PREFACE

The FORTRAN*-66 language contains most of the features of FORTRAN-63. The FORTRAN-66 compiler adapts current techniques to the particular capabilities of the Control Data® 6600 Computer System. Emphasis has been placed on producing highly efficient object programs while maintaining the efficiency of compilation.

This reference manual was written as a text for advanced FORTRAN-66 classes and as a reference manual for programmers using the FORTRAN-66 system. The manual assumes a basic knowledge of the FORTRAN language.

*FORTRAN is an abbreviation for FORmula TRANslation and was originally developed for International Business Machine equipment.

6600 COMPUTING SYSTEM

Main frame (center) — contains 10 peripheral and control processors, central processor, central memory, some I/O synchronizers.

Display console (foreground) — includes a keyboard for manual input and operator control, and two 10-inch display tubes for display of problem status and operator directives.

CONTROL DATA 607 tapes (left front) — ½ inch magnetic tape units for supplementary storage; binary or BCD data handled at 200, 556, or 800 bpi.

CONTROL DATA 626 tapes (left rear) — 1-inch magnetic tape units for supplementary storage; binary data handled at 800 bpi.

Disc file (right rear) — Supplementary mass storage device holds 500 million bits of information.

CONTROL DATA 405 card reader (right front) — reads binary or BCD cards at 1200 card per minute rate.
SYSTEM ORGANIZATION

The CONTROL DATA® 6600 is a large-scale, solid-state, general-purpose digital computing system. The advanced design techniques incorporated in the system provide for extremely fast solutions to data processing, scientific and control center problems.

Within the 6600 are eleven independent computers (Fig. 1). Ten of these are constructed with the peripheral and operating system in mind. These ten have separate memory and can execute programs independently of each other or the central processor. The eleventh computer, the central processor, is a very high-speed arithmetic device. The common element between these computers is the large central memory.

Figure 1  CONTROL DATA 6600
CENTRAL MEMORY
- 131,072 words
- 60-bit words
- Memory organized in 32 logically independent banks of 4096 words with corresponding multiphasing of banks
- Random access, coincident-current, magnetic core
- One major cycle for read-write
- Maximum memory reference rate to all banks—one address/minor cycle
- Maximum rate of data flow to/from memory—one word/minor cycle

DISPLAY CONSOLE
- Two display tubes
- Modes
  - Character
  - Dot
- Character size
  - Large — 16 characters/line
  - Medium — 32 characters/line
  - Small — 64 characters/line
- Characters
  - 26 alphabetic
  - 10 numeric
  - 11 special

Figure 2 BLOCK DIAGRAM OF 6600
1. ELEMENTS OF FORTRAN-66

1.1 CONSTANTS

Four basic types of constants are used in FORTRAN-66: integer, octal, floating point and Hollerith. Complex and double precision constants can be formed from floating point constants. The type of a constant is determined by its form. The computer word structure for each type is given in Appendix E.

1.1.1 INTEGER

Integer constants may consist of up to 18 decimal digits, in the range from \(-2^{30} - 1\) to \(2^{30} - 1\). Integer multiply and divide are executed in floating point modules. No double precision is performed on integer values; if multiply and divide are specified, operands and result will be taken modular \(2^{16}\).

*Examples:*

\[
\begin{align*}
63 & \quad 3647631 \\
-247 & \quad 2 \\
314159265 & \quad 464646464
\end{align*}
\]

1.1.2 OCTAL

Octal constants may consist of up to 20 octal digits. The form is:

\[n_1 \cdots n_B\]

*Examples:*

\[
\begin{align*}
77777777000000000000B \\
777700077777B \\
232323232323232323B \\
77B \\
7777777777777700B
\end{align*}
\]

1.1.3 FLOATING POINT

Real constants are represented by a string of up to 15 digits. A real constant may be expressed with a decimal point or with a fraction and an exponent representing a power of ten. The forms of real constants are:

\[nE \quad n \quad n \quad nE\pm s \quad nE\pm s \quad nE\pm s \quad nE\pm s \quad nE\pm s\]

n is the coefficient; s is the exponent to the base 10. The plus sign may be omitted for positive s. The range of s is 0 through 308.

*Examples:*

\[
\begin{align*}
3.1415768 & \quad 3.141592E-01 \\
314. & \quad 314.15E01 \\
.0749162 & \quad .31415E+01 \\
314159E-05 & \quad
\end{align*}
\]

Double precision constants are represented by a string of up to 29 digits. The forms are:

\[nD \pm s \quad nD \pm s \quad nD \quad nD \quad nD \quad nD \quad nD \quad nD \pm s \quad nD \pm s \quad n.D \pm s \quad n.D \pm s \quad
\]

n is the coefficient; s is the exponent to the base 10. The D must always appear. The plus sign may be omitted for positive s; the range of s is 0 through 308.

*Examples:*

\[
\begin{align*}
3.1415926535897932384626D \\
3.1415D \\
3.1415D0 \\
3141.598D-03 \\
3141.5D-04 \\
379867524430111D+01
\end{align*}
\]

Complex constants are represented by pairs of real constants separated by a comma and enclosed in parentheses (R\(_n\), R\(_i\)). The real part of a complex number is represented by R\(_n\), the imaginary part by R\(_i\). Either constant may be preceded by a \(\pm\) sign.

*Examples:*

\[
\begin{align*}
\text{FORTRAN-66} & \quad \text{Complex Number} \\
(1., 6.55) & \quad 1. +6.55i \\
(15., 16.7) & \quad 15. +16.7i \\
(-14.09, 1.654E-04) & \quad -14.09 +.0001654i \\
(0., -1.) & \quad -i
\end{align*}
\]

1.1.4 HOLLERITH

A Hollerith constant is a string of alphanumeric
characters of the form hHF; h is an unsigned decimal integer representing the length of the field f and must be 10 or less characters except when used in a format statement. Spaces are significant in the field f. When h is not a multiple of 10, the last computer word is left-justified with BCD spaces filling the remainder of the word.

An alternate form of a Hollerith constant is hRf. When h is less than or equal to 10, the computer word is right-justified with zero fill. When h is greater than 10 only the first 10 characters are retained and the excess characters are discarded.

Examples:

$$\begin{align*}
6\text{HCOCITO} & \quad 8\text{RCDC} \quad 6600 \\
4\text{HERGO} & \quad 8R \\
3\text{HSUM} & \quad 1R
\end{align*}$$

1.2 VARIABLES

FORTRAN-66 recognizes simple and subscripted variables. A simple variable represents a single quantity; a subscripted variable represents a single quantity within an array of quantities. The variable is either defined in a TYPE declaration or determined by the first letter of the variable name. A first letter of I, J, K, L, M, or N indicates a fixed point (integer) variable; any other first letter indicates a floating point variable. However, a TYPE declaration overrides any other naming convention. (See Section 4-1.)

1.2.1 SIMPLE

A simple variable is the name of a storage area in which values can be stored. The variable is referenced by the location name; the value specified by the name is always the current value stored in that location.

Simple integer variables are identified by at least one or up to 8 alphabetic or numeric characters; the first must be I, J, K, L, M, or N. Any integer value in the range from $-(2^{31} - 1)$ to $2^{31} - 1$ may be assigned to a simple integer variable.

Examples:

$$\begin{align*}
\text{N} & \quad \text{NOODGE} \\
\text{K2SO4} & \quad \text{M58} \\
\text{LOX} & \quad \text{M58}
\end{align*}$$

Since spaces are ignored in variable names, M58 and M 58 are identical.

Simple floating point variables are identified by at least one or up to 8 alphabetic or numeric characters; the first must be alphabetic and not I, J, K, L, M, or N. Any value from $10^{-36}$ to $10^{38}$ and zero can be assigned to a simple floating point variable. A TYPE declaration overrides any other naming convention.

Examples:

$$\begin{align*}
\text{VECTOR} & \quad A65302 \\
\text{BAGELS} & \quad \text{BATMAN}
\end{align*}$$

1.2.2 SUBSCRIPTED VARIABLE ARRAYS

A subscripted variable represents an element of an array. An array is a block of successive memory locations which is divided into areas for storage of variables. Each element of the array is referenced by the array name plus a subscript. The type of an array is determined by the array name or TYPE declaration. Arrays may have one, two, or three dimensions and the maximum number of elements is the product of the dimensions. A subscript can be an integer constant, an integer variable, or any integer expression. Any other constant, variable, or expression will be reduced to an integer value. The array name and its dimensions must be declared at the beginning of the program in a DIMENSION statement (section 4.2).

Array structure. Elements of arrays are stored by columns in ascending order of storage location. In the array declared as A(3,3,3):

$$\begin{align*}
\begin{bmatrix}
A_{111} & A_{121} & A_{131} \\
A_{211} & A_{221} & A_{231} \\
A_{311} & A_{321} & A_{331}
\end{bmatrix}
\end{align*}$$

$$\begin{align*}
\begin{bmatrix}
A_{112} & A_{122} & A_{132} \\
A_{212} & A_{222} & A_{232} \\
A_{312} & A_{322} & A_{332}
\end{bmatrix}
\end{align*}$$

$$\begin{align*}
\begin{bmatrix}
A_{113} & A_{123} & A_{133} \\
A_{213} & A_{223} & A_{233} \\
A_{313} & A_{323} & A_{333}
\end{bmatrix}
\end{align*}$$
The planes are stored in order, starting with the first, as follows:

\[A_{111} \rightarrow L \quad A_{151} \rightarrow L+3 \quad \ldots \quad A_{133} \rightarrow L+24\]
\[A_{211} \rightarrow L+1 \quad A_{251} \rightarrow L+4 \quad \ldots \quad A_{233} \rightarrow L+25\]
\[A_{311} \rightarrow L+2 \quad A_{351} \rightarrow L+5 \quad \ldots \quad A_{333} \rightarrow L+26\]

Program errors may result if subscripts are larger than the dimensions initially declared for the array. A single subscript notation may be used for a two or three dimensional array if it does not exceed the product of the declared dimensions.

### 1.2.3 Subscript Forms

**Subscripted integer variables**, the elements of an integer array, may be assigned the same values as simple integer values. An integer array is named by an integer variable name (1 to 8 alphabetic or numeric characters, the first of which is I, J, K, L, M, or N), or is designated integer by a TYPE INTEGER statement.

- **NEURON (6, 8, 6)**
- **L0034 (J, 3)**
- **MORPH (20, 20)**
- **N3 (1)**

**Subscripted floating point variables**, the elements of a floating point array, may be assigned the same values as simple floating point variables. A floating point variable array is named with a floating point variable name (1 to 8 alphabetic or numeric characters, the first of which is alphabetic and not I, J, K, L, M, or N), or is designated floating point by a TYPE REAL statement.

- **TMESIS (6, 4, 7)**
- **YCLEPT (46)**
- **PST (6, 8)**
- **SVELTE (37, 24, 35)**

Any computable arithmetic expression may be used as a subscript.

- \(A(1, J)\)
- \(A(\text{MAXF}(I, J, M))\)
- \(B(I+2, J+3, 2*K+1)\)
- \(B(J, \text{ATANF}(J))\)
- \(Q(14)\)
- \(C(I+K)\)
- \(P(KLIM, JLIM+5)\)
- \(MOTZ0 \ (3*K*ILIM+3.5)\)
- \(\text{SAM} (J-6)\)
- \(\text{WOW}(I(J)(K))\)

The location of an array element with respect to the first element is a function of the maximum array dimensions and the type of the array. Given DIMENSION \(A(L, M, N)\) the location of \(A(i, j, k)\), with respect to the first element \(A\) of the array, is given by

\[A + (i-1+L \ j-1+M \ k-1) \times E\]

The quantity in braces is the subscript expression. If it is not an integer value, it is truncated after evaluation.

\(E\) is the element length, that is, the number of storage words required for each element of the array; for real and integer arrays, \(E=1\). (See Appendix E)

1. Referring to the matrix in 1.2.2, the location of \(A(2,2,3)\) with respect to \(A(1,1,1)\) is:

\[
\text{Locn } (A(2,2,3)) = \text{Locn } (A(1,1,1) ) \\
+ \{2-1+3(1+3(2))\}
= L+22
\]

2. Given DIMENSION \(Z(5,5,5)\) and \(I=1, K=2, X=45^\circ, A=7.29, B=1.62\). The location, \(z\), of \(Z(\*K, \text{TANF}(X), A-B)\) with respect to \(Z(1,1,1)\) is:

\[
z = \text{Locn } (Z(1,1,1)) + (2-1+5) \\
\left(\left[\text{TANF}(X)\right] - 1 + 5[4.67]\right) \\
= \text{Locn } (Z(1,1,1)) + (2-1+5) \\
(1-1+5*4) \\
= \text{Locn } (Z(1,1,1)) + 101
\]

FORTRAN-66 permits the following relaxation of the representation of subscripted variables:

Given \(A(D_1,D_2,D_3)\):

- where the \(D_i\) are integer constants.

then \(A(IJ,K)\) implies \(A(I,J,K)\)

\(A(IJ)\) implies \(A(I,J,1)\)

\(A(I)\) implies \(A(I,1,1)\)

\(A\) implies \(A(1,1,1)\)

similarly, for \(A(D_1,D_2)\):

\(A(IJ)\) implies \(A(I,J)\)

\(A(I)\) implies \(A(I,1)\)

\(A\) implies \(A(1)\)

and for \(A(D_1)\):

\(A\) implies \(A(1)\)

However, the elements of a single-dimension array
A(D1) may not be referred to as A(I,J,K) or A(I,J).
Array allocation is discussed under Storage Allocation in Section 4.

1.3 STATEMENTS
The FORTRAN-66 elements are combined to form statements. An executable statement performs a calculation or directs control of the program; a non-executable statement provides the compiler with information regarding variable structure, array allocation, storage sharing requirements.

1.4 EXPRESSIONS
An expression is a constant, variable (simple or subscripted), function (section 7.2) or any combination of these separated by operators and parentheses, written to comply with the rules given for constructing a particular type of expression.

There are four kinds of expressions in FORTRAN-66: arithmetic and masking (Boolean) expressions which have numerical values, and logical and relational expressions which have truth values. For each type of expression, there is an associated group of operators and operands.
2. ARITHMETIC EXPRESSION AND REPLACEMENT STATEMENTS

2.1 ARITHMETIC REPLACEMENT STATEMENTS
The general form of the arithmetic replacement statement (arithmetic statement) is $A = E$, where $E$ is an arithmetic expression and $A$ is any variable name, simple or subscripted. The operator $=$ means that $A$ is replaced by the value of the evaluated expression, $E$, with conversion for mode if necessary.

2.2 ARITHMETIC EXPRESSIONS
An arithmetic expression can contain the following operators:

<table>
<thead>
<tr>
<th>OPERATOR</th>
<th>MEANING</th>
</tr>
</thead>
<tbody>
<tr>
<td>+</td>
<td>addition</td>
</tr>
<tr>
<td>−</td>
<td>subtraction</td>
</tr>
<tr>
<td>*</td>
<td>multiplication</td>
</tr>
<tr>
<td>/</td>
<td>division</td>
</tr>
<tr>
<td>**</td>
<td>exponentiation</td>
</tr>
</tbody>
</table>

Operands are: Constants
Variables (simple or subscripted)
Functions (see Chapter 7)

Examples:

A
3.141592
B + 16.8946
$(A - B(I, J + K))$
$G * C(J) + 4.1/(Z(I + J, 3*K)) * SINF(V)$
$(Q + V(M, MAXF(A, B)) * Y**2)/(G * H - F(K + 3))$
$-C + D(I, J) * 13.627$

Any variable (with or without subscripts), constant, or function is an arithmetic expression. These entities may be combined by using the arithmetic operators to form algebraic expressions.

Rules:

1. An arithmetic expression may not contain adjacent arithmetic operators: $X \text{ op op } Y$
2. If $X$ is an expression, then $(X), (X), \ldots$, et cetera, are expressions.
3. If $X, Y$ are expressions, then the following are expressions:
   $X + Y \quad X/Y \quad X - Y \quad X*Y$
4. Expressions of the form $X**Y$ and $X**(−Y)$ are legitimate, subject to the restrictions in section 2.3.
5. The following forms of implied multiplication are permitted:
   $\text{constant} \ldots \quad \text{implies constant} * \ldots$
   $(\ldots)(\ldots) \quad \text{implies} \ldots * (\ldots)$
   $(\ldots)\text{constant} \quad \text{implies} (\ldots)*\text{constant}$
   $(\ldots)\text{variable} \quad \text{implies} \ldots *\text{variable}$

2.2.1 ORDER OF EVALUATION
The hierarchy of arithmetic operation is:

** exponentiation class 1
/ division class 2
* multiplication class 3
+ addition class 3
− subtraction class 3

In an expression with no parentheses or within a pair of parentheses, in which unlike classes of operators appear, evaluation proceeds in the above order. In those expressions where operators of like classes appear, evaluation proceeds from left to right. For example, $A**B**C$ is evaluated as $(A**B)**C$.

