<tbody>
<tr>
<td>B (01-27-83)</td>
<td>Manual updated to PSR level 580. New RMKDEF statements were added to the xoj file for multiple index file recovery and clarifications were made of LIBTASK and recovery descriptions. Addition of the Login/Logout appendix, and revision of the Terminal Definition appendix and the Line Transmission Key appendix. This edition obsoletes all previous editions.</td>
</tr>
<tr>
<td>C (03-29-85)</td>
<td>Manual updated to NOS 2.4.1 at PSR level 630. This revision reflects the addition of the user statement to the TAF configuration file and of the send message task (STASK). Appendix G, Terminal Definition Commands, and appendix J, Accessing a Host, have been revised. The IBM 3270 terminal has been added to the set of supported terminals. Several technical and editorial changes have been made.</td>

60459500 C  3/4
The CONTROL DATA® Transaction Facility (TAF), Version 1.3, is a network host product. It is a network application that requires the facilities of the Network Access Method (NAM) and the 255x Series Communications Control Program (CCP). TAF runs as a subsystem of the Network Operating System (NOS), Version 2, and may be used with COMPASS, FORTRAN, or COBOL.

This manual documents the executive portion of TAF. The three data managers available for use with TAF are each documented in their respective reference manuals. These are:
- CDC® CYBER Database Control System, Version 2 (CDCS)
- CDC TAF/CRM Data Manager Version 1 (CRM)
- CDC TOTAL Data Manager Version 2

Refer to the list of related publications for full titles and publication numbers of the respective manuals.

AUDIENCE

This manual is for the data administrator and applications programmer. The data administrator (DA) is a person or a group of people responsible for installing and maintaining the transaction subsystem. This person or group sets up the database and describes the relationships among the various elements. The DA is concerned with the internal design of the system and can modify many of the system components to suit site requirements. An applications programmer is a person who writes tasks in FORTRAN, COBOL, or COMPASS to be used by the end user (terminal operator). Using these tasks, the terminal operator can access and update the database with little or no knowledge of TAF. New users of TAF should consult the TAF 1 User's Guide as a first source of information. It is an introductory text for inexperienced users.

The user must be familiar with basic NOS operations such as running a compilation job. The NOS 2 Reference Set, Volume 2, acquaints the new user with the fundamentals of NOS. The NOS 2 Reference Set, Volume 3, is for the high-level language applications programmer who is already familiar with NOS. The NOS 2 Reference Set, Volume 4, is for the COMPASS applications programmer.

TERMINOLOGY AND CONVENTIONS

References in this manual to the transaction subsystem imply every aspect of TAF. References to the transaction executive imply the controlling portion of TAF, the portion described in this manual. References to FORTRAN imply either FORTRAN Extended Version 4 or FORTRAN Version 5; TS mode is not allowed (that is, the SEQ, TS, and OPT=0 parameters are not allowed on the FTN command). References to COBOL imply Version 5.

Where brackets, [ ], are used in task request format descriptions, they indicate optional parameters.

The term alphanumeric refers to any combination of the letters A through Z and the numbers zero through nine; special characters are not included.

Conventions for word formats are as follows:
- Crosshatching indicates a field is not used by or is not applicable to TAF.
- Reserved fields may contain information useful to TAF internal processing. The user should not expect them to contain any particular values.
- Fields labeled with mnemonics indicate that a specific parameter must be inserted (generally described after the word format).
- Fields with numeric identifiers indicate the actual value that is used or returned for a particular request.

Models 815, 825, 835, 845, and 855 of the CYBER 170 Computer Systems share many of the functional and architectural attributes of the CYBER 180 computer systems (models 810, 830, 835, 840, 845, 850, 855, and 860). The term CYBER 180-class machines describes these similar models collectively.

Extended memory for model 176 is large central memory extended (LCME). Extended memory for models 865, 875 and CYBER 180-class machines is unified extended memory (UEM). Extended memory for models 865 and 875 may also include either extended core storage (ECS) or extended semiconductor memory (ESM). Extended memory for all other NOS computer systems is either ECS or ESM. ECS and ESM are the only forms of extended memory that can be shared in a linked shared device multainframe complex and can be accessed by a distributed data path (DDP).

In this manual, extended memory refers to all forms of extended memory unless otherwise noted.

Programming information for the various forms of extended memory can be found in the COMPASS 3 Reference Manual and in the appropriate computer system hardware reference manual.

The NOS 2 Manual Abstracts is a pocket-sized manual containing brief descriptions of the contents and intended audience of all NOS and NOS product manuals. The abstracts can be useful in determining the manuals of greatest interest to a particular user.

Control Data also publishes a Software Publications Release History, publication number 60481000, of all software manuals and revisions packets it has issued. This history lists the revision level of a particular manual that corresponds to the level of software installed at the site.

These manuals are available through Control Data sales offices or Control Data Literature Distribution Services (308 North Dale, St. Paul, Minnesota 55103).

