pass
GrabModeSync or GrabModeAsync.
time Specifies the time. You can pass either a timestamp or Current­
Time.

DESCRIPTION
The XGrabKeyboard function actively grabs control of the keyboard and gen­
erates FocusIn and FocusOut events. Further key events are reported only to
the grabbing client. XGrabKeyboard overrides any active keyboard grab by this
client. If owner_events is False, all generated key events are reported with
respect to grab window. If owner_events is True and if a generated key event
would normally be reported to this client, it is reported normally; otherwise, the
event is reported with respect to the grab window. Both KeyPress and
KeyRelease events are always reported, independent of any event selection made
by the client.

If the keyboard_mode argument is GrabModeAsync, keyboard event processing
continues as usual. If the keyboard is currently frozen by this client, then process­
ing of keyboard events is resumed. If the keyboard_mode argument is
GrabModeSync, the state of the keyboard (as seen by client applications) appears
to freeze, and the XWIN server generates no further keyboard events until the
grabbing client issues a releasing XAllowEvents call or until the keyboard grab is
released. Actual keyboard changes are not lost while the keyboard is frozen; they
are simply queued in the server for later processing.
If pointer_mode is GrabModeAsync, pointer event processing is unaffected by activation of the grab. If pointer_mode is GrabModeSync, the state of the pointer (as seen by client applications) appears to freeze, and the XWIN server generates no further pointer events until the grabbing client issues a releasing XAllowEvents call or until the keyboard grab is released. Actual pointer changes are not lost while the pointer is frozen; they are simply queued in the server for later processing.

If the keyboard is actively grabbed by some other client, XGrabKeyboard fails and returns AlreadyGrabbed. If grab window is not viewable, it fails and returns GrabNotViewable. If the keyboard is frozen by an active grab of another client, it fails and returns GrabFrozen. If the specified time is earlier than the last-keyboard-grab time or later than the current XWIN server time, it fails and returns GrabInvalidTime. Otherwise, the last-keyboard-grab time is set to the specified time (CurrentTime is replaced by the current XWIN server time).

XGrabKeyboard can generate BadValue and BadWindow errors.

The XUngrabKeyboard function releases the keyboard and any queued events if this client has it actively grabbed from either XGrabKeyboard or XGrabKey. XUngrabKeyboard does not release the keyboard and any queued events if the specified time is earlier than the last-keyboard-grab time or is later than the current XWIN server time. It also generates FocusIn and FocusOut events. The XWIN server automatically performs an UngrabKeyboard request if the event window for an active keyboard grab becomes not viewable.

**DIAGNOSTICS**

**BadValue**  
Some numeric value falls outside the range of values accepted by the request. Unless a specific range is specified for an argument, the full range defined by the argument's type is accepted. Any argument defined as a set of alternatives can generate this error.

**BadWindow**  
A value for a Window argument does not name a defined Window.

    Display *display;
    Time time;
XChangeActivePointerGrab(display, event_mask, cursor, time)
    Display *display;
    unsigned int event_mask;
    Cursor cursor;
    Time time;

ARGUMENTS
confine_to Specifies the window to confine the pointer in or None.
cursor Specifies the cursor that is to be displayed during the grab or None.
display Specifies the connection to the XWIN server.
event_mask Specifies which pointer events are reported to the client. The mask is the bitwise inclusive OR of the valid pointer event mask bits.
grab_window Specifies the grab window.
keyboard_mode Specifies further processing of keyboard events. You can pass GrabModeSync or GrabModeAsync.
owner_events Specifies a Boolean value that indicates whether the pointer events are to be reported as usual or reported with respect to the grab window if selected by the event mask.
pointer_mode Specifies further processing of pointer events. You can pass GrabModeSync or GrabModeAsync.
time Specifies the time. You can pass either a timestamp or CurrentTime.

DESCRIPTION
The XGrabPointer function actively grabs control of the pointer and returns GrabSuccess if the grab was successful. Further pointer events are reported only to the grabbing client. XGrabPointer overrides any active pointer grab by this client. If owner_events is False, all generated pointer events are reported with
If the pointer_mode is GrabModeAsync, pointer event processing continues as usual. If the pointer is currently frozen by this client, the processing of events for the pointer is resumed. If the pointer_mode is GrabModeSync, the state of the pointer, as seen by client applications, appears to freeze, and the XWIN server generates no further pointer events until the grabbing client calls XAllowEvents or until the pointer grab is released. Actual pointer changes are not lost while the pointer is frozen; they are simply queued in the server for later processing.

If the keyboard_mode is GrabModeAsync, keyboard event processing is unaffected by activation of the grab. If the keyboard_mode is GrabModeSync, the state of the keyboard, as seen by client applications, appears to freeze, and the XWIN server generates no further keyboard events until the grabbing client calls XAllowEvents or until the pointer grab is released. Actual keyboard changes are not lost while the pointer is frozen; they are simply queued in the server for later processing.

If a cursor is specified, it is displayed regardless of what window the pointer is in. If None is specified, the normal cursor for that window is displayed when the pointer is in grab_window or one of its subwindows; otherwise, the cursor for grab_window is displayed.

If a confine_to window is specified, the pointer is restricted to stay contained in that window. The confine_to window need have no relationship to the grab_window. If the pointer is not initially in the confine_to window, it is warped automatically to the closest edge just before the grab activates and enter/leave events are generated as usual. If the confine_to window is subsequently reconfigured, the pointer is warped automatically, as necessary, to keep it contained in the window.

The time argument allows you to avoid certain circumstances that come up if applications take a long time to respond or if there are long network delays. Consider a situation where you have two applications, both of which normally grab the pointer when clicked on. If both applications specify the timestamp from the event, the second application may wake up faster and successfully grab the pointer before the first application. The first application then will get an indication that the other application grabbed the pointer before its request was processed.

XGrabPointer generates EnterNotify and LeaveNotify events.

Either if grab_window or confine_to window is not viewable or if the confine_to window lies completely outside the boundaries of the root window, XGrabPointer fails and returns GrabNotViewable. If the pointer is actively grabbed by some other client, it fails and returns AlreadyGrabbed. If the pointer is frozen by an active grab of another client, it fails and returns GrabFrozen. If the specified time is earlier than the last-pointer-grab time or later than the current XWIN server time, it fails and returns GrabInvalidTime. Otherwise, the last-
pointer-grab time is set to the specified time (CurrentTime is replaced by the current XWIN server time).

XGrabPointer can generate BadCursor, BadValue, and BadWindow errors.

The XUngrabPointer function releases the pointer and any queued events if this client has actively grabbed the pointer from XGrabPointer, XGrabButton, or from a normal button press. XUngrabPointer does not release the pointer if the specified time is earlier than the last-pointer-grab time or is later than the current XWIN server time. It also generates EnterNotify and LeaveNotify events. The XWIN server performs an UngrabPointer request automatically if the event window or confine_to window for an active pointer grab becomes not viewable or if window reconfiguration causes the confine_to window to lie completely outside the boundaries of the root window.

The XChangeActivePointerGrab function changes the specified dynamic parameters if the pointer is actively grabbed by the client and if the specified time is no earlier than the last-pointer-grab time and no later than the current XWIN server time. This function has no effect on the passive parameters of a XGrabButton. The interpretation of event_mask and cursor is the same as described in XGrabPointer.

XChangeActivePointerGrab can generate a BadCursor and BadValue error.

NAME
XlfEvent, XCheckIfEvent, XPeekIfEvent – check the event queue with a predicate procedure

SYNTAX
XlfEvent(display, event_return, predicate, arg)
  Display *display;
  XEvent *event_return;
  Bool (*predicate)();
  char *arg;

Bool XCheckIfEvent(display, event_return, predicate, arg)
  Display *display;
  XEvent *event_return;
  Bool (*predicate)();
  char *arg;

XPeekIfEvent(display, event_return, predicate, arg)
  Display *display;
  XEvent *event_return;
  Bool (*predicate)();
  char *arg;

ARGUMENTS
arg Specifies the user-supplied argument that will be passed to the predicate procedure.
display Specifies the connection to the XWIN server.
event_return Returns either a copy of or the matched event's associated structure.
predicate Specifies the procedure that is to be called to determine if the next event in the queue matches what you want.

DESCRIPTION
The XlfEvent function completes only when the specified predicate procedure returns True for an event, which indicates an event in the queue matches. XlfEvent flushes the output buffer if it blocks waiting for additional events. XlfEvent removes the matching event from the queue and copies the structure into the client-supplied XEvent structure.

When the predicate procedure finds a match, XCheckIfEvent copies the matched event into the client-supplied XEvent structure and returns True. (This event is removed from the queue.) If the predicate procedure finds no match, XCheckIfEvent returns False, and the output buffer will have been flushed. All earlier events stored in the queue are not discarded.

The XPeekIfEvent function returns only when the specified predicate procedure returns True for an event. After the predicate procedure finds a match, XPeekIfEvent copies the matched event into the client-supplied XEvent structure without removing the event from the queue. XPeekIfEvent flushes the output buffer if it blocks waiting for additional events.

NAME
XrmInitialize, XrmParseCommand – initialize the Resource Manager and parse the command line

SYNTAX
void XrmInitialize();
void XrmParseCommand(database, table, table_count, name, argc_in_out, argv_in_out,)
    XrmDatabase *database;
    XrmOptionDescList table;
    int table_count;
    char *name;
    int *argc_in_out;
    char **argv_in_out;

ARGUMENTS
argo_in_out Specifies the number of arguments and returns the number of remaining arguments.
argv_in_out Specifies a pointer to the command line arguments and returns the remaining arguments.
database Specifies a pointer to the resource database.
name Specifies the application name.
table Specifies the table of command line arguments to be parsed.
table_count Specifies the number of entries in the table.

DESCRIPTION
The XrmInitialize function initializes the resource manager.
The XrmParseCommand function parses an (argc, argv) pair according to the specified option table, loads recognized options into the specified database with type "String," and modifies the (argc, argv) pair to remove all recognized options.
The specified table is used to parse the command line. Recognized entries in the table are removed from argv, and entries are made in the specified resource database. The table entries contain information on the option string, the option name, the style of option, and a value to provide if the option kind is XrmoptionNoArg. The argc argument specifies the number of arguments in argv and is set to the remaining number of arguments that were not parsed. The name argument should be the name of your application for use in building the database entry. The name argument is prefixed to the resourceName in the option table before storing the specification. No separating (binding) character is inserted. The table must contain either a period (.) or an asterisk (*) as the first character in each resourceName entry. To specify a more completely qualified resource name, the resourceName entry can contain multiple components.

NAME

XInstallColormap, XUninstallColormap, XListInstalledColormaps – control colormaps

SYNTAX

XInstallColormap(display, colormap)
  Display *display;
  Colormap colormap;

XUninstallColormap(display, colormap)
  Display *display;
  Colormap colormap;

Colormap *XListInstalledColormaps(display, w, num_return)
  Display *display;
  Window w;
  int *num_return;

ARGUMENTS

  colormap     Specifies the colormap.
  display      Specifies the connection to the XWIN server.
  num_return   Returns the number of currently installed colormaps.
  w            Specifies the window that determines the screen.

DESCRIPTION

The XInstallColormap function installs the specified colormap for its associated screen. All windows associated with this colormap immediately display with true colors. You associated the windows with this colormap when you created them by calling XCreateWindow, XCreateSimpleWindow, XChangeWindowAttributes, or XSetWindowColormap.

If the specified colormap is not already an installed colormap, the XWIN server generates a ColormapNotify event on each window that has that colormap. In addition, for every other colormap that is installed as a result of a call to XInstallColormap, the XWIN server generates a ColormapNotify event on each window that has that colormap.

XInstallColormap can generate a BadColor error.

The XUninstallColormap function removes the specified colormap from the required list for its screen. As a result, the specified colormap might be uninstalled, and the XWIN server might implicitly install or uninstall additional colormaps. Which colormaps get installed or uninstalled is server-dependent except that the required list must remain installed.

If the specified colormap becomes uninstalled, the XWIN server generates a ColormapNotify event on each window that has that colormap. In addition, for every other colormap that is installed or uninstalled as a result of a call to XUninstallColormap, the XWIN server generates a ColormapNotify event on each window that has that colormap.
XUninstallColormap can generate a BadColor error.

The XListInstalledColormaps function returns a list of the currently installed colormaps for the screen of the specified window. The order of the colormaps in the list is not significant and is no explicit indication of the required list. When the allocated list is no longer needed, free it by using XFree.

XListInstalledColormaps can generate a BadWindow error.

**DIAGNOSTICS**

<table>
<thead>
<tr>
<th>Error</th>
<th>Description</th>

XIntersectRegion (3X11)

NAME
XIntersectRegion, XUnionRegion, XUnionRectWithRegion, XSubtractRegion,
XXorRegion, XOffsetRegion, XShrinkRegion – region arithmetic

SYNTAX
XIntersectRegion(sra, srb, dr_return)
   Region sra, srb, dr_return;

XUnionRegion(sra, srb, dr_return)
   Region sra, srb, dr_return;

XUnionRectWithRegion(rectangle, src_region, dest_region_return)
   XRectangle *rectangle;
   Region src_region;
   Region dest_region_return;

XSubtractRegion(sra, srb, dr_return)
   Region sra, srb, dr_return;

XXorRegion(sra, srb, dr_return)
   Region sra, srb, dr_return;

XOffsetRegion(r, dx, dy)
   Region r;
   int dx, dy;

XShrinkRegion(r, dx, dy)
   Region r;
   int dx, dy;

ARGUMENTS

dest_region_return
   Returns the destination region.

dr_return
   Returns the result of the computation.

dx
   Specify the x and y coordinates, which define the amount you want to move or shrink the specified region.

dy

r
   Specifies the region.

rectangle
   Specifies the rectangle.

sra

srb
   Specify the two regions with which you want to perform the computation.

src_region
   Specifies the source region to be used.

DESCRIPTION
The XIntersectRegion function computes the intersection of two regions.
The XUnionRegion function computes the union of two regions.
The XUnionRectWithRegion function updates the destination region from a union of the specified rectangle and the specified source region.
The \texttt{XSubtractRegion} function subtracts \texttt{srb} from \texttt{sra} and stores the results in \texttt{dr_return}.

The \texttt{XXorRegion} function calculates the difference between the union and intersection of two regions.

The \texttt{XOffsetRegion} function moves the specified region by a specified amount.

The \texttt{XShrinkRegion} function reduces the specified region by a specified amount. Positive values shrink the size of the region, and negative values expand the region.

NAME

XInternAtom, XGetAtomName — create or return atom names

SYNTAX

Atom XInternAtom(display, atom_name, only_if_exists)
   Display *display;
   char *atom_name;
   Bool only_if_exists;

cchar XGetAtomName(display, atom)
   Display *display;
   Atom atom;

ARGUMENTS

atom
   Specifies the atom for the property name you want returned.

atom_name
   Specifies the name associated with the atom you want returned.

display
   Specifies the connection to the XWIN server.

only_if_exists
   Specifies a Boolean value that indicates whether XInternAtom creates the atom.

DESCRIPTION

The XInternAtom function returns the atom identifier associated with the specified atom_name string. If only_if_exists is False, the atom is created if it does not exist. Therefore, XInternAtom can return None. You should use a null-terminated ISO Latin-1 string for atom_name. Case matters; the strings thing, Thing, and thinG all designate different atoms. The atom will remain defined even after the client’s connection closes. It will become undefined only when the last connection to the XWIN server closes.

XInternAtom can generate BadAlloc and BadValue errors.

The XGetAtomName function returns the name associated with the specified atom. To free the resulting string, call XFree.

XGetAtomName can generate a BadAtom error.

DIAGNOSTICS

BadAlloc
   The server failed to allocate the requested resource or server memory.

BadAtom
   A value for an Atom argument does not name a defined Atom.

BadValue
   Some numeric value falls outside the range of values accepted by the request. Unless a specific range is specified for an argument, the full range defined by the argument’s type is accepted. Any argument defined as a set of alternatives can generate this error.

NAME
XListFonts, XFreeFontNames, XListFontsWithInfo, XFreeFontInfo - obtain or free font names and information

SYNTAX
char **XListFonts(display, pattern, maxnames, actual_count_return)

Display **display;
char *pattern;
int maxnames;
int *actual_count_return;

XFreeFontNames(list)
char *list[];

c char **XListFontsWithInfo(display, pattern, maxnames, count_return, info_return)

Display **display;
char *pattern;
int maxnames;
int *count_return;
XFontStruct **info_return;

XFreeFontInfo(names, free_info, actual_count)
char **names;
XFontStruct *free_info;
int actual_count;

ARGUMENTS
actual_count Specifies the actual number of matched font names returned by XListFontsWithInfo.

actual_count_return Returns the actual number of font names.

count_return Returns the actual number of matched font names.

display Specifies the connection to the XWIN server.

info_return Returns a pointer to the font information.

free_info Specifies the pointer to the font information returned by XListFontsWithInfo.

list Specifies the array of strings you want to free.

maxnames Specifies the maximum number of names to be returned.

names Specifies the list of font names returned by XListFontsWithInfo.

pattern Specifies the null-terminated pattern string that can contain wildcard characters.