In parenthetical expressions within parenthetical expressions, evaluation begins with the innermost expression. Parenthetical expressions are evaluated as they are encountered in the left to right scanning process.

When writing an integer expression, it is important to remember not only the left to right scanning process, but also that dividing an integer quantity by an integer quantity always yields a truncated
result; thus 11/3 = 3. The expression I*J/K may yield a different result than the expression J/K*I. For example, 4*3/2 = 6 but 3/2*4 = 4.

Examples:

In the following examples, R indicates an intermediate result in evaluation:

\[ \text{A**B/C+D*E*F-G is evaluated:} \]
\[ \text{A**B} \rightarrow R_1 \]
\[ \text{R_1/C} \rightarrow R_2 \]
\[ \text{D*E} \rightarrow R_3 \]
\[ \text{R_3*F} \rightarrow R_4 \]
\[ \text{R_4+R_5} \rightarrow R_6 \]
\[ \text{R_6-G} \rightarrow R_7 \quad \text{Evaluation completed} \]

\[ \text{A**B/(C+D)*(E*F-G) is evaluated:} \]
\[ \text{A**B} \rightarrow R_1 \]
\[ \text{C+D} \rightarrow R_2 \]
\[ \text{E*F-G} \rightarrow R_3 \]
\[ \text{R_4/R_5} \rightarrow R_4 \]
\[ \text{R_6*R_7} \rightarrow R_8 \quad \text{Evaluation completed} \]

If the expression contains a function, the function is evaluated first.

\[ \text{H(13)+C(IJ+2)*(COSF(Z)**2 is evaluated:} \]
\[ \text{COSF(Z)} \rightarrow R_1 \]
\[ \text{R_4*2} \rightarrow R_2 \]
\[ \text{R_6*C(IJ+2)} \rightarrow R_3 \]
\[ \text{R_3+H(13)} \rightarrow R_4 \quad \text{Evaluation completed} \]

The following is an example of an expression with embedded parentheses.

\[ \text{A*(B+(C/D)-E)} \text{ is evaluated:} \]
\[ \text{C/D} \rightarrow R_1 \]
\[ \text{R_1-E} \rightarrow R_2 \]
\[ \text{R_3+B} \rightarrow R_3 \]
\[ \text{R_3*A} \rightarrow R_4 \quad \text{Evaluation completed} \]

\[ \text{A*(SINF(X)+1.0)-(Z/(C*(D-(E+F))) is evaluated:} \]

2.3 MIXED MODE ARITHMETIC EXPRESSIONS

FORTRAN-66 permits full mixed mode arithmetic. Mixed mode arithmetic is accomplished through the special library subroutines. In the 6600 computer system, these routines include complex arithmetic. The five standard operand types are complex, double, real, integer, and logical.

Mixed mode arithmetic is completely general; however, most applications will probably mix operand types, real and integer, real and double, or real and complex. The following rules establish the relationship between the mode of an evaluated expression and the types of the operands it contains.

Rules:

1. The order of dominance of the standard operand types within an expression from highest to lowest is:
   - COMPLEX
   - DOUBLE
   - REAL
   - INTEGER
   - LOGICAL

2. The mode of an evaluated arithmetic expression is referred to by the name of the dominant operand type.

3. In expressions of the form A**B, the following rules apply:
   - B may be negative in which case the form is: A**(−B).
   - For the standard types (except logical) the mode/type relationships are:
For example, if A is complex and B is real, the mode of A**B is complex.

### 2.3.1 Evaluation

1. Given A, B type real; I, J type integer. The mode of expression A*B−1+J will be real because the dominant operand is type real. It is evaluated:
   - Convert I to real
   - Convert J to real
   - A*B→R₁ real
   - R₁−I→R₂ real
   - R₂+J→R₃ real Evaluation completed

2. The use of parentheses may change the evaluation. A,B,I,J are defined as above. A*B−(I−J) is evaluated:
   - I−J→R₁ integer
   - Convert R₁ to real→R₃
   - A*B→R₃ real
   - R₃−R₁→R₄ real Evaluation completed

3. Given C₁,C₂ type complex; A₁,A₂ type real. The mode of expression A₁*(C₁/C₂)+A₂ is complex because its dominant operand is type complex. It is evaluated:
   - C₁/C₂→R₁ complex
   - Convert A₁ to complex
   - Convert A₂ to complex
   - A₁*R₁→R₂ complex
   - R₂+A₂→R₃ complex Evaluation completed

4. Consider the expression C₁/C₂+(A₁−A₂) where the operands are defined as in 3 above. It is evaluated:
   - A₁−A₂→R₁ real
   - Convert R₁ to complex→R₂
   - C₁/C₂→R₃ complex
   - R₃+R₂→R₄ complex Evaluation completed

5. Mixed mode arithmetic with all standard types is illustrated by this example.

Given: C complex
       D double
       R real
       I integer
       L logical
       and the expression C*D+R/I−L

The dominant operand type in this expression is type complex; therefore, the evaluated expression is of mode complex. It is evaluated:

   - Convert D,R,I, and L to complex
   - R/I→R₁ complex
   - C*D→R₂ complex
   - R₁−L→R₃ complex
   - R₃+R₂→R₄ complex Evaluation completed

If the same expression is rewritten with parentheses as C*D+(R/I−L) the evaluation proceeds:

   - Convert I to real
   - Convert L to real
   - R/I→R₁ real
   - R₁−L→R₂ real
   - Convert D to complex
   - Convert R₂ to complex→R₃
   - C*D→R₄ complex
   - R₄+R₃→R₅ complex Evaluation completed

### 2.4 Mixed Mode Replacement Statement

The mode of an evaluated expression is determined by the type of the dominant operand. This, however, does not restrict the types that identifier A may assume. An expression of complex mode may replace A even if A is type real. The following chart shows the A, E relationship for all the standard modes.
**ARITHMETIC REPLACEMENT STATEMENT** \(A = E\)

- **A** is an Identifier
- **E** is an Arithmetic Expression
- \(\phi(f)\) is the Evaluated Arithmetic Expression

<table>
<thead>
<tr>
<th>TYPE of A</th>
<th>Complex</th>
<th>Double</th>
<th>Real</th>
<th>Integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Complex</td>
<td>Store real &amp; imaginary parts of (\phi(f)) in real &amp; imaginary parts of A.</td>
<td>Round (\phi(f)) to real. Store in real part of A. Store zero in imaginary part of A.</td>
<td>Store (\phi(f)) in real part of A. Store zero in imaginary part of A.</td>
<td>Convert (\phi(f)) to real &amp; store in real part of A. Store zero in imaginary part of A.</td>
</tr>
<tr>
<td>Double</td>
<td>Discard imaginary part of (\phi(f)) &amp; replace it with (\pm 0) according to real part of (\phi(f)).</td>
<td>Store (\phi(f)) (most &amp; least significant parts) in A (most &amp; least significant parts).</td>
<td>If (\phi(f)) is (\pm 0) as least significant part. Store in A, most &amp; least significant parts.</td>
<td>Convert (\phi(f)) to real. Fill out least significant half with binary zeros or ones accordingly as sign of (\phi(f)) is plus or minus. Store in A, most and least significant parts.</td>
</tr>
<tr>
<td>Real</td>
<td>Store real part of (\phi(f)) in A. Imaginary part is lost.</td>
<td>Round (\phi(f)) to real &amp; store in A. Least significant part of (\phi(f)) is lost.</td>
<td>Store (\phi(f)) in A.</td>
<td>Convert (\phi(f)) to real. Store in A.</td>
</tr>
<tr>
<td>Integer</td>
<td>Truncate real part of (\phi(f)) to INTEGER. Store in A. Imaginary part is lost.</td>
<td>Truncate (\phi(f)) to INTEGER &amp; store in A.</td>
<td>Truncate (\phi(f)) to INTEGER. Store in A.</td>
<td>Store (\phi(f)) in A.</td>
</tr>
<tr>
<td>Logical</td>
<td>If real part of (\phi(f)) (\neq 0), (1 \rightarrow A). If real part of (\phi(f) = 0), (0 \rightarrow A).</td>
<td>If (\phi(f) \neq 0), (1 \rightarrow A). If (\phi(f) = 0), (0 \rightarrow A).</td>
<td>Same as for double at left.</td>
<td>Same as for double at left.</td>
</tr>
</tbody>
</table>

When all of the operands in the expression E are of type logical, the expression is evaluated as though all the logical operands were integers.

For example, if \(L_1, L_2, L_3, L_4\) are logical variables, \(R\) is a real variable, and \(I\) is an integer variable, then

\[ I = L_1 \times L_2 + L_3 - L_4 \]

will be evaluated as though the \(L_i\) were all integers (0 or 1) and the resulting value will be stored, as an integer, in \(I\).

\[ R = L_1 \times L_2 + L_3 - L_4 \]

is evaluated as stated above, but the result is converted to a real (a floating point quantity) before it is stored in \(R\).
Examples:

Given:  C₁, A₁ complex
        D₁, A₂ double
        R₁, A₃ real
        I₁, A₄ integer
        L₁, A₅ logical

A₁ = C₁*C₂ - C₄/C₄
    (.905, 15.393) =
    (4.4,2.1)*(3.0,2.0) - (3.3,6.8)/(1.1,3.4)

The mode of the expression is complex. Therefore, the result of the expression is a two-word, floating point quantity. A₁ is type complex and the result replaces A₁.

A₃ = C₁
    4.4000 + 000 = (4.4,2.1)

The mode of the expression is complex. The type of A₃ is real; therefore, the real part of C₁ replaces A₃.

A₃ = C₁*(0.,-2)  4.2000 + 000 = (4.4,2.1)*(0.,-2)

The mode of the expression is complex. The type of A₃ is real.

A₄ = R₃/R₅*(R₃ - R₆) + I₁ - (I₅*R₅)
    3 = 8.4/4.2*(3.1 - 2.1) + 14 -(1*2.3)

The mode of the expression is real. The type of A₄ is integer; the result of the expression evaluation, a real, will be converted to an integer replacing A₄.

A₅ = D₃**2*(D₂ + (D₃*D₄) ) + (D₃*D₅*D₆)
    4.9680000000000000000000000000001 =
    2.0D**2*(3.2D +(4.1D*1.0D) ) + (3.2D*2.0D*3.2D)

The mode of the expression is double. The type of A₅ is double; the result of the expression evaluation, a double precision floating quantity, replaces A₅.

A₅ = C₁*R₃ - R₆ + I₁
    1 = (4.4,2.1)*8.4 - 4.2 + 14

The mode of the expression is complex. Since A₅ is type logical, an integer 1 will replace A₅ if the real part of the evaluated expression is not zero. If the real part is zero, zero replaces A₅.
3. LOGICAL/RELATIONAL AND MASKING EXPRESSIONS AND REPLACEMENT STATEMENTS

The general form of the logical/relation expression statement is \( L = E \), where \( L \) is a variable of type logical and \( E \) may be a logical, relational, or arithmetic expression.

3.1 LOGICAL EXPRESSION

A logical expression has the general form

\[ O_1 \text{ op } O_2 \text{ op } O_3 \ldots \]

The terms \( O_1 \) are logical variables, arithmetic expressions or relational expressions, and \( \text{op} \) is the logical operator .\text{AND}. indicating conjunction or .\text{OR}. indicating disjunction.

The logical operator .\text{NOT}. indicating negation appears in the form:

\[ .\text{NOT}. \ O_1 \]

The value of a logical expression is either true or false.

When an arithmetic expression appears as a term of a logical replacement statement, the value of the expression is examined. If the value is non-zero, the term has the value TRUE. If the value is equal to zero, the term has the value FALSE.

Logical expressions are generally used in logical IF-statements. (See section 5.3)

Rules:

1. The hierarchy of logical operations is:

   First .\text{NOT}.  
   then .\text{AND}.  
   then .\text{OR}.  

2. A logical variable or a relational expression is, in itself, a logical expression. If \( L_1, L_2 \) are logical expressions, then

   .\text{NOT}. \ L_1  
   \( L_1 \ .\text{AND}. \ L_2 \)  
   \( L_1 \ .\text{OR}. \ L_2 \)

are logical expressions. If \( L \) is a logical expression, \((L), (L)\) are logical expressions.

3. If \( L_1, L_2 \) are logical expressions and \( \text{op} \) is .\text{AND}. or .\text{OR}. then \( L_1 \ \text{op} \ \text{op} \ L_2 \) is never legitimate.

4. .\text{NOT}. may appear in combination with .\text{AND}. or .\text{OR}. only as follows:

   .\text{AND}. .\text{NOT}.  
   .\text{OR}. .\text{NOT}.  
   .\text{AND}. (.\text{NOT}.\ldots)  
   .\text{OR}. (.\text{NOT}.\ldots)

   .\text{NOT}. may appear with itself only in the form .\text{NOT}. (.\text{NOT}.\ldots)

5. If \( L_1, L_2 \) are logical expressions, the logical operators are defined as follows:

   .\text{NOT}. \ L_1 \quad \text{is false only if } L_1 \text{ is true}  
   L_1 .\text{AND}. L_2 \quad \text{is true only if } L_1, L_2 \text{ are both true}  
   L_1 .\text{OR}. L_2 \quad \text{is false only if } L_1, L_2 \text{ are both false}

Incorrect usages such as the following are not permitted:

Q.NOT. .OR.R  
C.AND. .NOT. .NOT.B  

The last expression is permissible in the form C.AND. .NOT.(.NOT.B)

Examples:

Logical Expressions

\{ \text{The product } A*B \text{ greater than } 16. \} .\text{AND}.  
\{ C \text{ equals } 3.141519 \}  
A*B .GT. 16 .AND. C .EQ. 3.141519
**3.2 RELATIONAL EXPRESSION**

A relational expression has the form:

\[ q_1 \text{ op } q_2 \]

The q’s are arithmetic expressions; op is an operator belonging to the set:

<table>
<thead>
<tr>
<th>Operator</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>.EQ.</td>
<td>Equal to</td>
</tr>
<tr>
<td>.NE.</td>
<td>Not equal to</td>
</tr>
<tr>
<td>.GT.</td>
<td>Greater than</td>
</tr>
<tr>
<td>.GE.</td>
<td>Greater than or equal to</td>
</tr>
<tr>
<td>.LT.</td>
<td>Less than</td>
</tr>
<tr>
<td>.LE.</td>
<td>Less than or equal to</td>
</tr>
</tbody>
</table>

A relation is true if \( q_1 \) and \( q_2 \) satisfy the relation specified by op. A relation is false if \( q_1 \) and \( q_2 \) do not satisfy the relation specified by op.

Relations are evaluated as illustrated in the relation, p .EQ. q. This is equivalent to the question, does \( p - q = 0 \)?

The difference is computed and tested for zero. If the difference is zero, the relation is true. If the difference is not zero, the relation is false. Relational expressions are converted internally to arithmetic expressions according to the rules of mixed mode arithmetic. These expressions are evaluated and compared with zero to determine the truth value of the corresponding relational expression. When expressions of mode complex are tested for zero, only
the real part is used in the comparison.

**Rules:**

1. The permissible forms of a relation are:
   
   \[
   q \quad (\text{where a non-zero value is true and a zero value is false})
   \]
   
   \[
   q_1 \text{ op } q_2 \quad q_1 \text{ op } q_2 \text{ AND } q_3 \text{ op } q_4
   \]

2. The evaluation of a relation of the form \( q_1 \text{ op } q_2 \) is from left to right. The relations \( q_1 \text{ op } q_2, q_1 \text{ op } (q_3), (q_1) \text{ op } q_2, (q_1) \text{ op } (q_3) \) are equivalent.

**Examples:**

\[
A \text{ .CT. 16.} \quad R(I) \text{ .GE. R(I-1)}
\]

\[
R - Q(I) \times Z \text{ .LE. 3.141592} \quad K \text{ .LT. 16}
\]

\[
B - C \text{ .NE. D+E} \quad I \text{ .EQ. J(K)}
\]

### 3.3 MASKING REPLACEMENT STATEMENT

The general form of the masking replacement statement is \( M = E \). The masking statement is distinguished from the logical statement in the following ways.

1. The type of \( M \) must be real or integer.

2. All operands in the expression \( E \) must be type real or integer. \( E \) may contain functions as well as variable or constant operands.

**Examples:**

Given: All variables of type real or integer.

\[
A(I) = B \text{ .OR. } \text{ .NOT. } C(I)
\]

\[
B = D \text{ .AND. } Q
\]

\[
C(I,J) = \text{ .NOT. } Z(K) \text{ .AND. } Q1 \text{ .OR. } \text{ .NOT. } Q2
\]

\[
\text{TEST} = \text{CELESTE .AND. 7HECLIPSE}
\]

\[
\text{AB} = D \text{ .OR. } \text{ FUNC(X,T)}
\]

### 3.4 MASKING EXPRESSIONS

In a FORTRAN-66 masking expression 60-bit arithmetic is performed bit-by-bit on the operands within the expression.