## SUBMITTING COMMENTS

The last page of this manual is a comment sheet. Please use it to give your opinion on the manual's usability, to suggest specific improvements, and to report any errors. If the comment sheet has already been used, you can mail your comments to:

Control Data Corporation
Publications and Graphics Division ARH219
4201 Lexington Avenue North
St. Paul, MN 55112

Additionally, if you have access to SOLVER, an online facility for reporting problems, you can use it to submit comments about the manual. Declare your problem type as DOC and use NS2 as the product identifier.

**60459500 C**
INTRODUCTION

TAF is a network product that controls transaction processing. Transaction processing consists of taking an existing collection of information, called a data base, and correcting old data or adding new data to create an up-to-date data base. Such a correction or addition is called a transaction.

In a transaction processing system, the data base must be efficiently structured and easily accessible to the user. A data manager provides these features. Control Data offers the following data managers for use with TAF.

- The CYBER Database Control System (CDCS).
- The CYBER Record Manager (CRM). (TAF supports only those features documented in the TAF/CRM Data Manager 1 Reference Manual.)
- The TOTAL Data Manager.

All data managers can operate concurrently. However, a single transaction can use only:

- CDCS and one other data manager,
- CDCS alone,
- One other data manager alone.

The main function of TAF is on-line transaction processing; that is, direct operator interface with the data base through a terminal.

ON-LINE TRANSACTION PROCESSING

Some advantages associated with on-line transaction processing are:

- The operator submitting the data through TAF can make immediate data corrections.
- The operator can verify that operations have completed successfully. TAF allows the operator to view additions or corrections to the data base to verify their accuracy.
- The data base is updated in seconds. TAF provides immediate updating capability, which allows other transactions to make use of the updated data base.

The most important feature of TAF is its efficient system resource utilization. TAF's transaction processing differs from other modes of operation in that a task only contains application code. Terminal communications are handled by one terminal communications interface. Data base communications are handled by one copy of a data base manager. When tasks need to be loaded, they are simply copied from a task library to a subcontrol point; none of the normal overhead of loading is incurred.

The TAF control point contains application tasks as subcontrol points. When a task completes, one of the following occurs:

- It may be immediately reused by other waiting transactions (no reloading is necessary).
- Another task may be loaded in its place.
- Other active tasks may be moved up in memory and the remaining memory returned to the system for use by non-TAF applications.

TAF will expand its memory to a maximum value as needed.

When there is no transaction activity, TAF size is reduced to a small amount of memory. When input is sensed, TAF rolls back in to service the request.

Figures 1-1, 1-2, and 1-3 summarize the TAF control point and its operation.

ON-LINE TRANSACTION PROCESSING

Some problems associated with on-line transaction processing and the methods that TAF uses to alleviate them include the following.

- It is difficult to schedule and control multiple jobs. TAF solves the problem of multiple job control scheduling by using subcontrol points. Like the operating system that controls and schedules jobs to control points (where they are processed), TAF controls and schedules transaction processing programs to portions of its control point called subcontrol points. Subcontrol points are protected from each other by CYBER hardware memory protection.
- The terminal interface is complicated. TAF minimizes terminal programming by using simple input/output (I/O) commands that are processed by the standard network terminal interface.
Figure 1-1. TAF Control Point for CDCS Data Manager

Figure 1-2. TAF Control Point for TAF/CRM Data Manager
BATCH INTERFACE
A batch interface with TAF is also available. The batch interface can generate large reports without tying up a terminal until the listing has been printed. The report can be printed at a high-speed central site printer. Batch mode can also be used for testing and debugging. The batch interface is described in section 5.

NETWORK INTERFACE
The network terminal interface uses NAM and 255x communications processors. This interface is used by all other network products (for example, Remote Batch Facility and Interactive Facility). If validated, terminal users may select these applications as well as TAF. The network provides the following features for transaction processing:

- Managing network protocol.
- Buffering and queuing data for regulating data flow.
- Supporting a wide variety of terminals through standardization of data formats as well as providing the ability to handle transparent data.
- Sharing network among communication-oriented services.

The network makes use of the interactive virtual terminal (IVT) concept. This concept abstracts certain functions of a variety of real terminals. The applications programmer need not be concerned with character sets and communications protocols.

- An IVT has an input/output device that sends or receives certain amounts of data termed logical lines. These logical lines are transformed into physical lines of characters of the appropriate character set for the real terminal.
- Logical lines that exceed the physical capacity of the real terminal are automatically folded into two or more physical lines.
- The spacing of logical lines of output can be further controlled by the use of format effectors.
- Output to a device may be optionally paged, so that data that would overwrite any output being displayed is not sent until the terminal user has acknowledged the preceding output.
- Both the application and the terminal user can redefine terminal characteristics of the actual terminal, which may differ from those assumed, and supply or redefine the operational controls provided.
When an application requires features not provided by the IVT but known to exist on the connected real terminal, the application may do one of the following:

- Embed appropriate control characters in the output text.
- Transfer data in transparent mode, in which case all transforms are inhibited, and the application has direct access to and responsibility for all real terminal features including the character set.

