This guide describes a subset of the features documented in Volumes 2, 3, and 4 of the NOS 2 Reference Set. Control Data cannot be responsible for the proper functioning of undescribed features and parameters.
Revision Record

Revision E reflects NOS 2.5.1 released in September 1986 at PSR level 664. Changes include the use of a personal identification entry during login and other miscellaneous changes to the login description.

Preface

This manual describes the CONTROL DATA* Network Operating System (NOS) Version 2. NOS controls the operation of CDC* CYBER 180 Computer Systems; CDC CYBER 170 Computer Systems; CDC CYBER 70 Computer Systems, Models 71, 72, 73, and 74; and CDC 6000 Computer Systems.

Organization and Audience

This manual is the first of four volumes in the NOS 2 Reference Set. Volume 1 shows you how to enter, run, and correct programs and how to create, retrieve, and maintain permanent files at an interactive terminal. Other topics covered include physical terminal connection and procedures for entering and leaving the system. It is written for the person who has had little or no experience using computer systems in general and NOS in particular. It it assumed that the user writing the programs is either familiar with a programming language or taking a programming class. Descriptions and examples use FORTRAN Version 5 and BASIC Version 3, but generally the information applies to other languages also. A glossary of terms is provided in appendix A. Use of this manual does not require familiarity with any other NOS manual, but for a general introduction, we recommend that you first read the NOS Version 2 System Overview.

Volume 2, Guide to System Usage, describes the general concepts of NOS and some of the utilities used with NOS. Topics included are job processing, file concepts, procedures, magnetic tape processing, modifying files, and loading files. This volume is a learning tool and does not contain comprehensive descriptions of all NOS commands. It is written for the applications or systems programmer who is unfamiliar with NOS.

Volume 3, System Commands, describes the system commands that form the user interface with NOS. It is written for all NOS users.

Volume 4, Program Interface, describes the COMPASS program interface with NOS. Detailed descriptions of function processors and macros available to COMPASS user programs are included. It is written for the experienced COMPASS applications programmer or systems programmer.

The reader of each volume should have a knowledge of the material contained in the preceding volumes.

Conventions and Assumptions

In this manual, entries you can make to the computer system are shown in blue. When you type an entry at a terminal, type the characters without pressing the shift key or any other key unless specifically instructed to do so. On most terminals, the letters you type will appear as lowercase letters. Therefore, in examples that show how your entries and the system's responses might look at a terminal, your entries are shown in lowercase blue letters, and system responses are shown in uppercase black letters.
However, general instructions in the text which give entries that you will type are shown in both uppercase and lowercase blue letters to indicate required characters. You must type the uppercase letters and the punctuation exactly as shown; you replace the lowercase letters with characters you have chosen. For example, an entry shown in the text as

```
SAVE, filename
```

could be entered at a terminal as

```
save, myfile
```

The notation yy/mm/dd is used throughout this manual to indicate the current date, for example, 84/01/06 means that the date is January 6, 1984. Similarly, the notation hh.mm.ss is used to indicate the current time, for example, 14.25.30 means that the time is 30 seconds after 2:25 p.m.

The procedures described in this manual (such as entering the system and using the carriage return, the termination sequence, the interruption sequence, and the cancel line sequence) assume you have a standard ASCII terminal and are using a standard NOS system. If you are using any other kind of terminal or if your computer center has made modifications to the system, you may need additional or amended procedures. Appendix B contains some additional information on terminals.

**Submitting Comments**

The last page of this manual is a comment sheet. Use the comment sheet to suggest specific improvements for the manual and to report any errors. If the comment sheet has already been used, you can mail your comments to:

Control Data Corporation  
Publications and Graphics Division  
ARH219  
4201 Lexington Avenue South  
St. Paul, MN 55126-6198

If you have access to SOLVER, an on-line problem reporting facility, you can use it to submit comments about the manual. Use NS2 as the product identifier.

**Related Publications**

Following is a list of NOS manuals that you may be interested in.

The NOS System Information Manual is an online manual that includes brief descriptions of all NOS and NOS product manuals. To view this manual, log in to NOS and enter the command `EXPLAIN`. The System Information Manual can be useful in determining which manuals are appropriate for your use.
Control Data manuals are available through Control Data sales offices or Control Data Literature Distribution Services, 308 North Dale Street, St. Paul, MN 55103.

## Index
This manual shows you how to use a terminal to communicate with your computer system. Knowing this will help you do your work faster and more efficiently. The computer system you are going to use is extremely powerful, but it is easy to use. It understands a large set of instructions, but allows you to perform most operations with just a few instructions.

How to Use This Manual

Sections 2 and 3 explain how you connect a terminal to the system, how you tell the system that you are ready to use it, and then how to leave the system when you are done. If somebody such as your employer or instructor has already given you exact, specific instructions on what to do once the system responds to you, then you will only need to read these sections for background information. If you have any problems, refer to section 7. This section describes some common problems users have and suggests solutions.

Sections 4, 5, and 6 show you how to enter a program, run it, and get the results back at your terminal. If the program doesn't work, these sections tell you how to correct and retry it. They also describe how you tell the system to save your program so you need not reenter it each time you use the terminal. We assume you are either taking a programming class or know a programming language already. This manual alone does not teach programming concepts or specific languages.

In this manual, entries you can make to the computer system are shown in blue. When you type an entry at a terminal, type the characters without pressing the shift key or any other key unless specifically instructed to do so. On most terminals, the letters you type will appear as lowercase letters. Therefore, in examples that show how your entries and the system's responses might look at a terminal, your entries are shown in lowercase blue letters, and system responses are shown in uppercase black letters.

However, general instructions in the text which give entries that you will type are shown in both uppercase and lowercase blue letters to indicate required characters. You must type the uppercase letters and the punctuation exactly as shown; you replace the lowercase letters with characters you have chosen. For example, an entry shown in the text as

```
SAVE, filename
```

could be entered at a terminal as

```
save,myfile
```
How to Use the System

Each time you use the system, you:

1. Connect your terminal to the system.

   Some terminals are wired so that they are always connected to the system. Other terminals you must connect to the system using telephone lines. The next section explains how you can tell the difference.

2. Tell the system that you are ready to start.

   This is called logging in to the system. The system asks for specific information to identify you as an authorized user. All you need do is respond to its prompting.

3. Do your work.

4. Tell the system that you're done.

   This is called logging out of the system. Just type

   **BYE**

Every person who uses the system, whether a beginner or an experienced programmer, follows these same steps. Section 2 describes step 1; section 3 describes steps 2 and 4.

The best way to become comfortable with the system is to experiment with it. It's almost impossible for you to accidentally damage the system or someone else's work. Before you can start, however, you need some information.

The following page, *Information Specific to Your System and Terminal*, lists the information you will need. You may want to fill in this sheet and keep all the information together. Before starting, however, you should either remove the page from the manual or make a copy for your own use. This is done to protect the information should you lose the manual or let others use it.

**NOTE**

Keeping this information in a safe, secure place prevents others from being able to access your programs and data.

The first section on the information sheet is for terminal settings. They are discussed in section 2 which explains how to set up your terminal. You can fill in this section later.

Next is a section for computer system phone numbers. For terminals that you must connect to the system by phone, you need to know the telephone numbers used to reach your system. Your employer, instructor, or someone at your computer center can give you these numbers. There may be one or several. Sometimes your computer center will associate certain phone numbers with certain characteristics of a terminal, such as terminal line speeds (the speed at which the terminal prints characters). You can list the numbers (and associated line speeds, if any) on the information sheet.
INFORMATION SPECIFIC TO YOUR SYSTEM AND TERMINAL

Terminal settings: ____________________________________________

________________________________________________________________________________________

Computer system phone numbers: ___________________________ Associated terminal line speeds: __________

________________________________________________________________________________________

Family name (If required): ________________________________

User name: ____________________________________________

Password: _____________________________________________

Personal ID (If required): _________________________________

Special procedures for login: __________________________________________

________________________________________________________________________________________

Interruption sequence: ______________________________________

Termination sequence: ______________________________________

Cancel line sequence: _____________________________________

Computer center phone number: ___________________________
You must be able to tell the system who you are. Again, your employer, instructor, or computer center personnel can give you:

- A family name (may not be required).
- A user name.
- A password.
- A personal identification (a personal ID may not be required).

The system asks you for some or all of this information when you log in. You can record these names on the information sheet.

Finally, ask your employer, instructor, or computer center personnel if there are any special procedures for using your particular terminals or system. For example, it's possible your system may actually consist of more than one physical computer. In this case, you'll be asked to choose one while you are logging in. This is the sort of additional information you could be given. You may want to insert these procedures in this manual or to record them on the information sheet.

The interruption sequence, termination sequence, and cancel line sequence are entries you may want to make while you're using the system. We'll talk more about them and show you what their usual values are later in this manual.

Now, go to a terminal. You don't need work ready yet. To start, you can connect the terminal, log in, and then log out.

If possible, have an experienced person show you how to connect the terminal, log in, and log out. This process is easy once you've seen it done, but the process on your system may differ slightly from that described in the next two sections of this manual. Because there are many kinds of terminals available and many ways your system could be modified, we've had to make certain assumptions about the terminals and system features that we describe. If you follow along using the next two sections and the system doesn't respond as expected, ask your computer center personnel for help.

If you run into problems anytime you're using a terminal, refer to section 7, *What to Do When You Have Problems.*
Many different kinds of terminals are available. Some communicate with you using a screen (somewhat like a television screen). Others type on paper (like a typewriter). But all terminals have a keyboard that you use to type instructions to the system. Every instruction that you type and the system’s response to that instruction appear either on the screen or the paper.

Display Screen Terminal

Printing Terminal

Setting Up Your Terminal

Before you can connect your terminal to the system, the terminal must be turned on and certain switches must be in the correct positions. The switches and their settings vary from terminal to terminal. If the terminal you're at has been used by other people working with the same system, the switches should be set correctly; don’t change them. Or, directions for setting the switches may be posted near the terminal. If you’re not sure what to do, ask someone to show you. You may want to record some of this information about your terminal on the information sheet in section 1.

Remember that certain terminal line speeds may be associated with certain phone numbers. If applicable, set the line speed switch to a number that matches one of those associated with the phone numbers you were given. If you’re not sure of the speed you should use, set the switch to any position (usually 10 to 30 characters per second). The system may be able to detect automatically what line speed you are using. Now you’re ready to connect your terminal to the system.
Connecting Your Terminal

Some terminals are wired so that they are automatically connected to the system when they’re turned on. You may hear them called hardwired terminals. Other terminals are connected to the system using a telephone and telephone lines. If there is no telephone near the terminal you are using, you can assume it is a hardwired terminal. In this case, you can skip the rest of this section and go on to section 3.