DESCRIPTION
The XListFonts function returns an array of available font names (as controlled by the font search path; see XSetFontPath) that match the string you passed to the pattern argument. The string should be ISO Latin-1; uppercase and lowercase do not matter. Each string is terminated by an ASCII null. The pattern string can contain any characters, but each asterisk (*) is a wildcard for any number of characters, and each question mark (?) is a wildcard for a single character. The
client should call \texttt{XFreeFontNames} when finished with the result to free the memory.

The \texttt{XFreeFontNames} function frees the array and strings returned by \texttt{XListFonts} or \texttt{XListFontsWithInfo}.

The \texttt{XListFontsWithInfo} function returns a list of font names that match the specified pattern and their associated font information. The list of names is limited to size specified by \texttt{maxnames}. The information returned for each font is identical to what \texttt{XLoadQueryFont} would return except that the per-character metrics are not returned. The pattern string can contain any characters, but each asterisk (*) is a wildcard for any number of characters, and each question mark (?) is a wildcard for a single character. To free the allocated name array, the client should call \texttt{XFreeFontNames}. To free the the font information array, the client should call \texttt{XFreeFontInfo}.

The \texttt{XFreeFontInfo} function frees the the font information array.

NAME
XLoadFont, XQueryFont, XLoadQueryFont, XFreeFont, XGetFontProperty, XUnloadFont – load or unload fonts

SYNTAX
Font XLoadFont(display, name)
   Display *display;
   char *name;
XFontStruct *XQueryFont(display, font_ID)
   Display *display;
   XID font_ID;
XFontStruct *XLoadQueryFont(display, name)
   Display *display;
   char *name;
XFreeFont(display, font_struct)
   Display *display;
   XFontStruct *font_struct;
Bool XGetFontProperty(font_struct, atom, value_return)
   XFontStruct *font_struct;
   Atom atom;
   unsigned long *value_return;
XUnloadFont(display, font)
   Display *display;
   Font font;

ARGUMENTS
atom Specifies the atom for the property name you want returned.
display Specifies the connection to the XWIN server.
gn Specifies the font.
font_ID Specifies the font ID or the GContext ID.
font_struct Specifies the storage associated with the font.
gc Specifies the GC.
name Specifies the name of the font, which is a null-terminated string.
value_return Returns the value of the font property.

DESCRIPTION
The XLoadFont function loads the specified font and returns its associated font ID. The name should be ISO Latin-1 encoding; uppercase and lowercase do not matter. If XLoadFont was unsuccessful at loading the specified font, a BadName error results. Fonts are not associated with a particular screen and can be stored as a component of any GC. When the font is no longer needed, call XUnloadFont.
XLoadFont can generate BadAlloc and BadName errors.
The \texttt{XQueryFont} function returns a pointer to the \texttt{XFontStruct} structure, which contains information associated with the font. You can query a font or the font stored in a \texttt{GC}. The font ID stored in the \texttt{XFontStruct} structure will be the \texttt{GContext} ID, and you need to be careful when using this ID in other functions (see \texttt{XGContextFromGC}). To free this data, use \texttt{XFreeFontInfo}.

\texttt{XLoadQueryFont} can generate a \texttt{BadAlloc} error.

The \texttt{XLoadQueryFont} function provides the most common way for accessing a font. \texttt{XLoadQueryFont} both opens (loads) the specified font and returns a pointer to the appropriate \texttt{XFontStruct} structure. If the font does not exist, \texttt{XLoadQueryFont} returns NULL.

The \texttt{XFreeFont} function deletes the association between the font resource ID and the specified font and frees the \texttt{XFontStruct} structure. The font itself will be freed when no other resource references it. The data and the font should not be referenced again.

\texttt{XFreeFont} can generate a \texttt{BadFont} error.

Given the atom for that property, the \texttt{XGetFontProperty} function returns the value of the specified font property. \texttt{XGetFontProperty} also returns \texttt{False} if the property was not defined or \texttt{True} if it was defined. A set of predefined atoms exists for font properties, which can be found in \texttt{<X11/Xatom.h>}. This set contains the standard properties associated with a font. Although it is not guaranteed, it is likely that the predefined font properties will be present.

The \texttt{XUnloadFont} function deletes the association between the font resource ID and the specified font. The font itself will be freed when no other resource references it. The font should not be referenced again.

\texttt{XUnloadFont} can generate a \texttt{BadFont} error.

NAME
XLookupKeysym, XRefreshKeyboardMapping, XLookupString, XRebindKeySym
- handle keyboard input events

SYNTAX

KeySym XLookupKeysym(key_event, index)
   XKeyEvent *key_event;
   int index;

XRefreshKeyboardMapping(event_map)
   XMappingEvent *event_map;

int XLookupString(event_struct, buffer_return, bytes_buffer, keysym_return,
   status_in_out)
   XKeyEvent *event_struct;
   char *buffer_return;
   int bytes_buffer;
   KeySym *keysym_return;
   XComposeStatus *status_in_out;

XRebindKeysym(display, keysym, list, mod_count, string, bytes_string)
   Display *display;
   KeySym keysym;
   KeySym list[];
   int mod_count;
   unsigned char *string;
   int bytes_string;

ARGUMENTS

buffer_return Returns the translated characters.
bytes_buffer Specifies the length of the buffer. No more than bytes_buffer of
translation are returned.
bytes_string Specifies the length of the string.
display Specifies the connection to the XWIN server.
event_map Specifies the mapping event that is to be used.
event_struct Specifies the key event structure to be used. You can pass
XKeyPressedEvent or XKeyReleasedEvent.
index Specifies the index into the KeySyms list for the event’s Key-
Code.
key_event Specifies the KeyPress or KeyRelease event.
keysym Specifies the KeySym that is to be.
keysym_return Returns the KeySym computed from the event if this argument
is not NULL.
list Specifies the KeySyms to be used as modifiers.
mod_count Specifies the number of modifiers in the modifier list.
XLookupKeysym(3X11)

status_in_out        Specifies or returns the XComposeStatus structure or NULL.
string              Specifies a pointer to the string that is copied and will be returned by XLookupString.

DESCRIPTION
The XLookupKeysym function uses a given keyboard event and the index you specified to return the KeySym from the list that corresponds to the KeyCode member in the XKeyPressedEvent or XKeyReleasedEvent structure. If no KeySym is defined for the KeyCode of the event, XLookupKeysym returns NoSymbol.

The XRefreshKeyboardMapping function refreshes the stored modifier and key-map information. You usually call this function when a MappingNotify event with a request member of MappingKeyboard or MappingModifier occurs. The result is to update Xlib's knowledge of the keyboard.

The XLookupString function is a convenience routine that maps a key event to an ISO Latin-l string, using the modifier bits in the key event to deal with shift, lock, and control. It returns the translated string into the user's buffer. It also detects any rebound KeySyms (see XRebindKeysym) and returns the specified bytes. XLookupString returns the length of the string stored in the tag buffer. If the lock modifier has the caps lock KeySym associated with it, XLookupString interprets the lock modifier to perform caps lock processing.

If present (non-NULL), the XComposeStatus structure records the state, which is private to Xlib, that needs preservation across calls to XLookupString to implement compose processing.

The XRebindKeysym function can be used to rebind the meaning of a KeySym for the client. It does not redefine any key in the XWIN server but merely provides an easy way for long strings to be attached to keys. XLookupString returns this string when the appropriate set of modifier keys are pressed and when the KeySym would have been used for the translation. Note that you can rebind a KeySym that may not exist.

SEE ALSO
XStringToKeysym(3X11)
Xlib - C Language X Interface
NAME
XrmMergeDatabases, XrmGetFileDatabase, XrmPutFileDatabase, XrmGetStringDatabase – manipulate resource databases

SYNTAX
void XrmMergeDatabases(source_db, target_db)
   XrmDatabase source_db, *target_db;

XrmDatabase XrmGetFileDatabase(filename)
   char *filename;

void XrmPutFileDatabase(database, stored_db)
   XrmDatabase database;
   char *stored_db;

XrmDatabase XrmGetStringDatabase(data)
   char *data;

ARGUMENTS
   data      Specifies the database contents using a string.
   database  Specifies the database that is to be used.
   filename  Specifies the resource database file name.
   source_db Specifies the resource database that is to be merged into the target database.
   stored_db Specifies the file name for the stored database.
   target_db Specifies a pointer to the resource database into which the source database is to be merged.

DESCRIPTION
The XrmMergeDatabases function merges the contents of one database into another. It may overwrite entries in the destination database. This function is used to combine databases (for example, an application specific database of defaults and a database of user preferences). The merge is destructive; that is, the source database is destroyed.

The XrmGetFileDatabase function opens the specified file, creates a new resource database, and loads it with the specifications read in from the specified file. The specified file must contain lines in the format accepted by XrmPutLineResource. If it cannot open the specified file, XrmGetFileDatabase returns NULL.

The XrmPutFileDatabase function stores a copy of the specified database in the specified file. The file is an ASCII text file that contains lines in the format that is accepted by XrmPutLineResource.

The XrmGetStringDatabase function creates a new database and stores the resources specified in the specified null-terminated string. XrmGetStringDatabase is similar to XrmGetFileDatabase except that it reads the information out of a string instead of out of a file. Each line is separated by a new-line character in the format accepted by XrmPutLineResource.

Xlib – C Language X Interface
NAME
XMapWindow, XMapRaised, XMapSubwindows - map windows

SYNTAX
XMapWindow(display, w)
Display *display;
Window w;
XMapRaised(display, w)
Display *display;
Window w;
XMapSubwindows(display, w)
Display *display;
Window w;

ARGUMENTS
display Specifies the connection to the XWIN server.
w Specifies the window.

DESCRIPTION
The XMapWindow function maps the window and all of its subwindows that have had map requests. Mapping a window that has an unmapped ancestor does not display the window but marks it as eligible for display when the ancestor becomes mapped. Such a window is called unviewable. When all its ancestors are mapped, the window becomes viewable and will be visible on the screen if it is not obscured by another window. This function has no effect if the window is already mapped.

If the override-redirect of the window is False and if some other client has selected SubstructureRedirectMask on the parent window, then the XWIN server generates a MapRequest event, and the XMapWindow function does not map the window. Otherwise, the window is mapped, and the XWIN server generates a MapNotify event.

If the window becomes viewable and no earlier contents for it are remembered, the XWIN server tiles the window with its background. If the window's background is undefined, the existing screen contents are not altered, and the XWIN server generates zero or more Expose events. If backing-store was maintained while the window was unmapped, no Expose events are generated. If backing-store will now be maintained, a full-window exposure is always generated. Otherwise, only visible regions may be reported. Similar tiling and exposure take place for any newly viewable inferiors.

If the window is an InputOutput window, XMapWindow generates Expose events on each InputOutput window that it causes to be displayed. If the client maps and paints the window and if the client begins processing events, the window is painted twice. To avoid this, first ask for Expose events and then map the window, so the client processes input events as usual. The event list will include Expose for each window that has appeared on the screen. The client's normal response to an Expose event should be to repaint the window. This method usually leads to simpler programs and to proper interaction with window managers.
XMapWindow(3X11)

XMapWindow can generate a BadWindow error.

The XMapRaised function essentially is similar to XMapWindow in that it maps the window and all of its subwindows that have had map requests. However, it also raises the specified window to the top of the stack.

XMapRaised can generate a BadWindow error.

The XMapSubwindows function maps all subwindows for a specified window in top-to-bottom stacking order. The XWIN server generates Expose events on each newly displayed window. This may be much more efficient than mapping many windows one at a time because the server needs to perform much of the work only once, for all of the windows, rather than for each window.

XMapSubwindows can generate a BadWindow error.

DIAGNOSTICS

BadWindow A value for a Window argument does not name a defined Window.

        Display *display;
        int event_type;
        XEvent *event_return;
    Bool XCheckTypedWindowEvent(display, w, event_type, event_return)
        Display *display;
        Window w;
        int event_type;
        XEvent *event_return;

ARGUMENTS
    display            Specifies the connection to the XWIN server.
    event_mask         Specifies the event mask.
    event_return       Returns the matched event's associated structure.
XNextEvent(3X11)

`event_return` Returns the next event in the queue.

`event_return` Returns a copy of the matched event's associated structure.

`event_type` Specifies the event type to be compared.

`w` Specifies the window whose event you are interested in.

DESCRIPTION

The `XNextEvent` function copies the first event from the event queue into the specified `XEvent` structure and then removes it from the queue. If the event queue is empty, `XNextEvent` flushes the output buffer and blocks until an event is received.

The `XPeekEvent` function returns the first event from the event queue, but it does not remove the event from the queue. If the queue is empty, `XPeekEvent` flushes the output buffer and blocks until an event is received. It then copies the event into the client-supplied `XEvent` structure without removing it from the event queue.

The `XWindowEvent` function searches the event queue for an event that matches both the specified window and event mask. When it finds a match, `XWindowEvent` removes that event from the queue and copies it into the specified `XEvent` structure. The other events stored in the queue are not discarded. If a matching event is not in the queue, `XWindowEvent` flushes the output buffer and blocks until one is received.

The `XCheckWindowEvent` function searches the event queue and then the events available on the server connection for the first event that matches the specified window and event mask. If it finds a match, `XCheckWindowEvent` removes that event, copies it into the specified `XEvent` structure, and returns `True`. The other events stored in the queue are not discarded. If the event you requested is not available, `XCheckWindowEvent` returns `False`, and the output buffer will have been flushed.

The `XMaskEvent` function searches the event queue for the events associated with the specified mask. When it finds a match, `XMaskEvent` removes that event and copies it into the specified `XEvent` structure. The other events stored in the queue are not discarded. If the event you requested is not in the queue, `XMaskEvent` flushes the output buffer and blocks until one is received.

The `XCheckMaskEvent` function searches the event queue and then any events available on the server connection for the first event that matches the specified mask. If it finds a match, `XCheckMaskEvent` removes that event, copies it into the specified `XEvent` structure, and returns `True`. The other events stored in the queue are not discarded. If the event you requested is not available, `XCheckMaskEvent` returns `False`, and the output buffer will have been flushed.

The `XCheckTypedEvent` function searches the event queue and then any events available on the server connection for the first event that matches the specified type. If it finds a match, `XCheckTypedEvent` removes that event, copies it into the specified `XEvent` structure, and returns `True`. The other events in the queue are not discarded. If the event is not available, `XCheckTypedEvent` returns `False`, and the output buffer will have been flushed.
The `XCheckTypedWindowEvent` function searches the event queue and then any events available on the server connection for the first event that matches the specified type and window. If it finds a match, `XCheckTypedWindowEvent` removes the event from the queue, copies it into the specified XEvent structure, and returns `True`. The other events in the queue are not discarded. If the event is not available, `XCheckTypedWindowEvent` returns `False`, and the output buffer will have been flushed.

XOpenDisplay (3X11)

NAME
XOpenDisplay, XCloseDisplay – connect or disconnect to XWIN server

SYNTAX
Display *XOpenDisplay(display_name)
        char *display_name;
XCloseDisplay(display)
        Display *display;

ARGUMENTS
    display       Specifies the connection to the XWIN server.
    display_name  Specifies the hardware display name, which determines the
display and communications domain to be used. On a UNIX-based system,
if the display_name is NULL, it defaults to the
value of the DISPLAY environment variable.

DESCRIPTION
The XOpenDisplay function returns a Display structure that serves as the connection
to the XWIN server and that contains all the information about that XWIN server. XOpenDisplay
connects your application to the XWIN server. If the hostname is a host machine name and a single colon (:) separates the hostname and
display number, XOpenDisplay connects using TCP streams. If the hostname is unix and a single colon (:) separates it from the display number, XOpenDisplay
connects using UNIX domain IPC streams. If the hostname is not specified, Xlib
uses whatever it believes is the fastest transport. A single XWIN server can support
any or all of these transport mechanisms simultaneously. A particular Xlib
implementation can support many more of these transport mechanisms.

If successful, XOpenDisplay returns a pointer to a Display structure, which is
defined in <X11/Xlib.h>. If XOpenDisplay does not succeed, it returns NULL. After a successful call to XOpenDisplay, all of the screens in the display can be
used by the client. The screen number specified in the display_name argument is returned by the DefaultScreen macro (or the XDefaultScreen function). You can
access elements of the Display and Screen structures only by using the informa-
tion macros or functions. For information about using macros and functions to
obtain information from the Display structure, see section 2.2.1, Xlib—C Language
X Interface.

The XCloseDisplay function closes the connection to the XWIN server for the
display specified in the Display structure and destroys all windows, resource IDs
(Window, Font, Pixmap, Colormap, Cursor, and GContext), or other resources
that the client has created on this display, unless the close-down mode of the
resource has been changed (see XSetCloseDownMode). Therefore, these win-
dows, resource IDs, and other resources should never be referenced again or an
error will be generated. Before exiting, you should call XCloseDisplay explicitly
so that any pending errors are reported as XCloseDisplay performs a final
XSync operation.

XCloseDisplay can generate a BadGC error.