**TASKS**

The applications programmer implements a transaction system by writing tasks. A task is a program with a TAF interface that performs a specific function. A single task or several tasks perform a sequence of events called a transaction. Tasks can read and update information on the user's data base. They can send messages to terminals and receive input. Tasks can also schedule other tasks to assist in completing transactions.

Tasks that run under TAF can be written in COBOL, FORTRAN, or COMPASS. A task differs from a normal batch or interactive program in that it contains calls to TAF commands and data manager commands and must have a common block (referred to as the communication block) defined. The communication block is needed to receive terminal input and pass data between tasks. (The communication block is described in section 2.)

Binary copies of each task are stored in the task library. The LIBTASK utility is used to place these binary copies on the task library. Section 10 describes the task library and LIBTASK.

Tasks written in COBOL must be compiled with the TAF parameter on the COBOL command. Tasks written in FORTRAN must be compiled with the Z parameter on the FORTRAN command (FORTRAN 4) or with D=0 on the FTM5 command (FORTRAN 5).

**TRANSACTION PROCESSING**

After following the login procedures outlined in appendix J, the user indicates the transaction to be performed by entering a code that is assigned by the system designers. Such a code could specify that a user is entering a loan payment; another code would be used to close out a loan, and so on. TAF performs initial input and places it in a communication block. This communication block is the means by which the data is passed from a terminal to a task or from task to task.

When a transaction is completed, the communication block is released and can be used by other transactions.

After the communication block has been constructed, TAF schedules an initial task (ITASK) to interpret the code the user entered. Using this code, ITASK requests TAF to schedule the appropriate task(s) to process the transaction. The task scheduled may also call other tasks to assist in completing the transaction.

**TAF REQUESTS**

Communication between terminals and tasks is accomplished by using TAF requests. Output can be sent to a transaction terminal from the task by using the SEND request. When this request is processed, control passes to TAF. TAF extracts the message from the task and passes it to the network. The message is then transmitted to the transaction terminal, and control passes back to the task for additional processing.

When a task requires additional input from the terminal, the WAITINP request is used. The task performs a SEND request to send output to the terminal, prompting the terminal operator for the needed input. The WAITINP request is then processed. Since the terminal operator takes seconds to respond to the request, the task is rolled out of central memory and the subcontrol point and communication block are released. These resources can then be used to process other transactions while the terminal operator is responding. When TAF receives the requested input, it places it into a new communication block, and the task is rolled into an available subcontrol point. The new communication block is passed to the task, and the task continues processing.

These and other requests are further described in sections 2 and 5.

**ENTERING THE TRANSACTION SUBSYSTEM**

The subsystem you will be accessing is the TAF subsystem. There are various procedures for accessing this transaction subsystem. These methods are discussed in detail in appendix J. Using appendix J, a coordinator of TAF activities at a particular site who knows the types of users and applications at the site can determine the most desirable access procedures.

Because of the flexibility of the network and the transaction subsystem, the procedure to access the transaction subsystem can vary substantially from site to site. Therefore, the coordinator of transaction subsystem operations at each site should provide each user, or terminal location, with a detailed login procedure for that site.

The site should also provide information concerning terminal characteristics. A variety of terminal classes is supported for use on the network with
TAF. Each of these terminal classes has characteristics, which the analyst can change by modifying the network files and which you can change by entering terminal definition commands.

A discussion of the terminal characteristics, the defaults for each terminal class, and the procedure for changing these characteristics at a terminal is included in appendix G.

IMPLEMENTING AN APPLICATION

The following steps specify the procedure for implementing an application.

1. Review this manual.
2. Design the application including:
   - Selection of the data manager (CDCS and/or CRM, or TOTAL) to allow the correct choice of file types, file structure, and file interaction.
   - Selection of recovery and backup techniques, including journalizing of files.
3. Describe and install the data base using the data manager. Refer to the appropriate data manager reference manual for this procedure.
4. Test load the data base using the data manager commands (usually done in batch mode).
5. Using the application design, write the application tasks to process transaction input.
6. Optionally modify ITASK to reflect the actual application. Tasks HSABT, LOGT, and SYMSG may also require modification. (Refer to section 11.)
7. Build a task library. (Refer to section 10.)
8. Build an xxJ file. (Refer to section 4.)
9. Build a network file, and use NDL to configure terminals and establish login sequences and terminal characteristics.
10. Build the TAF configuration file (TCF). (Refer to section 4.)
11. Test the system.

SUBCONTROL POINTS

The following discussion is intended for analysts and may be omitted by the applications programmer.