Although the masking operators are identical in appearance to the logical operators, their meanings are different. They are listed accordingly to hierarchy, and the following definitions apply:

- .NOT. complement the operand
- .AND. form the bit-by-bit logical product of two operands
- .OR. form the bit-by-bit logical sum of two operands

The operations are described below.

<table>
<thead>
<tr>
<th>( p )</th>
<th>( v )</th>
<th>( p \text{ .AND. } v )</th>
<th>( p \text{ .OR. } v )</th>
<th>.NOT. ( p )</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>0</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>1</td>
</tr>
</tbody>
</table>

**Rules:**

1. Let \( B_1 \) be masking expressions, variables or constants whose types are real or integer. Then the following are masking expressions.

   \[
   \text{.NOT. } B_1 \quad B_1 \text{ .AND. } B_2 \quad B_1 \text{ .OR. } B_2
   \]

2. If \( B \) is a masking expression, then \((B), ((B))\) are masking expressions.

3. .NOT. may appear with .AND. or .OR. only as follows:

   \[
   \text{.AND. } .\text{NOT.}
   \]

   \[
   \text{.OR. } .\text{NOT.}
   \]

   \[
   \text{.AND. } (\text{.NOT.} .\ldots)
   \]

   \[
   \text{.OR. } (\text{.NOT.} .\ldots)
   \]

4. Masking expressions of the following forms are evaluated from left to right.

   2. \( A \text{ .AND. } B \text{ .AND. } C \ldots\)

   3. \( A \text{ .OR. } B \text{ .OR. } C \ldots\)

5. Masking expressions may contain logical operands, parenthetical arithmetic expressions and statement functions.

**Examples:**

\[
A_1 \quad 777700000000000000000000 \text{ octal constant}
\]

\[
A_2 \quad 000000000000000077777777 \text{ octal constant}
\]
3.5 MULTIPLE REPLACEMENT STATEMENTS

The multiple replacement statement is a generalization of the replacement statements discussed earlier in this and the previous chapter, and its form is:

\[ \psi_n = \psi_{n-1} = \ldots = \psi_2 = \psi_1 = \text{expression} \]

The expression may be arithmetic, logical or masking. The \( \psi_i \) are variables subject to the following restrictions:

- Arithmetic or Logical Statement: \( \psi_i = \text{ZAP} \)
  - If \( \text{ZAP} \) is logical or arithmetic and:
    - If the variable \( \psi_i \) is type complex, double, real, or integer, then \( \psi_i = \text{ZAP} \) is an arithmetic statement.
    - If the variable \( \psi_i \) is type logical, then \( \psi_i = \text{ZAP} \) is a logical statement.

- Masking Statement: \( \psi_i = \text{ZAP} \)
  - If \( \text{ZAP} \) is a masking expression, \( \psi_i \) must be a type real or integer variable only.

The remaining \( n-1 \psi_i \) may be variables of any type and the multiple replacement statement replaces each of the variables \( \psi_i (2 \leq i \leq n) \) in turn with the value of \( \psi_i - 1 \) in a manner analogous to that employed in mixed mode arithmetic statements.

Examples:

- \( A \) real
- \( E,F \) complex
- \( G \) double
- \( I \) integer
- \( K \) logical

The numbers in the examples represent the evaluations of expressions.

\[ A = G = 3.1415926535897932384626D \]
\[ 3.141592654 \rightarrow A \]
\[ I = A = 4.6 \]
\[ 4.6 \rightarrow A \]
\[ 4 \rightarrow I \]
\[ A = I = 4.6 \]
\[ 4.0 \rightarrow A \]
\[ I = A = E = (10.2, 3.0) \]
\[ 10.2 \rightarrow E \text{ real} \]
\[ 3.0 \rightarrow E \text{ imaginary} \]
\[ 10.2 \rightarrow A \]
\[ 10 \rightarrow I \]
\[ F = A = I = E = (13.4, 16.2) \]
\[ 13.4 \rightarrow E \text{ real} \]
\[ 16.2 \rightarrow E \text{ imaginary} \]
\[ 13 \rightarrow I \]
\[ 13.0 \rightarrow A \]
\[ 13.0 \rightarrow F \text{ real} \]
\[ 0.0 \rightarrow F \text{ imaginary} \]
\[ K = I = -14.6 \]
\[ -14 \rightarrow I \]
\[ 1 \rightarrow K \]
\[ I = K = -14.6 \]
\[ 1 \rightarrow K \]
\[ 1 \rightarrow I \]
4. TYPE DECLARATIONS AND STORAGE ALLOCATIONS

4.1 TYPE DECLARATIONS
The TYPE declaration provides the compiler with information on the structure of variable and function identifiers. There are five standard variable types which are declared by one of the following statements:

<table>
<thead>
<tr>
<th>Statement</th>
<th>Characteristics</th>
</tr>
</thead>
<tbody>
<tr>
<td>TYPE COMPLEX List</td>
<td>2 words/element</td>
</tr>
<tr>
<td></td>
<td>Floating point</td>
</tr>
<tr>
<td>TYPE DOUBLE List</td>
<td>2 words/element</td>
</tr>
<tr>
<td></td>
<td>Floating point</td>
</tr>
<tr>
<td>TYPE REAL List</td>
<td>1 word/element</td>
</tr>
<tr>
<td></td>
<td>Floating point</td>
</tr>
<tr>
<td>TYPE INTEGER List</td>
<td>1 word/element</td>
</tr>
<tr>
<td></td>
<td>Integer</td>
</tr>
<tr>
<td>TYPE LOGICAL List</td>
<td>1 word/element</td>
</tr>
<tr>
<td></td>
<td>Logical (non-dimensioned)</td>
</tr>
<tr>
<td></td>
<td>1 bit/element, 32 bits/word</td>
</tr>
<tr>
<td></td>
<td>Logical (dimensioned)</td>
</tr>
</tbody>
</table>

A list is a string of identifiers separated by commas; subscripts are not permitted. An example of a list is: A, B1, CAT, D36F, EUPHORIA

Rules:
1. The TYPE declaration is non-executable and must precede the first executable statement in a given program.
2. An identifier may not be declared in two or more TYPE declarations.
3. An identifier not declared in a TYPE statement is an integer if the first letter of the identifier is I, J, K, L, M, N; for any other letter, it will be real.
4. If TYPE, DIMENSION or COMMON appear together, the order is immaterial.

Examples:
- TYPE COMPLEX A147, RIGGISH, ATILL2
- TYPE DOUBLE TEEPEE, B2BAZ
- TYPE REAL EL, CAMINO, REAL, IDE63
- TYPE INTEGER QUID, PRO, QUO
- TYPE LOGICAL GEORGE6

4.2 DIMENSION
A subscripted variable represents an element of an array of variables. Storage may be reserved for arrays by the non-executable statements DIMENSION or COMMON.

The standard form of the DIMENSION statement is:

```
DIMENSION V_1, V_2, ..., V_n
```

The variable names, V_{i}, may have 1, 2, or 3 integer constant subscripts separated by commas, as in SPACE (5, 5, 5). Under certain conditions within subprograms only, the subscripts may be integer variables. This is explained in section 6.11.

The number of computer words reserved for a given array is determined by the product of the subscripts in the subscript string, and the type of the variable.

In the statements

```
TYPE COMPLEX HERCULES
DIMENSION HERCULES (10, 20)
```

the number of elements in the array HERCULES is 200. Two words are used to store a complex element; therefore, the number of computer words reserved is 400. The argument is the same for double precision. For reals and integers the number of words in an array equals the number of elements in the array.

Rules:
1. The DIMENSION statement is non-executable and must precede the first executable statement in a given program.
2. An identifier may not be declared in two or more DIMENSION statements.
3. If TYPE, DIMENSION or COMMON appear together, the order is immaterial.
4. For any given dimensional variable, the dimensions may be declared either in a COMMON statement or in a DIMENSION statement. If declared in both, those of the DIMENSION statement override those declared in the COMMON statement.
5. Any number of DIMENSION statements may appear in a program section.
6. A zero subscript is treated as a one.
4.2.1 VARIABLE DIMENSIONS
When an array identifier and its dimensions appear as formal parameters in a function or subroutine, the dimensions may be assigned through the actual parameter list accompanying the function reference or subroutine call. The dimensions must not exceed the maximum array size specified by the DIMENSION statement in the calling program. See section 6.11 for details and examples.

4.3 COMMON
A program may contain or call subprograms. Areas of common information may be specified by the statement:

    COMMON/I.,/List/!2/!List . . .

I is a common block identifier. It may be blank; or consist of up to 8 characters. If the first character is a number, then all characters in the identifier must be numbers. The following are common identifiers:

    /AZ13/    /3597/
    /CAVEAT/  / /
    /0/       /X/

List is composed of simple variable identifiers and array identifiers (subscripted or non-subscripted). If a non-subscripted array name appears in the list, the dimensions are defined by the DIMENSION statement in that program.

Dimensions for arrays may also be given in the COMMON statement when a subscript string appears with the identifier. If dimensions are given in both, those in the DIMENSION statement are used.

Examples:

    COMMON A, B, C
    COMMON/ /A, B, C, D
    COMMON/BLOCK1/A, B/1234/C(10), D(10,10),E(10,10,10)
    COMMON/BLOCKA/D(15), F(3,3), GOSH(2, 3, 4), Q1

4.4 COMMON BLOCKS
The COMMON statement provides the programmer with a means of reserving blocks of storage area that are referenced by more than one subprogram. Data may be stored in common blocks by the DATA statement and are made available to any subprogram using the appropriate block.

4.4.1 BLOCK LENGTH
The length of a common block in computer words is determined from the number and type of the list identifiers. In the following statement, the length of the common block A is 12 computer words. The origin of the common block is Q(1). Q and R are real variables and S is complex.
COMMON/A/Q(4), R(4), S(2)

block A

origin

<table>
<thead>
<tr>
<th>Q(1)</th>
<th>Q(2)</th>
<th>Q(3)</th>
<th>Q(4)</th>
</tr>
</thead>
<tbody>
<tr>
<td>R(1)</td>
<td>R(2)</td>
<td>R(3)</td>
<td>R(4)</td>
</tr>
<tr>
<td>S(1)</td>
<td>S(1)</td>
<td>S(2)</td>
<td>S(2)</td>
</tr>
</tbody>
</table>

real part
imaginary part
real part
imaginary part

Example:

MAIN PROG
COMPLEX C
COMMON/TEST/C(20)/36/A,B,Z

The length of TEST is 40 computer words.
The subprogram may rearrange the allocation of words as in:
SUB PROG 1
COMMON/TEST/A(10),G(10),K(10)
TYPE COMPLEX A

The length of TEST is 40 words. The first 10 elements (20 words) of the block, represented by A, are complex elements. Array G is the next 10 words, and array K is the last 10 words. Within the subprogram, elements of G will be treated as floating point quantities; elements of K will be treated as integer quantities.

The length of a COMMON block must not be changed by the subprograms using the block. The identifiers used within the block may differ as shown above.

The following arrangements are equivalent:

```
TYPE DOUBLE A
DIMENSION A(10)
COMMON A(10)
 TYPE DOUBLE A
COMMON A
```

The label of a COMMON block is used only for block identification. The following is permissible:

```
COMMON /A/A(10)/B/B(5,5) /C/C (5,5,5)
```

4.5 EQUIVALENCE

The EQUIVALENCE statement permits variables to share locations in storage. The general form is:

```
EQUIVALENCE (A,B,...,(A1,B1,...),...)
```

(A,B,...) is an equivalence group of two or more simple or singly subscripted variable identifiers. A multiply subscripted variable can be represented only by a singly subscripted variable. The correspondence is:

```
A(i,j,k) = A(i + (j - 1) I + (k - 1)IJ
```

where i,j,k are integer constants: I and J are the integer constants appearing in DIMENSION A (I,J,K). For example, in DIMENSION A(2,3,4), the element A(1,1,2) is represented by A(7).

Examples:

EQUIVALENCE is most commonly used when two or more arrays can share the same storage locations. The lengths may be different or equal.

```
DIMENSION A(10,10), I(100)
EQUIVALENCE (A,I)
```

5 READ 10, A

6 READ 20, I

The EQUIVALENCE statement assigns the first element of array A and array I to the same storage location. The READ statement 5 stores the A array in consecutive locations. Before statement 6 is exe-
cuted all operations using A must be completed as
the values of array I are read into the storage loca-
tions previously occupied by A.

Rules:

1. EQUIVALENCE is non-executable and must
precede the first executable statement in the
program or subprogram.

2. If TYPE, DIMENSION, COMMON, or EQUIV-
ALENCE appear together, the order is imma-
terial.

3. Any variable or array may be made equivalent to
any other variable or array. The variable or array
may or may not be subscripted in the EQUIV-
ALENCE statement. A given identifier may be
repeated in more than one equivalence group,
but caution must be observed to avoid circular
references. A zero or one subscript is treated as
though the subscript were not present.

4. The EQUIVALENCE statement does not re-
arrange common, but arrays may be defined as
equivalent so that the length of the common
block is changed. The origin of the common block
must not be changed by the EQUIVALENCE
statement. The following simple examples illus-
trate changes in block lengths caused by the
EQUIVALENCE statement.

Given: Arrays A and B
Sa = subscript of A
Sb = subscript of B

Examples:
1. A in COMMON, B not in COMMON
Sb ≤ Sa is a permissible subscript
Sb > Sa is not
COMMON/1/A(4)
DIMENSION B(5)
EQUIVALENCE (A(3), B(2))
origin A(1)
A(2) B(1)
A(3) B(2)
A(4) B(3)
B(4)
length of block 1
B(5)
now 6 elements

2. B in COMMON, A not in COMMON
Sa ≤ Sb is a permissible subscript
Sa > Sb is not
COMMON/2/B(3)
DIMENSION A(2)
EQUIVALENCE (B(1), A(1))
origin B(1) A(1)
B(2) A(2)
B(3) A(2)
length of block 2
(not increased)

3. A, B not in COMMON
No restrictions on subscript arrangement.

4. A, B both in COMMON
No subscript arrangement is legal.

4.6 DATA

The programmer may assign constant values to
variables in the source program by using the DATA
statement either by itself or with a DIMENSION
statement. It may be used to store constant values
in variables contained in a common block.

DATA(I_1=List), (I_2=List),...

I is an identifier representing a simple variable,
array name, or a variable with integer constant sub-
scripts or integer variable subscripts.

List contains constants only and has the form
a_1, a_2, ..., k(b_1, b_2, ...), c_1, c_2, ...
k is an integer constant repetition factor that causes
the parenthetical list following it to be repeated k
times.

Rules:

1. DATA is non-executable and must precede the
first executable statement in any program or sub-
program in which it appears.

2. When DATA appears with TYPE, DIMENSION,
COMMON or EQUIVALENCE statements, the
order is immaterial.

3. DO loop-implying notation is permissible. This
notation may be used for storing constant values
in arrays.

DIMENSION X(10,10)
DATA (((X(1,J)), I = 1,10,2), J = 6,9,3)

= 2(5(3.1)))
DIMENSION GIB (10)
DATA ( (GIB(I), I=1,10) = 1., 2., 3., 7(4.32) )
ARRAY GIB

   not be preset in a DATA statement.

5. Either unsigned constants or constants preceded
   by a minus sign may be used. Negative octal con-
   stants are prefixed with minus signs.

6. There must be a one-to-one correspondence be-
   tween the identifiers and the list.

COMMON / TUP / C(3)
DATA (C = 1., 2, 3)

4.7 BANK
In FORTRAN-66 the BANK statement acts as a do-nothing statement.
5. CONTROL STATEMENTS

Program execution normally proceeds from one statement to the statement immediately following it in the program. Control statements can be used to alter this sequence or cause a number of iterations of a program section.

Control may be transferred to an executable statement only; a transfer to a non-executable statement results in a program error.

Iteration control provided by the DO statement causes a predetermined sequence of instructions to be repeated any number of times with the stepping of a simple integer variable after each iteration.

5.1 STATEMENT IDENTIFIERS

Statements are identified by numbers which can be referred to from other sections of the program. A statement number used as a label or tag appears in columns 1 through 5 on the same line as the statement on the coding form. The statement number N may lie in the range \( 1 \leq N \leq 99999 \). An identifier up to 5 digits long may occupy any of the first five columns; blanks are squeezed out and leading zeros are ignored. 1, 01, 001, 0001, are identical. (Appendix A).

5.2 GO TO STATEMENTS

Transfer of control is provided by GO TO statements.

5.2.1 UNCONDITIONAL GO TO

\[ \text{GO TO N} \]

This statement causes an unconditional transfer to the statement labeled N; N is a statement identifier.

5.2.2 ASSIGNED GO TO

\[ \text{GO TO } m, (n_1, n_2, \ldots, n_m) \]

This statement acts as a many-branch GO TO. \( m \) is an integer variable assigned an integer value \( n_i \) in a preceding ASSIGN statement. The \( n_i \) are statement numbers. A parenthetical list need not be present.

The comma after \( m \) is optional when the list is omitted. \( m \) cannot be the result of a computation. If \( m \) is computed, the object code is incorrect.