NAME
XParseGeometry, XGeometry, XParseColor – parse window geometry and color

SYNTAX
int XParseGeometry(parsestring, x_return, y_return, width_return, height_return)
    char *parsestring;
    int *x_return, *y_return;
    int *width_return, *height_return;

int XGeometry(display, screen, position, default_position, bwidth, fwidth, fheight,
    xadder, yadder, x_return, y_return, width_return, height_return)
    Display *display;
    int screen;
    char *position, *default_position;
    unsigned int bwidth;
    unsigned int fwidth, fheight;
    int xadder, yadder;
    int *x_return, *y_return;
    int *width_return, *height_return;

Status XParseColor(display, colormap, spec, exact_def_return)
    Display *display;
    Colormap colormap;
    char *spec;
    XColor *exact_def_return;

ARGUMENTS
bwidth 
    Specifies the border width.

 colormap 
    Specifies the colormap.

 position
    default_position 
    Specify the geometry specifications.

display 
    Specifies the connection to the XWIN server.

exact_def_return 
    Returns the exact color value for later use and sets the DoRed,
    DoGreen, and DoBlue flags.

fheight
fwidth
    Specify the font height and width in pixels (increment size).

parsestring
    Specifies the string you want to parse.

screen
    Specifies the screen.

spec 
    Specifies the color name string; case is ignored.

width_return
height_return
    Return the width and height determined.

xadder
yadder 
    Specify additional interior padding needed in the window.

x_return
XParseGeometry (3X11)

y_return Return the x and y offsets.

DESCRIPTION
By convention, X applications use a standard string to indicate window size and placement. XParseGeometry makes it easier to conform to this standard because it allows you to parse the standard window geometry. Specifically, this function lets you parse strings of the form:

\[
=][<width>x<height>][{+-}<xoffset>{+-}<yoffset>]
\]

The items in this form map into the arguments associated with this function. Items enclosed in <> are integers, items in [] are optional, and items enclosed in {} indicate "choose one of". Note that the brackets should not appear in the actual string.

The XParseGeometry function returns a bitmask that indicates which of the four values (width, height, xoffset, and yoffset) were actually found in the string and whether the x and y values are negative. By convention, -0 is not equal to +0, because the user needs to be able to say "position the window relative to the right or bottom edge." For each value found, the corresponding argument is updated. For each value not found, the argument is left unchanged. The bits are represented by XValue, YValue, WidthValue, HeightValue, XNegative, or YNegative and are defined in <X11/Xutil.h>. They will be set whenever one of the values is defined or one of the signs is set.

If the function returns either the XValue or YValue flag, you should place the window at the requested position.

You pass in the border width (bwidth), size of the increments fwidth and fheight (typically font width and height), and any additional interior space (xadder and yadder) to make it easy to compute the resulting size. The XGeometry function returns the position the window should be placed given a position and a default position. XGeometry determines the placement of a window using a geometry specification as specified by XParseGeometry and the additional information about the window. Given a fully qualified default geometry specification and an incomplete geometry specification, XParseGeometry returns a bitmask value as defined above in the XParseGeometry call, by using the position argument.

The returned width and height will be the width and height specified by default position as overridden by any user-specified position. They are not affected by fwidth, fheight, xadder, or yadder. The x and y coordinates are computed by using the border width, the screen width and height, padding as specified by xadder and yadder, and the fheight and fwidth times the width and height from the geometry specifications.

The XParseColor function provides a simple way to create a standard user interface to color. It takes a string specification of a color, typically from a command line or XGetDefault option, and returns the corresponding red, green, and blue values that are suitable for a subsequent call to XAllocColor or XStoreColor. The color can be specified either as a color name (as in XAllocNamedColor) or as an initial sharp sign character followed by a numeric specification, in one of the following formats:
The R, G, and B represent single hexadecimal digits (both uppercase and lowercase). When fewer than 16 bits each are specified, they represent the most-significant bits of the value. For example, #3a7 is the same as #3000a0007000. The colormap is used only to determine which screen to look up the color on. For example, you can use the screen’s default colormap.

If the initial character is a sharp sign but the string otherwise fails to fit the above formats or if the initial character is not a sharp sign and the named color does not exist in the server’s database, XParseColor fails and returns zero.

XParseColor can generate a BadColor error.

**DIAGNOSTICS**

- **BadColor** A value for a Colormap argument does not name a defined Colormap.

NAME
XPolygonRegion, XClipBox – generate regions

SYNTAX
Region XPolygonRegion(points, n, fill_rule)
   XPoint points[];
   int n;
   int fill_rule;
XClipBox(r, rect_return)
   Region r;
   XRectangle *rect_return;

ARGUMENTS
   fill_rule        Specifies the fill-rule you want to set for the specified GC. You
can pass EvenOddRule or WindingRule.
   n                Specifies the number of points in the polygon.
   points           Specifies an array of points.
   r                Specifies the region.
   rect_return      Returns the smallest enclosing rectangle.

DESCRIPTION
The XPolygonRegion function returns a region for the polygon defined by the
points array. For an explanation of fill_rule, see XCreateGC.
The XClipBox function returns the smallest rectangle enclosing the specified
region.

NAME
XPutBackEvent – put events back on the queue

SYNTAX
XPutBackEvent(display, event)
   Display *display;
   XEvent *event;

ARGUMENTS
   display Specifies the connection to the XWIN server.
   event Specifies a pointer to the event.

DESCRIPTION
The XPutBackEvent function pushes an event back onto the head of the display’s event queue by copying the event into the queue. This can be useful if you read an event and then decide that you would rather deal with it later. There is no limit to the number of times in succession that you can call XPutBackEvent.

NAME
XPutImage, XGetImage, XGetSubImage — transfer images

SYNTAX
XPutImage(display, d, gc, image, src_x, src_y, dest_x, dest_y, width, height)
  Display *display;
  Drawable d;
  GC gc;
  XImage *image;
  int src_x, src_y;
  int dest_x, dest_y;
  unsigned int width, height;

XImage *XGetImage(display, d, x, y, width, height, plane_mask, format)
  Display *display;
  Drawable d;
  int x, y;
  unsigned int width, height;
  long plane_mask;
  int format;

XImage *XGetSubImage(display, d, x, y, width, height, plane_mask, format,
  dest_image, dest_x, dest_y)
  Display *display;
  Drawable d;
  int x, y;
  unsigned int width, height;
  unsigned long plane_mask;
  int format;
  XImage *dest_image;
  int dest_x, dest_y;

ARGUMENTS
  d              Specifies the drawable.
  dest_image    Specify the destination image.
  dest_x        Specify the x and y coordinates, which are relative to the origin
                 of the drawable and are the coordinates of the subimage or
                 which are relative to the origin of the destination rectangle,
                 specify its upper-left corner, and determine where the subimage
                 is placed in the destination image.
  dest_y        display    Specifies the connection to the XWIN server.
  format        Specifies the format for the image. You can pass XYBitmap,  
                 XYPixmap, or ZPixmap.
  gc            Specifies the GC.
XPutImage

image Specifies the image you want combined with the rectangle.
plane_mask Specifies the plane mask.
src_x Specifies the offset in X from the left edge of the image defined by the XImage data structure.
src_y Specifies the offset in Y from the top edge of the image defined by the XImage data structure.
width Specify the width and height of the subimage, which define the dimensions of the rectangle.
height
x Specify the x and y coordinates, which are relative to the origin of the drawable and define the upper-left corner of the rectangle.
y
DESCRIPTION

The XPutImage function combines an image in memory with a rectangle of the specified drawable. If XYPixmap format is used, the depth must be one, or a BadMatch error results. The foreground pixel in the GC defines the source for the one bits in the image, and the background pixel defines the source for the zero bits. For XYPixmap and ZPixmap, the depth must match the depth of the drawable, or a BadMatch error results. The section of the image defined by the src_x, src_y, width, and height arguments is drawn on the specified part of the drawable.

This function uses these GC components: function, plane-mask, subwindow-mode, clip-x-origin, clip-y-origin, and clip-mask. It also uses these GC mode-dependent components: foreground and background.

XPutImage can generate BadDrawable, BadGC, BadMatch, and BadValue errors.

The XGetImage function returns a pointer to an XImage structure. This structure provides you with the contents of the specified rectangle of the drawable in the format you specify. If the format argument is XYPixmap, the image contains only the bit planes you passed to the plane_mask argument. If the plane_mask argument only requests a subset of the planes of the display, the depth of the returned image will be the number of planes requested. If the format argument is ZPixmap, XGetImage returns as zero the bits in all planes not specified in the plane_mask argument. The function performs no range checking on the values in plane_mask and ignores extraneous bits.

XGetImage returns the depth of the image to the depth member of the XImage structure. The depth of the image is as specified when the drawable was created, except when getting a subset of the planes in XYPixmap format, when the depth is given by the number of bits set to 1 in plane_mask.

If the drawable is a pixmap, the given rectangle must be wholly contained within the pixmap, or a BadMatch error results. If the drawable is a window, the window must be viewable, and it must be the case that if there were no inferiors or overlapping windows, the specified rectangle of the window would be fully visible on the screen and wholly contained within the outside edges of the window,
or a BadMatch error results. Note that the borders of the window can be included and read with this request. If the window has backing-store, the backing-store contents are returned for regions of the window that are obscured by noninferior windows. If the window does not have backing-store, the returned contents of such obscured regions are undefined. The returned contents of visible regions of inferiors of a different depth than the specified window’s depth are also undefined. The pointer cursor image is not included in the returned contents.

XGetImage can generate BadDrawable, BadMatch, and BadValue errors.

The XGetSubImage function updates dest_image with the specified subimage in the same manner as XGetImage. If the format argument is XYPixmap, the image contains only the bit planes you passed to the plane_mask argument. If the format argument is ZPixmap, XGetSubImage returns as zero the bits in all planes not specified in the plane_mask argument. The function performs no range checking on the values in plane_mask and ignores extraneous bits. As a convenience, XGetSubImage returns a pointer to the same XImage structure specified by dest_image.

The depth of the destination XImage structure must be the same as that of the drawable. If the specified subimage does not fit at the specified location on the destination image, the right and bottom edges are clipped. If the drawable is a pixmap, the given rectangle must be wholly contained within the pixmap, or a BadMatch error results. If the drawable is a window, the window must be viewable, and it must be the case that if there were no inferiors or overlapping windows, the specified rectangle of the window would be fully visible on the screen and wholly contained within the outside edges of the window, or a BadMatch error results. If the window has backing-store, then the backing-store contents are returned for regions of the window that are obscured by noninferior windows. If the window does not have backing-store, the returned contents of such obscured regions are undefined. The returned contents of visible regions of inferiors of a different depth than the specified window’s depth are also undefined.

XGetSubImage can generate BadDrawable, BadGC, BadMatch, and BadValue errors.

**DIAGNOSTICS**

<table>
<thead>
<tr>
<th>Error</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BadDrawable</td>
<td>A value for a Drawable argument does not name a defined Window or Pixmap.</td>
</tr>

NAME
XrmPutResource, XrmQPutResource, XrmPutStringResource,
XrmQPutStringResource, XrmPutLineResource – store database resources

SYNTAX
void XrmPutResource(database, specifier, type, value)
   XrmDatabase *database;
   char *specifier;
   char *type;
   XrmValue *value;
void XrmQPutResource(database, bindings, quarks, type, value)
   XrmDatabase *database;
   XrmBindingList bindings;
   XrmQuarkList quarks;
   XrmRepresentation type;
   XrmValue *value;
void XrmPutStringResource(database, specifier, value)
   XrmDatabase *database;
   char *specifier;
   char *value;
void XrmQPutStringResource(database, bindings, quarks, value)
   XrmDatabase *database;
   XrmBindingList bindings;
   XrmQuarkList quarks;
   char *value;
void XrmPutLineResource(database, line)
   XrmDatabase *database;
   char *line;

ARGUMENTS
bindings Specifies a list of bindings.
database Specifies a pointer to the resource database.
line Specifies the resource value pair as a single string. A single
   colon (:) separates the name from the value.
quarks Specifies the complete or partial name or the class list of the
   resource.
specifier Specifies a complete or partial specification of the resource.
type Specifies the type of the resource.
value Specifies the value of the resource, which is specified as a string.

DESCRIPTION
If database contains NULL, XrmPutResource creates a new database and returns
a pointer to it. XrmPutResource is a convenience function that calls
XrmStringToBindingQuarkList followed by:
XrmQPutResource(database, bindings, quarks, XrmStringToQuark(type), value)

If database contains NULL, XrmQPutResource creates a new database and returns a pointer to it.

If database contains NULL, XrmPutStringResource creates a new database and returns a pointer to it. XrmPutStringResource adds a resource with the specified value to the specified database. XrmPutStringResource is a convenience routine that takes both the resource and value as null-terminated strings, converts them to quarks, and then calls XrmQPutResource, using a "String" representation type.

If database contains NULL, XrmQPutStringResource creates a new database and returns a pointer to it. XrmQPutStringResource is a convenience routine that constructs an XrmValue for the value string (by calling strlen to compute the size) and then calls XrmQPutResource, using a "String" representation type.

If database contains NULL, XrmPutLineResource creates a new database and returns a pointer to it. XrmPutLineResource adds a single resource entry to the specified database. Any white space before or after the name or colon in the line argument is ignored. The value is terminated by a new-line or a NULL character. To allow values to contain embedded new-line characters, a "\n" is recognized and replaced by a new-line character. For example, line might have the value "xterm*background: green\n". Null-terminated strings without a new line are also permitted.

NAME

XQueryBestSize, XQueryBestTile, XQueryBestStipple – determine efficient sizes

SYNTAX

Status XQueryBestSize(display, class, which_screen, width, height, width_return, height_return)
    Display *display;
    int class;
    Drawable which_screen;
    unsigned int width, height;
    unsigned int *width_return, *height_return;

Status XQueryBestTile(display, which_screen, width, height, width_return, height_return)
    Display *display;
    Drawable which_screen;
    unsigned int width, height;
    unsigned int *width_return, *height_return;

Status XQueryBestStipple(display, which_screen, width, height, width_return, height_return)
    Display *display;
    Drawable which_screen;
    unsigned int width, height;
    unsigned int *width_return, *height_return;

ARGUMENTS

class
    Specifies the class that you are interested in. You can pass
    TileShape, CursorShape, or StippleShape.

display
    Specifies the connection to the XWIN server.

width
    Specify the width and height.

height
    Specifies any drawable on the screen.

width_return
    Return the width and height of the object best supported by the display hardware.

height_return

DESCRIPTION

The XQueryBestSize function returns the best or closest size to the specified size. For CursorShape, this is the largest size that can be fully displayed on the screen specified by which_screen. For TileShape, this is the size that can be tiled fastest. For StippleShape, this is the size that can be stippled fastest. For CursorShape, the drawable indicates the desired screen. For TileShape and StippleShape, the drawable indicates the screen and possibly the window class and depth. An InputOnly window cannot be used as the drawable for TileShape or StippleShape, or a BadMatch error results.

XQueryBestSize can generate BadDrawable, BadMatch, and BadValue errors.
The `XQueryBestSize` function returns the best or closest size, that is, the size that can be tiled fastest on the screen specified by `which_screen`. The drawable indicates the screen and possibly the window class and depth. If an `InputOnly` window is used as the drawable, a `BadMatch` error results.

`XQueryBestSize` can generate `BadDrawable` and `BadMatch` errors.

The `XQueryBestStipple` function returns the best or closest size, that is, the size that can be stippled fastest on the screen specified by `which_screen`. The drawable indicates the screen and possibly the window class and depth. If an `InputOnly` window is used as the drawable, a `BadMatch` error results.

`XQueryBestStipple` can generate `BadDrawable` and `BadMatch` errors.

**DIAGNOSTICS**

- **BadMatch**: An `InputOnly` window is used as a Drawable.
- **BadDrawable**: A value for a Drawable argument does not name a defined Window or Pixmap.
- **BadMatch**: The values do not exist for an `InputOnly` window.
- **BadValue**: Some numeric value falls outside the range of values accepted by the request. Unless a specific range is specified for an argument, the full range defined by the argument’s type is accepted. Any argument defined as a set of alternatives can generate this error.

NAME
XQueryColor, XQueryColors, XLookupColor – obtain color values

SYNTAX
XQueryColor(display, colormap, def_in_out)
- Display *display;
- Colormap colormap;
- XColor *def_in_out;

XQueryColors(display, colormap, defs_in_out, ncolors)
- Display *display;
- Colormap colormap;
- XColor defs_in_out[];
- int ncolors;

Status XLookupColor(display, colormap, color_name, exact_def_return, screen_def_return)
- Display *display;
- Colormap colormap;
- char *color_name;
- XColor *exact_def_return, *screen_def_return;

ARGUMENTS
colormap Specifies the colormap.
color_name Specifies the color name string (for example, red) whose color definition structure you want returned.
def_in_out Specifies and returns the RGB values for the pixel specified in the structure.
defs_in_out Specifies and returns an array of color definition structures for the pixel specified in the structure.
display Specifies the connection to the XWIN server.
exact_def_return Specifies the number of XColor structures in the color definition array.
ncolors Returns the exact RGB values.

DESCRIPTION
The XQueryColor function returns the RGB values for each pixel in the XColor structures and sets the DoRed, DoGreen, and DoBlue flags. The XQueryColors function returns the RGB values for each pixel in the XColor structures and sets the DoRed, DoGreen, and DoBlue flags.