Tasks reside at subcontrol points within the field length of the transaction executive. Each task runs with its own exchange package, reference address (relative to the transaction executive), and field length (a subset of the field length of the transaction executive). A task, therefore, can reside in any contiguous segment within the transaction executive field length. Memory is allocated in 100g word blocks located on even 100g word boundaries (for example, 32100g to 32200g). A subcontrol point consists of one 120g word block of memory for system use, followed by sufficient blocks to contain an entire task.

The subcontrol point feature allows the transaction executive to control each task. Some of the advantages associated with the subcontrol points are:

- Isolating one subcontrol point from other subcontrol points and the transaction executive. This means that no application program can destroy the transaction executive or circumvent system security.
- Blocking RA+1 requests from a subcontrol point. No requests are allowed directly from a subcontrol point to NOS. Any such requests are intercepted by the system monitors, which return control to the transaction executive. Thus, the only RA+1 requests a task can legally issue are those processed by the transaction executive. This includes requests to the data managers.

The transaction subsystem allows a maximum of 31 subcontrol points. An installation parameter sets the number of subcontrol points that the transaction executive initializes. When the transaction executive is loaded, the operator can select a number of subcontrol points other than this default value. The number of subcontrol points must not be less than 2 nor greater than 31. Once the transaction subsystem is initialized, no change in the number of subcontrol points is allowed. The optimum number of subcontrol points is selected by the site.

Each subcontrol point requires eight words of table space. No space, other than a table entry, is allocated for a subcontrol point unless it is active. Each active subcontrol point has 113g words reserved, beginning at RA, similar to those used for batch control points.

MULTIMAINFRAME

Under a multimainframe configuration, the transaction subsystem can be run on either or both mainframes. However, a data base and JOUR0 file (section 4) cannot be shared by the transaction subsystems. Each subsystem must have a unique data base.

EXTENDED MEMORY

TAF does not allow the use of your access to extended memory. However, the TAF procedure file can declare data files and libraries as extended memory-resident.
A task is isolated from the data manager and the remainder of the system by the transaction executive. The isolation guarantees that errors in a task do not propagate beyond the task. The following types of requests constitute the interface between the task and the transaction executive.

- Data manager requests
- Journal file requests
- Memory dump requests
- System requests
- Task scheduling requests
- Input/output requests
- Task control requests
- Task utility requests
- Application recovery requests
- System recovery requests

Internally, a task performs a request by loading address RA+1 of its subcontrol point. This activity is not visible to the applications programmer who uses the macros or calls given in this section. The transaction executive uses the request parameters to determine what processing is required by the task. The address field and any fields in a parameter list that reference an address contained within the task are verified to ensure that the address referenced is within the task field length.

Tasks communicate with each other and accumulate input by using the communication block. The communication block is discussed next, followed by the types of requests.

**COMMUNICATION BLOCK**

Communication between a chain of tasks is provided by the communication block. The initial input or the input from a terminal as a result of the WAITINP request (refer to Input/Output Requests later in this section) is also stored in the communication block. The communication block can be used to pass parameters or data from task to task. The format of the communication block is shown in figure 2-1. The length of terminal input is not restricted by the length of the communication block. The LOADCB request is available to read extra input that overflows the communication block (refer to the description of m in figure 2-1). If the communication block is passed between tasks in a transaction and overflow data is present, other tasks in the transaction can access this data with a LOADCB request.

If COBOL is used, the communication block must be described in the COMMON-STORAGE SECTION. Shown here is an example of such a description:

```
DATA DIVISION.
COMMON-STORAGE SECTION.
01 COMMUNICATION-BLOCK.
  03 CB-HEADER-AREA-WORD-ZERO.
  05 CB-DATA-BASE-NAME PIC X(2).
  05 CB-USER-TST-AREA PIC 9(6).
  05 CB-TRAN SEQ-NUMBER PIC 9(6).
  03 CB-HEADER-AREA-WORD-ONE.
  05 CB-USERNAME PIC X(7).
  05 CB-INPUT-STATUS-BYTE PIC 4(2).
  05 CB-MESSAGE-WORD-COUNT PIC 4.
  03 CB-MESSAGE-AREA PIC X(570).
  03 USER-AREA PIC X(90).
  03 CB-TRAILER-AREA.
  05 FILLER PIC X(4).
  05 CB-PACKED-DATE.
    07 CB-YEAR COMP-4 PIC 9.
    07 CB-MONTH COMP-4 PIC 9.
    07 CB-DAY COMP-4 PIC 9.
  05 CB-PACKED-TIME.
    07 CB-HOUR COMP-4 PIC 9.
    07 CB-MINUTE COMP-4 PIC 9.
    07 CB-SECOND COMP-4 PIC 9.
WORKING-STORAGE SECTION.
```

This will be referred to in the manual as the standard COBOL communication block because of the correspondence between it and the fields shown and described in figure 2-1. However, applications programmers may find it convenient to use a more abbreviated communication block when possible.