A terminal that requires a telephone uses either an acoustic coupler or a data set.

An acoustic coupler has two rubber cups into which the phone receiver will fit. The coupler is either built into the terminal or is a separate device beside the terminal. If it is a separate device, turn it on.

On the front of a data set is either a switch labeled TALK and DATA or individual buttons labeled TALK and DATA. Most commonly, the data set is separate from the terminal. Either set the switch to TALK or push the TALK button.

To connect your terminal to the system, call one of the phone numbers you were given. When the system is available, you hear a constant high-pitched tone. Usually this happens within a few rings. If it doesn’t, assume the system is not available and try again later. If the line is busy, try another phone number, if you have more than one.
When you hear a constant high-pitched tone, your next action depends on whether you are using a terminal with an acoustic coupler or a data set.

If the terminal uses an acoustic coupler, insert the phone receiver in the two rubber cups. Usually the coupler is marked to indicate how the receiver should be inserted.

If the terminal uses a data set, either set the switch on the front of the data set to DATA or push the DATA button. Then replace the phone receiver.

Usually an indicator on the terminal lights to let you know that it is connected to the system. Wait a full two seconds after the light comes on. You are now ready to log in to the system and do your work.
Entering and Leaving the System

Entering the System

When you log in to the system, your terminal is connected to the main computer using software and hardware that is known collectively as a network. A network transfers information back and forth between your terminal and the computer. Control Data offers two types of networks for use with NOS: the Control Data Distributed Communications Network (CDCNET) network and the Communications Control Program (CCP) network. The login and logout examples in this manual were generated using a CCP network. We will note in the examples any differences that may occur if you are using CDCNET, though the login and logout process is much the same for both networks.

In the first section, you were asked to gather some information (your family name, user name, and password, and, if applicable, your personal ID). The system now asks you for that information, one item at a time. All you have to do is respond with the names you were given. Figures 3-1 and 3-2 are two examples of logins as they might appear during a terminal session (a terminal session begins when you log in and ends when you log out). In the examples:

- The family name is SYSTEMA.
- The user name is JLC6021.
- The password is JLC6.

These examples do not show the use of the personal identification validation, because the use of the personal ID is optional from site to site. If you are required to enter a personal ID during login, the prompt for it will appear after you have entered your password. If you are prompted to enter a personal ID, simply enter the personal ID supplied to you by your site administrator and then press the carriage return.

Figure 3-1 shows a login with no errors. Figure 3-2 shows a login where the user makes a mistake typing the user name; the system asks for all the entries again. Everything that the user types is shown in lowercase blue letters. After each entry, the user presses the carriage return.

Try logging in using the information you were given. After the light that indicates terminal connection comes on, wait a full two seconds and then press the carriage return twice. (Depending on your terminal, this key may be labeled RETURN, CR, CARRIAGE RETURN, NEXT, SEND, NEW LINE, or ETX. If you're not sure which key is the carriage return, ask someone.)

The system responds to each carriage return with one or two blank lines. If you don’t see a response, press the carriage return again. The system then displays four lines that will look something like this:

WELCOME TO THE NOS SOFTWARE SYSTEM.
COPYRIGHT CONTROL DATA 1978, yyyy.
yy/mm/dd. hh:mm:ss. T01A78
CDC NETWORK OPERATING SYSTEM NOS 2

The first two lines are always the same. The third line gives the current date (yy/mm/dd) and time (hh:mm:ss) and a terminal name (you don’t need to be concerned about the name). The fourth line usually identifies your computer center or the system you’re using in more detail.

At this point, the system may ask for your family name with the following prompt.

FAMILY:

If it does, type the family name you were given and press the carriage return. If you are using a family name supplied by the system (a default name), pressing the carriage return is the only entry you need make. You must spell every entry correctly and follow each entry with a carriage return. If you do make a mistake, however, the system gives you an opportunity to retry your entries later.
Next, the system asks for your user name with the following prompt.

**USER NAME:**

Type the user name you were given.

Next the system asks for your password with the following prompt.

**PASSWORD:**

Type the password you were given. Although our examples show the password that is entered, some display terminals do not actually display the characters on the screen. Many printing terminals overprint several characters on a line and ask that you type your password on that line.

**PASSWORD:**

This is done to obscure your password and to protect the security of your user name should you lose or throw away paper printed out from a terminal session. Some display screen terminals will also overwrite this line with blanks.

If you are required to enter a personal identification, then the prompt for it will appear after the prompt for the password.

**Figure 3-1. Login with No Errors**

¹If your site maintains more than one computer, you might be required to select one at this time. Refer to a knowledgeable person at your site for any questions regarding this part of the login process.

²At some sites this may not be required during the initial login process.
Once the host system can identify the terminal used and the line speed, the user is prompted for the user name and password. The user name and password are case-sensitive, so remember to enter them correctly. If you enter your user name and password incorrectly, the system displays the message:

**IMPROPER LOGIN, TRY AGAIN.**

Check the names you just entered; you may have entered one incorrectly. For example, the letter 0, the numeral 0, the letter l, and the numeral 1 each has its own key on the terminal keyboard. If you type the letter 0 for the numeral 0 or the letter l for the numeral 1, the system regards it as an error. When the system prompts you, try again. If you are entering everything correctly, but the system still gives you the same message, tell your computer center personnel. It is a problem that they must handle.

1. If your site maintains more than one computer, you might be required to select one at this time. Refer to a knowledgeable person at your site for any questions regarding this part of the login process.
2. At some sites this may not be required during the initial login process.
If the system asks you to enter an application name, type

IAF

Don’t worry if your system does not request all the information indicated in the example terminal sessions or mentioned in the text. Your system has been set up to automatically use certain entries (defaults) for you.

When the system is ready for you to continue, it displays another identification line (which you needn’t be concerned with now) and the word

READY.

Now you are at the point where you can do your work. If you have specific instructions, begin them. If you want to enter and run a program, go on to section 4. If you have no work ready yet, you can either log out (as described below) or continue on to section 4. It contains practice programs that you can enter and run to become familiar with the system. When you are done, or at any time you want to end the terminal session, follow the instructions given next for leaving the system.

Leaving the System

When you have completed your work, or at any time the system is waiting for an instruction, and you want to end the terminal session, type

BYE

This tells the system that you want to leave. The system displays several lines that, for the examples we showed on login, look somewhat like this:

bye
UN=JLC6021 LOG OFF 10.49.38.
JSN=ABDV SRU-S 5.059
CHARACTERS= 55.146KCHS
IAF CONNECT TIME 00.26.53.
LOGGED OUT.
HOST DISCONNECTED CONTROL CHARACTER=(ESC)
ENTER INPUT TO CONNECT TO HOST

It's unlikely that you need to be concerned with these lines. They show the time you ended the terminal session, accounting information, the number of input and output characters used during the session, and other system information.

If your system uses CDCNET or is part of a multihost system, you may also see additional information on the status of the network displayed at this time.

If no one is waiting to use the terminal and it was turned off when you found it, turn it off again. If an acoustic coupler is used, hang up the phone. If a data set is used, either set the switch to TALK or push the TALK button.
Putting the Program on the System

After you've logged in and the system responds

```
READY
```

you must tell it what language you want to use. This book assumes that you are using FORTRAN or BASIC, so type

```
FORTRAN
```

or

```
BASIC
```

Your system may have other languages available also; if so, enter the name of the language you want to use. Remember, after each line you type, you must press the carriage return.

For its own use, the system is going to refer to your program as a file. (We'll talk more about files later.) When it asks

```
OLD, NEW, OR LIB FILE:
```

type

```
NEW
```

We're assuming that this is the first time you've used the system and that you have no existing files (programs). The system now asks what you want to name your file with the prompt

```
FILE NAME:
```

You can enter any name you want as long as it is made up of letters and/or numbers, begins with a letter, and is no more than seven characters. This name can be the same as the name of your program, but it need not be.

When the system is ready, it displays

```
READY
```

Now you simply begin typing your program, line by line, with each line followed by a carriage return. You must assign a number to each line, so that you can refer to specific lines later. The numbers must be sequential, because the system automatically sorts and orders the lines of the program according to these line numbers. We recommend numbering by tens, so that you can insert lines easily if you want to change the program after you have entered it.
The following example shows a user logging in, creating a new file named FORTEST, and entering a FORTRAN program that reads two numbers, multiplies them, and prints the result.

```
WELCOME TO THE NOS SOFTWARE SYSTEM.
COPYRIGHT CONTROL DATA 1978, yyyy.

yy/mm/dd. hh.mm.ss. T01A6D
CDC NETWORK OPERATING SYSTEM NOS 2
FAMILY: systema
USER NAME: jlc6021
PASSWORD: JLC6
T01A6D - APPLICATION: iaf
JSN: ACZH, NAMIAF

READY.
fortran
OLD, NEW, OR LIB FILE:new
FILE NAME:for test
READY.
10 program test
20 read *,i,j
30 i=i*j
40 print *,i
50 end
```

The following example shows a user logging in, creating a new file named BASTEST, and entering a BASIC program that reads two numbers, multiplies them, and prints the result.

```
WELCOME TO THE NOS SOFTWARE SYSTEM.
COPYRIGHT CONTROL DATA 1978, yyyy.

yy/mm/dd. hh.mm.ss. T01A6D
CDC NETWORK OPERATING SYSTEM NOS 2
FAMILY: systema
USER NAME: jlc6021
PASSWORD: JLC6
T01A6D - APPLICATION: iaf
JSN: ACZR, NAMIAF

READY.
basic
OLD, NEW, OR LIB FILE:new
FILE NAME:bastest
READY.
10 input i,j
20 i=i*j
30 print i
40 end
```

Now enter your own program or copy one of the examples. Don't worry about typing mistakes. We explain how to correct them next.
Correcting and Changing the Program

If you see an error in a line before you press the carriage return, you can backspace to the error and retype it. The backspace key is usually labeled BACK SPACE, BKSP, ←, or something similar. (If you can't find this key on your terminal, ask someone to show you the equivalent key or keys.) When you backspace, however, you are in effect erasing every character you backspace over, even though it may still appear at the terminal. After you have corrected the error, you must retype the rest of the line before pressing the carriage return.