5.2.3 ASSIGN STATEMENTS

\[ \text{ASSIGN N TO } m \]

This statement is used with the assigned GO TO statement. N is a statement number, \( m \) is a simple integer variable.

\[ \text{ASSIGN 10 TO LSWITCH} \]

\[ \ldots \]

\[ \text{GO TO LSWITCH,(5,10,15,20)} \]

Control will transfer to statement 10.

5.2.4 COMPUTED GO TO

\[ \text{GO TO } (n_1, n_2, \ldots, n_m)i \]

\[ \text{GO TO } (n_1, n_2, \ldots, n_m), i \]

This statement acts as a many-branch GO TO, where \( i \) is preset or computed prior to its use in the GO TO.

The \( n_i \) are statement numbers and \( i \) is a simple integer variable. If \( i \leq 1 \), a transfer to \( n_1 \) occurs; if \( i \geq m \), a transfer to \( n_m \) occurs. Otherwise, transfer is to \( n_i \).

For proper operations, \( i \) must not be specified by an ASSIGN statement.

\[ \text{ISWITCH} = 1 \]

\[ \text{GO TO (10,20,30),ISWITCH} \]

\[ \ldots \]

\[ 10 \text{ ISWITCH} = \text{ISWITCH} + 1 \]

\[ \text{GO TO (11,21,31),ISWITCH} \]

Control will transfer to statement 21.

5.3 IF STATEMENTS

Conditional transfer of control is provided by the one-, two-, and three-branch IF statements, the status of sense lights or switches.
5.3.1 THREE BRANCH IF (ARITHMETIC)
IF (A) n₁, n₂, n₃

A is an arithmetic expression and the nᵢ are statement numbers. This statement tests the evaluated quantity A and jumps accordingly.

\[ A < 0 \quad \text{jump to statement } n₁ \]
\[ A = 0 \quad \text{jump to statement } n₂ \]
\[ A > 0 \quad \text{jump to statement } n₃ \]

In the test for zero, +0= −0. When the mode of the evaluated expression is complex, only the real part is tested for zero.

\[
\begin{align*}
\text{IF}(A*B - C)\text{SINF}(X) & \text{10,10,20} \\
\text{IF}(1) & \text{5,6,7} \\
\text{IF}(A/B^*2) & \text{3,6,6}
\end{align*}
\]

5.3.2 TWO BRANCH IF (LOGICAL)
IF (L) n₁, n₂

L is a logical expression. The nᵢ are statement numbers.

The evaluated expression is tested for true (non-zero) or false (zero). If L is true, jump to statement n₁. If L is false, jump to statement n₂.

\[
\begin{align*}
\text{IF}(A \text{.GT. 16.} \text{.OR. I.EQ.0}) & \text{5,10} \\
\text{IF}(L) & \text{1,2} \\
\text{IF}(A*B - C) & \text{1,3} \\
\text{IF}(A*B/C) & \text{.LE. 14.32} \text{4,6}
\end{align*}
\]

5.3.3 ONE BRANCH IF (LOGICAL)
IF (L)s

L is a logical expression and s is a statement. If L is true (non-zero), execute statement s. If L is false (zero), continue in sequence to the statement following the IF logical.

\[
\begin{align*}
\text{IF} (L) \text{ GO TO 3 (L is logical)} \\
\text{IF} (L) Y = \text{SINF (X)} / 2
\end{align*}
\]

5.3.4 SENSE LIGHT
SENSE LIGHT i

The statement turns on the sense light i. SENSE LIGHT 0 turns off all sense lights. i may be a simple integer variable or constant (1 to 60).

\[
\text{IF}(\text{SENSE LIGHT } i) \text{ n₁, n₃}
\]

The statement test sense light i. If it is on, it is turned off and a jump occurs to statement n₁. If it is off, a jump occurs to statement n₃. i is a sense light and the nᵢ are statement numbers. i may be a simple integer variable or constant (1 to 60).

\[
\text{IF}(\text{SENSE LIGHT } 4) \text{10,20}
\]

5.3.5 SENSE SWITCH
IF(SENSE SWITCH i) n₁, n₂

If sense switch i is set (on), a jump occurs to statement n₁. If it is not set (off), a jump occurs to statement n₂; i may be a simple integer variable or constant. In the 6600, 1 ≤ i ≤ 6

\[
\begin{align*}
N = & 5 \\
\text{IF}(\text{SENSE SWITCH } N) \text{ 5,10}
\end{align*}
\]

5.4 FAULT CONDITION STATEMENTS

At execute time, the computer is set to interrupt on operand out of range. A program may be executed with an exit on any fault condition or by optional exits or tests provided by the program (SIPROS parameter).

\[
\begin{align*}
\text{IF DIVIDE CHECK} \text{ n₁, n₃} \\
\text{IF DIVIDE FAULT} \text{ n₁, n₃}
\end{align*}
\]

The above statements are equivalent. A divide fault occurs following division by zero. The statement checks for this fault; if it has occurred, the indicator is turned off and a jump to statement n₁ takes place. If no fault exists, a jump to statement n₂ takes place.

\[
\begin{align*}
\text{IF EXPONENT FAULT} \text{ n₁, n₃}
\end{align*}
\]

An exponent fault occurs when the result of a real or complex arithmetic operation exceeds the upper limits specified for these types. Results that are less than the lower limits are set to zero without indication. This statement is therefore a test for floating-point overflow only. If the fault occurs, the indicator is turned off, and a jump to statement n₁ takes place. If no fault exists, a jump to statement n₂ takes place.

\[
\begin{align*}
\text{IF OVERFLOW FAULT} \text{ n₁, n₃}
\end{align*}
\]

No overflow condition is provided on 60-bit sums and differences. A jump to statement n₂ is generated for the statement.
5.5 DO STATEMENTS

DO n i=m₁,m₂,m₃

This statement makes it possible to repeat groups of statements and to change the value of a fixed point variable during the repetition. n is the number of the statement ending the DO loop. i is the index variable (simple integer). The mᵢ are the indexing parameters; they may be any computable arithmetic expression. The initial value assigned to i is m₁, m₂ is the largest value assigned to i, and m₃ is the amount added to i after each DO loop is executed. If m₃ does not appear, it is assigned the value 1. The values of m₁ and m₃ may be changed at any time.

The DO statement, the statement labeled n, and any intermediate statements constitute a DO loop. Statement n may not be an IF or GO TO statement or another DO statement. See Transmission of Arrays section 7.1.1 and DATA Statement section 4.6 for usage of implied DO loops.

5.5.1 DO LOOP EXECUTION

The initial value of i, m₁, is compared with m₂ before executing the DO loop and, if it does not exceed m₂, the loop is executed. After this step, i is increased by m₃; i is again compared with m₂; this process continues until i exceeds m₂ as shown below. Control then passes to the statement immediately following n, and the DO loop is satisfied.

If m₁ exceeds m₂ on the initial entry to the loop, the loop is not executed and control passes to the next statement after statement n.

When the DO loop is satisfied, the index variable i is no longer well defined. If a transfer out of the DO loop occurs before the DO is satisfied, the value of i is preserved and may be used in subsequent statements.

5.5.2 DO NESTS

When a DO loop contains another DO loop, the grouping is called a DO nest. The last statement of a nested DO loop must either be the same as the last statement of the outer DO loop or occur before it. If D₁,D₂,...,Dₘ represent DO statements, where the subscripts indicate that D₁ appears before D₂ appears before D₃, and n₁,n₂,..,nₘ represent the corresponding limits of the Dᵢ, then nₘ must appear before nₘ₋₁...n₂ must appear before n₁.

[Diagram of nesting DO loops shown]
Examples:

DO loops may be nested in common with other DO loops:

```
DO 1 I = 1,10,2
   .
   .
   .
DO 2 J = 1,5
   .
   .
   .
DO 3 K = 2,8
   .
   .
   .
3 CONTINUE
   .
   .
   .
2 CONTINUE
   .
   .
   .
DO 4 L = 1,3
   .
   .
   .
4 CONTINUE
   .
   .
   .
1 CONTINUE
```

```
DO 100 L = 2,LIMIT
   .
   .
   .
DO 10 I = 1,10
   .
   .
   .
DO 10 J = 1,10
   .
   .
   .
10 CONTINUE
   .
   .
   .
DO 20 K = K1,K2
   .
   .
   .
20 CONTINUE
   .
   .
   .
DO 5 I = 1,5
   .
   .
   .
DO 5 J = 1,10
   .
   .
   .
DO 5 K = J,15
   .
   .
   .
5 CONTINUE
```
5.5.3 DO LOOP TRANSFER

In a DO nest, a transfer may be made from one DO loop into a DO loop that contains it; and a transfer out of a DO nest is permissible.

The special case is transferring out of a nested DO loop and then transferring back to the nest. In a DO nest, if the range of \( i \) includes the range of \( j \) and a transfer out of the range of \( j \) occurs, then a transfer into the range of \( i \) or \( j \) is permissible.

A transfer from the outer DO loop to the last statement should not be made when that statement is also the last statement of an inner DO loop. If such a transfer is made, control will transfer to the inner DO loop.

Example:

```
DO 10 I = J,K,L
    .
    .
5 GO to 10
DO 10 II = JJ,KK,LL
    .
    .
10 CONTINUE
```

This will cause control to pass the inner DO loop.

In the following diagram, EXTR represents a portion of the program outside of the DO nest.

![Diagram](image)

5.5.4 DO PROPERTIES

1. The indexing parameters \( m_1, m_2, m_3 \) may be any executable arithmetic expression.

2. The indexing parameters \( m_1 \) and \( m_2 \), if variable, may assume positive or negative values, or zero.

3. The values of \( m_1 \) and \( m_2 \) may be changed during the execution of the DO loop.

4. \( i \) is initially \( m_1 \). As soon as \( i \) exceeds \( m_2 \), the loop is terminated.

5. DO loops may be nested 50 deep.

5.6 CONTINUE

CONTINUE

The CONTINUE statement is most frequently used as the last statement of a DO loop to provide a transfer address for IF and GO TO instructions that are intended to begin another repetition of the loop. If CONTINUE is used elsewhere in the source program, it acts as a do-nothing instruction; and control passes to the next sequential program statement.

5.7 PAUSE

PAUSE

PAUSE n

PAUSE or PAUSE n act as do-nothing instructions.

5.8 STOP

STOP

STOP n

STOP or STOP n cause immediate exit to the monitor. n is an arbitrary number, not more than 5 digits in length.

5.9 END

END

END marks the physical end of a program or subprogram. It is executable in the sense that it effects return from a subprogram in the absence of a RETURN.

The END statement may include the name of the program or subprogram which it terminates. This name, however, is ignored.

The END statement is not connected with the dollar sign, which is used as a separator, nor does it make use of the continuation. When punched into a card, it must be the only entry in the card and must be punched within columns 7 through 72.
6. FUNCTIONS AND SUBPROGRAMS

Sets of instructions may be written as independent subroutines or function subprograms which can be referred to by the main program. The mode of a function subprogram is determined by the name of the subroutine in the same manner as variable modes are determined. Subroutine subprogram names are not classified by mode. The program or function name must be unique within that subprogram.

6.1 MAIN PROGRAMS AND SUBPROGRAMS

A main program may be written with or without references to subprograms. In all cases, the first statement must be of the following form where name is an alphanumeric identifier, 1-8 characters. The first character must be alphabetic; the remaining characters may be alphabetic or numeric.

```
PROGRAM name
```

A main program may refer to both subroutines and functions which are compiled independently of the main program. A calling program is a main program or subprogram that refers to subroutines and functions.

6.2 FUNCTIONAL SUBPROGRAM

The first statement of function subprograms must have the form:

```
FUNCTION F (p_1, p_2, ..., p_n)
```

F is the function name and the p_i are formal parameters. A function name is constructed and its type determined in the same way as a variable identifier. The parameters may be array names, non-subscripted variables, or names of other function or subroutine subprograms. A function, together with its arguments, may be used any place in an expression that a variable identifier may be used.

A function reference is a call upon a computational procedure for the return of a single value associated with the function identifier. This procedure may be defined by a single statement in the program (arithmetic statement function), in the compiler (library function), or in a multi-statement subprogram compiled independently of a main program (function subprogram).

The name of a function subprogram may occur as an operand in an arithmetic statement. The function reference must supply the function with at least one argument and it may contain up to 63. The form of the function reference is:

```
F (p_1, p_2, ..., p_n)
```

F is the function name and p_i are function arguments or actual parameters. The corresponding arguments appearing with the function name in a function definition are called formal parameters. Because formal parameters are local to the subprogram in which they appear, they may or may not correspond to the actual parameters in the calling subprogram.

Type-FUNCTION statements are permitted in addition to the FUNCTION F (p_1, p_2, ..., p_n) statement where mode is determined by the first character or a TYPE declaration. The alternate forms are:

```
REAL FUNCTION F (p_1, p_2, ..., p_n)
INTEGER FUNCTION F (p_1, p_2, ..., p_n)
DOUBLE PRECISION FUNCTION F (p_1, p_2, ..., p_n)
COMPLEX FUNCTION F (p_1, p_2, ..., p_n)
LOGICAL FUNCTION F (p_1, p_2, ..., p_n)
```

F is the function name, and p_i are formal parameters. The type-FUNCTION statement declares the type of the result returned by the function.

**Rules:**

1. The type of the function is determined from the naming conventions specified for variables in section 4.1 or from the type-FUNCTION statement.

2. The name of a function must not appear in a DIMENSION statement. The name must appear, however, at least once as any of the following:

```
the left-hand identifier of a replacement statement
an element of an input list
an actual parameter of a subprogram call
```

3. No element of a formal parameter list may appear in a COMMON, EQUIVALENCE, DATA, or EXTERNAL statement within the function subprogram.
4. When a formal parameter represents an array, it must be declared in a DIMENSION statement within the function subprogram. If it is not declared, only the first element of the array is available to the function subprogram.

5. In referring to a function subprogram the following forms of the actual parameters are permissible:
   - arithmetic expression
   - constant or variable, simple or subscripted array name
   - function reference
   - subroutine

When the name of a function subprogram appears as an actual parameter, that name must also appear in an EXTERNAL statement in the calling program. When the name of a function subprogram is used as an actual parameter, it may be in either of two forms:
   a. FUNCTION PUSH (ARG1)
   b. FUNCTION PUSH (FUNCT, ARG2)

To call these functions, then, the calling program uses, respectively, the forms:
   a. A = PUSH (CALC(X))
   b. A = PUSH (CALC, X)

When a subroutine appears as an actual parameter, the subroutine name may appear alone or with a parameter list. When a subroutine appears with a parameter list, the subroutine name and its parameters must appear as separate actual parameters:

Level I—Calling program

A = PUSH (DAB, W, X)

B = PUSH (DABL, Y, Z)

Level II—Function statement and subroutine call

FUNCTION PUSH (SUB, ARG1, ARG2)

CALL SUB (ARG1, ARG2)

6.3 LIBRARY FUNCTIONS

Function subprograms which are used frequently have been written and stored in a reference library and are available to the programmer through the compiler.

FORTRAN-66 contains the standard library functions available in earlier versions of FORTRAN. A list of these functions is in Appendix D. When one appears in the source program, the compiler identifies it as a library function and generates a calling sequence within the object program.

In the absence of a TYPE declaration, the type of the function identifier is determined by its first letter or by the type-FUNCTION statement. However, for standard library functions the modes of the results have been established through usage. The compiler recognizes the standard library functions and associates the established types with the results.

For example, in the function identifier LOGF, the first letter, L, would normally cause that function to return an integer result. This is contrary to established FORTRAN usage. The compiler recognizes LOGF as a standard library function and permits the return of a real result.

6.4 EXTERNAL STATEMENT

When the actual parameter list of a function or subroutine reference contains a function or subroutine name, that name must be declared in an EXTERNAL statement. Its form is:

EXTERNAL identifier1, identifier2, ... 

Identifier, is the name of a function or subroutine. The EXTERNAL statement must precede the first executable statement of any program in which it appears. When it is used, EXTERNAL always appears in the calling program; it must not be used with arithmetic statement functions.
Examples:

1. Function Subprogram

   FUNCTION GREATER (A,B)
   IF (A.GT.B) 10,20
   10 GREATER = A - B
      RETURN
   20 GREATER = A + B
      END

   Calling Program Reference
   Z(I,J) = F1 + F2 - GREATER(C - D, 3.*I/J)

2. Function Subprogram

   FUNCTION PHI(ALFA, PHI2)
   PHI = PHI2(ALFA)
   END

   Calling Program Reference
   EXTERNAL SINF

   C = D - PHI(Q(K), SINF)

From its call in the main program, the formal parameter ALFA is replaced by Q(K), and the formal parameter PHI2 is replaced by SINF. PHI will be replaced by the sine of Q(K).