**Notes**

- COMP-4 is specified for data areas intended for numerical information. Refer to the COBOL 5 Reference Manual for information on the relationship between the number of digits specified in the picture clause for COMP-4 data and the number of bits reserved.

†The standard CMR-supported, compiler-generated I/O calls from FORTRAN and COBOL are not allowed. The COBOL SORT verb is not supported.
Data base that the originating terminal is validated to use.

Image of originating terminal user area from the terminal status table (refer to section 8). Contains the recovery flag. (Refer to the TARO and TSIM requests for more information.)

Assigned by the transaction executive to each newly initiated transaction. This number is generated by incrementing a counter by one and identifies the transaction, or task chain, throughout its life in the subsystem.

The first octal digit of the transaction sequence number. It is the identifier for the network file under which the user running this transaction is defined. The value is zero to seven.

One- to seven-character user name, left-justified with binary zero fill from the terminal status table.

Bit 17 of word 1 is set to one if this communication block was created by a TAF-originated transaction. Word 2, and possibly 3, of the communication block contains additional information (operating system or network-defined conditions that may be processed by TAF-originated tasks). Refer to section 11 for information concerning required system tasks.

Bit 16 of word 1 is set to one if this communication contains data on which a parity error occurred during terminal input.

Bit 15 of word 1 is set to one if this communication block was created by a batch transaction (BTRAN request).

Bit 14 of word 1 is set to one if CDCS aborts.

Bit 13 of word 1 is set to one if TAF is idling down.

Bit 12 of word 1 is set to one if additional input to be loaded by means of the LOADCB request exists.

Length of the input message is words in the communication block proper.

A message from a terminal (as a result of initial terminal input, WAITINF, or BWAITINF requests) begins at word 2 and is terminated by 12 bits of zero in positions 11-0 of the last word of the message. All remaining message area words contain binary zero. The maximum length of a terminal message is 57 words. This area may also contain data from a BTRAN request. The maximum length of a BTRAN message is 62 words. In all cases, the length of the message is in the message word count field. The information contained in this area is available to you, and its contents is passed to any communication block generated by the processing of a CALLTSK or CALLRTN request. To retain the terminal input, you may only write in words message word count+2 through 67. If there is no need to retain the terminal input, the entire area can be used.

Date and time in packed binary format from the operating system PDATE macro.

The main purpose of these fields is to notify the system task ITASK of certain conditions. Under COBOL, the EXTRACT routine allows examination of these fields. Also, a COBOL data type, computational-4, can be used to access these fields more easily; computational-4 data types are allowed only on COBOL Version 5.2 and above. ITASK is described in section 12, and EXTRACT is described later in this section.

Figure 2-1. Communication Block Format
If FORTRAN is used, the communication block must be in the first block of labeled common.

If more data is input than can be contained in the communication block, the LOADCB request may be used to obtain the input.

REQUESTS

The following paragraphs describe the various types of requests a task can make. They describe task scheduling, input/output, task control, and task utility requests and show the formats for making these requests from tasks written in FORTRAN, COBOL, and COMPASS.

DATA MANAGER REQUESTS

A task can make data manager requests to one of the data managers, (CDCS, CRM, or TOTAL) supported by the transaction subsystem. (Refer to the preface for a list of the publications that document these data managers and the requests used.)

JOURNAL FILE REQUESTS

A task can supplement automatic journaling by writing data on a journal file. Journal files and the journal requests are discussed in section 4.

MEMORY DUMP REQUESTS

These requests are discussed in section 6.

SYSTEM REQUESTS

System requests from transaction tasks are limited to the following.

COMPASS Macros

- ABORT
- DATE x
- ENDRUN
- JDATE x
- MEMORY (as described below)
- MESSAGE x (to console B display, line one only)
- PDATE x
- RTIME x
- TIME x

FORTRAN Functions and Subroutine Calls

- DATE(x) or CALL DATE(x)
- JDATE(x) or CALL JDATE(x)
- TIME(x) or CALL TIME(x)

60459500 B

COBOL Statements

- ACCEPT x FROM DATE.
- ACCEPT x FROM TIME.
- ACCEPT item FROM TTY.
- DISPLAY item UPON TTY.

These requests are described in detail in Volume 4 of the NOS 2 Reference Set, FORTRAN Extended 4 Reference Manual, FORTRAN 5 Reference Manual, and the COBOL 5 Reference Manual. (Refer to the preface for publication numbers.)

MEMORY REQUESTS (COMPASS ONLY)

Tasks can interrogate the status of and change their central memory (CM) field length (FL) via the RA+1 requests MEM and RFL. The format of these calls is documented for the MEMORY macro in the NOS 2 Reference Set, Volume 4. The use of these requests in TAF is restricted as follows:

- Memory requests should be issued with the recall (r parameter); otherwise, control may be returned before the request is processed.