If you have already pressed the carriage return when you see the mistake, you can still change, delete, or insert lines using the line numbers as references. Either you can do this as soon as you see the mistake, or you can wait until you've entered the entire program. Suppose you entered the FORTRAN program in the first example like this:

```
10 program test
20 trsf *,i,j
30 print *,i
40 stop
50 end
```

To change a line, simply retype the entire line, including the line number, as you would like it to appear.

```
20 read *,i,j
```

The system automatically replaces the line in the program.

To delete a single line, such as line 40, type

```
delete,40
```

The system deletes the entire line that started with 40.

To delete several consecutive lines, include the first and last line numbers separated by two periods. For example, typing

```
delete,20..40
```

would delete lines 20, 30, and 40 from the program.

If you leave out a line or find later that you need to add one between two existing lines, pick a number between the two existing line numbers. Type it and the new line as you want it to appear.

```
25 i=i*j
```

The system automatically inserts the new line.
If you insert several lines in the same area of a program, you may run out of line numbers. If this happens, type

```
RESEQ
```

and the system resequences the program with new line numbers. To check it, type

```
LIST
```

and the system prints the resequenced program.

```
reseq
READY.
list
000100 PROGRAM TEST
00110 READ *,I,J
00120 I=I*J
00130 PRINT *,I
00140 END
```

With just these techniques, you can correct any program at any time. There are many other ways to change a program, but they are essentially short cuts to accomplish the same thing. If you're interested, the system's primary editing commands are described in Volume 3, System Commands.

In addition, there are several text editors which may be available on your system. They provide even more capabilities, including the ability to edit lines that don't begin with line numbers (for example, a collection of data). We'll talk more about text editors in section 5 but if you want to see some examples now, go to appendix C.

**Using the Program**

Now that you have a program on the system, you can list it at your terminal, run (or execute) it, and save it for future use.

To list the contents of your program, type

```
LIST
```

and the system displays the contents of your program.

```
list
10 PROGRAM TEST
20 READ *,I,J
25 I=I*J
30 PRINT *,I
50 END
```

READY.

To display several consecutive lines, include the first and last line numbers separated by two periods. For example,

```
list,20..30
```

displays lines 20, 25, and 30.

Using the program you have created, try a few combinations to see how they work.
Running a program is the same thing as executing a program. You might hear both terms used. To run your program and get the results at your terminal, type

**RUN**

The following example runs the FORTRAN program that was just entered and listed.

<table>
<thead>
<tr>
<th>Terminal Session</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>run</code></td>
<td></td>
</tr>
<tr>
<td><code>? 4 15</code></td>
<td>The system requests data for program execution by printing a question mark. You enter your data and press the carriage return. The system returns the result.</td>
</tr>
<tr>
<td><code>60</code></td>
<td></td>
</tr>
<tr>
<td><code>SRU 0.289 UNTS.</code></td>
<td>This number is a measure of system use; you needn't be concerned with it.</td>
</tr>
</tbody>
</table>

**RUN COMPLETE.**

Remember, typing

**RUN**

runs the program only once. When the system responds

**RUN COMPLETE**

the program is done and the system is waiting for you to tell it what to do next. If you enter numbers now, the system assumes you are entering line numbers and it inserts them in your program.

The programs you create at your terminal are temporary. When you log out, they disappear completely unless you save them. To save your program, type

**SAVE**

The system makes a copy of the program and puts it in permanent storage under the file name you entered earlier. The next time you log in to use the system, ask for the file and the system will retrieve it for you.
The following example shows how to create, list, run, and save the BASIC program we showed in this section.

```
READY.
basic
OLD, NEW, OR LIB FILE: new
FILE NAME: bastest
READY.
10 input i,j
20 i=i*j
30 print i
40 end
list
10 INPUT I,J
20 I=I*J
30 PRINT I
40 END

READY.
run
? 7 12
 84

RUN COMPLETE.
save
READY.
```

Suppose you end this terminal session, log in later, and want to run the program you saved. When the system is ready, type

```
OLD
```

The system asks which file you want. Enter the name you gave to the file when you created it. When the system says

```
READY
```

the program is available to you as if you had just entered it. You can then use any of the commands shown in this section to change it, list it, or run it, as we show in the following examples.

run
BASTEST is run.

Remember, programs that you saved are not automatically available at the terminal when you log in. You must ask for them explicitly.

Notice that you didn’t have to tell the system what language you wanted to use this time. That’s because the system remembers what language you were using when you saved the file.
Getting Help

The instructions you give the system are called commands. Many commands are actually the word that describes the operation you want the system to perform, like LIST or SAVE. If you can’t remember the name of a command or want to know more about that command, type

HELP

Then just follow the instructions.

The system gives you three choices and asks you to pick one.

• You can get help with a particular command.
• You can read from a manual that will be displayed at your terminal.
• You can see a list of acceptable commands.

When you choose to get help with a particular command, the system tells you what the command does and then prompts you for any information needed to use the command, such as a file name. When it has the information it needs, the system performs the command.

Interrupting a System Operation†

To interrupt a system operation, such as running or listing a program, hold down the control key (labeled CONTROL, CTRL, or something similar) and press

P

Then release both keys and press the carriage return. (This combination of keys is called the interruption sequence. If it doesn’t work on your terminal, ask someone what the equivalent key or keys are. You may want to record this sequence on the information sheet in section 1.)

The system displays

* INTERRUPTED *

To continue the operation, press the carriage return.

Stopping a System Operation†

To stop a system operation, such as running or listing a program, hold down the control key (labeled CONTROL, CTRL, or something similar) and press the

T

Then release both keys and press the carriage return. (This combination of keys is called the termination sequence. If it doesn’t work on your terminal, ask someone what the equivalent key or keys are. You may want to record this sequence on the information sheet in section 1.)

The system displays

* TERMINATED *

You can then enter a new command.

† If your site is using CDCNET, then the key sequences used to interrupt or terminate a system operation will be different from the ones listed here. Contact your site personnel for help or refer to the CDCNET Terminal Interface Usage Manual.
In the preceding section you used only one file at a time, the one that held your program. As you use the system more, you will probably want to have several files available during a terminal session. To use files effectively, you should know some things about them and the commands you use to manipulate them.

A file is a collection of information that you and the system refer to by a common name. A file contains anything you want, for example, a program, data to be used in a program, data resulting from the execution of a program, text data, or reports. A file is either permanent or temporary.

**Permanent Files**

Permanent files are those that you explicitly save during a terminal session. You can retrieve them from permanent storage at any time. When you retrieve a permanent file, the system makes a copy of the file for you to use. Any changes you make to the file are only on the copy; the actual file in permanent storage is not changed. To save the changed version of the file, you must either replace the permanent file with the changed version or save the changed version as a new file with a new file name.

**Temporary Files**

All files that you use at your terminal during a terminal session are temporary. That is, they disappear when you log out. This includes the copy of a permanent file, although the permanent file itself is kept for you by the system. You create or bring a file to the terminal:

- As a new, empty file (as we did when entering the program in the preceding section).
- As a copy of a permanent file (as we did when retrieving the program in the preceding section).
- As data resulting from the execution of a program.

You can designate one of your temporary files as the primary file (we describe how later in this section). In fact, the program you created in the preceding section was a primary file. The primary file has some special features.

- You can enter information into a primary file either directly from the keyboard (as we described in the preceding section) or by using the TEXT command (which we describe later in this section).
- You can edit the primary file using line numbers (also described in the preceding section).
- The primary file is the file the system uses by default if you don't specify a file name on a command. That's why you could list, run, and save your program by entering only the name of the command. There are a few special file names that you shouldn't use when naming your primary files. For example, avoid names that start with several Z's as well as names that start with the letters SCR. If you do choose to begin your file names with these letters, some of the system commands may not work for you.
The primary file is positioned to its beginning before every operation performed on it. The system has a pointer that keeps track of where you are within a file. For example, as the system lists a file, the pointer moves down the file. When the pointer reaches the end of the file, the system stops listing. If the file is a primary file, the system automatically goes back to the beginning (rewinds the file) before the next operation. That's why you could use your program in the preceding section without worrying about where you were positioned within the file. The system does not automatically rewind nonprimary files. Before every use, you must enter a command (REWIND) to rewind them.

You will usually have one file that you use more than the others. Typically it is the file containing your program. Therefore, you will probably make that file your primary file and use one or more nonprimary files for data to be used in and/or resulting from your program's execution.

In the rest of this section, we use some figures to illustrate how file commands work. The symbol □ represents a primary file. If the box is shaded, ☑, it represents a nonprimary file. The name of the file is in the upper left corner. The relative positions of the files have no significance. Figure 5-1 illustrates primary and nonprimary files.

![Figure 5-1. Primary and Nonprimary Files](image)

In this section, you will also learn how to specify a particular file name on a command. Wherever you have to fill in the name of one of your files, the word filename is shown in lowercase letters. You must still enter anything shown in uppercase letters exactly as shown. For example,

```
SAVE, filename
```

means you can save a file by typing

```
SAVE,
```

followed by the name of the file.
Designating a Primary File

In the preceding section you created a primary file by specifying a programming language immediately after logging in and responding to prompts by the system. At any time during a terminal session you can also create a new, empty file and designate it the primary file simply by typing

```
NEW
```

The system then asks you for the new file's name as before. If you want to combine these two steps, you can include the file name with the NEW command like this:

```
NEW, filename
```

All of the files that were available at your terminal, including the old primary file, disappear (files in permanent storage are not affected). If you want to keep them available, include /ND (for no drop) in the command like this:

```
NEW, filename/ND
```

The old primary file then becomes a nonprimary file available at the terminal. Figure 5-2 illustrates the NEW command. Figure 5-3 shows it in an example.

![Figure 5-2. Creating a New, Empty File and Designating It the Primary File (NEW Command)](image)
You use NEW only when creating a new, empty file. To designate a file already existing at your terminal as the new primary file, type

    PRIMARY, filename

filename is the name of the file you are designating as primary. The old primary file is changed to a nonprimary file and remains available at the terminal. Other files at the terminal are not affected by this command.
Figure 5-4 illustrates the PRIMARY command.

<table>
<thead>
<tr>
<th>Sequence of User Entries</th>
<th>Files Available at the Terminal</th>
</tr>
</thead>
<tbody>
<tr>
<td>User has already created three files, A, B, and C. A is the primary file.</td>
<td>A</td>
</tr>
<tr>
<td>PRIMARY,B</td>
<td>A</td>
</tr>
<tr>
<td>Makes file B the primary file. File A becomes a non-primary file. File C is not affected.</td>
<td></td>
</tr>
</tbody>
</table>

Figure 5-4. Designating an Existing File as the Primary File (PRIMARY Command)

**Entering Information into the Primary File**

You can enter information into the primary file either directly (as we described in the preceding section) or by using the TEXT command. Previously, you entered lines with line numbers. The TEXT command allows you to enter information without line numbers. Typically, it is used to create files containing data or text rather than a program.