XQueryColor and XQueryColors can generate BadColor and BadValue errors.

The XLookupColor function looks up the string name of a color with respect to the screen associated with the specified colormap. It returns both the exact color values and the closest values provided by the screen with respect to the visual type of the specified colormap. You should use the ISO Latin-1 encoding; uppercase and lowercase do not matter. XLookupColor returns nonzero if the name existed in the color database or zero if it did not exist.
DIAGNOSTICS

BadColor  A value for a Colormap argument does not name a defined Colormap.

BadValue  Some numeric value falls outside the range of values accepted by the request. Unless a specific range is specified for an argument, the full range defined by the argument's type is accepted. Any argument defined as a set of alternatives can generate this error.

NAME

XQueryPointer – get pointer coordinates

SYNTAX

Bool XQueryPointer(display, w, root_return, child_return, root_x_return, root_y_return, win_x_return, win_y_return, mask_return)

Display *display;
Window w;
Window *root_return, *child_return;
int *root_x_return, *root_y_return;
int *win_x_return, *win_y_return;
unsigned int *mask_return;

ARGUMENTS

child_return
  Returns the child window that the pointer is located in, if any.
display
  Specifies the connection to the XWIN server.
mask_return
  Returns the current state of the modifier keys and pointer buttons.
root_return
  Returns the root window that the pointer is in.
root_x_return
  Return the pointer coordinates relative to the root window’s origin.
root_y_return
  Return the pointer coordinates relative to the root window’s origin.
w
  Specifies the window.
win_x_return
  Return the pointer coordinates relative to the specified window.
win_y_return
  Return the pointer coordinates relative to the specified window.

DESCRIPTION

The XQueryPointer function returns the root window the pointer is logically on and the pointer coordinates relative to the root window’s origin. If XQueryPointer returns False, the pointer is not on the same screen as the specified window, and XQueryPointer returns None to child_return and zero to win_x_return and win_y_return. If XQueryPointer returns True, the pointer coordinates returned to win_x_return and win_y_return are relative to the origin of the specified window. In this case, XQueryPointer returns the child that contains the pointer, if any, or else None to child_return.

XQueryPointer returns the current logical state of the keyboard buttons and the modifier keys in mask_return. It sets mask_return to the bitwise inclusive OR of one or more of the button or modifier key bitmasks to match the current state of the mouse buttons and the modifier keys.

XQueryPointer can generate a BadWindow error.

DIAGNOSTICS

BadWindow A value for a Window argument does not name a defined Window.

SEE ALSO

XGetWindowAttributes(3X11),
XQueryTree(3X11)
Xlib – C Language X Interface
XQueryTree(3X11)

NAME
XQueryTree — query window tree information

SYNTAX
Status XQueryTree(display, w, root_return, parent_return, children_return, nchildren_return)
    Display *display;
    Window w;
    Window *root_return;
    Window *parent_return;
    Window **children_return;
    unsigned int *nchildren_return;

ARGUMENTS
    children_return  Returns a pointer to the list of children.
    display          Specifies the connection to the XWIN server.
    nchildren_return Returns the number of children.
    parent_return    Returns the parent window.
    root_return      Returns the root window.
    w                Specifies the window whose list of children, root, parent, and
                     number of children you want to obtain.

DESCRIPTION
The XQueryTree function returns the root ID, the parent window ID, a pointer to
the list of children windows, and the number of children in the list for the
specified window. The children are listed in current stacking order, from bottom-
most (first) to topmost (last). XQueryTree returns zero if it fails and nonzero if it
succeeds. To free this list when it is no longer needed, use XFree.

BUGS
This really should return a screen *, not a root window ID.

SEE ALSO
XGetWindowAttributes(3X11), XQueryPointer(3X11), Xlib — C Language X Interface
NAME
XRaiseWindow, XLowerWindow, XCirculateSubwindows, XCirculateSubwindowsUp, XCirculateSubwindowsDown, XRestackWindows – change window stacking order

SYNTAX
XRaiseWindow(display, w)
   Display *display;
   Window w;

XLowerWindow(display, w)
   Display *display;
   Window w;

XCirculateSubwindows(display, w, direction)
   Display *display;
   Window w;
   int direction;

   Display *display;
   Window w;

XCirculateSubwindowsDown(display, w)
   Display *display;
   Window w;

XRestackWindows(display, windows, nwindows);
   Display *display;
   Window windows[];
   int nwindows;

ARGUMENTS
direction      Specifies the direction (up or down) that you want to circulate the window. You can pass RaiseLowest or LowerHighest.
display       Specifies the connection to the XWIN server.
nwindows      Specifies the number of windows to be restacked.
w             Specifies the window.
windows       Specifies an array containing the windows to be restacked.

DESCRIPTION
The XRaiseWindow function raises the specified window to the top of the stack so that no sibling window obscures it. If the windows are regarded as overlapping sheets of paper stacked on a desk, then raising a window is analogous to moving the sheet to the top of the stack but leaving its x and y location on the desk constant. Raising a mapped window may generate Expose events for the window and any mapped subwindows that were formerly obscured.

If the override-redirect attribute of the window is False and some other client has selected SubstructureRedirectMask on the parent, the XWIN server generates a ConfigureRequest event, and no processing is performed. Otherwise, the window is raised.
XRaiseWindow can generate a BadWindow error.

The XLowerWindow function lowers the specified window to the bottom of the stack so that it does not obscure any sibling windows. If the windows are regarded as overlapping sheets of paper stacked on a desk, then lowering a window is analogous to moving the sheet to the bottom of the stack but leaving its x and y location on the desk constant. Lowering a mapped window will generate Expose events on any windows it formerly obscured.

If the override-redirect attribute of the window is False and some other client has selected SubstructureRedirectMask on the parent, the XWIN server generates a ConfigureRequest event, and no processing is performed. Otherwise, the window is lowered to the bottom of the stack.

XLowerWindow can generate a BadWindow error.

The XCirculateSubwindows function circulates children of the specified window in the specified direction. If you specify RaiseLowest, XCirculateSubwindows raises the lowest mapped child (if any) that is occluded by another child to the top of the stack. If you specify LowerHighest, XCirculateSubwindows lowers the highest mapped child (if any) that occludes another child to the bottom of the stack. Exposure processing is then performed on formerly obscured windows. If some other client has selected SubstructureRedirectMask on the window, the XWIN server generates a CirculateRequest event, and no further processing is performed. If a child is actually restacked, the XWIN server generates a CirculateNotify event.

XCirculateSubwindows can generate BadValue and BadWindow errors.

The XCirculateSubwindowsUp function raises the lowest mapped child of the specified window that is partially or completely occluded by another child. Completely unobscured children are not affected. This is a convenience function equivalent to XCirculateSubwindows with RaiseLowest specified.

XCirculateSubwindowsUp can generate a BadWindow error.

The XCirculateSubwindowsDown function lowers the highest mapped child of the specified window that partially or completely occludes another child. Completely unobscured children are not affected. This is a convenience function equivalent to XCirculateSubwindows with LowerHighest specified.

XCirculateSubwindowsDown can generate a BadWindow error.

The XRestackWindows function restacks the windows in the order specified, from top to bottom. The stacking order of the first window in the windows array is unaffected, but the other windows in the array are stacked underneath the first window, in the order of the array. The stacking order of the other windows is not affected. For each window in the window array that is not a child of the specified window, a BadMatch error results.

If the override-redirect attribute of a window is False and some other client has selected SubstructureRedirectMask on the parent, the XWIN server generates ConfigureRequest events for each window whose override-redirect flag is not set, and no further processing is performed. Otherwise, the windows will be restacked in top to bottom order.
XRaiseWindow(3X11)

XRestackWindows can generate BadWindow error.

NAME
XReadBitmapFile, XWriteBitmapFile, XCreatePixmapFromBitmapData, XCreateBitmapFromData – manipulate bitmaps

SYNTAX
int XReadBitmapFile(display, d, filename, width_return, height_return, bitmap_return, x_hot_return, y_hot_return)
    Display *display;
    Drawable d;
    char *filename;
    unsigned int *width_return, *height_return;
    Pixmap *bitmap_return;
    int *x_hot_return, *y_hot_return;

int XWriteBitmapFile(display, filename, bitmap, width, height, x_hot, y_hot)
    Display *display;
    char *filename;
    Pixmap bitmap;
    unsigned int width, height;
    int x_hot, y_hot;

Pixmap XCreatePixmapFromBitmapData(display, d, data, width, height, fg, bg, depth)
    Display *display;
    Drawable d;
    char *data;
    unsigned int width, height;
    unsigned long fg, bg;
    unsigned int depth;

Pixmap XCreateBitmapFromData(display, d, data, width, height)
    Display *display;
    Drawable d;
    char *data;
    unsigned int width, height;

ARGUMENTS
bitmap Specifies the bitmap.
bitmap_return Returns the bitmap that is created.
d Specifies the drawable that indicates the screen.
data Specifies the data in bitmap format.
data Specifies the location of the bitmap data.
depth Specifies the depth of the pixmap.
display Specifies the connection to the XWIN server.
fg Specify the foreground and background pixel values to use.
bg
filename Specifies the file name to use. The format of the file name is operating-system dependent.
The XReadBitmapFile function reads in a file containing a bitmap. The file can be either in the standard X version 10 format (that is, the format used by X version 10 bitmap program) or in the X version 11 bitmap format. If the file cannot be opened, XReadBitmapFile returns BitmapOpenFailed. If the file can be opened but does not contain valid bitmap data, it returns BitmapFileInvalid. If insufficient working storage is allocated, it returns BitmapNoMemory. If the file is readable and valid, it returns BitmapSuccess.

XReadBitmapFile returns the bitmap’s height and width, as read from the file, to width_return and height_return. It then creates a pixmap of the appropriate size, reads the bitmap data from the file into the pixmap, and assigns the pixmap to the caller’s variable bitmap. The caller must free the bitmap using XFreePixmap when finished. If name_x_hot and name_y_hot exist, XReadBitmapFile returns them to x_hot_return and y_hot_return; otherwise, it returns -1,-1.

XReadBitmapFile can generate BadAlloc and BadDrawable errors.

The XWriteBitmapFile function writes a bitmap out to a file. While XReadBitmapFile can read in either X version 10 format or X version 11 format, XWriteBitmapFile always writes out X version 11 format. If the file cannot be opened for writing, it returns BitmapOpenFailed. If insufficient memory is allocated, XWriteBitmapFile returns BitmapNoMemory; otherwise, on no error, it returns BitmapSuccess. If x_hot and y_hot are not -1, -1, XWriteBitmapFile writes them out as the hotspot coordinates for the bitmap.

XWriteBitmapFile can generate BadDrawable and BadMatch errors.

The XCreatePixmapFromBitmapData function creates a pixmap of the given depth and then does a bitmap-format XPutImage of the data into it. The depth must be supported by the screen of the specified drawable, or a BadMatch error results.

XCreatePixmapFromBitmapData can generate BadAlloc and BadMatch errors.

The XCreateBitmapFromData function allows you to include in your C program (using #include) a bitmap file that was written out by XWriteBitmapFile (X version 11 format only) without reading in the bitmap file. The following example creates a gray bitmap:

XReadBitmapFile (3X11)

#include "gray.bitmap"

Pixmap bitmap;
bitmap = XCreateBitmapFromData(display, window, gray_bits, gray_width, gray_height);

If insufficient working storage was allocated, XCreateBitmapFromData returns None. It is your responsibility to free the bitmap using XFreePixmap when finished.

XCreateBitmapFromData can generate a BadAlloc error.

DIAGNOSTICS

BadAlloc The server failed to allocate the requested resource or server memory.

BadDrawable A value for a Drawable argument does not name a defined Window or Pixmap.

BadMatch An InputOnly window is used as a Drawable.

Xlib — C Language X Interface
NAME

XRecolorCursor, XFreeCursor, XQueryBestCursor - manipulate cursors

SYNTAX

XRecolorCursor(display, cursor, foreground_color, background_color)
   Display *display;
   Cursor cursor;
   XColor *foreground_color, *background_color;
XFreeCursor(display, cursor)
   Display *display;
   Cursor cursor;
Status XQueryBestCursor(display, d, width, height, width_return, height_return)
   Display *display;
   Drawable d;
   unsigned int width, height;
   unsigned int *width_return, *height_return;

ARGUMENTS

background_color Specifies the RGB values for the background of the source.
cursor Specifies the cursor.
d Specifies the drawable, which indicates the screen.
display Specifies the connection to the XWIN server.
foreground_color Specifies the RGB values for the foreground of the source.
width
height Specify the width and height of the cursor for which you want the size information.
width_return
height_return Return the best width and height that is closest to the specified width and height.

DESCRIPTION

The XRecolorCursor function changes the color of the specified cursor, and if the cursor is being displayed on a screen, the change is visible immediately.
XRecolorCursor can generate a BadCursor error.

The XFreeCursor function deletes the association between the cursor resource ID and the specified cursor. The cursor storage is freed when no other resource references it. The specified cursor ID should not be referred to again.
XFreeCursor can generate a BadCursor error.

Some displays allow larger cursors than other displays. The XQueryBestCursor function provides a way to find out what size cursors are actually possible on the display. It returns the largest size that can be displayed. Applications should be prepared to use smaller cursors on displays that cannot support large ones.
XQueryBestCursor can generate a BadDrawable error.
XRecolorCursor (3X11)

DIAGNOSTICS
  BadCursor       A value for a Cursor argument does not name a defined Cursor.
  BadDrawable     A value for a Drawable argument does not name a defined
                  Window or Pixmap.

SEE ALSO
  XCreateFontCursor(3X11),
  XDefineCursor(3X11)

NAME
XReparentWindow — reparent windows

SYNTAX
XReparentWindow(display, w, parent, x, y)

Display *display;
Window w;
Window parent;
int x, y;

ARGUMENTS
display Specifies the connection to the XWIN server.
pARENT Specifies the parent window.
w Specifies the window.
x y Specify the x and y coordinates of the position in the new parent window.

DESCRIPTION
If the specified window is mapped, XReparentWindow automatically performs an UnmapWindow request on it, removes it from its current position in the hierarchy, and inserts it as the child of the specified parent. The window is placed in the stacking order on top with respect to sibling windows.

After reparenting the specified window, XReparentWindow causes the XWIN server to generate a ReparentNotify event. The override redirect member returned in this event is set to the window’s corresponding attribute. Window manager clients usually should ignore this window if this member is set to True. Finally, if the specified window was originally mapped, the XWIN server automatically performs a MapWindow request on it.

The XWIN server performs normal exposure processing on formerly obscured windows. The XWIN server might not generate Expose events for regions from the initial UnmapWindow request that are immediately obscured by the final MapWindow request. A BadMatch error results if:

• The new parent window is not on the same screen as the old parent window.
• The new parent window is the specified window or an inferior of the specified window.
• The specified window has a ParentRelative background, and the new parent window is not the same depth as the specified window.

XReparentWindow can generate BadMatch and BadWindow errors.

DIAGNOSTICS
BadWindow A value for a Window argument does not name a defined Window.

SEE ALSO
XChangeSaveSet(3X11)
Xlib — C Language X Interface
NAME
XSaveContext, XFindContext, XDeleteContext, XUniqueContext – associative
look-up routines

SYNTAX

int XSaveContext(display, w, context, data)
Display *display;
Window w;
XContext context;
caddr_t data;

int XFindContext(display, w, context, data_return)
Display *display;
Window w;
XContext context;
caddr_t *data_return;

int XDeleteContext(display, w, context)
Display *display;
Window w;
XContext context;

XContext XUniqueContext()

ARGUMENTS
context Specifies the context type to which the data belongs.
data Specifies the data to be associated with the window and type.
data_return Returns a pointer to the data.
display Specifies the connection to the XWIN server.
w Specifies the window with which the data is associated.

DESCRIPTION
If an entry with the specified window and type already exists, XSaveContext
overrides it with the specified context. The XSaveContext function returns a
nonzero error code if an error has occurred and zero otherwise. Possible errors
are XCNOMEM (out of memory).

Because it is a return value, the data is a pointer. The XFindContext function
returns a nonzero error code if an error has occurred and zero otherwise. Possible errors are
XCNOENT (context-not-found).

The XDeleteContext function deletes the entry for the given window and type
from the data structure. This function returns the same error codes that
XFindContext returns if called with the same arguments. XDeleteContext does
not free the data whose address was saved.

The XUniqueContext function creates a unique context type that may be used in
subsequent calls to XSaveContext.

SEE ALSO

NAME
XSelectInput — select input events

SYNTAX
XSelectInput(display, w, event_mask)
   Display *display;
   Window w;
   long event_mask;

ARGUMENTS
display Specifies the connection to the XWIN server.
event_mask Specifies the event mask.
w Specifies the window whose events you are interested in.

DESCRIPTION
The XSelectInput function requests that the XWIN server report the events associated with the specified event mask. Initially, X will not report any of these events. Events are reported relative to a window. If a window is not interested in a device event, it usually propagates to the closest ancestor that is interested, unless the do_not...,propagate mask prohibits it.