- There is an upper limit beyond which a task is not allowed to increase its CM space; this limit is referred to as the maximum task field length (MFL). The MFL for each task is equal to the task FL plus the value specified by the EF LIBTASK directive for the task (refer to section 10). If a task attempts to exceed this value, it may be aborted (refer to documentation of the MEMORY macro NA parameter in the NOS 2 Reference Set, Volume 4).

- Field length cannot be decreased to less than the last word address of the default communication block transfer address rounded up to the nearest 100s.

- A non-CM-resident task making a memory request may be rolled out of CM if the request cannot be satisfied initially.

- Since a task making a memory request may be rolled out, it may be desirable to free locked data manager resources prior to the request.

Tasks will also be allowed to use the common memory manager (CMM) with the following restrictions:

- The processing performed by CMM for the task must not result in CMM using the fast dynamic loader or the task will be aborted.

- The preceding restrictions on use of MEM and RFL requests apply.

Common memory manager requests are documented in detail in the Common Memory Manager 1 Reference Manual.
MESSAGE REQUESTS

COMPASS tasks can issue messages to the operator or the JOURO file by using the RA+1 request MSG. The function code determines the disposition of the message. Function code zero causes the message to be written to only the JOURO file. Function code one causes the message to be placed in line one of the B display.

FORTRAN termination messages are also written to the JOURO file.

COBOL and FORTRAN tasks can issue messages to TAF's dayfile by using the TMSG request. The tasks that issue this request must reside in the system task library. Tasklib.

The TMSG request issues a message to TAF's dayfile.

The format is:

COBOL

ENTER TMSG USING message[,length].

message A 01-level data item containing the dayfile message.

length A computational-1 data item specifying the length of the message in characters. The maximum length is 80 characters.

FORTRAN

CALL TMSG(message,length)

message The name of the array that contains the dayfile message.

length An integer specifying the length of the message in characters. The maximum length is 80 characters.

TASK SCHEDULING REQUESTS

A task, including ITASK (refer to section 11), can call in order a list of other tasks. This process is referred to as task scheduling. The following four requests can be used to schedule tasks.

• CALLRTN

Calls up to five tasks. Upon completion of the called chain of tasks, returns control to the calling task.

• CALLTSK

Calls up to five tasks. The task making the call either ceases or continues to run, allowing the new task chain to proceed independently.

• NEWTRAN

Initiates up to five new tasks (COMPASS only).

• TRANCHK

Checks to see if a specific task is active (COMPASS only).

NOTE

If a list has either no tasks or more than five tasks, TAF aborts the task and issues the following error message on the screen.

TASK REQUEST ARGUMENT ERROR

CALLRTN Request

The CALLRTN request is used to request that the transaction executive schedule a task or series of tasks, with control returning to the calling task upon completion of the called tasks. A CALLRTN request cannot be made while data manager requests are outstanding. The current communication block is passed to the called tasks and returned to the caller when the caller is reinitiated. Upon return, the caller begins execution immediately after the CALLRTN request. Only the information in the communication block may have changed. Return from the called tasks to the caller takes place automatically after the last called task ceases. A task waiting for return may be temporarily rolled from memory.

The format is:

COBOL

ENTER CALLRTN USING task1 task2...taskn.

taski Parameter whose value is a one- to seven-character alphanumeric task name. The tasks are scheduled by CALLRTN in the order specified. From one to five tasks can be specified.

FORTRAN

CALL CALLRTN(task1,task2,...,taskn)

taski Parameter whose value is a one- to seven-character alphanumeric task name, left-justified with either blank or binary zero fill to a word boundary. The tasks are scheduled by CALLRTN in the order specified. From one to five tasks can be specified.
CALLRTN address

address Address of a list of from one to five task names. Each task name must be left-justified with binary zero fill to a word boundary. The list is terminated by a word of binary zeros. Tasks are scheduled by CALLRTN in the order they appear on the list.

NOTE

If task1, specified on a CALLRTN request, makes a CALLRTN request, task1 + 1 through taskn, specified on the original CALLRTN request, are not scheduled. (Refer to figure 2-4.)

The following diagrams illustrate CALLRTN processing.

In figure 2-2, TASK A, at subcontrol point X, executes a CALLRTN to TASK B. TAF will first load a copy of TASK B to an available subcontrol point (unless a serially reusable copy of TASK B is already at a subcontrol point or CM-resident). TAF will then copy the contents of TASK A's communication block (CB) to TASK B's communication block area. TASK B begins execution. When TASK B has completed execution, TAF will copy the communication block, which was probably modified by TASK B, back to TASK A and allow TASK A to continue execution at the instruction immediately following the CALLRTN command.