First, create a new, empty primary file with the NEW command. Then type

```
TEXT
```

When the system responds

```
ENTER TEXT MODE.
```

enter the information without line numbers, ending each line with a carriage return.
If you see a mistake on a line before you've pressed the carriage return, either you can backspace over the mistake and reenter the line from that point, or you can delete the line by holding down the control key (labeled CONTROL, CTRL, or something similar) and pressing the X key, then releasing them and pressing the carriage return. (This is called the cancel line sequence. If this sequence doesn't work on your terminal, ask someone what the equivalent key or keys are. You may want to record this sequence on the information sheet in section 1.)

In text mode, once you have entered a line and pressed the carriage return, you can't change the line unless you use one of the system's editing facilities, such as the Full Screen Editor. Refer to appendix C for some basic Full Screen Editor commands. If the Full Screen Editor is not available on your system, try one of the other editors, XEDIT or Text Editor. You can find out how to use XEDIT, Text Editor, and more about the Full Screen Editor from the manuals listed in the preface.

When you are finished entering information and are at the beginning of a new line, press either the ETX key, the interruption sequence (usually the control key and the P key), or the termination sequence (usually the control key and the T key). Then press the carriage return. The system responds:

   EXIT TEXT MODE.

To add more lines, type

   TEXT

and repeat the procedure. The new lines are added to the end of the file. Figure 5-5 shows a user creating a file that contains data to be used in a program.

<table>
<thead>
<tr>
<th>Terminal Session</th>

<td>2 1 5</td>
<td></td>
</tr>
<tr>
<td>1.5197 1.5197 1.5197</td>
<td></td>
</tr>
<tr>
<td>0 0 0</td>
<td></td>
</tr>
</tbody>
</table>

Figure 5-5. Example of Creating a Data File
When you're entering text into a primary file in text mode, you might want to use uppercase and lowercase letters. On most terminals, your entry appears as lowercase letters but the system automatically converts it to uppercase letters. To tell the system not to convert lowercase letters to uppercase letters, type

ASCII

before entering text mode. When you are done using text mode and want to return to the normal mode of operation, type

NORMAL

The system then begins converting lowercase letters to uppercase again. You shouldn't mix ASCII and normal mode when entering data into a file. Lowercase letters entered under ASCII mode are translated incorrectly if they are listed under normal mode.

Figure 5-6 shows a user entering uppercase and lowercase letters in ASCII mode.
<table>
<thead>

<td></td>
</tr>
<tr>
<td>normal</td>
<td></td>
</tr>
</tbody>
</table>

Figure 5-6. Example of Using ASCII Mode
Saving a File

As we said in the preceding section, to save a primary file, just type

```
SAVE
```

To save a nonprimary file, include the file name like this:

```
SAVE, filename
```

Figure 5-7 illustrates the SAVE command. Figure 5-3 shows it in an example.

If you already have a permanent file with that name, the system tells you

```
filename ALREADY PERMANENT
```

To replace the file in permanent storage with a copy of your primary file, type

```
REPLACE
```

To replace a file in permanent storage with a copy of a nonprimary file, include the file name like this:

```
REPLACE, filename
```

Figure 5-8 illustrates the REPLACE command. Figure 5-9 shows it in an example.

The language you are using when you save or replace a file is automatically associated with the file when you retrieve it. You don’t need to enter the name of the language.

---

**Sequence of User Entries**

<table>
<thead>
<tr>
<th>User has already created files A and B. File A is the primary file.</th>
</tr>
</thead>
</table>

<table>

Figure 5-9. Example of Retrieving and Replacing a Copy of a Permanent File
Retrieving a Copy of a Permanent File for Use as a Primary File

To retrieve a copy of a permanent file and make it the primary file, type

OLD

The system asks for the name of the file. To combine these two steps, include the file name in the command like this:

OLD, filename

If you already have a primary file, it and all other files currently at your terminal are no longer available to you at the terminal. To keep them at the terminal, include /ND (for no drop) in the command like this:

OLD, filename /ND

The old primary file (if there was one) becomes a nonprimary file and remains available, along with the other files.

If the system displays

filename NOT FOUND.

you have no permanent file with that name. Check your spelling of the file name. If you’re not sure whether the name is correct, type

CATLIST

This command gives you a list of all your permanent files. It’s possible you saved the file using a slightly different name than you remember.

The language you were using when you saved the file is associated with the file automatically when you retrieve it. You don’t need to enter the name of the language.
Figure 5-10 illustrates the OLD command. Figure 5-9 shows it in an example.

<table>
<thead>
<tr>
<th>Sequence of User Entries</th>
<th>Files Available at the Terminal</th>
<th>Files in Permanent Storage</th>
</tr>
</thead>
<tbody>
<tr>
<td>User has just logged in.</td>
<td>A</td>
<td>A</td>
</tr>
<tr>

<td></td>
<td>B</td>
</tr>
<tr>
<td>Makes a copy of saved file C for use as the primary file. File B becomes a nonprimary file still available at the terminal.</td>
<td></td>
<td>C</td>
</tr>
</tbody>
</table>

Figure 5-10. Retrieving Copies of Permanent Files as Primary Files (OLD Command)
Retrieving a Copy of a Permanent File for Use as a Nonprimary File

To retrieve a copy of a permanent file for use as a nonprimary file, type

    GET, filename

and the name of the file like this:

    GET, filename

Remember, since it is not a primary file, you must specify the file name when you want a command to operate on a nonprimary file.

To list the contents of the file at the terminal, type

    LIST, F=filename

Nonprimary files are not repositioned before every operation as is the primary file. If you try to perform an operation using a nonprimary file and it doesn't work correctly, the file may be positioned at its end.

    REWIND, filename

and try the command again.

You can't edit a nonprimary file simply by entering the changes with line numbers. The system would assume that you wanted the changes made to your primary file. To edit a nonprimary file, you must use one of the text editors available on your system. Appendix C shows you how to edit a nonprimary file using Full Screen Editor.

Figure 5-11 illustrates the GET, LIST, and REWIND commands.

</tbody>
</table>

Figure 5-11. GET, LIST, and REWIND Commands
Changing a Permanent File

You can change a permanent file that has line numbers the same way you changed a program in the preceding section. First you must make it the primary file, using either the OLD or PRIMARY command. Then follow the same directions for line replacement, deletion, and insertion given in the preceding section.

You can change a nonprimary file either by making it the primary file and using the methods we described in the preceding section or by using one of the text editors available on your system. Appendix C describes some basic Full Screen Editor directives.

Examples of permanent file changes are shown in figures 5-9 and 5-12. Remember, the system changes only the copy at your terminal. To save the changes, you must either replace the file in permanent storage with your changed copy or, if you want to save the changes and also keep the original version of the file, save the changed copy with a new file name.

```
SAVE,oldname=newname
```

Then the original version remains as it was and the changed version of the file is saved. Figure 5-13 illustrates this variation of the SAVE command. Figure 5-12 shows it in an example.

### Figure 5-12. Saving a File with Changes Under a New Name
### Figure 5-13. Saving Both the Original and Changed Versions of a File (SAVE Command)

**Sequence of User Entries**

- User has already retrieved a copy of file A as the primary file.
- User makes changes to the copy of file A at the terminal.
- `SAVE,A=D`
  - Saves a copy of the changed version of file A under the file name D. The changed file A is still available at the terminal.
- `OLD,A`
  - Retrieves the original file A.
- `OLD,D`
  - Retrieves file D (the changed version of file A).

**Files Available at the Terminal**

- A
- A

**Files in Permanent Storage**

- A
- B
- C
- D
- A
- B
- C
- D
Listing and Rewinding Files

The commands to list and rewind files have already been mentioned briefly. In summary:

- To list the contents of a primary file, type
  ```
  LIST
  ```

- To list the contents of a nonprimary file, type
  ```
  LIST,F=filename
  ```

- To rewind a nonprimary file, type
  ```
  REWIND, filename
  ```

Remember to rewind nonprimary files, particularly a file containing data to be used in program execution (refer to section 6). If you run the program once and then run it a second time without rewinding the data file (which is nonprimary), the program won't produce the correct results because it has no data (that is, because the system pointer is at the end of the nonprimary file).

Listing the Names of Your Permanent Files

To get a list of your permanent files, type

```
CATLIST
```

and the system displays the names of your files similar to this.

```
catlist
  CATALOG OF  JLC6021  FM/SYSTEMA 82/03/19. 16.57.31.
  INDIRECT ACCESS FILES
  BASTEST  DATA  FORTEST  HEXFILE  OCTFILE
  5 INDIRECT ACCESS FILES,  TOTAL PRUS = 5.
```

The files you've saved are called indirect access files, because you access a copy of the file, not the file itself. The TOTAL PRUS entry at the bottom refers to the size of your files. It's unlikely that you need be concerned with this entry.
Removing a Permanent File from the System

To remove the permanent file associated with your primary file, type

PURGE

To remove other permanent files, type

PURGE,filename

If you were using a copy of the file at your terminal, it is still available, but it disappears when you log out. Figure 5-14 illustrates the PURGE command.

![Diagram of PURGE command examples]

**Figure 5-14. Purging Files in Permanent Storage (PURGE Command)**
Connecting Files to Your Programs

So far in this manual, the system has requested data for program execution (input data) by displaying a question mark at the terminal and waiting for you to enter the data from the keyboard. The system then displayed the results of program execution (output data) at the terminal.

However, if you have a lot of data to enter, you can put it on a file and instruct the system to get the data from the file (that is, to read the file). In the same way, if you expect a lot of data to be displayed as the result of program execution, you can create a file and instruct the system to enter the results in the file (that is, to write the file).

**Reading and Writing Data Files in FORTRAN**

In order for the system to read or write a file used within a FORTRAN program, you must first associate a number with the file using the FORTRAN OPEN statement.

```fortran
OPEN (UNIT=number, FILE='filename')
```

The number is a number you choose between 1 and 99. In the FORTRAN program, this number is associated with the file that you name following `FILE`.

The file name follows the rules you've used previously to create file names. It can be both letters and numbers, must begin with a letter, and must be no more than seven characters. You must include an apostrophe ('') before and after the file name.