3. Function Subprogram

   FUNCTION PSYCHE (A,B,X)
   CALL X
   PSYCHE = A/B*2.*(A - B)
   END

   Calling Program Reference
   EXTERNAL EROS

   R = S - PSYCHE (TLIM, ULIM, EROS)

In the function subprogram, TLIM, ULIM replaces A, B. The CALL X is a call to a subroutine named EROS. EROS appears in an EXTERNAL statement so that the compiler recognizes it as a subroutine name rather than a variable identifier.

4. Function Subprogram

   FUNCTION AL(W,X,Y,Z)
   CALL W(X,Y,Z)
   AL = Z**4
   RETURN
   END

   Calling Program Reference
   EXTERNAL SUM

   G = AL(SUM, E, V, H)

In the function subprogram the name of the subroutine (SUM) and its parameters (E, V, H) replace W and X, Y, Z. SUM appears in the EXTERNAL statement so that the compiler treats it as a subroutine name rather than a variable identifier.

6.5 STATEMENT FUNCTIONS

Statement functions are defined when used as an operand in a single arithmetic or logical statement in the source program and apply only to the particular program or subprogram in which the definition appears. They have the form

   F(p_1, p_2, ..., p_n) = E \quad 1 \leq n \leq 63

F is the function name, p_i are the formal parameters, and E is an expression.

Rules:

1. The function name must not appear in a DIMENSION, EQUIVALENCE, COMMON or EXTERNAL statement.

2. The formal parameters usually appear in the expression E. When the statement function is executed, formal parameters are replaced by the corresponding actual parameters of the function reference. Each of the formal parameters may be TYPE REAL or INTEGER only, but they may not be declared in a TYPE statement. Each of the actual parameters may be any computable arithmetic expression, but there must be agreement in order, number and type between the actual and formal parameters. Formal parameters must be simple variables.
3. E may be an arithmetic or logical expression.
4. E may contain subscripted variables.
5. The expression E may refer to library functions, previously defined statement function and function subprograms.
6. All statement functions must precede the first executable statement of the program or subprogram, but they must follow all declarative statements (DIMENSION, TYPE, et cetera).

Examples:

\[
\text{TYPE COMPLEX Z} \\
Z(X,Y) = (1.0)\times\text{EXP}(X)\times\text{COS}(Y) \\
+ (0.0)\times\text{EXP}(X)\times\text{SIN}(Y) \\
\]

This arithmetic statement function computes the complex exponential \(Z(x,y) = e^{ixy}\).

6.6 SUBROUTINE PROGRAM

A reference to a subroutine is a call upon a computational procedure. This procedure may return none, one or more values. No value is associated with the name of the subroutine, and the subroutine must be called by a CALL statement.

The first statement of subroutine subprograms must have the form:

\[
\text{SUBROUTINE S} \\
or \\
\text{SUBROUTINE S (p_1, p_2, \ldots p_n)} \\
1 \leq n \leq 63
\]

S is the subroutine name which follows the rules for variable identifiers, and \(p_i\) are the formal parameters which may be array names, non-subscripted variables, or names of other function or subroutine subprograms.

Rules:

1. The name of the subroutine may not appear in any declarative statement (TYPE, DIMENSION) in the subroutine.

2. No element of a formal parameter list may appear in a COMMON, EQUIVAENCE, DATA, or EXTERNAL statement within the subroutine subprogram.

4. When a formal parameter represents an array, it must be declared in a DIMENSION statement within the subroutine. If it is not declared, only the first element of the array is available to the subroutine.

6.7 CALL

The executable statement in the calling program for referring to a subroutine subprogram is of the form:

\[
\text{CALL S} \\
or \\
\text{CALL S (p_1, p_2, \ldots p_n)} \\
1 \leq n \leq 63
\]

S is the subroutine name, and \(p_i\) are the actual parameters. The CALL statement transfers control to the subroutine. When a RETURN or END statement is encountered in the subroutine, control is returned to the next executable statement following the CALL in the calling program. If the CALL statement is the last statement in a DO, looping continues until satisfied. Subprograms may be called from a main program or from other subprograms. Any subroutine called, however, may not call the calling program. That is, if program A calls subprogram B, subprogram B may not call program A. Furthermore, a program or subprogram may not call itself.

Rules:

1. The subroutine returns values through formal parameters which are substituted for actual parameters or through common variables.

2. The subroutine name may not appear in any declarative statement (TYPE, DIMENSION, et cetera). No value is associated with its name.

3. In the subroutine call, the following forms of actual parameters are permissible:
   - arithmetic expression
   - constant or variable, simple or subscripted array name
   - function reference
   - subroutine or function name
   - logical expression

When the name of a function subprogram appears as an actual parameter, that name must also appear in an EXTERNAL statement in the calling program. When the name of a function subprogram is used as an actual parameter, it may be in either of two forms:

a. FUNCTION POSH (ARG3)

b. FUNCTION POSH (FUNCT, ARG4)
To call these functions, then, the calling program uses, respectively, the forms:

a. \[ B = \text{POSH (CALC(X))} \]
b. \[ B = \text{POSH (CALC,X)} \]

When a subroutine appears as an actual parameter, the subroutine name may appear alone or with a parameter list.

When a subroutine appears with a parameter list, the subroutine name and its parameters must appear as separate actual parameters.

Level I—Calling program

\[
A = \text{PULL (DIS,A,B)}
\]

\[
B = \text{PULL (DIS,C,D)}
\]

Level II—Function statement and subroutine call

FUNCTION PULL (SUB,\textit{ARG1},\textit{ARG2})

CALL SUB (\textit{ARG1}, \textit{ARG2})

PULL = --

END

Level III—Subroutine definition

SUBROUTINE DIS (\textit{DUMMY 1}, \textit{DUMMY 2})

END

SUBROUTINE DISP (\textit{DUMMY 3}, \textit{DUMMY 4})

END

Logical expressions may be actual parameters.

Examples:

1. **Subroutine Subprogram**

   **SUBROUTINE BLVDLDR (A,B,W)**

   \[ W = 2.0B/A \]

   **END**

   **Calling Program References**

   **CALL BLVDLDR (X(I),Y(I),W)**

   \[ \]

   \[
   \text{CALL BLVDLDR (X(I)+H/2.,Y(I)+C(I)/2.,W)}
   \]

   \[
   \text{CALL BLVDLDR (X(I)+H,Y(I)+C(3),Z)}
   \]

2. **Subroutine Subprogram (Matrix Multiply)**

   **SUBROUTINE MATMULT**

   **COMMON/BLK1/X(20,20),Y(20,20),Z(20,20)**

   **DO 10 \( I=1,20 \)**

   **DO 10 \( J=1,20 \)**

   \[ Z(I,J)=0. \]

   **DO 10 \( K=1,20 \)**

   **10 \( Z(I,J) = (I,J) + X(I,K)*Y(K,J) \)**

   **RETURN**

   **END**

   **Calling Program Reference**

   **COMMON/BLK1/A(20,20),B(20,20),C(20,20)**

   \[
   \]

   **CALL MATMULT**

4. Because formal parameters are local to the subroutine in which they appear, they may be the same as names appearing outside the subroutine.

5. Actual and formal parameters must agree in order, type and, for the first call of the subprogram, in number (example 4).
3. **Subroutine Subprogram**

```fortran
SUBROUTINE ISHTAR (Y,Z)
COMMON/1/X(100)
Z=0.
DO 5 I=1,100
5 Z=Z+X(I)
CALL Y
RETURN
END
```

**Calling Program Reference**

```fortran
COMMON/1/A(100)
EXTERNAL PRNTIT

CALL ISHTAR (PRNTIT,SUM)
```

### 6.8 PROGRAM ARRANGEMENT

FORTRAN-66 assumes that all statements and comments appearing between a PROGRAM, SUBROUTINE or FUNCTION statement and an END statement belong to one program. A typical arrangement of a set of main program and subprograms follows.

```fortran
PROGRAM SOMTHING

END

SUBROUTINE S1

END

SUBROUTINE S2

END
```

### 6.9 RETURN AND END

A subroutine normally contains one or several RETURN statements that indicate the end of logic flow within the subroutine and return control to the calling program. The form is:

```fortran
RETURN
```

In function references, control returns to the statement containing the function. In subroutine subprograms, control returns to the calling program.

The END statement marks the physical end of a program, subroutine subprogram or function subprogram. If the RETURN statement is omitted, END acts as a return to the calling program.

A RETURN statement in the main program causes an exit to the monitor.

### 6.10 ENTRY

This statement provides alternate entry points to a function or subroutine subprogram. Its form is:

```fortran
ENTRY name
```

Name is an alphanumeric identifier, and may appear within the subprogram only in the ENTRY statement. Each entry identifier must appear in a separate ENTRY statement. The maximum number of entry points, including the subprogram name, is 20. The formal parameters, if any, appearing with the FUNCTION or SUBROUTINE statement do not appear with the ENTRY statement. ENTRY may appear anywhere within the subprogram except it must not appear within a DO; it can not be labeled.

In the calling program, the reference to the entry name is made just as though reference were being made to the FUNCTION or SUBROUTINE in which the ENTRY is imbedded. Rules 5 and 6 of 6.2 apply.

ENTRY names must agree in type with the function or subroutine name.
Examples:

FUNCTION JOE (X,Y)
10 JOE=X+Y
RETURN
ENTRY JAM
IF(X.GT.Y)10,20
20 JOE=X-Y
END

This could be called from the main program as follows:

Z=A+B-JOE(3.*P,Q-1)

R=S+JAM(Q,2.*P)

6.11 VARIABLE DIMENSIONS IN SUBPROGRAMS

In many subprograms, especially those performing matrix manipulation, the programmer may wish to vary the dimension of the arrays each time the subprogram is called.

This is accomplished by specifying the array identifier and its dimensions as formal parameters in the FUNCTION or SUBROUTINE statement heading a subprogram. In the subroutine call from the calling program, the corresponding actual parameters specified are used by the called subprogram. The maximum dimension which any given array may assume is determined by a DIMENSION statement in the main program at compile time.

Rules:

1. The rules of 6.2, 6.5, and 6.7 apply.
2. The formal parameters representing the array dimensions must be simple integer variables. The array identifier must also be a formal parameter.
3. The actual parameters representing the array dimensions may be integer constants or integer variables.

4. If the total number of elements of a given array in the calling program is N, then the total number of elements of the corresponding array in the subprogram may not exceed N.

Examples:

1. Consider a simple matrix add routine written as a subroutine:

SUBROUTINE MATADD(X,Y,Z,M,N)
DIMENSION X(M,N),Y(M,N),Z(M,N)
DO 10 I=1,M
DO 10 J=1,N
10 Z(I,J)=X(I,J)+Y(I,J)
RETURN
END

The arrays X,Y,Z and the variable dimensions M,N must all appear as formal parameters in the SUBROUTINE statement and also appear in the DIMENSION statement as shown. If the calling program contains the array allocation declaration

DIMENSION A(10,10), B(10,10), C(10,10)
DIMENSION D(4,8), E(4,8), F(4,8)
DIMENSION P(3,12), Q(3,12), R(3,12)

the program may call the subroutine MATADD from several places within the main program, varying the array dimension within MATADD each time as follows:

CALL MATADD (A,B,C,10,10)

CALL MATADD (D,E,F,4,8)

CALL MATADD (P,Q,R,3,12)

The compiler does not check to see if the limits of the array established by the DIMENSION statement in the main program are exceeded.
The following 6600 FORTRAN program permits variation of N from call to call:

```fortran
SUBROUTINE MATRAN (Y, YPRIME, N)
DIMENSION Y(4,N), YPRIME (N, 4)
DO 7 I=1,N
    DO 7 J=1,4
        7 YPRIME (I,J) = Y(J,I)
END
```
7. FORMAT SPECIFICATIONS

Data transmission between storage and an external unit requires the FORMAT statement and the I/O control statement (Chapter 9). The I/O statement specifies the input/output device and process—READ, WRITE, and so forth, and a list of data to be moved. The FORMAT statement specifies the manner in which the data are to be moved. In binary tape statements no FORMAT statement is used.

7.1 THE I/O LIST

The list portion of an I/O control statement indicates the data elements and the order, from left to right, of transmission. Elements may be simple variables or array names (subscripted or non-subscripted). They may be constants on output only. List elements are separated by commas, and the order must correspond to the order of the FORMAT specifications.

7.1.1 TRANSMISSION OF ARRAYS

Part or all of an array can be represented as a list item. Multi-dimensioned arrays may appear in the list, with values specified for the range of the subscripts in an implied DO loop.

The general forms are:

(a) transmission by columns
   \((A(I,J,K), I=m_1,m_2,m_3, J=n_1,n_2,n_3, K=p_1,p_2,p_3)\)

(b) transmission by rows
   \((A(I,J,K), J=n_1,n_2,n_3, I=m_1,m_2,m_3)\)

\(m_1,n_1,p_1\) are any computable arithmetic expression. If \(m_3, n_3\) or \(p_3\) is omitted, it is construed as being 1.

\(I,J,K\) are subscripts of \(A\). If a subscript is omitted when transmitting an array, a DO statement is generated for the missing subscript using the entire range of values.

The I/O list may contain nested DO loops to any depth within the overall DO nest limit of 50 (including the nest depth in which the I/O statement resides).

Example:

DO loops nested 5 deep:

\((A(I,J,K), I=m_1,m_2,m_3, J=n_1,n_2,n_3, K=p_1,p_2,p_3)\)

During execution, each subscript (index variable) is set to the initial index value: \(I=i_1, J=j_1, K=k_1, M=m_1, N=n_1\).

The first index variable defined in the list is incremented first. Data named in the implied DO loops are transmitted in increments according to the third DO loop parameter until the second DO loop parameter is exceeded. If the third parameter is omitted, the increment value is 1. When the first index variable reaches the maximum value, it is reset; the next index variable to the right is incremented; and the process is repeated until the last index variable has been incremented.

An implied DO loop may also be used to transmit a simple variable more than one time. In \((A,K=1,10)\), \(A\) will be transmitted 10 times.

Example:

As an element in an input/output list, the expression

\((A(I,J,K), I=m_1,m_2,m_3, J=n_1,n_2,n_3)\)

implies a nest of DO loops of the form

\[\text{DO}\ 10\ K=p_1,p_2,p_3\]

\[\text{DO}\ 10\ J=n_1,n_2,n_3\]

\[\text{DO}\ 10\ I=m_1,m_2,m_3\]

Transmit \(A(I,J,K)\)

10 CONTINUE

To transmit the elements of a 3 by 3 matrix by columns:

\((A(I,J), I=1,3, J=1,3)\)

To transmit the elements of a 3 by 3 matrix by rows:

\((A(I,J), J=1,3, I=1,3)\)

If a multi-dimensioned array name appears in a list without subscripts, the entire array is transmitted. For example, a multi-dimensioned, non-subscripted list element, SPECS, with an associated DIMENSION SPECS \((7,5,3)\) statement is transmitted as though under control of the nested DO loops.

\[\text{DO}\ 10\ K=1,3\]

\[\text{DO}\ 10\ J=1,5\]

7-1
DO 10 I=1,7
Transmit SPECS (I,J,K)
10 CONTINUE
or as though under control of an implied DO loop,
... ((SPECS(I,J,K), I=1,7), J=1,5),
K=1,3), ...

I/O Lists:
( (BUZ(K,2*I-1), K=1,5), I=1,13,2)
Q(3), Z(2,2), (TUP(3*I-4), I=2,10)
(RAZ(K), K=1, LIM1, LIM2)

7.2 FORMAT STATEMENT
The BCD I/O control statements require a FOR-MAT statement which contains the specifications
relating to the internal-external structure of the
corresponding I/O list elements.

FORMAT (speci,...,k(specm,...),specn,...) Spec, is a format specification and k is an optional
repetition factor which must be an unsigned integer
constant. The FORMAT statement is non-executable,
and may appear anywhere in the program.

7.3 FORMAT SPECIFICATIONS
The data elements in I/O lists are converted from
external to internal or from internal to external
representation according to FORMAT conversion
specifications. FORMAT specifications may also
contain editing codes.

FORTRAN-66 conversion specifications
Ew.d Single precision floating point
with exponent
Fw.d Single precision floating point
without exponent
Dw.d Double precision floating point
with exponent
C(Zw.d,Zw.d) Complex conversion; Z may be
E or F conversion
Iw Decimal integer conversion
Ow Octal integer conversion
Aw Alphanumeric conversion
Rw Alphanumeric conversion
Lw Logical conversion
nP Scaling factor

FORTRAN-66 editing specifications
wX Intra-line spacing
*...* Heading and labeling
wH

7-2

/ Begin new record
n/ Create n-1 blank records.
Both w and d are unsigned integer constants. w
specifies the field width, the number of character
positions in the record; and d specifies the number
digits to the right of the decimal within the field.

7.4 CONVERSION SPECIFICATIONS

7.4.1 EW.D OUTPUT
E conversion is used to convert floating point num-
bers in storage to the BCD character form for out-
put. The field occupies w positions in the output
record; the corresponding floating point number
will appear right justified in the field as

| a...a aE±e ee | −307 ≤ eee ≤ 307

a...a are the most significant digits of the
integer and fractional part and eee are the digits
in the exponent. If d is zero or blank, the decimal
point and digits to the right of the decimal do not
appear as shown above. Field w must be wide
enough to contain the significant digits, signs, deci-
mal point, E, and the exponent. Generally, w is
greater than or equal to d + 7.