The CALLRTN command allows a chain (list) of up to five tasks to be called. Figure 2-3 shows TASK A calling a chain of three tasks. As each task in the chain is completed, TAF will automatically pass the communication block to the next task in the chain and allow that task to execute. When the last task in the chain has completed, TAF will pass the
CALLTSK Request

The CALLTSK request is used to request that the transaction executive schedule a task or series of tasks (task chain). Included in this request is a parameter option that enables task branching or a CEASE function to be performed after the call is honored. If the task is not to cease on this call, a branching of the chain initiates a new chain that is independent of the original chain. The new chain is assigned a new sequence number for unique identification within the transaction subsystem (figure 2-1). The number of branches allowed by a transaction is controlled by an assembly constant MAXBN. If a CALLTSK request without a CEASE request is issued from a recoverable transaction, recovery may be affected. Refer to CALLTSK without CEASE and Recovery in section 7.

The format is:

**COBOL**

```
ENTER CALLTSK USING task code task1...taskn.
```

code Parameter whose value is nonzero if the calling task is to continue after the request, initiating an independent task chain. If the value of this parameter is zero, the calling task ceases after this request. If not specified, the default is zero.

task Parameter whose value is a one-to seven-character alphanumeric task name. This task is the next task to call in the present task chain (same sequence number) if code is set to zero; otherwise, it is the first task of a branch chain (the called task gets a different sequence number and proceeds independently of the calling task).

task1 Parameter whose value is a one-to seven-character alphanumeric task name, left-justified with either blank or binary zero fill to a word boundary. From zero to four tasks can be specified. These tasks are scheduled after the one specified in the task parameter.

**FORTRAN**

```
CALL CALLTSK(task,code,task1,...,taskn)
```

task Parameter whose value is a one-to seven-character alphanumeric task name, left-justified with either blank or binary zero fill to a word boundary. This task is the next task to call in the present task chain (same sequence number) if code is set to zero; otherwise, it is the first task of a branch chain (the called task gets a different sequence number and proceeds independently of the calling task).

code Integer whose value is nonzero if the calling task is to continue after the request, initiating an independent task chain. If the value of this parameter is zero, the calling task ceases after this request. If not specified, the default is zero.

task1 Parameter whose value is a one-to seven-character alphanumeric task name, left-justified with either blank or binary zero fill to a word boundary. From zero to four tasks can be specified. These tasks are scheduled after the one specified in the task parameter.

The following figures illustrate CALLTSK processing.

Figure 2-5 shows TASK A making a CALLTSK with a CEASE request to TASK B. TAF will load a copy of TASK B to an available subcontrol point (this step is not necessary if a serially reusable copy of TASK B is already at a subcontrol point or is CM-resident). The communication block will be copied from TASK A to TASK B. TASK A's subcontrol point is released for use by other transactions, and TASK B is allowed to begin execution.

![Figure 2-5. CALLTSK with CEASE Request](image-url)
The CALLTSK without a CEASE request allows a new asynchronous chain to be started. In figure 2-6, TASK A uses this command to call TASK B. TAF will copy the contents of TASK A's communication block to a new communication block. A copy of TASK B will be loaded to an available subcontrol point (unless a serially reusable copy of TASK B is already at a subcontrol point or is CM-resident). The new communication block will be copied to TASK B. TASK A is allowed to continue execution and TASK B is allowed to begin execution.

NEWTRAN Request (COMPASS Only)

The NEWTRAN request initiates a new transaction chain with a unique sequence number and with the data base, user area, and user name set to zero in the communication block. The NEWTRAN request is designed for system use, primarily by ITASK, and is provided only for COMPASS.

The format is:

COMPASS
NEWTRAN address

address Address of a parameter table in the form shown in figure 2-7.

sequence The transaction executive returns a new 24-bit binary transaction sequence number in this field.

task1 One- to seven-character task name, left-justified with binary zero fill. From one to five tasks can be specified; the list is terminated by a word of binary zeros. NEWTRAN schedules the task in the order they appear on the list.

Figure 2-7. NEWTRAN Parameter Table
TRANCHK Request

The TRANCHK request determines the status of a transaction. This request is provided only for COMPASS.

The format is:

```
COMPASS
TRANCHK address
```

address Address of a parameter table in the form shown in figure 2-8.

INPUT/OUTPUT REQUESTS

The following requests are associated with input/output:

- **WAITINP**
  Places terminal input data in the communication block. Equivalent to a read request.

- **LOADCB**
  Reads data that overflowed the communication block.

- **SETCHT**
  Sets character type for terminal input.

- **SEND**
  Sends data to terminal. Equivalent to a write request.

- **RELSCB**
  Releases memory used for extra communication blocks.

- **TSTM**
  Reads terminal status table.

- **TARO**
  Writes into terminal status table.

---

**Figure 2-8. TRANCHK Parameter Table**

<table>
<thead>
<tr>
<th>59</th>
<th>41</th>
<th>17</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>sequence</td>
<td></td>
<td>status</td>
<td></td>
</tr>
</tbody>
</table>

**sequence**
Binary transaction sequence number which identifies the transaction (task or task chain).

**status**
The system returns one of the following as status in this field.

1. The task chain is still active.
2. The task chain is inactive.
• LIMITS
Limits total number of requests (RA+1 calls) a task can make.