For example, in order for the system to read and write files named DATA and RESULT, you could use the OPEN statements:

```fortran
OPEN (UNIT=76, FILE='DATA')
OPEN (UNIT=3, FILE='RESULT')
```

After associating a number with the file, you must specify that number in a FORTRAN READ or WRITE statement like this:

```fortran
READ(number, format) variables
WRITE(number, format) variables
```

In both these statements, `number` is the number associated with the file in the OPEN statement, `format` is the statement number of the appropriate FORMAT statement, and `variables` is a list of the FORTRAN variables you want to read or write.

To read variables A, B, and C from file DATA, you could use a READ statement like this:

```fortran
READ(76,100)A,B,C
```

To write A, B, and C on file RESULT, you could use a WRITE statement like this:

```fortran
WRITE(3,200)A,B,C
```

If file RESULT does not exist when the WRITE statement is executed, the system creates it.

Figure 6-1 shows how to connect a file to a FORTRAN program.
old,forare
READY.

list
10   PROGRAM TRY
20   OPEN (UNIT=3,FILE='DATA')
30   1 READ (3,100) A, B, C
40   100 FORMAT (3F7.0)
50   IF (A .EQ. 0.0) STOP
60   S = (A + B + C) / 2.0
70   RDCL=S * (S-A) * (S-B) * (S-C)
80   IF (RDCL .LT. 0.0) GO TO 2
90   AREA = SQRT(RDCL)
100  200 PRINT 200, A, B, C, AREA
110  2 CONTINUE
120  300 PRINT 300, A, B, C
130  GO TO 1
140  CONTINUE
150  END

The user retrieves a
program created earlier
and lists it. The
program reads three
numbers, which are
sides of a triangle, and
calculates the area of
the triangle.

get,data
READY.

list,f=data
3.0000 4.0000 5.0000
2.0000 1.0000 5.0000

executed again. This
time the results appear.

run
SRU 0.349 UNTS.
RUN COMPLETE.

Figure 6-1. Connecting a File to a FORTRAN Program
Reading and Writing Data Files in BASIC

In order for the system to read or write a file used within a BASIC program, you must first associate a number with the file, using one or more FILE statements in the BASIC program.

FILE #number="filename"

You must include the number sign (#) before the number, the equal sign (=) before the file name, and quotation marks (" ) before and after the file name. The number can be between 1 and 131071. The file name can be both letters and numbers, must begin with a letter, and must be no more than seven characters. To specify more than one file, you can either put them on one FILE statement separated by commas or put one file each on several FILE statements.

For example, to allow the system to read and write files named DATA and RESULT, you could use:

FILE #76="DATA",#3="RESULT"

or

FILE #76="DATA"

FILE #3="RESULT"

After associating a number with the file in a FILE statement, you must specify that number in a BASIC INPUT (read) or PRINT (write) statement like this:

INPUT #number,variables

PRINT #number,variables

or

PRINT #number USING linenumber variables

In all forms of the statements, variables is a list of the BASIC variables you want to read or write. In the PRINT USING statement, linenumber is the line number of the image line to follow when printing.

To read variables A, B, and C from file DATA, you could use an INPUT statement like this:

INPUT #76,A,B,C

To write A, B, and C on file RESULT, you could use either:

PRINT #3,A,B,C

or

PRINT #3 USING 180,A,B,C

If file RESULT does not exist when the PRINT statement is executed, the system creates it.

Figure 6-2 shows how to connect a file to a BASIC program.

**Figure 6-2. Connecting a File to a BASIC Program**
What To Do When You Have Problems

This section describes some of the more common problems that users have and suggests some possible solutions. If you have difficulty after reading this, ask your employer, instructor, or computer center personnel for help.

Setting Up Your Terminal
If you're having problems with your terminal and aren't sure of the proper switch settings, try these. They are the most common.

- Duplex switch set to HALF. If you enter data but nothing is printed, check the duplex switch on your terminal; it is probably set incorrectly.
- Parity switch set to EVEN.
- Line-speed switch set to match the speed of the phone line you plan to use. If you're not sure of the speed you should use, set the switch to any position (usually 10 to 30 characters per second). The system may be able to detect automatically what line speed you are using.
- The line/local switch (sometimes called the mode switch) set to the line (online) position.

Make sure the terminal is plugged in and turned on. If a separate acoustic coupler is used, it too must be turned on. For any type of acoustic coupler, check that the phone receiver is inserted with the cord facing the correct direction.

During the Dialing Process
If you dial the phone number and it rings unanswered or is busy, either the system may not be operating, or the maximum number of users may be using that phone line already. Try other numbers if you have them. If you still get no response (response is a constant, high-pitched tone), try again later.

During the Login Process
If you hear the high-pitched tone, connect your terminal, and press the carriage return twice, but don't get a login message, go back to Setting Up Your Terminal in this section and check the switch settings mentioned. If the switches are all set correctly and the system still doesn't print anything at your terminal, tell your computer center personnel. It may be a problem with the equipment.
If the login sequence has started and the system displays the message

**IMPROPER LOGIN, TRY AGAIN.**

you've entered some of your login information incorrectly. The system prompts you for the information again and you can retry the procedure. If this happens four times, the system assumes you are not an authorized user; it displays

**USER RETRY LIMIT.**

**LOGIN TERMINATED.**

and disconnects the terminal. If this happens, tell your computer center personnel. They will help you with the problem.

If you get the message

**MULTIPLE CONCURRENT LOGINS PROHIBITED**

your site does not allow you to have more than one network application running at a time. Usually this means that you are logged into the system at one terminal and you are currently attempting to log into the system at a second terminal. In order for you to log into the system through the second terminal, you must first log out of the system at the first terminal.

If you have received this message and you are not currently logged in at another terminal, then contact a knowledgeable person at your site for more help.

If you get the message

**INVALID APPLICATION, TRY AGAIN.**

and the system prompts you for an application, enter

IAF

If you get the same message, or the message

**APPLICATION RETRY LIMIT.**

**LOGGED OUT.**

tell your computer center personnel.

When you get the message

**APPLICATION NOT PRESENT.**

or

**CONNECTION REJECTED.**

log out and try again later. You haven't made any mistakes; the system is just not available at this time. If you continue to get the

**CONNECTION REJECTED**

message, tell your computer center personnel.

The message

**TIMEOUT.**

means you waited too long to respond to a request from the system. Usually the time limit during the login procedure is 2 minutes. If this happens, connect your terminal again and retry the login sequence.
During the Terminal Session

When the system can't understand what you want done, or when it detects an error of any sort, it tries to diagnose the problem and to give you a message that explains the error and tells you what to do. At any time during your terminal session, you may get messages such as

**INCORRECT COMMAND**

that indicate you've entered information that the system doesn't recognize. If this happens, check your last entry to make sure that everything is spelled correctly and that commas are included where required. Remember that the letter 0, the numeral 0, the letter 1, and the numeral 1 each has its own key on the terminal keyboard. If you type the letter 0 for the numeral 0, or the letter 1 for the numeral 1, the system regards it as an error.

If you get a system message that you don't understand, refer to Volume 3 of the NOS 2 Reference Set, appendix B, for more information.

At times, you may get messages that do not come from the system but instead, come from the programming language you are using. These messages usually appear when you try to compile or run a program that has an error in it. Most programming languages have reference manuals that explain these messages. The manual that you will need depends on the language you are using. For example, if you try to run a BASIC program and you get a message telling you that you made an error, refer to the BASIC Reference Manual for an explanation of that message.

If the terminal gives you some sort of audible signal and displays the message

**TERMINAL TIMEOUT IN 30 SECONDS.**

you are waiting too long to enter an instruction (command) or data. The default time limit is 10 minutes, but it may be different at your site. Check with your site administrator to be sure.

When you get this message, any entry, even a carriage return, is sufficient to keep the terminal active. If you don't enter anything within 30 seconds of the signal, the system logs you out automatically. You can log in again and try to resume your work as described in *After Accidental Disconnection from the System* later in this section.

**NOTE**

Output queued in the network can be lost in the event of terminal timeout. If you suspend output to the terminal (for example, you strike any key while running a program that is sending information to the terminal) and a timeout occurs, continuation of the session can cause the output to be lost.
During Program Execution

If you get the message

*TIME LIMIT*
ENTER T TO CONTINUE OR CR KEY TO STOP

your program needs more time to execute. Just follow the directions; type

T

to get more time or press the carriage return to stop the program.

If you get the message

*SRU LIMIT*
ENTER S TO CONTINUE OR CR KEY TO STOP

your program needs more system resources. Again, just follow the instructions; type

S

to continue your program execution or press the carriage return to stop the program.

If these messages continue during program execution, be sure to check your program for any
errors that may be present, such as incorrect loop statements.

Any time you want the system to stop what it’s doing, hold down the control key (labeled
CONTROL, CTRL, or something similar) and press the T key. Then release both keys and press
the carriage return. (This combination of keys is called the termination sequence. If it doesn’t work
on your terminal, ask someone what the equivalent key or keys are.)

After Accidental Disconnection from the System

A mechanical failure or system malfunction may disconnect you from the system unexpectedly. If
this happens, log in again. The system tells you if you can recover your work by listing one or
more recoverable jobs. The system refers to your terminal session as a job and gives it a job
sequence name (JSN). You may have noticed a job sequence name being printed during the login
process. The job sequence name printed during your previous login should match the name of the
job that the system says you can now recover.

NOTE
If your site maintains more than one network, always use the same network when you attempt to
recover a job unless you have no other alternative.

To continue your previous terminal session, type the job sequence name. To start a new session,
type

GO

Figure 7-1 shows a user being disconnected, logging back in, and resuming work from the previous
terminal session.

**Comments**

The user logs in.

The system assigns job sequence name ADDQ to the terminal session.

The user retrieves saved file FORTEST and tries to list it.

At this point, the terminal is disconnected.

The user logs back in.

The system says that job ADDQ has been suspended and can be recovered, so the user enters that name.

At this point, job ADDQ is recovered and is in an idle state. All of the files and conditions of the job are the same as they were before the terminal became disconnected.

The user lists the primary file.

Figure 7-1. Recovering a Terminal Session After Disconnection
The information in this manual is sufficient for you to enter programs and to correct them, run them, and save them. In addition, you’ve been introduced to some important system concepts, such as that of the primary file.

It’s quite possible that the commands in this book are the only ones you will ever need to do your work. But if you find your needs increasing, or if you’re curious, we suggest you go on to NOS 2 Reference Set, Volume 2, Guide to System Usage. Volume 2 explains more of the basic concepts of the system, for both interactive and batch users, and describes more system commands.