If the field is not wide enough to contain the output
value, asterisks are inserted for the entire field. If
the field is longer than the output value, the quan-
tity is right justified with blanks in the excess posi-
tions to the left.

For P-scaling on output, see section 7.6.2.

Examples:
A contains −67.32 or +67.32
PRINT 10, A
10 FORMAT (E11.3)
Result: −6.732E+001 or 6.732E+001
PRINT 20, A
20 FORMAT (E14.3)
Result: ^^^ − 6.732E+001 or ^^^ 6.732E+001

A contains −67.32
PRINT 30, A
30 FORMAT (E 10.3)
Result: ******** Provision not made for
sign
PRINT 40, A
40 FORMAT (E 11.4)
Result: ******** Same as above
7.4.2 Ew.d input

The E specification converts the number in the input field (specified by w) to a real and stores it in the appropriate location in memory.

Subfield structure of the input field:

```
<table>
<thead>
<tr>
<th>+</th>
<th>+</th>
</tr>
</thead>
<tbody>
<tr>
<td>digit</td>
<td>E xx ...</td>
</tr>
</tbody>
</table>
```

integer fraction exponent

The total number of characters in the input field is specified by w; this field is scanned from left to right; blanks within the field are interpreted as zeros.

The coefficient subfield, composed of an integer and/or a fraction, begins with a sign (+ or −) or a digit and contains a string of digits (a sequence of consecutive numbers). The fraction portion which begins with a decimal point contains a string of digits. The subfield is terminated by a D, E, a + or −, or the end of the input field.

An exponent subfield begins with a D, E, a + or a −. When it begins with E or D, the + or − appears between the E or D and the string of digits in the subfield. The value of this string of digits must be less than 310.

Permissible subfield combinations:

- +1.6327E −04 integer fraction exponent
- −32.7216 integer fraction
- +328+5 integer exponent
- .629E −1 fraction exponent
- +136 integer only
- .07628431 fraction only
- E −06 (interpreted as zero) exponent only

Rules:

1. In the Ew.d input specification, d acts as a negative power of ten scaling factor when the decimal point is not present. The internal representation of the input quantity will be:

   \[(\text{integer subfield}) \times 10^d \times 10^{(\text{exponent subfield})}\]

For example, if the specification is E7.8, the input quantity 3267+05 is converted and stored as: 3267 \times 10^9 \times 10^0 = 3.267.

2. If E conversion is specified, but a decimal point occurs in the input constants, the decimal point will override d. The input quantity 3.67294+5 may be read by any specification but is always stored as 3.67294 \times 10^5.

3. When d does not appear, it is assumed to be zero.

4. The field length specified by w in Ew.d must always be the same as the length of the input field containing the input number. When it is not, incorrect numbers may be read, converted and stored as shown below. The field w includes the significant digits, signs, decimal point, E, and exponent.

```
READ 20,A,B,C
20 FORMAT (E9.3,E7.2,E10.3)
```

The input quantities appear on a card in three contiguous field columns 1 through 24:

```
9 5 10
+6.47E-01-2.36+5.321E+02
```

The second specification (E7.2) exceeds the physical field width of the second value by two characters. Reading proceeds as follows:

```
9
7
10
+6.47E-01
-2.36
+5.321E+02
```

First +6.47E-01 is read, converted and placed in location A.
Next, $-2.36 + 5$ is read, converted and placed in location B. The number actually desired was $-2.36$, but the specification error (E7.2 instead of E5.2) caused the two extra characters to be read. The number read ($-2.36 + 5$) is a legitimate input representation under the definitions and restrictions.

Finally $321E+02$ is read, converted and placed in location C. Here again, the input number is legitimate; and it is converted and stored, even though it is not the number desired.

The above example illustrates a situation where numbers are incorrectly read, converted, and stored, and yet there is no immediate indication that an error has occurred.

**Examples:**

<table>
<thead>
<tr>
<th>Input Field</th>
<th>Specification</th>
<th>Converted Value</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>$+143.26E-03$</td>
<td>E11.2</td>
<td>.14326</td>
<td>All subfields present</td>
</tr>
<tr>
<td>$-12.437629E+1$</td>
<td>E13.6</td>
<td>$-124.37629$</td>
<td>All subfields present</td>
</tr>
<tr>
<td>$8936E+004$</td>
<td>E9.10</td>
<td>.008936</td>
<td>No fraction subfield. Input number converted as $8936 \times 10^{-1}$</td>
</tr>
<tr>
<td>$327.625$</td>
<td>E7.3</td>
<td>327.625</td>
<td>No exponent subfield</td>
</tr>
<tr>
<td>$4.376$</td>
<td>E5</td>
<td>4.376</td>
<td>No d in specification</td>
</tr>
<tr>
<td>$.0003627+5$</td>
<td>E11.7</td>
<td>$-36.27$</td>
<td>Integer subfield contains only</td>
</tr>
<tr>
<td>$-11.11E1$</td>
<td>E3.0</td>
<td>10.0</td>
<td>No fraction subfield. Input number converted as $1. \times 10^3$</td>
</tr>
<tr>
<td>E06</td>
<td>E10.6</td>
<td>0.0</td>
<td>No integer or fraction subfield. Zero stored regardless of exponent field contents</td>
</tr>
<tr>
<td>$.6$</td>
<td>E6.3</td>
<td>10.0</td>
<td>Blanks are interpreted as zeros</td>
</tr>
</tbody>
</table>

### 7.4.3 FW.D OUTPUT

The field occupies w positions in the output record; the corresponding list element must be a floating point quantity, and it will appear as a decimal number; right justified in the field w, as:

$\pm 8 \ldots 8.8 \ldots 8$

8 represents the most significant digits of the number. The number of places to the right of the decimal point is specified by d. If d is zero or omitted, the fractional digits do not appear. If the number is positive, the plus sign is suppressed.

If the field is too short to accommodate the number, asterisks will appear in the output field.

If the field w is longer than required to accommodate the number, it is right justified with blanks occupying the excess field positions to the left.

**Examples:**

- A contains $+32.694$
  - PRINT 10,A
  - 10 FORMAT(F7.3)
  - Result: $\pm 32.694$

- A contains $-32.694$
  - PRINT 11,A
  - 11 FORMAT(F10.3)
  - Result: $-3.2694$

### 7.4.4 FW.D INPUT

This specification is a modification of Ew.d. The input field consists of an integer and a fraction subfield. An omitted subfield is assumed to be zero. All rules listed under Ew.d input apply. P-scaling is permissible.
Examples:
Fw.d Input

<table>
<thead>
<tr>
<th>Input Field</th>
<th>Specification</th>
<th>Converted Value</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>367.2593</td>
<td>F8.4</td>
<td>367.2593</td>
<td>Integer and fraction field</td>
</tr>
<tr>
<td>37925</td>
<td>F5.7</td>
<td>.0037925</td>
<td>No fraction subfield. Input number converted as 37925 × 10^{-5}</td>
</tr>
<tr>
<td>−4.7366</td>
<td>F7</td>
<td>−4.7366</td>
<td>No d in specification</td>
</tr>
<tr>
<td>.62543</td>
<td>F6.5</td>
<td>.62543</td>
<td>No integer subfield</td>
</tr>
<tr>
<td>.62543</td>
<td>F6.d</td>
<td>.62543</td>
<td>Decimal point overrides d of specification</td>
</tr>
<tr>
<td>+144.15E−03</td>
<td>F11.2</td>
<td>.14415</td>
<td>Exponents are legitimate in F input and may have P-scaling</td>
</tr>
</tbody>
</table>

7.4.5 DW.D OUTPUT
The field occupies w positions of the output record; the corresponding list element which must be a double precision quantity appears as a decimal number, right justified in the field w:
\[ \Delta \alpha \ldots \Delta E \pm \varepsilon e \quad -307 \leq \varepsilon e e \leq 307 \]

D conversion corresponds to Ew.d output except that 29 is the maximum number of significant digits in the fraction.

7.4.6 DW.D INPUT
D conversion corresponds to Ew.d input except that 29 is the maximum number of significant digits permitted in the combined integer-fraction field. P-scaling is not applicable. D is acceptable in place of E as the beginning of an exponent field.

Example:

```
TYPE DOUBLE Z,Y
READ1, Z,Y
1 FORMAT (D24.17,D15)
```

Input card:

```
-6.31675298443769217E-03 + 2.718926453147
```

7.4.7 C(Z1,W1,D1,Z2,W2,D2) OUTPUT

Z is either E or F. The field occupies \( w_1 + w_2 \) positions in the output record, and the corresponding list element must be complex. \( w_1 + w_2 \) are two real values; \( w_1 \) represents the real part of the complex number and \( w_2 \) represents the imaginary part. The value may be one of the following forms:

\[ \Delta \delta \ldots \delta \exp \Delta \delta \ldots \delta \exp \quad (Ew.d,Ew.d) \]
\[ \Delta \delta \ldots \delta \exp \Delta \delta \ldots \delta \ldots \delta \quad (Ew.d,Fw.d) \]
\[ \Delta \delta \ldots \delta \ldots \delta \Delta \delta \ldots \delta \exp \quad (Fw.d,Ew.d) \]
\[ \Delta \delta \ldots \delta \ldots \delta \Delta \delta \ldots \delta \ldots \delta \quad (Fw.d,Fw.d) \]

Exp is \[ \pm e, e, e \].

The restrictions for Ew.d and Fw.d apply.

If spaces are desired between the two output numbers, the second specification should indicate a field (\( w_2 \)) larger than required.

Example:

```
TYPE COMPLEX A
PRINT 10,A
10 FORMAT (C(F7.2,F9.2))
```

real part of A is 362.92
imaginary part of A is −46.73

Result:  
\[ A \quad 362.92 \quad \underline{AAA}−46.73 \]

7.4.8 C(Z1,W1,D1,Z2,W2,D2) INPUT

Z is either E or F and the input quantity occupies \( w_1 + w_2 \) character positions. The first \( w_1 \) characters are the representation of the real part of the complex number, and the remaining \( w_2 \) characters are the representation of the imaginary part of the complex number.

The restrictions for Ew.d and Fw.d apply.
Example:

```
TYPE COMPLEX A,B
READ 10,A,B
10 FORMAT (C(F6.2,F6.2), C(E10.3,E10.3))
```

Input card:

```
-42.13 + 13.91 + 1.456E+03 - 1.216E-01
```

7.4.9 IW OUTPUT

I specification is used to output decimal integer values. The output quantity occupies w output record positions; it will appear right justified in the field w, as:

\[ \Delta \delta \ldots \delta \]

\( \delta \) is the most significant decimal digits (maximum 18) of the integer. If the integer is positive, the + sign is suppressed.

If the field w is larger than required, the output quantity is right justified with blanks occupying excess positions to the left. If the field is too short, characters are discarded from the left.

Example:

```
PRINT 10,I,J,K
10 FORMAT (18,110,15) J contains +4762937
K contains +13
```

Result:

```
-3762 AAA 4762937 AAA 13
```

7.4.10 IW INPUT

The field is w characters in length and the corresponding list element must be a decimal integer quantity.

7.4.11 OW OUTPUT

O specification is used to output octal integer values. The output quantity occupies w output record positions, and it will appear right justified in the field as: \( \delta \delta \ldots \delta \).

The \( \delta \) are octal digits. If w is 20 or less, the rightmost w digits appear. If w is greater than 20, the number is right justified in the field with blanks to the left of the output quantity. A negative number is output in its machine form (one's complement).

7.4.12 OW INPUT

Octal integer values are converted under O specification. The field is w octal integer characters in length and the corresponding list element must be an integer quantity.

The input field w consists of an integer subfield only (maximum of 20 octal digits). The only characters that may appear in the field are +, or -, blank and 0 through 7. Only one sign is permitted;
it must precede the first digit in the field. Blanks are interpreted as zeros.

**Example:**

```
TYPE INTEGER P,Q,R
READ 10,P,Q,R
10 FORMAT (O10,O12,O2)
```

Input Card:

```
373737376666664444-0
10 12 2
```

In memory:

```
P: 000000000037373737
Q: 00000006666640444
R: 777777777777777777
```

A negative number is represented in complement form.

A negative octal number is represented internally in 20-digit seven’s complement form obtained by subtracting each digit of an octal number from seven. For example, if \(-703\) is an input quantity, its internal representation is 77777777777777777777. That is,

```
77777777777777777777
-00000000000000703
77777777777777777774
```

**7.4.13 AW OUTPUT**

A conversion is used to output alphanumeric characters. If \(w\) is 10 or more, the output quantity appears right justified in the output field, blanks fill to left. If \(w\) is less than 10 the output quantity represents the leftmost \(w\) characters, left justified in the field.

**7.4.14 AW INPUT**

This specification will accept as list elements any set of six bit characters including blanks. The internal representation is BCD; the field width is \(w\) characters.

If \(w\) exceeds 10, the input quantity will be the rightmost characters. If \(w\) is 10 or less, the input quantity goes to the designated storage locations as a left justified BCD word, the remaining spaces are blank-filled.

**7.4.15 RW OUTPUT**

This specification is the same as the Aw specification with the following exception. If \(w\) is less than 10 the output quantity represents the rightmost characters.
7.4.16 RW INPUT
If \( w \) is less than 10, the input quantity goes to the designated storage location as a right justified binary zero filled word.

\[
\begin{align*}
\text{w} &\geq 10 \text{ output} \\
\text{w} &> 10 \text{ input}
\end{align*}
\]

\[
\begin{array}{c}
\text{field} \\
\boxed{10 \text{ BCD char.}}
\end{array}
\]

\[
\begin{align*}
\text{w} < 10 \text{ output} \\
\text{w} \leq 10 \text{ input}
\end{align*}
\]

\[
\begin{array}{c}
\text{field} \\
\boxed{10 \text{ BCD char.}}
\end{array}
\]

Example:  (Compare with previous example)

\[
\begin{align*}
\text{READ} &\ 10,Q,P,O \\
10 &\ \text{FORMAT (R10,R10,R4)}
\end{align*}
\]

Input card:

\[
\begin{array}{c}
\text{col. 1} \\
\text{LUX MENTIS LUX ORBIS LUX} \\
\boxed{10 \quad 10 \quad 4}
\end{array}
\]

In memory:

\[
\begin{align*}
\text{Q:} &\quad \text{LUXbMENTIS} \\
\text{P:} &\quad \text{bLUXbORBIS} \\
\text{O:} &\quad 000000bLUX
\end{align*}
\]

7.4.17 LW OUTPUT
L specification is used to output logical values. The input/output field is \( w \) characters long and the corresponding list element must be a logical element.

If \( w \) is greater than 1, 1 or 0 is printed right justified in the field \( w \) with blank fill to the left.

Example:

\[
\begin{align*}
\text{TYPE} \quad \text{LOGICAL} &\ 1, J, K, L \\
\text{PRINT} &\ 5, I, J, K, L \\
5 &\ \text{FORMAT (4L3)}
\end{align*}
\]

Result:

\[
\boxed{\_\_\_ 1, \_\_\_ 0, \_\_\_ 1, \_\_\_ 1}
\]

7.4.18 LW INPUT
This specification will accept logical quantities as list elements. A zero or a blank in the field \( w \) is stored as zero. A one in the field \( w \) is stored as one. Only one such character (0 to 1) may appear in any input field. Any character other than 0, 1, or blank is incorrect.

7.5 EDITING SPECIFICATIONS

7.5.1 wx

This specification may be used to include \( w \) blanks in an output record or to skip \( w \) characters on input to permit spacing of input/output quantities.

Examples:

\[
\begin{align*}
\text{PRINT} &\ 10, A, B, C \\
10 &\ \text{FORMAT} \\
&\ (12, 6X, F6.2, 6X, E13.5) \\
\text{READ} &\ 11, R, S, T \\
11 &\ \text{FORMAT (F5.2, 3X, F5.2, 6X, F5.2)} \text{ or} \\
&\ \text{FORMAT (F5.2, 3XF5.2, 6XF5.2)}
\end{align*}
\]

Input card:

\[
\begin{array}{c}
\text{col. 1} \\
14.62, S, 13.78, \text{COST}, 15.97 \\
\boxed{14.62, S, 13.78, \text{COST}, 15.97}
\end{array}
\]

In memory:

R = 14.62

\[
\begin{array}{c}
\text{col. 1} \\
S = 13.78 \\
\boxed{14.62, S, 13.78, \text{COST}, 15.97}
\end{array}
\]

T = 15.97

In the specification list, the comma following X is optional.
7.5.2 WH OUTPUT

This specification provides for the output of any set of six-bit characters, including blanks, in the form of comments, titles, and headings. w is an unsigned integer specifying the number of characters to the right of the H that will be transmitted to the output record. H denotes a Hollerith field. The comma following the H specification is optional.