Setting the event-mask attribute of a window overrides any previous call for the same window but not for other clients. Multiple clients can select for the same events on the same window with the following restrictions:

- Multiple clients can select events on the same window because their event masks are disjoint. When the XWIN server generates an event, it reports it to all interested clients.
- Only one client at a time can select CirculateRequest, ConfigureRequest, or MapRequest events, which are associated with the event mask SubstructureRedirectMask.
- Only one client at a time can select a ResizeRequest event, which is associated with the event mask ResizeRedirectMask.
- Only one client at a time can select a ButtonPress event, which is associated with the event mask ButtonPressMask.

The server reports the event to all interested clients.

XSelectInput can generate a BadWindow error.

DIAGNOSTICS
BadWindow A value for a Window argument does not name a defined Window.

NAME
XSetArcMode, XSetSubwindowMode, XSetGraphicsExposure – GC convience routines

SYNTAX
XSetArcMode(display, gc, arc_mode)
    Display *display;
    GC gc;
    int arc_mode;
XSetSubwindowMode(display, gc, subwindow_mode)
    Display *display;
    GC gc;
    int subwindow_mode;
XSetGraphicsExposures(display, gc, graphics_exposures)
    Display *display;
    GC gc;
    Bool graphics_exposures;

ARGUMENTS
arc_mode Specifies the arc mode. You can pass ArcChord or ArcPieSlice.
display Specifies the connection to the XWIN server.
gc Specifies the GC.
graphics_exposures Specifies a Boolean value that indicates whether you want GraphicsExpose and NoExpose events to be reported when calling XCopyArea and XCopyPlane with this GC.
subwindow_mode Specifies the subwindow mode. You can pass ClipByChildren or IncludeInferiors.

DESCRIPTION
The XSetArcMode function sets the arc mode in the specified GC.
XSetArcMode can generate BadAlloc, BadGC, and BadValue errors.
The XSetSubwindowMode function sets the subwindow mode in the specified GC.
XSetSubwindowMode can generate BadAlloc, BadGC, and BadValue errors.
The XSetGraphicsExposures function sets the graphics-exposures flag in the specified GC.
XSetGraphicsExposures can generate BadAlloc, BadGC, and BadValue errors.

DIAGNOSTICS
BadAlloc The server failed to allocate the requested resource or server memory.
BadGC A value for a GContext argument does not name a defined GContext.
BadValue  Some numeric value falls outside the range of values accepted by the request. Unless a specific range is specified for an argument, the full range defined by the argument’s type is accepted. Any argument defined as a set of alternatives can generate this error.

XSetClassHint(3X11)  

NAME
XSetClassHint, XGetClassHint - set or get class hint

SYNTAX
XSetClassHint(display, w, class_hints)
   Display *display;
   Window w;
   XClassHint *class_hints;
Status XGetClassHint(display, w, class_hints_return)
   Display *display;
   Window w;
   XClassHint *class_hints_return;

ARGUMENTS
   class_hints  Specifies a pointer to a XClassHint structure that is to be used.
   class_hints_return  Returns the XClassHint structure.
   display  Specifies the connection to the XWIN server.
   w  Specifies the window.

DESCRIPTION
The XSetClassHint function sets the class hint for the specified window.
XSetClassHint can generate BadAlloc and BadWindow errors.
The XGetClassHint function returns the class of the specified window. To free
res_name and res_class when finished with the strings, use XFree.
XGetClassHint can generate a BadWindow error.

PROPERTY
   WM_CLASS

NAME
XSetClipOrigin, XSetClipMask, XSetClipRectangles - GC convenience routines

SYNTAX
XSetClipOrigin(display, gc, clip_x_origin, clip_y_origin)
  Display *display;
  GC gc;
  int clip_x_origin, clip_y_origin;
XSetClipMask(display, gc, pixmap)
  Display *display;
  GC gc;
 Pixmap pixmap;
XSetClipRectangles(display, gc, clip_x_origin, clip_y_origin, rectangles, n, ordering)
  Display *display;
  GC gc;
  int clip_x_origin, clip_y_origin;
  XRectangle rectangles[];
  int n;
  int ordering;

ARGUMENTS
  display       Specifies the connection to the XWIN server.
  clip_x_origin Specify the x and y coordinates of the clip-mask origin.
  clip_y_origin
  gc            Specifies the GC.
  n             Specifies the number of rectangles.
  ordering      Specifies the ordering relations on the rectangles. You can pass
                Unsorted, YSorted, YXSorted, or YXBanded.
  pixmap        Specifies the pixmap or None.
  rectangles    Specifies an array of rectangles that define the clip-mask.

DESCRIPTION
The XSetClipOrigin function sets the clip origin in the specified GC. The clip-mask
origin is interpreted relative to the origin of whatever destination drawable
is specified in the graphics request.

XSetClipOrigin can generate BadAlloc and BadGC errors.

The XSetClipMask function sets the clip-mask in the specified GC to the
specified pixmap. If the clip-mask is set to None, the pixels are are always
drawn (regardless of the clip-origin).

XSetClipMask can generate BadAlloc, BadGC, BadMatch, and BadValue
errors.

The XSetClipRectangles function changes the clip-mask in the specified GC to
the specified list of rectangles and sets the clip origin. The output is clipped to
remain contained within the rectangles. The clip-origin is interpreted relative to
the origin of whatever destination drawable is specified in a graphics request. The
rectangle coordinates are interpreted relative to the clip-origin. The rectangles
should be nonintersecting, or the graphics results will be undefined. Note that
the list of rectangles can be empty, which effectively disables output. This is the
opposite of passing None as the clip-mask in XCreateGC, XChangeGC, and
XSetClipMask.

If known by the client, ordering relations on the rectangles can be specified with
the ordering argument. This may provide faster operation by the server. If an
incorrect ordering is specified, the XWIN server may generate a BadMatch error,
but it is not required to do so. If no error is generated, the graphics results are
undefined. Unsorted means the rectangles are in arbitrary order. YSorted
means that the rectangles are nondecreasing in their Y origin. YXSorted addi-
tionally constrains YSorted order in that all rectangles with an equal Y origin are
nondecreasing in their X origin. YXBandes additionally constrains YXSorted by
requiring that, for every possible Y scanline, all rectangles that include that scan-
line have an identical Y origins and Y extents.

XSetClipRectangles can generate BadAlloc, BadGC, BadMatch, and BadValue
errors.

DIAGNOSTICS

BadAlloc The server failed to allocate the requested resource or server
memory.

BadGC A value for a GContext argument does not name a defined
GContext.

BadMatch Some argument or pair of arguments has the correct type and
range but fails to match in some other way required by the
request.

BadValue Some numeric value falls outside the range of values accepted
by the request. Unless a specific range is specified for an argu-
ment, the full range defined by the argument’s type is accepted.
Any argument defined as a set of alternatives can generate this
error.

Xlib – C Language X Interface
NAME
XSetCloseDownMode, XKillClient – control clients

SYNTAX
XSetCloseDownMode(display, close_mode)
    Display *display;
    int close_mode;
XKillClient(display, resource)
    Display *display;
    XID resource;

ARGUMENTS
    close_mode Specifies the client close-down mode. You can pass DestroyAll,
             RetainPermanent, or RetainTemporary.
    display Specifies the connection to the XWIN server.
    resource Specifies any resource associated with the client that you want
             to destroy or AllTemporary.

DESCRIPTION
The XSetCloseDownMode defines what will happen to the client’s resources at
connection close. A connection starts in DestroyAll mode. For information on
what happens to the client’s resources when the close_mode argument is Retain­
Permanent or RetainTemporary, see section 2.6, Xlib—C Language X
Interface.

XSetCloseDownMode can generate a BadValue error.

The XKillClient function forces a close-down of the client that created the
resource if a valid resource is specified. If the client has already terminated in
either RetainPermanent or RetainTemporary mode, all of the client’s resources
are destroyed. If AllTemporary is specified, the resources of all clients that have
terminated in RetainTemporary are destroyed (see section 2.6, Xlib—C Language
X Interface). This permits implementation of window manager facilities that aid
debugging. A client can set its close-down mode to RetainTemporary. If the
client then crashes, its windows would not be destroyed. The programmer can
then inspect the application’s window tree and use the window manager to dest­
roy the zombie windows.

XKillClient can generate a BadValue error.

DIAGNOSTICS
BadValue Some numeric value falls outside the range of values accepted
by the request. Unless a specific range is specified for an argu­
ment, the full range defined by the argument’s type is accepted.
Any argument defined as a set of alternatives can generate this
error.

NAME
XSetCommand – set command atom

SYNTAX
XSetCommand(display, w, argv, argc)

Display *display;
Window w;
char **argv;
int argc;

ARGUMENTS
argc Specifies the number of arguments.
argv Specifies the application’s argument list.
display Specifies the connection to the XWIN server.
w Specifies the window.

DESCRIPTION
The XSetCommand function sets the command and arguments used to invoke
the application. (Typically, argv is the argv array of your main program.)
XSetCommand can generate BadAlloc and BadWindow errors.

PROPERTY
WM_COMMAND

DIAGNOSTICS
BadAlloc The server failed to allocate the requested resource or server
memory.

Xlib – C Language X Interface
NAME
XSetErrorHandler, XGetErrorText, XDisplayName, XSetIOErrorHandler, XGetErrorDatabaseText – default error handlers

SYNTAX
XSetErrorHandler (handler)
   int (*handler)();

XGetErrorText (display, code, buffer_return, length)
   Display *display;
   int code;
   char *buffer_return;
   int length;

   char *XDisplayName (string)
      char *string;

XSetIOErrorHandler (handler)
   int (*handler)();

XGetErrorDatabaseText (display, name, message, default_string, buffer_return, length)
   Display *display;
   char *name, *message;
   char *default_string;
   char *buffer_return;
   int length;

ARGUMENTS
   buffer_return    Returns the error description.
   code             Specifies the error code for which you want to obtain a description.
   default_string   Specifies the default error message if none is found in the database.
   display          Specifies the connection to the XWIN server.
   handler          Specifies the program’s supplied error handler.
   length           Specifies the size of the buffer.
   message          Specifies the type of the error message.
   name             Specifies the name of the application.
   string           Specifies the character string.

DESCRIPTION
Xlib generally calls the program’s supplied error handler whenever an error is received. It is not called on BadName errors from OpenFont, LookupColor, or AllocNamedColor protocol requests or on BadFont errors from a QueryFont protocol request. These errors generally are reflected back to the program through the procedural interface. Because this condition is not assumed to be fatal, it is acceptable for your error handler to return. However, the error handler should not call any functions (directly or indirectly) on the display that will generate protocol requests or that will look for input events.
The **XGetErrorText** function copies a null-terminated string describing the specified error code into the specified buffer. It is recommended that you use this function to obtain an error description because extensions to Xlib may define their own error codes and error strings.

The **XDisplayName** function returns the name of the display that **XOpenDisplay** would attempt to use. If a NULL string is specified, **XDisplayName** looks in the environment for the display and returns the display name that **XOpenDisplay** would attempt to use. This makes it easier to report to the user precisely which display the program attempted to open when the initial connection attempt failed.

The **XSetIOErrorHandler** sets the fatal I/O error handler. Xlib calls the program's supplied error handler if any sort of system call error occurs (for example, the connection to the server was lost). This is assumed to be a fatal condition, and the called routine should not return. If the I/O error handler does return, the client process exits.

The **XGetErrorDatabaseText** function returns a message (or the default message) from the error message database. Xlib uses this function internally to look up its error messages. On a UNIX-based system, the error message database is `/usr/lib/X11/XErrorDB`.

The name argument should generally be the name of your application. The message argument should indicate which type of error message you want. Xlib uses three predefined message types to report errors (uppercase and lowercase matter):

- **XProtoError**: The protocol error number is used as a string for the message argument.
- **XlibMessage**: These are the message strings that are used internally by the library.
- **XRequest**: The major request protocol number is used for the message argument. If no string is found in the error database, the default_string is returned to the buffer argument.

NAME
XSendEvent, XDisplayMotionBufferSize, XGetMotionEvents – send events

SYNTAX
Status XSendEvent(display, w, propagate, event_mask, event_send)
Display *display;
Window w;
Bool propagate;
long event_mask;
XEvent *event_send;

unsigned long XDisplayMotionBufferSize(display)
Display *display;

XTimeCoord *XGetMotionEvents(display, w, start, stop, nevents_return)
Display *display;
Window w;
Time start, stop;
int *nevents_return;

ARGUMENTS
| display       | Specifies the connection to the XWIN server. |
| event_mask    | Specifies the event mask.                  |
| event_send    | Specifies a pointer to the event that is to be sent. |
| nevents_return| Returns the number of events from the motion history buffer. |
| propagate     | Specifies a Boolean value.                 |
| start         | Specify the time interval in which the events are returned from the motion history buffer. You can pass a timestamp or CurrentTime. |
| stop          |                                               |
| w             | Specifies the window the event is to be sent to, PointerWindow, or InputFocus. |

DESCRIPTION
The XSendEvent function identifies the destination window, determines which clients should receive the specified events, and ignores any active grabs. This function requires you to pass an event mask. For a discussion of the valid event mask names, see section 8.3. This function uses the w argument to identify the destination window as follows:

- If w is PointerWindow, the destination window is the window that contains the pointer.
- If w is InputFocus and if the focus window contains the pointer, the destination window is the window that contains the pointer; otherwise, the destination window is the focus window.

To determine which clients should receive the specified events, XSendEvent uses the propagate argument as follows:
XSendEvent (3X11)

- If event_mask is the empty set, the event is sent to the client that created the destination window. If that client no longer exists, no event is sent.
- If propagate is False, the event is sent to every client selecting on destination any of the event types in the event_mask argument.
- If propagate is True and no clients have selected on destination any of the event types in event-mask, the destination is replaced with the closest ancestor of destination for which some client has selected a type in event-mask and for which no intervening window has that type in its do-not-propagate-mask. If no such window exists or if the window is an ancestor of the focus window and InputFocus was originally specified as the destination, the event is not sent to any clients. Otherwise, the event is reported to every client selecting on the final destination any of the types specified in event_mask.

The event in the XEvent structure must be one of the core events or one of the events defined by an extension (or a BadValue error results) so that the XWIN server can correctly byte-swap the contents as necessary. The contents of the event are otherwise unaltered and unchecked by the XWIN server except to force send_event to True in the forwarded event and to set the serial number in the event correctly.

XSendEvent returns zero if the conversion to wire protocol format failed and returns nonzero otherwise. XSendEvent can generate BadValue and BadWindow errors.

The server may retain the recent history of the pointer motion and do so to a finer granularity than is reported by MotionNotify events. The XGetMotionEvents function makes this history available.

The XGetMotionEvents function returns all events in the motion history buffer that fall between the specified start and stop times, inclusive, and that have coordinates that lie within the specified window (including its borders) at its present placement. If the start time is later than the stop time or if the start time is in the future, no events are returned. If the stop time is in the future, it is equivalent to specifying CurrentTime. XGetMotionEvents can generate a BadWindow error.

XSetFillStyle, XSetFillRule - GC convenience routines

SYNTAX
XSetFillStyle(display, gc, fill_style)
Display *display;
GC gc;
int fill_style;

XSetFillRule(display, gc, fill_rule)
Display *display;
GC gc;
int fill_rule;

ARGUMENTS

display Specifies the connection to the XWIN server.
fill_rule Specifies the fill-rule you want to set for the specified GC. You can pass EvenOddRule or WindingRule.
fill_style Specifies the fill-style you want to set for the specified GC. You can pass FillSolid, FillTiled, FillStippled, or FillOpaqueStippled.
gc Specifies the GC.

DESCRIPTION
The XSetFillStyle function sets the fill-style in the specified GC.
XSetFillStyle can generate BadAlloc, BadGC, and BadValue errors.
The XSetFillRule function sets the fill-rule in the specified GC.
XSetFillRule can generate BadAlloc, BadGC, and BadValue errors.

DIAGNOSTICS

BadAlloc The server failed to allocate the requested resource or server memory.

BadGC A value for a GContext argument does not name a defined GContext.

BadValue Some numeric value falls outside the range of values accepted by the request. Unless a specific range is specified for an argument, the full range defined by the argument's type is accepted. Any argument defined as a set of alternatives can generate this error.

NAME
XSetFontPath, XGetFontPath, XFreeFontPath - set, get, or free the font search path

SYNTAX

XSetFontPath(display, directories, ndirs)
  Display *display;
  char **directories;
  int ndirs;

cchar **XGetFontPath(display, npaths_return)
  Display *display;
  int *npaths_return;

XFreeFontPath(list)
  char **list;

ARGUMENTS

directories    Specifies the directory path used to look for a font. Setting the path to the empty list restores the default path defined for the XWIN server.

display        Specifies the connection to the XWIN server.

list           Specifies the array of strings you want to free.

ndirs          Specifies the number of directories in the path.

npaths_return  Returns the number of strings in the font path array.

DESCRIPTION

The XSetFontPath function defines the directory search path for font lookup. There is only one search path per XWIN server, not one per client. The interpretation of the strings is operating system dependent, but they are intended to specify directories to be searched in the order listed. Also, the contents of these strings are operating system dependent and are not intended to be used by client applications. Usually, the XWIN server is free to cache font information internally rather than having to read fonts from files. In addition, the XWIN server is guaranteed to flush all cached information about fonts for which there currently are no explicit resource IDs allocated. The meaning of an error from this request is operating system dependent.