*NOS 2 Reference Set, Volume 3, System Commands,* is the reference manual for all system commands discussed in this manual and in Volume 2.

You may want to check with your employer, instructor, or computer center personnel for advice on which manual they would recommend and how you can get a manual. Ordering information is also provided in the preface.
Appendixes

A  Glossary
B  Additional Information About Terminals
C  Using the Full Screen Editor
D  Using Full Screen Applications
Acoustic Coupler

A device in which you place a telephone receiver to connect a terminal to a telephone line. The telephone line is in turn connected to the system. After dialing the system, you place the telephone receiver in the rubber cups of the acoustic coupler, ensuring that the telephone-cord end of the receiver is at the correct end (marked on the coupler). An acoustic coupler is either built into the terminal (common on portable terminals) or a separate part (common on nonportable terminals). Contrast with Data Set.

Alphanumeric Characters

The letters of the alphabet (A through Z) and the digits (0 through 9).

ASCII Mode

Mode which uses the entire ASCII character set. ASCII stands for American Standard Code for Information Interchange. It is a code that can represent 128 characters, including uppercase and lowercase letters, numbers, and special characters. In ASCII mode, you can enter uppercase and lowercase letters and the system will not translate them all to uppercase as it does in normal mode. Contrast with Normal Mode.

BASIC

Beginner's All-Purpose Symbolic Instruction Code. A high-level programming language used for fairly simple programs.

Cancel Line Sequence

The character or sequence of characters that cancels the entry of the current line. When you type a line, the system does not accept it until you press the carriage return. If you enter the cancel line sequence before you press the carriage return, the line is ignored by the system. The sequence may differ on the terminal you're using, but usually you hold down the control key and press the X key. Then release both keys and press the carriage return.

Catalog

A collection of information about the permanent files associated with a particular user name. Every user who saves permanent files has a permanent file catalog. Each time you create, modify, or purge a permanent file, the system updates your catalog accordingly. You can list the names of your permanent files and other information about them using the CATLIST command.
Command
An instruction you give to the system that causes it to perform an operation.

Control Key
A terminal key labeled CONTROL, CTRL, CNTL, CNTRL, or something similar. Many terminals require the control key to be pressed and held while another key is pressed for the cancel line sequence, interruption sequence, or termination sequence.

Data Set
A device, similar in appearance to a normal telephone, that is used to connect a terminal to a telephone line. The telephone line is in turn connected to the system. After dialing the system, you either set the switch on the front of the data set to DATA or press the DATA button. You then replace the telephone receiver. The connection is made without placing the receiver in a separate device. Contrast with Acoustic Coupler.

Default
A value or name supplied by the system, if you do not supply it. For example, if you enter LIST without specifying a file name, the primary file (the default) is listed.

Duplex
Mode of transmission on a communication line. You need be concerned about duplex mode only to the extent of checking that the duplex switch on your terminal is set correctly for the line being used. Although the switch is normally set to HALF, personnel at your computer center can tell you the correct setting for your terminal. If you enter data but nothing is printed, check the duplex switch on your terminal; it is probably set incorrectly.

Execution
The process of carrying out an instruction or a sequence of instructions (a program) by a computer.

Family Name
Name of the permanent file storage device or set of devices on which all of your permanent files are stored. When you request a permanent file, the system looks for it on this family (group) of devices. Usually a system has only one family of permanent file devices, but it is possible to have alternate families in the system. You may have to specify which family you are using when you log in. Your family name is given to you by your employer, instructor, or computer center personnel.
File

A collection of information referred to by a file name (from one through seven characters, either letters or numbers). You can create a file at the terminal or retrieve a file from permanent file storage for use during a terminal session.

FORTRAN

Formula Translation. A high-level programming language used for fairly complicated programs.

Full Screen Application

Any program that uses screen mode processing to display output information or to request user input of program data.

FSE (Full Screen Editor)

See Full Screen Editor.

Full Screen Editor

A text editor that gives you two methods of editing: line editing and screen editing. Line editing can be used on any kind of terminal and allows you to edit a line by typing a directive and specifying the appropriate line number. Screen editing can be used only on certain display terminals and allows you to move the cursor about freely on the screen and use special function keys on the keyboard to perform editing operations.

Hardwired Terminal

A terminal that is always connected to the system. To begin a terminal session on a hardwired terminal, all you need to do is identify the terminal by pressing the proper key(s), and the login sequence begins (refer to Entering the System in section 3).

IAF (Interactive Facility)

See Interactive Facility.

Interactive Facility

A program within NOS which provides a terminal operator with interactive (or conversational) processing capability. IAF is the application used in this manual.

Indirect Access File

The type of file described in this manual. When you access (retrieve) a file, you get a copy of the file and can make changes to the copy but not directly to the file.
Interruption Sequence

The character or sequence of characters that interrupts a system operation (for example, listing a program or running a program). It may differ on the terminal you’re using, but usually you hold down the control key and press the P key. Then release both keys and press the carriage return. To resume the operation, you press the carriage return.

Job Sequence Name

A four-character name assigned by the system to your terminal session. It is displayed at the end of the login procedure. If the system disconnects you before you are done with your work, you can log in again, and you may be able to resume your work by specifying the job sequence name assigned to your previous terminal session.

JSN (Job Sequence Name)

See Job Sequence Name.

Line/Local Switch

Determines transmission of data. For normal operations, the switch should be set to the line position. When set to the local position, entries are printed at the terminal, but they are not transmitted to the system (even though the terminal is connected). This switch is also called the mode switch.

Line Mode Processing

A method of interactive usage in which program data or system commands are entered and executed on a line by line basis. Contrast with screen mode processing.

Line Speed

Rate of transmission of information between the terminal and the system measured in either characters per second or baud. (In general, the baud rate is 10 times the character-per-second rate.) Your computer center may restrict some terminals or phone lines to certain line speeds; ask personnel there what line speeds you can use.

Local File

A name used by the system to refer to a temporary file available at the terminal.

Login

Procedure during which you identify yourself to the system as an authorized user. To identify yourself, you enter certain responses to prompts from the system. These responses are given to you initially by your employer, instructor, or computer center personnel. They usually include a family name, user name, and password.
Logout
Procedure by which you end a terminal session. You type BYE.

Mode Switch
See Line/Local Switch.

Network
A system of hardware and software that can be used to connect terminals to computers and computers to other computers.

Nonprimary File
A file that is available for use at the terminal but is not the primary file. Nonprimary files are often used to store the data needed to run a program or to store the data resulting from the execution of a program. Nonprimary files are not automatically rewound before a read or write operation. Contrast with Primary File.

Normal Mode
Mode in which the system translates any lowercase letters that you enter to uppercase letters. Contrast with ASCII Mode.

Parity
Mode indicating a method of error detection. You need be concerned about parity mode only to the extent of checking that the parity switch on your terminal is set correctly. Personnel at your computer center can tell you the correct setting for your terminal. Parity is either even, odd, or disabled (not used). When used, a special bit (the parity bit) is set or cleared in the string of binary digits, so that the sum of the digits set, including the parity bit, is always even or always odd. When data is read, the sum is checked and, if it doesn't agree with the parity setting (even or odd), the system knows the data is incorrect.

Password
A name or word you enter during login to provide extra security for your user name. A unique password ensures that no one else can log into the system with your user name and access your files. Your password is given to you by your employer, instructor, or computer center personnel.

Permanent File
A file you create at the terminal and then save, so that you can retrieve it at a later terminal session. When you retrieve the file, the system makes a copy of the file for use at the terminal. The original file remains unchanged, even if you make changes to the copy at your terminal. If you want to save the changed copy of the file in place of the original file, you enter the REPLACE command.
Primary File

The file on which operations are performed if no other file name is specified. You designate the primary file with the NEW, OLD, or PRIMARY command. The system automatically rewind the primary file to its beginning before every operation performed on it.

Program

A sequence of instructions that are executed by a computer to perform a task. A program can be composed of several subprograms.

PRU

Physical record unit. It is a unit of size that is applied to files.

R

Run

See Execution.

S

Screen Mode Processing

A method of interactive usage in which formatted display screens are used to display output information or to request user input of program data. Contrast with line mode processing.

SRU (System Resource Unit)

See System Resource Unit.

System

Software and hardware that control the execution of computer programs and provide scheduling, error detection, input/output control, accounting, compilation, storage assignment, and related services.

System Resource Unit

A unit measuring system use that the system displays following certain operations and your logout.

T

Temporary File

A file at the terminal that disappears when you either log out or enter the NEW or OLD command without /ND. You create a temporary file either by entering information in a primary file, retrieving a permanent file (thus making a temporary copy at your terminal), or as a result of program execution.
Terminal Session

Period between the time you physically connect the terminal to the system in preparation for login to the time you log out.

Termination Sequence

The character or sequence of characters that terminates a system operation that is currently in progress (for example, listing a program or running a program). It may differ on the terminal you’re using, but usually you hold down the control key and press the T key. Then release both keys and press the carriage return.

Text Mode

Mode of entering information into a primary file without specifying line numbers. It is usually used to create data files. If a file does not contain line numbers, you can change lines only by using a text editor, such as Full Screen Editor.

User Name

Name given to you by your employer, instructor, or computer center personnel. Your user name has certain resources and privileges assigned to it. When you log in, you specify your user name to identify yourself to the system, so that it knows that you are an authorized user and what resources you are entitled to use. Your user name also represents a specific catalog in the permanent file system. All files you make permanent are associated with your user name and this catalog.
This manual has assumed that you have a standard ASCII terminal that has auto-recognition defined for the line. To start the login process on that kind of terminal, you press the carriage return twice (described in section 3). To start the login procedure on any other kind of terminal, follow these procedures.

- On standard ASCII terminals that have a fixed speed defined for the line, simply complete the connection from your terminal to the host. That is, if you use either an acoustic coupler or a data set, take the appropriate steps to dial into the system. If your terminal is directly wired to the host, simply turn your terminal on.

- On mode 4A terminals, press the SEND key. (On these terminals, the SEND key takes the place of the carriage return.)

- On mode 4C terminals, press ETX. (On these terminals, the ETX key takes the place of the carriage return.)

- On all other terminals, press the carriage return. Wait until the system responds with two blank lines, then type a right parenthesis

) followed by a carriage return.
The Full Screen Editor has been designed to take advantage of the features found on certain display screen terminals. For example, the Full Screen Editor can fill a screen with lines of a file and allow you to edit anywhere on the screen by moving the cursor to a particular position. Then you can either type directly over existing characters or, by pressing a single key, perform an editing operation at that position. The Full Screen Editor also has directives that can be used on any terminal to edit line by line.