Examples:

Source program:

```
PRINT 20
20 FORMAT(25H BLANKS COUNT IN AN H FIELD.)
```

produces output record:

```
\* BLANKS COUNT IN AN H FIELD.
```

Source program:

```
PRINT 30, A
30 FORMAT(6H LMAX=,F5.2)
```

A contains 1.5 comma is optional

produces output record:

```
\* LMAX = \* 1.50
```

7.5.3 WH INPUT

The H field may be used to read a new heading into an existing H field.

Example:

Source program:

```
READ 10
10 FORMAT (27H THIS IS A VARIABLE HEADING)
```

Input card:

```
col. 1
\* THIS IS A VARIABLE HEADING
```

27 cols

After the READ, the FORMAT statement labeled 10 will contain the alphanumeric information read from the input card; a subsequent reference to statement 10 in an output control statement would act as follows:

```
PRINT 10 produces the printer line:
\* THIS IS A VARIABLE HEADING
```

7.5.4 *N CHAR.* OUTPUT

This specification can be used as an alternate form of wH to output headings, titles, and comments. Any 6-bit character (except asterisk) between the asterisks will be output. The first asterisk denotes the beginning of the Hollerith field; the second asterisk terminates the field.

Examples:

1. Source program:

```
PRINT 10
10 FORMAT (*ASUBTOTALS*)
```

produces the output records: SUBTOTALS

2. If an asterisk accidentally occurs in the characters to be output, it will terminate the field and the characters following the asterisk will be interpreted as incorrect format specifications.

Source program:

```
PRINT 10
10 FORMAT (*ABC*BE*)
```

produces the output record: ABC The conversion routine will attempt to interpret BE as a format specification.

7.5.5 *..* INPUT

This specification is used in place of wH to read a new heading into an existing Hollerith field. Characters are stored in the heading until an asterisk is encountered in the input field or until all the spaces in the format specification are filled. If the format specification contains n spaces and the mth character (m<n) in the input field is an asterisk, all characters to the left of the asterisk will be stored in the heading and the remaining character positions in the heading will be filled with blanks.

Examples:

1. Source program:

```
READ 10
10 FORMAT (*HFTRTFORTAN FOR THE 6600*)
```

Input card:

```
FORTAN FOR THE 6600
```

A subsequent reference to statement 10 in an output control statement:

```
PRINT 10 produces:
FORTAN FOR THE 6600
```

7-9
2. Source program:
   READ 10
   10 FORMAT (*AAAAAA*)

   Input card: HEAD*LINE
   PRINT 10 produces: HEADAAA

7.5.6 NEW RECORD

The slash, /, which signals the end of a BCD record may occur anywhere in the specifications list. It need not be separated from the other list elements by commas; consecutive slashes may appear in a list. During output, it is used to skip lines, cards, or tape records. During input, it specifies that control passes to the next record or card. k+1 consecutive slashes produce k blank lines, or n/ produces n-1 blank lines during output and skips n-1 records or cards during input.

Examples:

   PRINT 10
   10 FORMAT (20X,7HHEADING///6X,
   5HHINPUT,19X,H6HOUTPUT) line 1
   Print-out: HEADING line 2
              INPUT    OUTPUT line 3
Statement 10 in the example may also be written:

   10 FORMAT (20X,7HHEADING3///6X,
   5HHINPUT,19X,H6HOUTPUT)

Each line corresponds to a BCD record. The second and third records are null and produce the line spacing illustrated.

   Internally:
   A = -11.6     C = 46.327
   B = .325      D = -14.261
   PRINT 11,A,B,C,D
11 FORMAT (2E12.2/2F7.3)
   Result: AA --1.16E+001,AA 3.25E-001
            \46.327 - 14.261
   PRINT 11,A,B,C,D
11 FORMAT (2E12.2/2F7.3)
   Result: AA --1.16E+001,AA 3.25E-001
            \46.327 - 14.261
   PRINT 15, (A(1),=,1.9)
15 FORMAT (8H RESULTS2/(3F8.2))
   Result:
   RESULTS
   3.62   -4.03   -9.78
   -6.33   7.12    3.49
   6.21   -6.74   -1.18

7.6 NP SCALE FACTOR

A scale factor may precede the F conversion and E conversion. The scale factor is:

   \text{External number} = \text{Internal number} \times 10^{\text{scale factor}}

The scale factor applies to Fw.d on both input and output and to Ew.d and Dw.d on output only. A scaled specification is written as:

\[
\text{n}P \begin{cases} 
\text{D} \\
\text{E} \\
\text{F} \\
\end{cases} \text{w.d}
\]

n is a signed integer constant. The nP specification may appear with complex conversion, C(Zw.d,Zw.d); each word is scaled separately according to Fw.d or Ew.d scaling.

7.6.1 FW.D SCALING

Input

The number in the input field is divided by $10^n$ and stored. For example, if the input quantity 314.1592 is read under the specification 2PF8.4, the internal number is $314.1592 \times 10^{-4} = 3.141592$.

Output

The number in the output field is the internal number multiplied by $10^n$. In the output representation, the decimal point is fixed; the number moves to the left or right depending on whether the scale factor is plus or minus. For example, the internal number 3.1415926536 may be represented on output under scaled F specifications as follows:

\begin{tabular}{ll}
\text{Specification} & \text{Output Representation} \\
F13.6 & 3.141593 \\
1PF13.6 & 31.415927 \\
3PF13.6 & 3141.592654 \\
-1PF13.6 & .314159 \\
\end{tabular}

7.6.2 EW.D SCALING

Output

The scale factor has the effect of shifting the output number left n places while reducing the exponent by n. Using 3.1415926538 some output representations corresponding to scaled E specifications are:

\begin{tabular}{ll}
\text{Specification} & \text{Output Representation} \\
E20.2 & 3.14E+000 \\
1PE20.2 & 31.42E-001 \\
2PE20.2 & 314.16E-002 \\
3PE20.2 & 3141.59E-003 \\
4PE20.2 & 31415.93E-004 \\
5PE20.2 & 314159.27E-005 \\
-1PE20.2 & 0.31E+001 \\
\end{tabular}
7.6.3 SCALING RESTRICTIONS

The scale factor is assumed to be zero if no other value has been given; however, once a value has been given, it will hold for all D,E and F specifications following the scale factor within the same FORMAT statement. To nullify this effect in subsequent D,E and F specifications, a zero scale factor, 0 P, must precede a D,E, or F specification. Scale factors on D or E input specifications are ignored.

The scaling specification \( nP \) may appear independently of an E or F specification, but it will hold for all E and F specifications that follow within the same FORMAT statement unless changed by another \( nP \).

(3P, 3I9, F10.2) same as
(3I9, 3PF10.2)

7.7 REPEATED FORMAT SPECIFICATIONS

Any FORMAT specification may be repeated by using an unsigned integer constant repetition factor, \( k \), as follows: \( k(\text{spec}) \), spec is any conversion specification except \( nP \). For example, to print two quantities \( K,L \):

PRINT 10 K,L
10 FORMAT (I2,I2)

Specifications for \( K,L \) are identical; the FORMAT statement may be: 10 FORMAT (2I2).

When a group of FORMAT specifications repeats itself, as in: FORMAT (E15.3,F6.1,I4,I4,E15.3,F6.1, I4,I4), the use of \( k \) produces: FORMAT (2(E15.3, F6.1,2I4)).

The parenthetical grouping of FORMAT specifications is called a repeated group. Repeated groups may be nested to 10 levels.

FORMAT \( (n1,(-n2,(-n3,\ldots,n_n))) \) \)

Therefore, FORMAT statements like the following example are legal.

FORMAT (1H1.5(25X,13(5X,F6.2)))

7.7.1 UNLIMITED GROUPS

FORMAT specifications may be repeated without the use of a repetition factor. The innermost parenthetical group that has no repetition factor is unlimited and will be used repeatedly until the I/O list is exhausted. Parentheses are the controlling factors in repetition. The right parenthesis of an unlimited group is equivalent to a slash. Specifications to the right of an unlimited group can never be reached.

The following are format specifications for output data:

\( (E16.3,F20.7,(2I4,2(I3,F7.1)),F8.2) \)

Print fields according to E16.3 and F20.7. Since 2(I3,F7.1) is a repeated parenthetical group, print fields according to (2I4,2I3,F7.1)), which does not have repetition operator, until the list elements are exhausted. F8.2 will never be reached.

7.8 VARIABLE FORMAT

FORMAT lists may be specified at the time of execution. The specification list including left and right parentheses, but not the statement number or the word FORMAT, is read under A conversion or in a DATA statement and stored in an integer array. The name of the array containing the specifications may be used in place of the FORMAT statement number in the associated input/output operation. The array name that appears with or without subscript specifies the location of the first word of the FORMAT information.

Examples:

1. Assume the following FORMAT specifications:

\( (E12.2,F8.2,I7,2E20.3,F9.3,I4) \)

This information could be punched in an input card and read by a program such as:

DIMENSION IVAR(4)
READ 1, (IVAR(I),I = 1,4)
1 FORMAT(3A8,A6)

The elements of the input card will be placed in storage as follows:

IVAR : \( (E12.2,F \)
IVAR+1 : 8.2,I7,2
IVAR+2 : E20.3,F9
IVAR+3 : .3,I4)bb

7-11
A subsequent output statement in the same program could refer to these FORMAT specifications as:

```
PRINT IVAR(1),A,B,I,C,D,E,J
```

or

```
PRINT IVAR,A,B,I,C,D,E,J
```

This would produce exactly the same result as the program:

```
PRINT 10,A,B,I,C,D,E,J
```

2. DIMENSION LAIS(4)
   DATA (LAIS=8(E12.2,F8H8.2,2I7),
         8H(F8.2,E1,H2.2,2I7))

Output statements:
   When I=1
   PRINT LAIS (I),A,B,I,J
   or
   PRINT LAIS,A,B,I,J

This is also the same as:

```
PRINT 1,A,B,I,J
1 FORMAT (E12.2,F8.2,2I7)
```

When I=3

```
PRINT LAIS (I),C,D,I,J
```

This is the same as:

```
PRINT 2,C,D,I,J
2 FORMAT (F8.2,E12.2,2I7)
```
8. INPUT-OUTPUT STATEMENTS

Input-output statements transfer information between the memory unit and one of the following external devices:

- An 80 column card reader
- An 80 column card punch
- A 136 column printer
- A magnetic tape unit

The external unit, i, may be specified by an integer variable or a constant, 1 ≤ i ≤ 49. Logical values are established for physical units by SÍPROS.

The FORMAT statement number for BCD data transmission is represented by n; and may be the statement number, a variable identifier or a formal parameter. Binary data transmission does not require a FORMAT statement.

The input-output list is specified by L. Binary information is transmitted with odd parity checking bits. BCD information is transmitted with even parity checking bits.

8.1 WRITE STATEMENTS

PRINT n,L

Transfers information from the memory locations given by the list (L) identifiers to the standard output medium. This information is transferred as line printer images in accordance with the FORMAT specification n.

PUNCH n,L

transfers information from the memory locations given by the list (L) identifiers to the standard punch medium. This information is transferred as card images in accordance with the FORMAT specification n.

WRITE (i,n)L

and WRITE OUTPUT TAPE i,n,L are equivalent forms which transfer information from memory to a specified unit (i) using the number of list elements (L) to determine the number of logical records that will be written on that unit. Each logical record is one physical record containing up to 136 characters; the information is recorded in even parity (BCD mode).

WRITE(i)L

and WRITE TAPE i,L are equivalent forms which transfer information from memory to a specified unit (i) using the number of list elements (L) to determine the number of logical records that will be written on that unit. If there is only one physical record in the logical record, the first word contains the integer i.

If there are n physical records in the logical record, the first word of the first n - 1 physical records contain zero; the first word of the nth physical record contains the integer n. This first word indicates how many physical records exist in a logical record, and it is used in the BACKSPACE Statement. The information is recorded in odd parity (binary mode). If the LIST is omitted, the WRITE(i) statement acts as a do-nothing.

Examples:

WRITE OUTPUT TAPE 10,20,A,B,C

20 FORMAT (3F10.6)

WRITE (10,20) Q1,Q2,Q3

DIMENSION A(260), B(4)

WRITE (10) A,B

DO 5 I = 1, 10

5 WRITE TAPE 6,AMAX(1),(M(I,J),J = 1,5)

WRITE OUTPUT TAPE 4,21

21 FORMAT (33H THIS STATEMENT HAS NO DATA LIST.)

8.2 READ STATEMENTS

READ n,L

reads one or more card images, converting the information from left to right, in accordance with the FORMAT specification (n), and stores the converted data in the memory locations named by the list (L) identifiers. The images read may come from 80-column Hollerith cards, or from magnetic tapes, prepared off-line, containing 80-character records in BCD mode.
READ(i,n)L
and READ INPUT TAPE i,n,L are equivalent forms which transfer information from a specified logical unit (i) to memory locations named by the list (L) identifiers. The number of list elements and the FORMAT specifications must conform to the record structure on the logical unit (up to 136 characters in the BCD mode).

READ(i)L
and READ TAPE i,L are equivalent forms which transfer information from a specified logical unit (i) to memory. The number of words in the list must be equal to or less than the number of words in the record on the logical unit. A record read by READ (i)L should be the result of a binary mode WRITE statement. If the statement occurs without a list, READ(i), the tape on unit i moves forward one logical record.

Examples:

```
READ 10,A,B,C
10 FORMAT (3F10.4)
READ (2,13) (Z(K), K = 1,8)
13 FORMAT (F10.4)
READ INPUT TAPE 6,20, Q1,Q2,Q3,Q4
20 FORMAT (4E11.3)
READ (6) (A(I,J), I = 1,100, J = 1,50)
READ TAPE 6, ( A(I,J), I = 1,100, J = 1,50)
READ (5)  (skip one logical record on unit 5)
```

8.3 BUFFER STATEMENTS

There are three primary differences between the buffer I/O control statements and the read/write I/O control statements.

1. The mode of transmission (BCD or binary) is tacitly implied by the form of the read/write control statement. In a buffer control statement, parity must be specified by a parity indicator.

2. The read/write control statements are associated with a list, and in BCD transmission with a FORMAT statement. The buffer control statements are not.

3. A buffer control statement initiates data transmission, and then returns control to the program, permitting the program to perform other tasks while data transmission is in progress.

In the descriptions that follow, these definitions hold:

i  logical unit number: integer constant or variable.

p  parity indicator: 0 for even parity (BCD); 1 for odd parity (binary).

A  variable identifier: first word of data block to be transmitted.

B  variable identifier: last word of data block to be transmitted. The location represented by A must be equal to or less than the location represented by B.

BUFFER IN (i,p) (A,B)
transmits information from unit i in mode p to memory locations A through B. If a magnetic tape containing BCD records written by WRITE(i,n) is used by BUFFER IN, only one physical record will be read. If a magnetic tape written by WRITE(i) is read by BUFFER IN, only one physical record is read.

BUFFER OUT (i,p) (A,B)
transmits information from memory locations A through B, to unit i in mode p. The physical record written contains B - A + 1 words, or a maximum of 512 words.

8.4 TAPE HANDLING STATEMENTS

The logical unit number, i, may be an integer variable or constant.

REWIND i
rewinds the magnetic tape mounted on unit i. If tape is already rewound, the statement acts as a do-nothing.

BACKSPACE i
backspaces the magnetic tape mounted on unit i one logical record. (A logical record is a physical record; except for tapes written by a WRITE(i)L statement). If tape is at load point (rewound) this statement acts as a do-nothing.

END FILE i
writes an end-of-file on the magnetic tape mounted on unit i.
The tape handling statements cannot be used on the standard input, standard output, or standard punch media.

8.5 STATUS CHECKING STATEMENTS

IF(EOF,i)\(n_1,n_2\)

checks the previous read (write) operation to determine if an end-of-file (end-of-tape) has been encountered on unit \(i\). If it has, control is transferred to statement \(n_1\); if not, control is transferred to statement \(n_2\).

IF(IOCHECK,i)\(n_1,n_2\)

checks the previous read (write) operation to determine if a parity error has occurred on unit \(i\). If it has, control is transferred to statement \(n_1\); if not, control is transferred to statement \(n_2\).

IF(UNIT,i)\(n_1,n_2,n_3,n_4\)

is the status checking statement used with buffer control. It should always appear before the first statement that uses any of the variables transferred in the buffer mode to avoid loss of information. The \(n_i\) are statement numbers and the following criteria apply:

- Check the status of the last buffering operation on unit \(i\) and transfer control to statement
- \(n_1\) if buffer operation is not complete
- \(n_2\) if buffer operation is complete and NO error occurred
- \(n_3\) if buffer operation is complete and an EOF or EOT occurred
- \(n_4\) if buffer operation is complete and parity or buffer length errors occurred.

A buffer length error occurs on read only to indicate that a record of length \(k\) words has been read into a buffer area where word length is greater than \(k\).