XSetFontPath can generate a BadValue error.

The XGetFontPath function allocates and returns an array of strings containing the search path. When it is no longer needed, the data in the font path should be freed by using XFreeFontPath.

The XFreeFontPath function frees the data allocated by XGetFontPath.
DIAGNOSTICS

BadValue Some numeric value falls outside the range of values accepted by the request. Unless a specific range is specified for an argument, the full range defined by the argument's type is accepted. Any argument defined as a set of alternatives can generate this error.

NAME
XSetIconName, XGetIconName — set or get icon names

SYNTAX
XSetIconName(display, w, icon_name)
   Display *display;
   Window w;
   char *icon_name;
Status XGetIconName(display, w, icon_name_return)
   Display *display;
   Window w;
   char **icon_name_return;

ARGUMENTS
   display  Specifies the connection to the XWIN server.
   icon_name  Specifies the icon name, which should be a null-terminated string.
   icon_name_return  Returns a pointer to the window’s icon name, which is a null-terminated string.
   w  Specifies the window.

DESCRIPTION
The XSetIconName function sets the name to be displayed in a window’s icon.
XSetIconName can generate BadAlloc and BadWindow errors.
The XGetIconName function returns the name to be displayed in the specified window’s icon. If it succeeds, it returns nonzero; otherwise, if no icon name has been set for the window, it returns zero. If you never assigned a name to the window, XGetIconName sets icon_name_return to NULL. When finished with it, a client must free the icon name string using XFree.
XGetIconName can generate a BadWindow error.

PROPERTY
WM_ICON_NAME

NAME
XSetIconSizes, XGetIconSizes - set or get icon size hints

SYNTAX
XSetIconSizes(display, w, size_list, count)
Display *display;
Window w;
XIconSize *size_list;
int count;

Status XGetIconSizes(display, w, size_list_return, count_return)
Display *display;
Window w;
XIconSize **size_list_return;
int *count_return;

ARGUMENTS
display Specifies the connection to the XWIN server.
count Specifies the number of items in the size list.
count_return Returns the number of items in the size list.
size_list Specifies a pointer to the size list.
size_list_return Returns a pointer to the size list.
w Specifies the window.

DESCRIPTION
The XSetIconSizes function is used only by window managers to set the supported icon sizes.
XSetIconSizes can generate BadAlloc and BadWindow errors.
The XGetIconSizes function returns zero if a window manager has not set icon sizes or nonzero otherwise. XGetIconSizes should be called by an application that wants to find out what icon sizes would be most appreciated by the window manager under which the application is running. The application should then use XSetWMHints to supply the window manager with an icon pixmap or window in one of the supported sizes. To free the data allocated in size_list_return, use XFree.
XGetIconSizes can generate a BadWindow error.

PROPERTY
WM_ICON_SIZE

NAME
XSetInputFocus, XGetInputFocus — control input focus

SYNTAX
XSetInputFocus(display, focus, revert_to, time)
   Display *display;
   Window focus;
   int revert_to;
   Time time;

XGetInputFocus(display, focus_return, revert_to_return)
   Display *display;
   Window *focus_return;
   int *revert_to_return;

ARGUMENTS
display Specifies the connection to the XWIN server.
focus Specifies the window, PointerRoot, or None.
focus_return Returns the focus window, PointerRoot, or None.
revert_to Specifies where the input focus reverts to if the window
   becomes not viewable. You can pass RevertToParent, RevertToPointerRoot, or RevertToNone.
revert_to_return Returns the current focus state (RevertToParent, RevertToPointerRoot, or RevertToNone).
time Specifies the time. You can pass either a timestamp or CurrentTime.

DESCRIPTION
The XSetInputFocus function changes the input focus and the last-focus-change
   time. It has no effect if the specified time is earlier than the current last-focus-change
   time or is later than the current XWIN server time. Otherwise, the last-focus-change
   time is set to the specified time (CurrentTime is replaced by the
   current XWIN server time). XSetInputFocus causes the XWIN server to generate
   FocusIn and FocusOut events.

Depending on the focus argument, the following occurs:
• If focus is None, all keyboard events are discarded until a new focus win-
   dow is set, and the revert_to argument is ignored.
• If focus is a window, it becomes the keyboard’s focus window. If a generated
   keyboard event would normally be reported to this window or one
   of its inferiors, the event is reported as usual. Otherwise, the event is
   reported relative to the focus window.
• If focus is PointerRoot, the focus window is dynamically taken to be the
   root window of whatever screen the pointer is on at each keyboard event.
   In this case, the revert_to argument is ignored.

The specified focus window must be viewable at the time XSetInputFocus is
called, or a BadMatch error results. If the focus window later becomes not view-
able, the XWIN server evaluates the revert_to argument to determine the new
focus window as follows:
XSetInputFocus(3X11)

- If revert_to is RevertToParent, the focus reverts to the parent (or the closest viewable ancestor), and the new revert_to value is taken to be RevertToNone.
- If revert_to is RevertToPointerRoot or RevertToNone, the focus reverts to PointerRoot or None, respectively. When the focus reverts, the XWIN server generates FocusIn and FocusOut events, but the last-focus-change time is not affected.

XSetInputFocus can generate BadMatch, BadValue, and BadWindow errors.
The XGetInputFocus function returns the focus window and the current focus state.

DIAGNOSTICS

BadValue Some numeric value falls outside the range of values accepted by the request. Unless a specific range is specified for an argument, the full range defined by the argument's type is accepted. Any argument defined as a set of alternatives can generate this error.

BadWindow A value for a Window argument does not name a defined Window.

XSetLineAttribute, XSetDashes - GC convenience routines

SYNTAX
XSetLineAttributes(display, gc, line_width, line_style, cap_style, join_style)
    Display *display;
    GC gc;
    unsigned int line_width;
    int line_style;
    int cap_style;
    int join_style;

XSetDashes(display, gc, dash_offset, dash_list, n)
    Display *display;
    GC gc;
    int dash_offset;
    char dash_list[];
    int n;

ARGUMENTS
    cap_style   Specifies the line-style and cap-style you want to set for the specified GC. You can pass CapNotLast, CapButt, CapRound, or CapProjecting.
    dash_list   Specifies the dash-list for the dashed line-style you want to set for the specified GC.
    dash_offset Specifies the phase of the pattern for the dashed line-style you want to set for the specified GC.
    display     Specifies the connection to the XWIN server.
    gc          Specifies the GC.
    join_style  Specifies the line join-style you want to set for the specified GC. You can pass JoinMiter, JoinRound, or JoinBevel.
    line_style  Specifies the line-style you want to set for the specified GC. You can pass LineSolid, LineOnOffDash, or LineDoubleDash.
    line_width  Specifies the line-width you want to set for the specified GC.
    n           Specifies the number of elements in dash_list.

DESCRIPTION
The XSetLineAttributes function sets the line drawing components in the specified GC.
XSetLineAttributes can generate BadAlloc, BadGC, and BadValue errors.
The XSetDashes function sets the dash-offset and dash-list attributes for dashed line styles in the specified GC. There must be at least one element in the specified dash_list, or a BadValue error results. The initial and alternating elements (second, fourth, and so on) of the dash list are the even dashes, and the others are the odd dashes. Each element specifies a dash length in pixels. All of
the elements must be nonzero, or a BadValue error results. Specifying an odd-length list is equivalent to specifying the same list concatenated with itself to produce an even-length list.

The dash-offset defines the phase of the pattern, specifying how many pixels into the dash-list the pattern should actually begin in any single graphics request. Dashing is continuous through path elements combined with a join-style but is reset to the dash-offset each time a cap-style is applied at a line endpoint.

The unit of measure for dashes is the same for the ordinary coordinate system. Ideally, a dash length is measured along the slope of the line, but implementations are only required to match this ideal for horizontal and vertical lines. Failing the ideal semantics, it is suggested that the length be measured along the major axis of the line. The major axis is defined as the x axis for lines drawn at an angle of between -45 and +45 degrees or between 315 and 225 degrees from the x axis. For all other lines, the major axis is the y axis.

XSetDashes can generate BadAlloc, BadGC, and BadValue errors.

**DIAGNOSTICS**

**BadAlloc**

The server failed to allocate the requested resource or server memory.

**BadGC**

A value for a GContext argument does not name a defined GContext.

**BadValue**

Some numeric value falls outside the range of values accepted by the request. Unless a specific range is specified for an argument, the full range defined by the argument's type is accepted. Any argument defined as a set of alternatives can generate this error.

NAME
XSetNormalHints, XGetNormalHints — set or get normal state hints

SYNTAX
XSetNormalHints(display, w, hints)
    Display *display;
    Window w;
    XSizeHints *hints;

    Status XGetNormalHints(display, w, hints_return)
    Display *display;
    Window w;
    XSizeHints *hints_return;

ARGUMENTS
    display        Specifies the connection to the XWIN server.
    hints          Specifies a pointer to the size hints for the window in its normal
                    state.
    hints_return   Returns the size hints for the window in its normal state.
    w              Specifies the window.

DESCRIPTION
The XSetNormalHints function sets the size hints structure for the specified window. Applications use XSetNormalHints to inform the window manager of the size or position desirable for that window. In addition, an application that wants to move or resize itself should call XSetNormalHints and specify its new desired location and size as well as making direct Xlib calls to move or resize. This is because window managers may ignore redirected configure requests, but they pay attention to property changes.

To set size hints, an application not only must assign values to the appropriate members in the hints structure but also must set the flags member of the structure to indicate which information is present and where it came from. A call to XSetNormalHints is meaningless, unless the flags member is set to indicate which members of the structure have been assigned values.

XSetNormalHints can generate BadAlloc and BadWindow errors.

The XGetNormalHints function returns the size hints for a window in its normal state. It returns a nonzero status if it succeeds or zero if the application specified no normal size hints for this window.

XGetNormalHints can generate a BadWindow error.

PROPERTY
WM_NORMAL_HINTS

DIAGNOSTICS
    BadAlloc            The server failed to allocate the requested resource or server
                        memory.
    BadWindow          A value for a Window argument does not name a defined Window.

XSetPointerMapping (3X11)

NAME
XSetPointerMapping, XGetPointerMapping – manipulate pointer settings

SYNTAX

```c
int XSetPointerMapping(display, map, nmap)
Display *display;
unsigned char map[];
int nmap;
```

```c
int XGetPointerMapping(display, map_return, nmap)
Display *display;
unsigned char map_return[];
int nmap;
```

ARGUMENTS
- `display`: Specifies the connection to the XWIN server.
- `map`: Specifies the mapping list.
- `map_return`: Returns the mapping list.
- `nmap`: Specifies the number of items in the mapping list.

DESCRIPTION
The `XSetPointerMapping` function sets the mapping of the pointer. If it succeeds, the XWIN server generates a MappingNotify event, and `XSetPointerMapping` returns MappingSuccess. Elements of the list are indexed starting from one. The length of the list must be the same as `XGetPointerMapping` would return, or a BadValue error results. The index is a core button number, and the element of the list defines the effective number. A zero element disables a button, and elements are not restricted in value by the number of physical buttons. However, no two elements can have the same nonzero value, or a BadValue error results. If any of the buttons to be altered are logically in the down state, `XSetPointerMapping` returns MappingBusy, and the mapping is not changed.

`XSetPointerMapping` can generate a BadValue error.

The `XGetPointerMapping` function returns the current mapping of the pointer. Elements of the list are indexed starting from one. `XGetPointerMapping` returns the number of physical buttons actually on the pointer. The nominal mapping for a pointer is the identity mapping: map[i]=i. The nmap argument specifies the length of the array where the pointer mapping is returned, and only the first nmap elements are returned in map_return.

DIAGNOSTICS
- **BadValue**: Some numeric value falls outside the range of values accepted by the request. Unless a specific range is specified for an argument, the full range defined by the argument’s type is accepted. Any argument defined as a set of alternatives can generate this error.

NAME
XSetScreenSaver, XForceScreenSaver, XActivateScreenSaver, XResetScreenSaver,
XGetScreenSaver — manipulate the screen saver

SYNTAX
XSetScreenSaver(display, timeout, interval, prefer_blanking, allow_exposures)
   Display *display;
   int timeout, interval;
   int prefer_blanking;
   int allow_exposures;
XForceScreenSaver(display, mode)
   Display *display;
   int mode;
XActivateScreenSaver(display)
   Display *display;
XResetScreenSaver(display)
   Display *display;
XGetScreenSaver(display, timeout_return, interval_return, prefer_blanking_return,
   allow_exposures_return)
   Display *display;
   int *timeout_return, *interval_return;
   int *prefer_blanking_return;
   int *allow_exposures_return;

ARGUMENTS
allow_exposures Specifies the screen save control values. You can pass DontAl­
lowExposures, AllowExposures, or DefaultExposures.
allow_exposures_return Returns the current screen save control value (DontAl­
lowExposures, AllowExposures, or DefaultExposures).
display Specifies the connection to the XWIN server.
interval Specifies the interval between screen saver alterations.
interval_return Returns the interval between screen saver invocations.
mode Specifies the mode that is to be applied. You can pass Screen­
SaverActive or ScreenSaverReset.
prefer_blanking Specifies how to enable screen blanking. You can pass Don­
tPreferBlanking, PreferBlanking, or DefaultBlanking.
prefer_blanking_return Returns the current screen blanking preference (DontPrefer­
Blanking, PreferBlanking, or DefaultBlanking).
timeout Specifies the timeout, in seconds, until the screen saver turns on.
timeout_return Returns the timeout, in minutes, until the screen saver turns on.
DESCRIPTION
Timeout and interval are specified in seconds. A timeout of 0 disables the screen saver, and a timeout of -1 restores the default. Other negative values generate a BadValue error. If the timeout value is nonzero, XSetScreenSaver enables the screen saver. An interval of 0 disables the random-pattern motion. If no input from devices (keyboard, mouse, and so on) is generated for the specified number of timeout seconds once the screen saver is enabled, the screen saver is activated.

For each screen, if blanking is preferred and the hardware supports video blanking, the screen simply goes blank. Otherwise, if either exposures are allowed or the screen can be regenerated without sending Expose events to clients, the screen is tiled with the root window background tile randomly re-origined each interval minutes. Otherwise, the screens’ state do not change, and the screen saver is not activated. The screen saver is deactivated, and all screen states are restored at the next keyboard or pointer input or at the next call to XForceScreenSaver with mode ScreenSaverReset.

If the server-dependent screen saver method supports periodic change, the interval argument serves as a hint about how long the change period should be, and zero hints that no periodic change should be made. Examples of ways to change the screen include scrambling the colormap periodically, moving an icon image around the screen periodically, or tiling the screen with the root window background tile, randomly re-origined periodically.

XSetScreenSaver can generate a BadValue error.

If the specified mode is ScreenSaverActive and the screen saver currently is deactivated, XForceScreenSaver activates the screen saver even if the screen saver had been disabled with a timeout of zero. If the specified mode is ScreenSaverReset and the screen saver currently is enabled, XForceScreenSaver deactivates the screen saver if it was activated, and the activation timer is reset to its initial state (as if device input had been received).

XForceScreenSaver can generate a BadValue error.

The XActivateScreenSaver function activates the screen saver.

The XResetScreenSaver function resets the screen saver.

The XGetScreenSaver function gets the current screen saver values.

DIAGNOSTICS
BadValue
Some numeric value falls outside the range of values accepted by the request. Unless a specific range is specified for an argument, the full range defined by the argument’s type is accepted. Any argument defined as a set of alternatives can generate this error.

SEE ALSO
Xlib – C Language X Interface
NAME
XSetSelectionOwner, XGetSelectionOwner, XConvertSelection – manipulate window selection

SYNTAX
XSetSelectionOwner(display, selection, owner, time)
   Display *display;
   Atom selection;
   Window owner;
   Time time;
Window XGetSelectionOwner(display, selection)
   Display *display;
   Atom selection;
XConvertSelection(display, selection, target, property, requestor, time)
   Display *display;
   Atom selection, target;
   Atom property;
   Window requestor;
   Time time;

ARGUMENTS
   display  Specifies the connection to the XWIN server.
   owner    Specifies the owner of the specified selection atom. You can pass a window or None.
   property Specifies the property name. You also can pass None.
   requestor Specifies the requestor.
   selection Specifies the selection atom.
   target   Specifies the target atom.
   time     Specifies the time. You can pass either a timestamp or Current-Time.

DESCRIPTION
The XSetSelectionOwner function changes the owner and last-change time for the specified selection and has no effect if the specified time is earlier than the current last-change time of the specified selection or is later than the current XWIN server time. Otherwise, the last-change time is set to the specified time, with CurrentTime replaced by the current server time. If the owner window is specified as None, then the owner of the selection becomes None (that is, no owner). Otherwise, the owner of the selection becomes the client executing the request.