The Full Screen Editor has two ways of editing: line editing and screen editing. Line editing allows you to edit on a line by line basis using line numbers. You type in a directive, specifying the line number you want to be affected by the directive. You can perform line editing on any terminal, whether it’s a display terminal or a printing terminal.

Screen editing allows you to edit by moving the cursor to a position within a displayed file and either entering the characters directly or pressing a key that performs the operation. You can perform screen editing on any of these display terminals: Control Data Corporation Viking 721, CDC 722, CDC 722-30, DEC VT100,† Zenith Z19,† and Heathkit H19,† Lear Siegler ADM3A,† Lear Siegler ADM5,† Tektronix 4115,† and IBM 3270.†

If you don’t have one of these terminals, you may still be able to use the screen editing feature. Through the use of a special software program described in the NOS Screen Formatting Reference Manual, it may be possible to make your display terminal operate in screen mode. Check with your site administrator for more information.

This appendix shows you how to edit a file using line editing and screen editing. Some of the line spacing shown in the terminal sessions is changed to allow easier reading of the comments.

First we’ll show an example of line editing. You can always use the line editing directives regardless of the kind of terminal you’re using.

Suppose the data file created in figure 5-5

```
3 4 5
2 1 5
1.5197 1.5197 1.5197
0 0 0
```

had been entered like this instead.

```
3 4 5
1.5297 1.597 1.51987
2 1 5
0 0 0
```

†DEC is a registered trademark of the Digital Equipment Corporation. Zenith Z19 is a product of the Zenith Corporation. Heathkit H19 is a product of the Heath Corporation. Lear Siegler ADM3A and Lear Siegler ADM5 are products of Lear Siegler Incorporated. Tektronix 4115 is a product of Tektronix Incorporated. IBM 3270 is a product of International Business Machines Corporation.
Follow this example to see what a few Full Screen Editor directives can do.

<table>
<thead>
<tr>
<th>Terminal Session</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>fse, data</td>
<td>This command starts the Full Screen Editor. If a file name is not included, the Full Screen Editor asks for the file name or, if the editor has already been used during this terminal session, it edits the same file.</td>
</tr>
<tr>
<td>EDIT: DATA</td>
<td>PRINT ALL displays the whole file. Notice that the Full Screen Editor has added line numbers that were not in the original file. They are used only by the Full Screen Editor and disappear when editing is through.</td>
</tr>
<tr>
<td>NOS FULL SCREEN EDITOR</td>
<td>The user wants to insert a new line after line 1.</td>
</tr>
</tbody>
</table>

?? print all
1 3 4 5
2 1.5297 1.597 1.51987
3 21 5
4 0 0 0

?? insert 1
2 ? 2 1 5
3 ?

?? print all
1 3 4 5
2 2 1 5
3 1.5297 1.597 1.51987
4 21 5
5 0 0 0

?? delete 4
4 21 5

?? print all
1 3 4 5
2 2 1 5
3 1.5297 1.597 1.51987
4 0 0 0

The user wants to insert a new line after line 1.

When prompted by a single question mark, the user enters the new line. Pressing the carriage return after the question mark tells the Full Screen Editor to stop inserting lines.

Just to check, the user displays the file again. Notice that the subsequent line numbers have increased by one.

The user deletes the fourth line.

The user checks the file again.
Terminal Session

?? alter 3

2 1 5
1.5197 1.51197 1.5197
0 0 0

Comments

Next the user wants to alter line 3 which has several errors.

The Full Screen Editor displays the line to be changed. To replace a character, the user spaces over to it and types the new character.

Now the user wants to alter line 3 by inserting a character.

To insert a character, the user spaces over to the position where the character should be, types \^ (the circumflex), and the new character.

Finally the user wants to delete a character from line 3.

To delete a character, the user spaces over to the character and types # (the number sign).

The user displays the entire file again and sees that it is correct.

QUIT stops the Full Screen Editor.

When the file is listed after editing, notice that the line numbers no longer appear.

Remember, these changes are made only on the copy of the file at your terminal. To keep them, you must save or replace the file.
In summary, for line editing:

<table>
<thead>
<tr>
<th>Entry</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FSE, filename</td>
<td>Starts editing on the file specified.</td>
</tr>
<tr>
<td>PRINT ALL</td>
<td>Displays the entire file.</td>
</tr>
<tr>
<td>INSERT number</td>
<td>Inserts following the line specified by number.</td>
</tr>
<tr>
<td>DELETE number</td>
<td>Deletes the line specified by number.</td>
</tr>
<tr>
<td>ALTER number</td>
<td>Alters the line specified by number. Characters can be replaced one-for-one, inserted (using ^), and deleted (using #).</td>
</tr>
<tr>
<td>QUIT</td>
<td>Ends editing on the file.</td>
</tr>
</tbody>
</table>

Now we'll show the same example using screen editing. Remember, you must have a display terminal that supports screen editing to perform screen editing. We'll assume that a Viking 721 is used.

First you must tell the system that you want to use screen mode rather than line mode which is the default. Type

```
   screen,721
```

When the system responds

```
   READY
```

type

```
   FSE, filename
```

In this case, the command that starts the Full Screen Editor is

```
   fse, data
```

As in the earlier example, the file DATA

```
   3 4 5
   1.5297 1.597 1.51987
   21 5
   0 0 0
```

will be changed to

```
   3 4 5
   2 1 5
   1.5197 1.5197 1.5197
   0 0 0
```
After entering the FSE command, the following screen is displayed.

To move the cursor while using screen editing, press one of the arrows on the 2, 4, 6, or 8 keys to the right of the main keyboard.

On some terminals, like the CDC 722, you must press the shift key along with the arrow.
The rest of this example shows partial screens with comments to the right.

<table>
<thead>
<tr>
<th>Terminal Session</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>File DATA</strong> Lines 1 thru 4 Size 4</td>
<td>The line under 3 represents the current position of the cursor.</td>
</tr>
<tr>
<td>3 4 5</td>
<td></td>
</tr>
<tr>
<td>1.5297 1.597 1.51987</td>
<td></td>
</tr>
<tr>
<td>21 5</td>
<td></td>
</tr>
<tr>
<td>0 0 0</td>
<td></td>
</tr>
</tbody>
</table>

Pressing the down arrow (that is, the number 2 key) moves the cursor to the second line.

<table>
<thead>
<tr>
<th>File DATA</th>
<th>Lines 1 thru 4 Size 4</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>3 4 5</td>
<td></td>
<td></td>
</tr>
<tr>
<td>1.5297</td>
<td>1.597 1.51987</td>
<td></td>
</tr>
<tr>
<td>21 5</td>
<td></td>
<td></td>
</tr>
<tr>
<td>0 0 0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Pressing the shift key (\(\text{\textsuperscript{\textcircled{2}}}\)) and the insert key (\text{INSRT}) (on the upper righthand side of the keyboard) inserts a blank line where the cursor is positioned.

<table>
<thead>
<tr>
<th>File DATA</th>
<th>Lines 1 thru 5 Size 5</th>
<th>The user can then type in the new line. When the carriage return is pressed, the line at the top is updated to show 5 lines.</th>
</tr>
</thead>
<tbody>
<tr>
<td>3 4 5</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2 1 5</td>
<td></td>
<td></td>
</tr>
<tr>
<td>1.5297</td>
<td>1.597 1.51987</td>
<td></td>
</tr>
<tr>
<td>21 5</td>
<td></td>
<td></td>
</tr>
<tr>
<td>0 0 0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The cursor is positioned to the next line and the character to be edited, 2.

<table>
<thead>
<tr>
<th>File DATA</th>
<th>Lines 1 thru 5 Size 5</th>
<th>The character in error is simply typed over and the correct character, 1, replaces it.</th>
</tr>
</thead>
<tbody>
<tr>
<td>3 4 5</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2 1 5</td>
<td></td>
<td></td>
</tr>
<tr>
<td>1.5197</td>
<td>1.597 1.51987</td>
<td></td>
</tr>
<tr>
<td>21 5</td>
<td></td>
<td></td>
</tr>
<tr>
<td>0 0 0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Terminal Session

File DATA Lines 1 thru 5 Size 5
3 4 5
2 1 5
1.5197 1.597 1.51987
21 5
0 0 0

Comments

The cursor is again moved, this time to the position where a character should be inserted.

File DATA Lines 1 thru 5 Size 5
3 4 5
2 1 5
1.5197 1.597 1.51987
21 5
0 0 0

Pressing the (INSRT) key inserts a blank where the new character can be inserted.

File DATA Lines 1 thru 5 Size 5
3 4 5
2 1 5
1.5197 1.5197 1.51987
21 5
0 0 0

The new character is simply typed in.

File DATA Lines 1 thru 5 Size 5
3 4 5
2 1 5
1.5197 1.5197 1.5197
21 5
0 0 0

The cursor is moved to the 8, a character to be deleted.

File DATA Lines 1 thru 5 Size 5
3 4 5
2 1 5
1.5197 1.5197 1.5197
21 5
0 0 0

Pressing the (DELETE) key (on the upper righthand side of the keyboard) deletes the 8 and automatically moves the rest of the line over.

File DATA Lines 1 thru 5 Size 5
3 4 5
2 1 5
1.5197 1.5197 1.5197
21 5
0 0 0

The cursor is moved down to the fourth line. This line should be deleted.

File DATA Lines 1 thru 5 Size 5
3 4 5
2 1 5
1.5197 1.5197 1.5197
21 5
0 0 0

Pressing the shift key (□) and the (DELETE) key deletes the entire line. The file is now correct.
Pressing the function key labeled F6 at the top of the keyboard stops the Full Screen Editor. The system responds:

```
FILE: DATA
FILE: FSEPROC (NO CHANGES)
READY.
```

Remember, the changes are made only on the copy of the file at your terminal. To keep them, you must save or replace the file.