Example:

<table>
<thead>
<tr>
<th>(n)</th>
<th>Program</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>GO TO (50,4)J</td>
<td>Not finished. Do calculations at 50.</td>
</tr>
<tr>
<td>50</td>
<td>{ Some computation not involving information in locations A-Z }</td>
<td></td>
</tr>
<tr>
<td>7</td>
<td>J = J + 1</td>
<td>Calculations complete; increase flag by 1. Go to 4.</td>
</tr>
<tr>
<td>70</td>
<td>GO TO 4</td>
<td></td>
</tr>
<tr>
<td>8</td>
<td>PRINT 70</td>
<td>End-of-file error.</td>
</tr>
<tr>
<td>80</td>
<td>FORMAT(12H EOF UNIT 10)</td>
<td></td>
</tr>
<tr>
<td>200</td>
<td>REWIND 10</td>
<td>Rewind tape and stop.</td>
</tr>
<tr>
<td>6</td>
<td>CONTINUE</td>
<td>Stop.</td>
</tr>
<tr>
<td>8</td>
<td>PRINT 80</td>
<td></td>
</tr>
</tbody>
</table>

8.6 ENCODE/DECODE STATEMENTS

The ENCODE/DECODE statements are comparable to the WRITE/READ statements, the essential difference being that no peripheral equipment is used in the data transfer. Information is transferred under FORMAT specifications from one area of memory to another.

In the following descriptions, \(n\) and \(L\) have the same meanings as were defined for input-output statements.

- \(c\) is an integer constant or integer variable specifying the record length (characters).
- \(V\) is a variable identifier or an array identifier.

**ENCODE \((c,n,V)L\)**

The information of the list variables \((L)\) is converted according to the \(n\) FORMAT statement and stored in the locations identified by \(V\).

**DECODE \((c,n,V)L\)**
The information in the locations identified by V is converted according to the n FORMAT statement and stored in the list variables (L).

Example:
1. The following is one method of packing the partial contents of two words into one word. Information is stored in core as follows:
   \[ \text{LOC(1)}: \text{SSSSSSxxxxx} \]
   
   \[ \text{LOC(6)}: \text{xxxxxxaaaaa} \quad 10 \text{ BCD ch/ wd.} \]

To form SSSSaaaaa in storage location NAME:

\[ \text{DECODE(10,1,LOC(6))TEMP} \]
\[ 1 \quad \text{FORMAT(5X,A5)} \]
\[ \text{ENCODE(10,2,NAME) LOC(1),TEMP} \]
\[ 2 \quad \text{FORMAT(2A5)} \]

The DECODE statement places the last 5 BCD characters of LOC(6) into the first 5 characters of TEMP. The ENCODE statement packs the first 5 characters of LOC(1) and TEMP into NAME.

A more straightforward way of accomplishing this is with masking statements. Using the R specification, the program may be shortened to:

\[ \text{ENCODE (10,1,NAME) LOC(1),LOC(6)} \]
\[ 1 \quad \text{FORMAT (A5,R5)} \]

2. DECODE may be used to calculate a field definition in a FORMAT specification at object time. Assume that in the statement FORMAT (2A10, Im) the programmer wishes to specify m at some point in the program, subject to the restriction 2 \leq m \leq 9. The following program permits m to vary.

\[ \text{IF(M .LT. 10 .AND. M .GT. 1),1,2} \]
\[ 1 \quad \text{ENCODE (10,100,SPECMAT) M} \]
\[ 100 \quad \text{FORMAT (7H(2A10,I,J1,1H))} \]

\[ \text{PRINT SPECMAT,A,B,J} \]

M is tested to insure it is within limits. If not, control goes to statement 2 which could be an error routine. If M is within limits, ENCODE packs the integer value of M with the characters: (2A10,I). This packed FORMAT is stored in SPECMAT. SPECMAT contains (2A10,1m).

The print statement will print A and B under specification A10, and the quantity J under specification I2, or I3 or \ldots or I9 according to the value of m.
APPENDIX
A. CODING PROCEDURES

CODING FORM
FORTRAN-66 forms contain 80 columns in which the characters of the language are written, one character per column.

STATEMENTS
The statements of FORTRAN-66 are written in columns 7 through 72. Statements longer than 60 columns may be carried to the next line by using a continuation designator. More than one statement may be written on a line. Blanks may be used freely in FORTRAN statements to provide readability. Blanks are significant, however, in H fields.

STATEMENT SEPARATOR $*
The special character $ may be used to write more than one statement on a line. Statements so written may also use the continuation feature. A $ symbol may not be used as a statement separator with FORMAT statements or continuations of FORMAT statements.

These statements are equivalent:

\[
\begin{align*}
I=10 & \quad I=10 \, $ JLIM=1 \, $ \\
JLIM=1 & \quad K=K+1 \, $ \text{GO TO 10} \\
K=K+1 & \\
\text{GO TO 10} &
\end{align*}
\]

Also:

\[
\begin{align*}
\text{DO } 1 I=1, 10 & \quad \text{DO } 11=1, 10 \, $ A(I) \\
A(I)=B(I)+C(I) & \quad =B(I)+C(I) \\
1 \, \text{CONTINUE} & \quad 1 \, \text{CONTINUE} \, $ I=3 \\
I=3 &
\end{align*}
\]

COMMENT CARD
Comment information is designated by a C in column 1 of a statement. Comment information will appear in the source program, but it is not translated into object code. Columns 2 through 80 may be used. Continuation is not permitted; that is, each line of comments must be preceded by the C designator in column 1.

All comment cards belonging to a specific program, or subprogram, should appear between the PROGRAM, SUBROUTINE, or FUNCTION statement and the END statement.

STATEMENT IDENTIFIERS
Any statement may have an identifier but only statements referred to elsewhere in the program require identifiers. A statement identifier is a string of 1 to 5 digits occupying any column positions 1 through 5.

If I is an identifier, $1 \leq I \leq 99999$; leading zeros are ignored; 1, 01, 001, 0001 are equivalent forms. Zero is not a statement identifier. In any given program or subprogram each statement identifier must be unique. If the statement identifier is followed by a character other than blank in column 6, the statement identifier is ignored.

Statement identifiers of Declarative statements (excepting FORMAT) are ignored by the compiler, except for diagnostic purposes.

CONTINUATION
The first line of every statement must have a blank in column 6. If statements occupy more than one line, all subsequent lines must have a FORTRAN character other than blank or zero in column 6. A FORTRAN-66 statement may have up to 660 operators, delimiters (commas or parentheses) and identifiers within it. The compiler will accept up to nine continuation cards.

IDENTIFICATION FIELD
Columns 73 through 80 are always ignored in the translation process. These columns, therefore, may be used for identification when the program is to be punched on cards. Usually these columns contain sequencing information provided by the programmer.

PUNCHED CARDS
Each line of the coding form corresponds to one 80-column card; the terms line and card are often used interchangeably. Source programs and data
can be read into the computer from cards; a relocatable binary deck or data, can be punched directly onto cards.

Blank cards appearing within the input card deck are ignored.

When cards are being used for data input, all 80 columns may be used.

**CARRIAGE CONTROL**

When printing on-line, the first character of a record transmitted by a PRINT statement is a carriage control character for spacing on the printer. The carriage control characters are:

<table>
<thead>
<tr>
<th>Character</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Blank or any character other than the following</td>
<td>Single space after printing</td>
</tr>
<tr>
<td>0</td>
<td>Double space before printing</td>
</tr>
<tr>
<td>1</td>
<td>Eject page before printing</td>
</tr>
<tr>
<td>+</td>
<td>Suppress spacing after printing, causing two successive records to be printed on the same line.</td>
</tr>
</tbody>
</table>

The characters, 0 1 +, are not printed; any other causes single spacing and is not printed.

When printing off-line, the printer control is determined by a printer routine for a particular installation.

*Any compiled calls to RANF(N), used as a function, treat the resulting value as real.
E. QUANTITIES AND WORD STRUCTURE

FORTRAN-66 manipulates floating point and integer quantities. Floating point quantities have an exponent and a fractional part. The following classes of numbers are floating point quantities.

REAL
Exponent and sign 11 bits; fraction and sign 49 bits; range of number, (in magnitude) \(10^{-308} \leq N \leq 10^{308}\) and zero; precision approximately 14½ decimal digits.

DOUBLE
Each half is independently packed.

COMPLEX
Two reals as defined above.

Integer quantities do not have a fractional part. The following classes of numbers are integer quantities:

INTEGER
Represented by 60 bits, first bit is the sign; range of number (in magnitude) \(0 \leq N \leq 2^{60} - 1\); precision is up to 17½ decimal digits.

LOGICAL
1 bit represents the value TRUE.
0 bit represents the value FALSE.

HOLLERITH
Binary coded decimal (BCD) representation treated as an integer number.

A FORTRAN-66 program may contain any or all of these classes of numbers in the forms of constants, variables, elements of arrays, evaluated functions and so forth. Variables, arrays and functions are associated with types assigned by the programmer. The type of a constant is determined by its form.

WORD STRUCTURE
The word structure of the quantities in FORTRAN-66 is shown below:

*ELEMENT LENGTH
F. PROGRAM SEGMENTATION

In general, the complex for a central processor program is assumed to be made up of control programs, subroutines, and common data blocks. The initiating control program, any common subroutines and data blocks comprise a permanent segment in core. Any subsequent control programs, subroutines and their data blocks are arranged dynamically in core in segments according to requests encountered during execution, and as defined by segmentation control cards.

The compiling process handles all programs and subroutines individually. The routines are compiled separately and, in binary form, are put together with segmentation specifications at execute time. Linkage between segments and between routines is handled at load time. Although a routine may appear in any number of segments, only one copy need be compiled and placed with the job.

Definition of Terms

Basic Segment — a fixed arrangement of a control program, subroutines, and common data blocks.

Normal Segment — an arrangement of a control program, subroutines, and common data read into central memory dynamically as required. It is defined by a segment control card and loaded by means of the LOAD statement. Normal segments may be overlayed.

Control Program — defined with a PROGRAM card and is the only executable program within a basic segment or a normal segment.

Subroutine — a routine defined by a SUBROUTINE card and executed by means of a CALL statement.

LOAD — is a macro defined as the overlay segment request.

The contents of a segment are provided by segmentation control cards at load time and are specified as a combination of control programs, subroutines, and other segments. The overlay operation when executed does not disturb the contents of the basic segment. However, it does destroy all other requested segments operated prior to the loading of the overlay. Overlay requests may occur without restriction in any segment and are coded in line where the decision is reached that an overlay is required.

Two independent segmentation concepts are provided under a single programming mechanism. The first method allows a basic segment, which resides permanently, in core, to initiate loading, and to control routing to the various subroutines in the job. Under this concept, control flows back and forth between the basic segment and any routine in the other segments, but always returns to the basic segment prior to the initiation of an overlay. When an overlay is initiated, control continues to the next instruction in line (no control transfer occurs).

The second method provides a program chaining operation. Under this method each successive overlay has its own control program and provides control routing through the various routines in that overlay. Each new overlay destroys the preceding one. Since loading is initiated by the overlay, it is necessary that a control transfer be made in conjunction with the load request.

An overlay request may occur in any segment. However, a transfer address must be provided if the request is made from other than the basic segment. The transfer address, if required, is taken to be that of the control program which has a trace of asterisks all the way through to the LOAD statement. An example of a segmented program and the tracing of control through the segments with asterisks follows:

EXAMPLE: (Control in Normal Segments)

Assume the basic segment is loaded consisting of non-executable statements defining common data and storage areas and a load request:

```
LOAD    * SEG1 *
```

SEG1 is defined as:

```
SEG1 = *PROGRAM A*, SUBROUTINE A1, SUBROUTINE A2
```

After the load is accomplished, control is shifted to Program A as a result of asterisks around SEG1 and Program A in the definition of SEG1.
Assume a load request is given in SEG1:

\[
\text{LOAD } \ast \text{SEG2}\ast
\]

\[
\text{SEG2} = \ast\text{PROGRAM B}\ast, \text{SUBROUTINE B1, SUBROUTINE B2}
\]

The load is then performed and control turned over to Program B.

Suppose an overlay request exists within SEG2 which includes both segments SEG1 and SEG2, plus Program C. In addition, suppose control is to be shifted back to Program A after SEG3 has been loaded. The specification of the third segment may take one of several forms:

1. SEG3 = \ast\text{PROGRAM A}\ast, \text{SUBROUTINE A1, SUBROUTINEA2, PROGRAM B, SUBROUTINE B1, SUBROUTINE B2, PROGRAM C}

2. SEG3 = \ast\text{SEG1}\ast, \text{PROGRAM B, SUBROUTINE B1, SUBROUTINE B2, PROGRAM C}

3. SEG3 = \ast\text{SEG1}\ast, \ast\text{SEG2}\ast, \text{PROGRAM C}

where slashes indicate the enclosed is a segment name.

Upon a LOAD \ast\text{SEG3}\ast statement, each of these three forms will produce the same core arrangement and transfer control to Program A since it is the only routine in this segment specification which has an asterisk trace through the segment definitions to the LOAD statement. Program A is asterisked (definition 1 above contains asterisks around Program A, definitions 2 and 3 above have asterisks around SEG1, which contains Program A enclosed with asterisks), SEG3 is asterisked in the LOAD statement.

However, if control is desired for Program C, SEG3 may then be defined as:

\[
\text{SEG3} = \ast\text{SEG1}\ast, \ast\text{SEG2}\ast, \ast\text{PROGRAM C}\ast
\]

or either of the other two forms may be used with Program C enclosed with the asterisks.

A transfer address is not necessary when the basic segment maintains control throughout the execution of the object program. In this instance, segments consist of subroutines which are executed by means of a CALL statement. An example of a segmented program with control residing in the basic segment follows:

EXAMPLE: (Control in Basic Segment)

Assume the basic segment is loaded and executing. At some point within the basic segment, a load request is coded:

\[
\text{LOAD SEG4}
\]

SEG4 is defined as:

\[
\text{SEG4} = \ast\text{SUBROUTINE A, SUBROUTINE A1, SUBROUTINE A2}\ast
\]

After the load is accomplished, all programming conventions relative to subroutine calls and communications may be followed. However, when the tasks of the routines in the normal segment are completed, control always reverts to the calling program in the basic segment which may then request the loading of another segment.

With reference to these examples, general characteristics of segment specifications are stated as follows:

1. Segments may be defined as a combination of routines and other segments. There is no limit on the depth used in the specification. Segment hierarchies may be conveniently defined as specifying large and highly overlapping segments.

2. There is no requirement that a one-to-one correspondence exist between segment definitions and segments referenced in LOAD statements. Extra segments may be defined which contain common groupings of routines and these segments may then be used to define the larger segments. Each segment referenced by a LOAD statement must be defined by a segmentation card; if not, the entire job is aborted.

3. With the chaining method, control is passed to a program in the loaded segment by an unbroken chain of asterisks from the LOAD statement through the segment specifications to the program name. This provides the necessary control routine capability.
4. There is no requirement that program or subroutine names appear uniquely in the combination of segments that define a segment. The union of the segments designates the routines to be loaded. This assures that there is no loss in core utilization due to name redundancies.

5. Segment identifiers used in the definition of other segments are surrounded by slash marks (/) to distinguish them from program and subroutine names. If a segment name is enclosed in asterisks, the asterisks are placed inside the slash marks.

The following restrictions are made:

1. If the LOAD statement specifies a transfer of control, one and only one program in the loaded segment must be designated as recipient of the control by meeting characteristic number 3.

2. No mixing of the two methods is permissible although a one-time switch may be made from the basic segment concept to the chaining concept. Once the chaining process is used, there is no way to return control to the PROGRAM in the basic segment.

A core map taken at the completion of the loading of the basic segment would show the control programs, the programmer subroutines in the basic segment, one copy of common data blocks, and one copy of library subroutines and functions referenced by these basic segment routines. The block of memory required for this segment is permanently reserved. The next location after this block is the initial address for all normal segments called by a LOAD statement.

If there are additional segments specified to accompany the basic segment in the initial load or when an overlay request occurs, these segments are brought in from the disk and relocated at the initial overlay address. Addresses for common blocks referenced in the segments are determined from their location within the basic segment, or they are assigned and inserted where appropriate. Also one copy of any library subroutine, not previously required or loaded, is added to the program and linkages for all routines are then made.

When a transfer is indicated by the segment specification (asterisks around NAME), a similar name form is sought from the segment name list and control is routed to its single entry point.
G. FORTRAN ERROR PRINTOUTS

Listed below are the diagnostic error printouts currently available with FORTRAN-66. A one (1) before the statement indicates that no further compilation takes place. However, the subsequent FORTRAN statements are diagnosed for errors. A zero (0) before the statement indicates that the program will be compiled, but execution is likely to be subject to error.

1********UNRECOGNIZABLE STATEMENT
1*FUNCTION STATEMENT FORMAT ERROR
1*SUBROUTINE STATEMENT FORMAT ERROR
1**SUBROUTINE OR VARIABLE NAME TOO LONG
1*MORE THAN 20 ENTRIES
1**ERROR IN CALL STATEMENT****