If the new owner (whether a client or None) is not the same as the current owner of the selection and the current owner is not None, the current owner is sent a SelectionClear event. If the client that is the owner of a selection is later terminated (that is, its connection is closed) or if the owner window it has specified in the request is later destroyed, the owner of the selection automatically reverts to None, but the last-change time is not affected. The selection atom is uninterpreted by the XWIN server. XGetSelectionOwner returns the owner window,
which is reported in SelectionRequest and SelectionClear events. Selections are
global to the XWIN server.

XSetSelectionOwner can generate BadAtom and BadWindow errors.
The XGetSelectionOwner function returns the window ID associated with the
window that currently owns the specified selection. If no selection was specified,
the function returns the constant None. If None is returned, there is no owner
for the selection.

XGetSelectionOwner can generate a BadAtom error.

XConvertSelection requests that the specified selection be converted to the
specified target type:

- If the specified selection has an owner, the XWIN server sends a Selection-
  Request event to that owner.
- If no owner for the specified selection exists, the XWIN server generates a
  SelectionNotify event to the requestor with property None.

In either event, the arguments are passed on unchanged. There are two
predefined selection atoms: PRIMARY and SECONDARY.

XConvertSelection can generate BadAtom and BadWindow errors.

DIAGNOSTICS

BadAtom A value for an Atom argument does not name a defined Atom.

BadWindow A value for a Window argument does not name a defined Window.

NAME
XSetSizeHints, XGetSizeHints – set or get window size hints

SYNTAX
XSetSizeHints(display, w, hints, property)
   Display *display;
   Window w;
   XSizeHints *hints;
   Atom property;
Status XGetSizeHints(display, w, hints_return, property)
   Display *display;
   Window w;
   XSizeHints *hints_return;
   Atom property;

ARGUMENTS
   display Specifies the connection to the XWIN server.
   hints Specifies a pointer to the size hints.
   hints_return Returns the size hints.
   property Specifies the property name.
   w Specifies the window.

DESCRIPTION
The XSetSizeHints function sets the XSizeHints structure for the named property and the specified window. This is used by XSetNormalHints and XSetZoomHints, and can be used to set the value of any property of type WM_SIZE_HINTS. Thus, it may be useful if other properties of that type get defined.

XSetSizeHints can generate BadAlloc, BadAtom, and BadWindow errors.

XGetSizeHints returns the XSizeHints structure for the named property and the specified window. This is used by XGetNormalHints and XGetZoomHints. It also can be used to retrieve the value of any property of type WM_SIZE_HINTS. Thus, it may be useful if other properties of that type get defined. XGetSizeHints returns a nonzero status if a size hint was defined or zero otherwise.

XGetSizeHints can generate BadAtom and BadWindow errors.

DIAGNOSTICS
   BadAlloc The server failed to allocate the requested resource or server memory.
   BadAtom A value for an Atom argument does not name a defined Atom.
   BadWindow A value for a Window argument does not name a defined Window.

NAME
XSetStandardColormap, XGetStandardColormap - set or get standard colormaps

SYNTAX
XSetStandardColormap(display, w, colormap, property)
  Display *display;
  Window w;
  XStandardColormap *colormap;
  Atom property; /* RGB_BEST_MAP, etc. */
Status XGetStandardColormap(display, w, colormap_return, property)
  Display *display;
  Window w;
  XStandardColormap *colormap_return;
  Atom property; /* RGB_BEST_MAP, etc. */

ARGUMENTS
  colormap          Specifies the colormap.
  colormap_return  Returns the colormap associated with the specified atom.
  display           Specifies the connection to the XWIN server.
  property          Specifies the property name.
  w                 Specifies the window.

DESCRIPTION
The XSetStandardColormap function usually is only used by window managers. To create a standard colormap, follow this procedure:
1. Open a new connection to the same server.
2. Grab the server.
3. See if the property is on the property list of the root window for the screen.
4. If the desired property is not present:
   • Create a colormap (not required for RGB_DEFAULT_MAP)
   • Determine the color capabilities of the display.
   • Call XAllocColorPlanes or XAllocColorCells to allocate cells in the colormap.
   • Call XStoreColors to store appropriate color values in the colormap.
   • Fill in the descriptive members in the XStandardColormap structure.
   • Attach the property to the root window.
   • Use XSetCloseDownMode to make the resource permanent.
5. Ungrab the server.
XSetStandardColormap can generate BadAlloc, BadAtom, and BadWindow errors.
The `XGetStandardColormap` function returns the colormap definition associated with the atom supplied as the property argument. For example, to fetch the standard `GrayScale` colormap for a display, you use `XGetStandardColormap` with the following syntax:

```
xGetStandardColormap(dpy, DefaultRootWindow(dpy), &cmap, XA_RGB_GRAY_MAP);
```

Once you have fetched a standard colormap, you can use it to convert RGB values into pixel values. For example, given an `XStandardColormap` structure and floating-point RGB coefficients in the range 0.0 to 1.0, you can compose pixel values with the following C expression:

```
pixel = base_pixel
    + ((unsigned long) (0.5 + r * red_max)) * red_mult
    + ((unsigned long) (0.5 + g * green_max)) * green_mult
    + ((unsigned long) (0.5 + b * blue_max)) * blue_mult;
```

The use of addition rather than logical OR for composing pixel values permits allocations where the RGB value is not aligned to bit boundaries.

`XGetStandardColormap` can generate `BadAtom` and `BadWindow` errors.

**DIAGNOSTICS**

- **BadAlloc** The server failed to allocate the requested resource or server memory.
- **BadAtom** A value for an Atom argument does not name a defined Atom.
- **BadWindow** A value for a Window argument does not name a defined Window.

**SEE ALSO**

`Xlib - C Language X Interface`
NAME
XSetStandardProperties - set standard window manager properties

SYNTAX
XSetStandardProperties(display, w, window_name, icon_name, icon_pixmap, argv, argc, hints)

Display *display;
Window w;
char *window_name;
char *icon_name;
Pixmap icon_pixmap;
char **argv;
int argc;
XSizeHints *hints;

ARGUMENTS
argc Specifies the number of arguments.
argv Specifies the application's argument list.
display Specifies the connection to the XWIN server.
hints Specifies a pointer to the size hints for the window in its normal state.
icon_name Specifies the icon name, which should be a null-terminated string.
icon_pixmap Specifies the bitmap that is to be used for the icon or None.
w Specifies the window.
window_name Specifies the window name, which should be a null-terminated string.

DESCRIPTION
The XSetStandardProperties function provides a means by which simple applications set the most essential properties with a single call. XSetStandardProperties should be used to give a window manager some information about your program's preferences. It should not be used by applications that need to communicate more information than is possible with XSetStandardProperties. (Typically, argv is the argv array of your main program.)

XSetStandardProperties can generate BadAlloc and BadWindow errors.

PROPERTIES
WM_NAME, WM_ICON_NAME, WM_HINTS, WM_COMMAND, and WM_NORMALHINTS

DIAGNOSTICS
BadAlloc The server failed to allocate the requested resource or server memory.

BadWindow A value for a Window argument does not name a defined Window.

XSetForeground(display, gc, foreground)
  Display *display;
  GC gc;
  unsigned long foreground;
XSetBackground(display, gc, background)
  Display *display;
  GC gc;
  unsigned long background;

ARGUMENTS
background Specifies the background you want to set for the specified GC.
display Specifies the connection to the XWIN server.
foreground Specifies the foreground you want to set for the specified GC.
function Specifies the function you want to set for the specified GC.
gc Specifies the GC.
plane_mask Specifies the plane mask.

DESCRIPTION
The XSetState function sets the foreground, background, plane mask, and function components for the specified GC.
XSetState can generate BadAlloc, BadGC, and BadValue errors.
XSetFunction sets a specified value in the specified GC.
XSetFunction can generate BadAlloc, BadGC, and BadValue errors.
The XSetPlaneMask function sets the plane mask in the specified GC.
XSetPlaneMask can generate BadAlloc and BadGC errors. The XSetForeground function sets the foreground in the specified GC. XSetForeground can generate BadAlloc and BadGC errors. The XSetBackground function sets the background in the specified GC. XSetBackground can generate BadAlloc and BadGC errors.

**DIAGNOSTICS**

- **BadAlloc** - The server failed to allocate the requested resource or server memory.
- **BadGC** - A value for a GContext argument does not name a defined GContext.
- **BadValue** - Some numeric value falls outside the range of values accepted by the request. Unless a specific range is specified for an argument, the full range defined by the argument’s type is accepted. Any argument defined as a set of alternatives can generate this error.

NAME
XSetTile, XSetStipple, XSetTSOrigin - GC convenience routines

SYNTAX
XSetTile(display, gc, tile)
   Display *display;
   GC gc;
   Pixmap tile;
XSetStipple(display, gc, stipple)
   Display *display;
   GC gc;
   Pixmap stipple;
XSetTSOrigin(display, gc, ts_x_origin, ts_y_origin)
   Display *display;
   GC gc;
   int ts_x_origin, ts_y_origin;

ARGUMENTS
   display Specifies the connection to the XWIN server.
   gc Specifies the GC.
   stipple Specifies the stipple you want to set for the specified GC.
   tile Specifies the fill tile you want to set for the specified GC.
   ts_x_origin Specify the x and y coordinates of the tile and stipple origin.
   ts_y_origin

DESCRIPTION
The XSetTile function sets the fill tile in the specified GC. The tile and GC must
have the same depth, or a BadMatch error results.
XSetTile can generate BadAlloc, BadGC, BadMatch, and BadPixmap errors.

The XSetStipple function sets the stipple in the specified GC. The stipple and
GC must have the same depth, or a BadMatch error results.
XSetStipple can generate BadAlloc, BadGC, BadMatch, and BadPixmap errors.

The XSetTSOrigin function sets the tile/stipple origin in the specified GC. When
graphics requests call for tiling or stippling, the parent's origin will be interpreted
relative to whatever destination drawable is specified in the graphics request.
XSetTSOrigin can generate BadAlloc and BadGC errors.

DIAGNOSTICS
BadAlloc The server failed to allocate the requested resource or server
memory.
BadGC A value for a GContext argument does not name a defined
GContext.
BadMatch Some argument or pair of arguments has the correct type and
range but fails to match in some other way required by the
request.
BadPixmap  A value for a Pixmap argument does not name a defined Pixmap.

NAME
XSetTransientForHint, XGetTransientForHint – set or get transient for hint

SYNTAX
XSetTransientForHint(display, w, prop_window)
Display *display;
Window w;
Window prop_window;
Status XGetTransientForHint(display, w, prop_window_return)
Display *display;
Window w;
Window *prop_window_return;

ARGUMENTS

display  Specifies the connection to the XWIN server.
w      Specifies the window.
prop_window  Specifies the window that the WM_TRANSIENT_FOR property is to be set to.
prop_window_return  Returns the WM_TRANSIENT_FOR property of the specified window.

DESCRIPTION
The XSetTransientForHint function sets the WM_TRANSIENT_FOR property of the specified window to the specified prop_window.
XSetTransientForHint can generate BadAlloc and BadWindow errors.
The XGetTransientForHint function returns the WM_TRANSIENT_FOR property for the specified window.
XGetTransientForHint can generate a BadWindow error.

PROPERTY
WM_TRANSIENT_FOR

DIAGNOSTICS
BadAlloc  The server failed to allocate the requested resource or server memory.
BadWindow  A value for a Window argument does not name a defined Window.

NAME
XSetWMHints, XGetWMHints – set or get window manager hints

SYNTAX
XSetWMHints(display, w, wmhints)
   Display *display;
   Window w;
   XWMHints *wmhints;

   XWMHints *XGetWMHints(display, w)
   Display *display;
   Window w;

ARGUMENTS
   display Specifies the connection to the XWIN server.
   w Specifies the window.
   wmhints Specifies a pointer to the window manager hints.

DESCRIPTION
The XSetWMHints function sets the window manager hints that include icon
information and location, the initial state of the window, and whether the appli­
cation relies on the window manager to get keyboard input.

XSetWMHints can generate BadAlloc and BadWindow errors.

The XGetWMHints function reads the window manager hints and returns NULL
if no WM_HINTS property was set on the window or a pointer to a XWMHints
structure if it succeeds. When finished with the data, free the space used for it by
calling XFree.

XGetWMHints can generate a BadWindow error.

PROPERTY
   WM_HINTS

DIAGNOSTICS
   BadAlloc The server failed to allocate the requested resource or server
            memory.

   BadWindow A value for a Window argument does not name a defined Win­
               dow.

**NAME**

XSetZoomHints, XGetZoomHints – set or get zoom state hints

**SYNTAX**

XSetZoomHints(display, w, zhints)
   Display *display;
   Window w;
   XSizeHints *zhints;

Status XGetZoomHints(display, w, zhints_return)
   Display *display;
   Window w;
   XSizeHints *zhints_return;

**ARGUMENTS**

display Specifies the connection to the XWIN server.
w Specifies the window.
zhints Specifies a pointer to the zoom hints.
zhints_return Returns the zoom hints.

**DESCRIPTION**

Many window managers think of windows in one of three states: iconic, normal, or zoomed. The XSetZoomHints function provides the window manager with information for the window in the zoomed state.

XSetZoomHints can generate BadAlloc and BadWindow errors.

The XGetZoomHints function returns the size hints for a window in its zoomed state. It returns a nonzero status if it succeeds or zero if the application specified no zoom size hints for this window.

XGetZoomHints can generate a BadWindow error.

**PROPERTY**

WM_ZOOM_HINTS

**DIAGNOSTICS**

BadAlloc The server failed to allocate the requested resource or server memory.

BadWindow A value for a Window argument does not name a defined Window.

NAME

XStoreBytes, XStoreBuffer, XFetchBytes, XFetchBuffer, XRotateBuffers – manipulate cut and paste buffers

SYNTAX

XStoreBytes(display, bytes, nbytes)
   Display *display;
   char *bytes;
   int nbytes;

XStoreBuffer(display, bytes, nbytes, buffer)
   Display *display;
   char *bytes;
   int nbytes;
   int buffer;

char *XFetchBytes(display, nbytes_return)
   Display *display;
   int *nbytes_return;

char *XFetchBuffer(display, nbytes_return, buffer)
   Display *display;
   int *nbytes_return;
   int buffer;

XRotateBuffers(display, rotate)
   Display *display;
   int rotate;

ARGUMENTS

buffer Specifies the buffer in which you want to store the bytes or from which you want the stored data returned.

bytes Specifies the bytes, which are not necessarily ASCII or null-terminated.

display Specifies the connection to the XWIN server.
nbytes Specifies the number of bytes to be stored.
nbytes_return Returns the number of bytes in the buffer.
rotate Specifies how much to rotate the cut buffers.

DESCRIPTION

Note that the cut buffer's contents need not be text, so zero bytes are not special. The cut buffer's contents can be retrieved later by any client calling XFetchBytes.

XStoreBytes can generate a BadAlloc error.

If the property for the buffer has never been created, a BadAtom error results.

XStoreBuffer can generate BadAlloc and BadAtom errors.

The XFetchBytes function returns the number of bytes in the nbytes return argument, if the buffer contains data. Otherwise, the function returns NULL and sets nbytes to 0. The appropriate amount of storage is allocated and the pointer returned. The client must free this storage when finished with it by calling
XFree. Note that the cut buffer does not necessarily contain text, so it may contain embedded zero bytes and may not terminate with a null byte.

The XFetchBuffer function returns zero to the nbytes_return argument if there is no data in the buffer.

XFetchBuffer can generate a BadValue error.

The XRotateBuffers function rotates the cut buffers, such that buffer 0 becomes buffer n, buffer 1 becomes n + 1 mod 8, and so on. This cut buffer numbering is global to the display. Note that XRotateBuffers generates BadMatch errors if any of the eight buffers have not been created.

XRotateBuffers can generate a BadMatch error.

DIAGNOSTICS
- BadAlloc The server failed to allocate the requested resource or server memory.
- BadAtom A value for an Atom argument does not name a defined Atom.
- BadMatch Some argument or pair of arguments has the correct type and range but fails to match in some other way required by the request.
- BadValue Some numeric value falls outside the range of values accepted by the request. Unless a specific range is specified for an argument, the full range defined by the argument's type is accepted. Any argument defined as a set of alternatives can generate this error.

SEE ALSO

NAME
XStoreColors, XStoreColor, XStoreNamedColor – set colors

SYNTAX
XStoreColors(display, colormap, color, ncolors)
Display *display;
Colormap colormap;
XColor color[];
int ncolors;

XStoreColor(display, colormap, color)
Display *display;
Colormap colormap;
XColor *color;

XStoreNamedColor(display, colormap, color, pixel, flags)
Display *display;
Colormap colormap;
char *color;
unsigned long pixel;
int flags;

ARGUMENTS

color  Specifies the pixel and RGB values or the color name string (for example, red).
color  Specifies an array of color definition structures to be stored.
colormap  Specifies the colormap.
display  Specifies the connection to the XWIN server.
flags  Specifies which red, green, and blue components are set.
ncolors  Specifies the number of XColor structures in the color definition array.
pixel  Specifies the entry in the colormap.