In summary, for screen editing:

<table>
<thead>
<tr>
<th>Entry</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FSE, filename</td>
<td>Starts editing on the file specified.</td>
</tr>
<tr>
<td>4</td>
<td>Moves the cursor in the direction indicated by the arrow (up, down, left, or right). The arrows are located on the numbers 2, 4, 6, and 8 to the right of the main keyboard.</td>
</tr>
<tr>
<td>(INSRT)</td>
<td>Inserts a blank at the current position of the cursor.</td>
</tr>
<tr>
<td>(INSRT)</td>
<td>Inserts a blank line at the current position of the cursor.</td>
</tr>
<tr>
<td>DELETE</td>
<td>Deletes the character at the current position of the cursor.</td>
</tr>
<tr>
<td>DELETE</td>
<td>Deletes the line at the current position of the cursor.</td>
</tr>
<tr>
<td>F6 function key</td>
<td>Ends editing on the file.</td>
</tr>
</tbody>
</table>

There are many more advanced features available on the Full Screen Editor. You can find out more by reading the Full Screen Editor user's guide mentioned in the preface.
Interactive programs running on NOS can be used in either line or screen mode. Line mode processing requires the program to handle terminal input and output on a line by line basis. For each line of data which you enter, you must press the carriage return and wait for that line of data to be processed before you can continue. This is the sort of processing that you are probably already familiar with, and, with the exception of the screen mode discussion in appendix C, is also the kind of processing that this manual has previously dealt with in its examples.

Full screen processing, however, presents you with a full screen of information at once. You may then enter information in any order which you desire by moving the cursor to the appropriate position on the screen and typing your response. Processing of the information begins only after all of the required information has been entered on the screen. Any program that allows you to use full screen processing is known as a full screen application.

This section shows you how to use a full screen application. It informs you of some of the possible problems you might encounter when using a full screen application, and it tells you what to do should you encounter those problems.

NOTE

Before running a full screen application, you must use the SCREEN command described in appendix C of this manual.

Terminals

If you are having trouble running a full screen application, chances are the problems are caused by the terminal you are using. NOS supports a number of different terminals for use with full screen applications and allows many other terminals to be set up for use with them. Thus, there is a wide variety of terminals that you may encounter when you are using full screen applications.

Of course, all of the terminals that can run a full screen application have certain minimal capabilities. However, all of these terminals do not necessarily have the same characteristics beyond those minimum capabilities. Differences can occur in what keys exist on a keyboard, how the keys are labeled, and in how the keys are arranged on the keyboard. Other differences occur in the terminal's hardware and software. The more sophisticated, or smarter, a terminal is, the easier it will be for you to run a full screen application. The less sophisticated, or dumber, a terminal is, the harder it will be to run a full screen application.

In the sections that follow in this appendix, we will point out some of the more common problems users may have with terminals. Fortunately, none of the problems you might encounter will be insurmountable. In fact, the better acquainted you get with your terminal and its features, the fewer the problems you will have. But until you are well acquainted with your terminal, you may need to either consult your terminal's hardware reference manual or speak with someone who is already familiar with your terminal about its particular characteristics.
Entering Information to a Full Screen Application

Information that a full screen application sends to your screen typically looks like information would on a sheet of paper. The information is presented to you one screen at a time, and any given application may have more than one screen of information to present to you. Figure D-1 is an example of what a full screen application might look like on your screen.

![Sample Input Screen](image)

To find the area of a triangle

Enter values for Side A: 
Side B: 
Side C: 

Press: NEXT to execute 
f6 to quit

Figure D-1. Sample Input Screen

To enter information into the application, you must move the cursor to one of the input fields and type the information requested. In almost all full screen applications, an input field is designated by an underlined area (see figure D-1). However, in some full screen applications this may not necessarily be true. For instance, FSE is a full screen application, but the input fields are not underlined because the majority of the screen is an input field. In any case, when a screen load of information is first presented to you, the cursor is automatically placed at the beginning of the first input field. Simply type the requested information and then move to the next input field.
There are several different ways to move to the next input field. Usually the slowest way of moving from one input field to the next is to use the arrow keys, as described in Appendix C. This method, however, has the advantage of working the same way on all terminals which support full screen applications.

The tab key will also move you to another input field. Each time you press the tab key your cursor will be moved one input field ahead without sending any information to the application for processing. However, if you pressed your tab key and the cursor is not moved ahead to the next input field, then you have a terminal that requires you to press the carriage return after the tab key. On these terminals, the cursor moves ahead one input field for each time you press the tab key before the carriage return. For example, if you are in the first input field, and you press the tab key twice and then the carriage return, then the cursor will be placed in the third input field on your screen.

The final way to move to a different field is to use function keys. Application programmers set up function keys that perform certain tasks when you press them (see the section on function keys in this appendix). It is possible, though, that not all of the function keys on your keyboard have been defined for use with your application. If this is the case, then any undefined function keys on your keyboard work the same way that your tab key does.

Once you have filled up the input fields on your screen with data, look at them to make sure the data is correct. If for any reason you wish to go back and change the data you have typed into an input field, you may do so by using the arrow, tab or function keys. To correct or change any of the data you have typed in, simply use the arrow, tab or function keys in the manner described previously to move to the appropriate input field. Once you are there, type the correct information over the old data. When you are using the tab or function keys, the first input field on your screen is the next field after the last input field on your screen.

After you have correctly entered all of the required information requested on the screen, press the carriage return. Pressing the carriage return causes your terminal to send the information on the screen to the application for processing. The application will then either present the next screen of information to you, or display any necessary error messages.

Error Messages

Usually error messages are caused either by writing the wrong kind of data into an input field or by attempting to enter data when the cursor is in an area other than input field. If you attempt to input the wrong kind of data into an input field (for example, attempting to input a real number when an integer value is required), then an error message will appear in the first line of your screen, and the cursor will be placed at the beginning of the field where the incorrect data was entered. The error message should give you some idea of what kind of data the application is looking for in that field. To correct the field, type the correct data over the old data and press the carriage return. Make sure, however, that none of the original incorrect data is still visible on the screen before pressing the carriage return. In general, what you see in the input field is what is sent to the application for processing. Use the space bar to blank out any of the old data which is still visible in the input field.
If you attempt to enter data into areas on the screen other than the input fields, then several different things may happen depending on the terminal you are using. Some terminals, such as the Viking 721, will not allow you to enter data anywhere on the screen but in the input fields. Terminals of this type sustain protected fields. That is, the terminal knows where the input fields are and will not allow you to type outside of them. Other terminals, such as the CDC 722, do not sustain protected fields. On terminals such as these, what you type will overwrite anything that previously existed on that part of the screen.

In either case, anything that is typed outside of the input field will not be sent to the application. Remember that an input field is any underlined area on your screen (see figure D-1). If part of your data exists inside and the rest exists outside of an input field, then the data is truncated to include only that part of the data which is inside of the input field. If any of your data exists outside of an input field, the message

Please confirm

will appear on the first line of your screen, the output fields where you attempted to type data will be repainted, and the cursor will be placed in the field where the data should have been entered. You must then either correct or accept any data existing in that field.

Here are some other messages that you may see:

PLEASE ENTER
PLEASE CORRECT
PLEASE PRESS FUNCTION KEY
PLEASE REENTER INPUT

The PLEASE ENTER is the default message that appears when you try to execute an application where you have not provided required information. The default message will not appear if the application writer has defined a help message for that parameter.

PLEASE CORRECT is the default message if you have entered invalid data.

PLEASE PRESS FUNCTION KEY means that the procedure has no input fields and that you should not try to input any data. Rather, press the function key that performs the function you wish to execute next.

PLEASE REENTER INPUT can be caused by two things: one, if you have pressed a key or combination of keys that could not be recognized by the application, and two, if you have typed data before the application was ready to receive it.

Common Problems

One common problem that you may have is that you might not always understand what the application is asking you to input in a given field. This is usually because the information on the screen is too cryptic for a first time user of the application to understand. If you have this problem, then try pressing the help key when the cursor is in the field in question. Full screen application writers often build help routines into their applications. Otherwise, ask somebody who is familiar with the application to help you or simply experiment. Well written applications will allow you to recover gracefully from incorrect entries.

Another problem you might have is that you may be prompted to reenter information even though the information already entered on your screen appears to be both correct and placed correctly in the input field. There are several reasons why this might happen. One is that for various reasons, NOS may not have received the information you tried to send. If this appears to be the problem, simply reenter the indicated data.
You may also be prompted to reenter data if the system has painted your screen wrong. Painting is the process the system uses to fill the screen with information. If you attempt to type anything before your screen has been completely painted, then you will cause your screen to look different than it actually should. Since full screen applications look for input from fixed areas on the screen regardless of what was actually painted there, a mispainted screen can cause problems when you attempt to enter data. If your screen has been painted wrong, then depending on the terminal you are using, type one of the following:

- `shift erase and the carriage return`
- `shift clear and the carriage return`.

This will cause your screen to be repainted without sending any information for processing.

### The Carriage Return and Other Function Keys

Function keys are the keys on your keyboard marked F1, F2, F3, etc. or Pf1, Pf2, Pf3, etc. These keys allow NOS full screen application writers to define special, often complex functions which can be executed by pressing a single key. All terminals that support full screen applications have a minimum number of function keys. However, some terminals have more of these keys than others do, so NOS also allows almost any key or sequence of keys on the keyboard to be defined as a function key. Any function key which has not been defined for use with the application by the programmer acts as a tab key.

When you are using a full screen application, any function keys that have been defined for your use should be labeled at the bottom of the screen. The cursor may be positioned anywhere on your screen when you use a function key; it does not have to be in an input field. Using a function key usually does not leave a mark on the screen. However, on some terminals such as the CDC 722, a character is always left on the screen after pressing a function key. This character does not affect any information it happens to overwrite, so it can be ignored. Repainting the screen causes the function key character to be deleted from the screen.

The carriage return is also considered to be a function key. Pressing the carriage return usually causes the terminal to send information to the system for execution. However, application programmers are able to program a different function key other than the carriage return to perform this task. In either case, the proper key to press should be labeled in the bottom lines of your screen.

After you have pressed the carriage return, there occasionally may be a pause before the system responds to your terminal again and sends the next screen of information for you to look at. If this happens, do not continue pressing the carriage return. In this situation, continually pressing the carriage return will only cause the system to send you the error message:

```
Please reenter input.
```

Generally you only want to press the carriage return when you wish to have information on the screen sent to the application for processing. However, terminals such as the CDC 722 also require you to press the carriage return after each use of a function key. If you are using a terminal like this, you also are required to press the carriage return after typing the help key.
If you are having trouble finding a particular function key on your keyboard, ask someone who is familiar with your terminal to help you or consult your terminal's hardware documentation. Since NOS allows you to define almost any key as a function key, finding a particular function key on your keyboard may not always be easy or obvious. In general, though, any given function key should be labeled on your keyboard exactly as indicated in the last few lines of your screen.

NOTE

For help on any questions involving function keys on the Full Screen Editor, refer to the NOS Full Screen Editor User's Guide.