DESCRIPTION
The XStoreColors function changes the colormap entries of the pixel values specified in the pixel members of the XColor structures. You specify which color components are to be changed by setting DoRed, DoGreen, and/or DoBlue in the flags member of the XColor structures. If the colormap is an installed map for its screen, the changes are visible immediately. XStoreColors changes the specified pixels if they are allocated writable in the colormap by any client, even if one or more pixels generates an error. If a specified pixel is not a valid index into the colormap, a BadValue error results. If a specified pixel either is unallocated or is allocated read-only, a BadAccess error results. If more than one pixel is in error, the one that gets reported is arbitrary.

XStoreColors can generate BadAccess, BadColor, and BadValue errors.

The XStoreColor function changes the colormap entry of the pixel value specified in the pixel member of the XColor structure. You specified this value in the pixel member of the XColor structure. This pixel value must be a read/write cell and a valid index into the colormap. If a specified pixel is not a valid index into the
colormap, a **BadValue** error results. **XStoreColor** also changes the red, green, and/or blue color components. You specify which color components are to be changed by setting **DoRed**, **DoGreen**, and/or **DoBlue** in the flags member of the **XColor** structure. If the colormap is an installed map for its screen, the changes are visible immediately.

**XStoreColor** can generate **BadAccess**, **BadColor**, and **BadValue** errors.

The **XStoreNamedColor** function looks up the named color with respect to the screen associated with the colormap and stores the result in the specified colormap. The pixel argument determines the entry in the colormap. The flags argument determines which of the red, green, and blue components are set. You can set this member to the bitwise inclusive OR of the bits **DoRed**, **DoGreen**, and **DoBlue**. If the specified pixel is not a valid index into the colormap, a **BadValue** error results. If the specified pixel either is unallocated or is allocated read-only, a **BadAccess** error results. You should use the ISO Latin-1 encoding; uppercase and lowercase do not matter.

**XStoreNamedColor** can generate **BadAccess**, **BadColor**, **BadName**, and **BadValue** errors.

**DIAGNOSTICS**

- **BadAccess**: A client attempted to free a color map entry that it did not already allocate.
- **BadAccess**: A client attempted to store into a read-only color map entry.
- **BadColor**: A value for a Colormap argument does not name a defined Colormap.
- **BadName**: A font or color of the specified name does not exist.
- **BadValue**: Some numeric value falls outside the range of values accepted by the request. Unless a specific range is specified for an argument, the full range defined by the argument’s type is accepted. Any argument defined as a set of alternatives can generate this error.

XStoreName(3X11)

NAME
XStoreName, XFetchName – set or get window names

SYNTAX
XStoreName(display, w, window_name)
Display *display;
Window w;
char *window_name);

Status XFetchName(display, w, window_name_return)
Display *display;
Window w;
char **window_name_return;

ARGUMENTS
display Specifies the connection to the XWIN server.
w Specifies the window.
window_name Specifies the window name, which should be a null-terminated string.

window_name_return Returns a pointer to the window name, which is a null-terminated string.

DESCRIPTION
The XStoreName function assigns the name passed to window_name to the specified window. A window manager can display the window name in some prominent place, such as the title bar, to allow users to identify windows easily. Some window managers may display a window’s name in the window’s icon, although they are encouraged to use the window’s icon name if one is provided by the application.

XStoreName can generate BadAlloc and BadWindow errors.

The XFetchName function returns the name of the specified window. If it succeeds, it returns nonzero; otherwise, if no name has been set for the window, it returns zero. If the WM_NAME property has not been set for this window, XFetchName sets window_name_return to NULL. When finished with it, a client must free the window name string using XFree.

XFetchName can generate a BadWindow error.

PROPERTY
WM_NAME

DIAGNOSTICS
BadAlloc The server failed to allocate the requested resource or server memory.

BadWindow A value for a Window argument does not name a defined Window.

NAME

XStringToKeysym, XKeysymToString, XKeyCodeToKeysym, XKeysymToKeyCode
- convert keysym

SYNTAX

KeySym XStringToKeysym (string)
char *string;

char *XKeysymToString (keysym)
KeySym keysym;

KeySym XKeyCodeToKeysym (display, keycode, index)
Display *display;
KeyCode keycode;
int index;

KeyCode XKeysymToKeyCode (display, keysym)
Display *display;
KeySym keysym;

ARGUMENTS

display Specifies the connection to the XWIN server.
index Specifies the element of KeyCode vector.
keycode Specifies the KeyCode.
keysym Specifies the KeySym that is to be searched for or converted.
string Specifies the name of the KeySym that is to be converted.

DESCRIPTION

Valid KeySym names are listed in <X11/keySymdef.h> by removing the XK_ prefix from each name. If the specified string does not match a valid KeySym, XStringToKeysym returns NoSymbol.

The returned string is in a static area and must not be modified. If the specified KeySym is not defined, XKeysymToString returns a NULL.

The XKeyCodeToKeysym function uses internal Xlib tables and returns the KeySym defined for the specified KeyCode and the element of the KeyCode vector. If no symbol is defined, XKeyCodeToKeysym returns NoSymbol.

If the specified KeySym is not defined for any KeyCode, XKeysymToKeyCode returns zero.

SEE ALSO

XLookupKeysym(3X11)
Xlib - C Language X Interface
XSynchronize(3X11)

NAME
XSynchronize, XSetAfterFunction – enable or disable synchronization

SYNTAX
int (*XSynchronize(display, onoff))()
  Display *display;
  Bool onoff;
int (*XSetAfterFunction(display, procedure))()
  Display *display;
  int (*procedure)();

ARGUMENTS
  display  Specifies the connection to the XWIN server.
  procedure Specifies the function to be called after an Xlib function that
               generates a protocol request completes its work.
  onoff    Specifies a Boolean value that indicates whether to enable or
            disable synchronization.

DESCRIPTION
The XSynchronize function returns the previous after function. If onoff is True,
XSynchronize turns on synchronous behavior. If onoff is False, XSynchronize
turns off synchronous behavior.

The specified procedure is called with only a display pointer. XSetAfterFunction
returns the previous after function.

NAME

XTextExtents, XTextExtents16, XQueryTextExtents, XQueryTextExtents16 - compute or query text extents

SYNTAX

XTextExtents(font_strud, string, nchars, direction_return, font_ascent_return, font_descent_return, overall_return)
    XFontStruct *font_strud;
    char *string;
    int nchars;
    int *direction_return;
    int *font_ascent_return, *font_descent_return;
    XCharStruct *overall_return;

XTextExtents16(font_strud, string, nchars, direction_return, font_ascent_return, font_descent_return, overall_return)
    XFontStruct *font_strud;
    XChar2b *string;
    int nchars;
    int *direction_return;
    int *font_ascent_return, *font_descent_return;
    XCharStruct *overall_return;

XQueryTextExtents(display, font_ID, string, nchars, direction_return, font_ascent_return, font_descent_return, overall_return)
    Display *display;
    XID font_ID;
    char *string;
    int nchars;
    int *direction_return;
    int *font_ascent_return, *font_descent_return;
    XCharStruct *overall_return;

XQueryTextExtents16(display, font_ID, string, nchars, direction_return, font_ascent_return, font_descent_return, overall_return)
    Display *display;
    XID font_ID;
    XChar2b *string;
    int nchars;
    int *direction_return;
    int *font_ascent_return, *font_descent_return;
    XCharStruct *overall_return;

ARGUMENTS

direction_return  Returns the value of the direction hint (FontLeftToRight or FontRightToLeft).

display        Specifies the connection to the XWIN server.
**XTextExtents (3X11)**

- `font_ID`: Specifies either the font ID or the GContext ID that contains the font.
- `font_ascent_return`: Returns the font ascent.
- `font_descent_return`: Returns the font descent.
- `font_struct`: Specifies a pointer to the XFontStruct structure.
- `nchars`: Specifies the number of characters in the character string.
- `string`: Specifies the character string.
- `overall_return`: Returns the overall size in the specified XCharStruct structure.

**DESCRIPTION**

The XTextExtents and XTextExtents16 functions perform the size computation locally and, thereby, avoid the round-trip overhead of XQueryTextExtents and XQueryTextExtents16. Both functions return an XCharStruct structure, whose members are set to the values as follows.

The ascent member is set to the maximum of the ascent metrics of all characters in the string. The descent member is set to the maximum of the descent metrics. The width member is set to the sum of the character-width metrics of all characters in the string. For each character in the string, let W be the sum of the character-width metrics of all characters preceding it in the string. Let L be the left-side-bearing metric of the character plus W. Let R be the right-side-bearing metric of the character plus W. The lbearing member is set to the minimum L of all characters in the string. The rbearing member is set to the maximum R.

For fonts defined with linear indexing rather than 2-byte matrix indexing, each XChar2b structure is interpreted as a 16-bit number with byte1 as the most-significant byte. If the font has no defined default character, undefined characters in the string are taken to have all zero metrics.

The XQueryTextExtents and XQueryTextExtents16 functions return the bounding box of the specified 8-bit and 16-bit character string in the specified font or the font contained in the specified GC. These functions query the XWIN server and, therefore, suffer the round-trip overhead that is avoided by XTextExtents and XTextExtents16. Both functions return a XCharStruct structure, whose members are set to the values as follows.

The ascent member is set to the maximum of the ascent metrics of all characters in the string. The descent member is set to the maximum of the descent metrics. The width member is set to the sum of the character-width metrics of all characters in the string. For each character in the string, let W be the sum of the character-width metrics of all characters preceding it in the string. Let L be the left-side-bearing metric of the character plus W. Let R be the right-side-bearing metric of the character plus W. The lbearing member is set to the minimum L of all characters in the string. The rbearing member is set to the maximum R.
For fonts defined with linear indexing rather than 2-byte matrix indexing, each XChar2b structure is interpreted as a 16-bit number with byte1 as the most-significant byte. If the font has no defined default character, undefined characters in the string are taken to have all zero metrics.

XQueryTextExtents and XQueryTextExtents16 can generate BadFont and BadGC errors.

**DIAGNOSTICS**

- **BadFont**
  A value for a Font or GContext argument does not name a defined Font.

- **BadGC**
  A value for a GContext argument does not name a defined GContext.

NAME
XTextWidth, XTextWidth16 – compute text width

SYNTAX
int XTextWidth(font_struct, string, count)
XFontStruct *font_struct;
char *string;
int count;

int XTextWidth16(font_struct, string, count)
XFontStruct *font_struct;
XChar2b *string;
int count;

ARGUMENTS
  count          Specifies the character count in the specified string.
  font_struct   Specifies the font used for the width computation.
  string        Specifies the character string.

DESCRIPTION
The XTextWidth and XTextWidth16 functions return the width of the specified 8-bit or 2-byte character strings.

SEE ALSO
XTextExtents(3X11)

NAME
XTranslateCoordinates - translate window coordinates

SYNTAX

Bool XTranslateCoordinates(display, src_w, dest_w, src_x, src_y, dest_x_return, 
    dest_y_return, child_return)
    Display *display;
    Window src_w, dest_w;
    int src_x, src_y;
    int *dest_x_return, *dest_y_return;
    Window *child_return;

ARGUMENTS
child_return Returns the child if the coordinates are contained in a mapped 
    child of the destination window.

dest_w Specifies the destination window.

dest_x_return Return the x and y coordinates within the destination window.

dest_y_return

display Specifies the connection to the XWIN server.

src_w Specifies the source window.

src_x Specify the x and y coordinates within the source window.

src_y

DESCRIPTION
The XTranslateCoordinates function takes the src_x and src_y coordinates rela­
tive to the source window's origin and returns these coordinates to dest_x_return and 
dest_y_return relative to the destination window's origin.

If XTranslateCoordinates returns zero, src_w and dest_w are on different 
screens, and dest_x_return and dest_y_return are zero. If the coordinates are con­
tained in a mapped child of dest_w, that child is returned to child_return. Other­
wise, child_return is set to None.

XTranslateCoordinates can generate a BadWindow error.

DIAGNOSTICS

BadWindow A value for a Window argument does not name a defined Win­
dow.

NAME
XrmUniqueQuark, XrmStringToQuark, XrmQuarkToString, XrmStringToQuarkList, XrmStringToBindingQuarkList - manipulate resource quarks

SYNTAX
XrmQuark XrmUniqueQuark()
#define XrmStringToName(string) XrmStringToQuark(string)
#define XrmStringToClass(string) XrmStringToQuark(string)
#define XrmStringToRepresentation(string) XrmStringToQuark(string)
XrmQuark XrmStringToQuark(string)
char *string;
#define XrmNameToString(name) XrmQuarkToString(name)
#define XrmClassToString(class) XrmQuarkToString(class)
#define XrmRepresentationToString(type) XrmQuarkToString(type)
char *XrmQuarkToString(quark)
XrmQuark quark;
#define XrmStringToNameList(str, name) XrmStringToQuarkList(str, (name))
#define XrmStringToClassList(str, class) XrmStringToQuarkList(str, (class))
void XrmStringToQuarkList(string, quarks)
return;
XrmStringToBindingQuarkList(string, bindings, quarks)
return;

ARGUMENTS
 bindings_return Returns the binding list.
quark Specifies the quark for which the equivalent string is desired.
quarks_return Returns the list of quarks.
string Specifies the string for which a quark is to be allocated.

DESCRIPTION
The XrmUniqueQuark function allocates a quark that is guaranteed not to represent any string that is known to the resource manager.
These functions can be used to convert to and from quark representations. The string pointed to by the return value must not be modified or freed. If no string exists for that quark, XrmQuarkToString returns NULL.
The XrmQuarkToString function converts the specified resource quark representation back to a string.
The XrmStringToQuarkList function converts the null-terminated string (generally a fully qualified name) to a list of quarks. The components of the string are separated by a period or asterisk character.
A binding list is a list of type XrmBindingList and indicates if components of name or class lists are bound tightly or loosely (that is, if wildcarding of intermediate components is specified).

typedef enum {XrmBindTightly, XrmBindLoosely} XrmBinding, *XrmBindingList;

XrmBindTightly indicates that a period separates the components, and XrmBindLoosely indicates that an asterisk separates the components.

The XrmStringToBindingQuarkList function converts the specified string to a binding list and a quark list. Component names in the list are separated by a period or an asterisk character. If the string does not start with period or asterisk, a period is assumed. For example, "a.b*c" becomes:

```
quarks  a  b  c
bindings  loose  tight  loose
```

Xlib – C Language X Interface
XUnmapWindow(3X11)

NAME

XUnmapWindow, XUnmapSubwindows - unmap windows

SYNTAX

XUnmapWindow(display, w)
    Display *display;
    Window w;

XUnmapSubwindows(display, w)
    Display *display;
    Window w;

ARGUMENTS

display    Specifies the connection to the XWIN server.
w        Specifies the window.

DESCRIPTION

The XUnmapWindow function unmaps the specified window and causes the
XWIN server to generate an UnmapNotify event. If the specified window is
already unmapped, XUnmapWindow has no effect. Normal exposure processing
on formerly obscured windows is performed. Any child window will no longer
be visible until another map call is made on the parent. In other words, the
subwindows are still mapped but are not visible until the parent is mapped.
Unmapping a window will generate Expose events on windows that were form­
erly obscured by it.

XUnmapWindow can generate a BadWindow error.

The XUnmapSubwindows function unmaps all subwindows for the specified
window in bottom-to-top stacking order. It causes the XWIN server to generate
an UnmapNotify event on each subwindow and Expose events on formerly
obscured windows. Using this function is much more efficient than unmapping
multiple windows one at a time because the server needs to perform much of the
work only once, for all of the windows, rather than for each window.

XUnmapSubwindows can generate a BadWindow error.

DIAGNOSTICS

BadWindow    A value for a Window argument does not name a defined Win­
dow.

Xlib - C Language X Interface
NAME
XWarpPointer - move pointer

SYNTAX
XWarpPointer(display, src_w, dest_w, src_x, src_y, src_width, src_height, dest_x, 

dest_y)
Display *display;
Window src_w, dest_w;
int src_x, src_y;
unsigned int src_width, src_height;
int dest_x, dest_y;

ARGUMENTS
dest_w Specifies the destination window or None.
dest_x
dest_y Specify the x and y coordinates within the destination window.
display Specifies the connection to the XWIN server.
src_x
src_y
src_width
src_height Specify a rectangle in the source window.
src_w Specifies the source window or None.

DESCRIPTION
If dest_w is None, XWarpPointer moves the pointer by the offsets (dest_x, 
dest_y) relative to the current position of the pointer. If dest_w is a window, 
XWarpPointer moves the pointer to the offsets (dest_x, dest_y) relative to the ori­
gin of dest_w. However, if src_w is a window, the move only takes place if the 
specified rectangle src_w contains the pointer.

The src_x and src_y coordinates are relative to the origin of src_w. If src_height 
is zero, it is replaced with the current height of src_w minus src_y. If src_width is 
zero, it is replaced with the current width of src_w minus src_x.

There is seldom any reason for calling this function. The pointer should normally 
be left to the user. If you do use this function, however, it generates events just 
as if the user had instantaneously moved the pointer from one position to 
another. Note that you cannot use XWarpPointer to move the pointer outside 
the confine_to window of an active pointer grab. An attempt to do so will only 
move the pointer as far as the closest edge of the confine_to window.

XWarpPointer can generate a BadWindow error.

DIAGNOSTICS
BadWindow A value for a Window argument does not name a defined Win­
dow.