• BWAITINP
Specifies that terminal input data is to be placed in a location in the task field length that is not reserved for the communication block.

• TPSTAT
Returns a value indicating that the active terminal subsystem is NAM.

• BEGIN
Specifies the area where the terminal transmission is to be placed in the task field length. It does not return the communication block to the first word address of the task unless the task requests.

WAITINP Request

The WAITINP request (wait for terminal input) reads data from a terminal. Internally, this request informs the transaction executive that the next input received from a terminal is to be passed directly to the requesting task and is not to initiate a new transaction. The data entered is placed in the message area of the communication block. The data held in the communication block prior to the WAITINP is lost.

The first parameter is a data item or variable whose value the system sets to indicate the reception of terminal input or an error condition. An optional second parameter of the request specifies a time limit, after which processing of the transaction is restarted even if no input has been received from the terminal.

NOTE
CM-resident tasks and tasks not associated with a terminal (batch origin) are not permitted to make a WAITINP request (task aborts).

At least one message (SEND) must be sent to the terminal before making a WAITINP request, and at least one SEND request from the original task chain must follow a message received following a WAITINP request.

No data manager requests may be active when a task makes a WAITINP request. All tasks that make WAITINP requests must be entered in the task library with the scheduling queue limit set to one. (Refer to section 10.)

WAITINP does not cause any data manager cease requests to be issued. Therefore, any resources locked or reserved by a transaction prior to a WAITINP continue to be locked or reserved during and after the WAITINP.

When a WAITINP request is processed, all communication blocks are released and the task is rolled out. All data in the communication block, except the transaction sequence number, will be lost, so the user should save any data to be preserved prior to the request. When input arrives from the terminal, a new communication block is generated, and the task is restarted. The new communication block will contain the transaction sequence number associated with the task prior to the WAITINP request. If the request does not return a normal status, the information in the communication block is meaningless.

The format is:

COBOL

ENTER WAITINP USING status time.

status Computational-l item that the system sets to indicate the status of the WAITINP request. Upon completion of the request, status has one of the following values.

0 The request processed normally; terminal input appears in the normal input portion (begins in the third word) of the communication block.

< 0 Another task is waiting for input from the originating terminal. The WAITINP request must be reassigned if input is desired.

> 0 The time delay elapsed before input was received from the terminal.

time Computational-l item that contains the time limit, in decimal seconds, to wait for input. If not specified, the default is 380 seconds. The maximum value is 2048 seconds.

FORTRAN

CALL WAITINP(status,time)

status Integer variable that the system sets to indicate the status of the WAITINP request. Upon completion of the request, status has one of the following values.

0 The request processed normally; terminal input appears in the normal input portion (begins in the third word) of the communication block.

< 0 Another task is waiting for input from the originating terminal. The WAITINP request must be reassigned if input is desired.
The time delay elapsed before input was received from the terminal.

time Integer time limit, in decimal seconds, to wait for input. If not specified, the default is 480 seconds. The maximum value is 2048 seconds.

Status of the WAITINP macro is determined by the following:

- Word 2 of the communication block contains 1 if the time delay elapsed before input was received from the terminal.
- The X6 register contains a negative value if another task is waiting for input from the originating terminal. The WAITINP request must be reissued if input is desired. (Word 2 of the communication block should be checked before X6 is checked.)
- The X6 register is set to zero if the request processed normally; terminal input appears in the normal input portion (begins in the third word) of the communication block. (Word 2 of the communication block should be checked before X6 is checked.)

LOADCB Request

If the transaction input data exceeds the message area of the communication block, bit 12 of word 1 of the communication block (the i field) is set. The LOADCB request loads the remainder of the input message into a user-defined buffer. This buffer is a single contiguous block of storage for all additional communication blocks. No headers or trailers appear in this area.

The maximum input size is determined by an installation parameter.

The data that remains after the communication block message area fills (referred to here as overflow data) is transferred to the user-defined buffer. If the LOADCB request is made with no data overflow (i field not set) or if a RELSCB request was made prior to the LOADCB request, no data is transferred and the status word is set to zero. If the overflow data consists of more words than will fit in the buffer, the buffer is filled, and the status word is set to a value greater than the number of words in the buffer. If the overflow data can be contained in the buffer, the overflow data is transferred to the buffer, and the number of words transferred is set in the status word.

The overflow data can be requested as many times during a transaction as desired. Each time, the overflow data is transmitted as specified previously.

The format is:

```COBOL
ENTER LOADCB USING buffer status r.
```

```FORTRAN
CALL LOADCB(buffer,length,status,r)
```

As stated in the description of the status parameter, the LOADCB request can be referenced as a FORTRAN function. The format of the function is LOADCB(buffer,length,status,r); the parameters are the same as those already described. The value of the function is the value of the status parameter.

The LOADCB macro status is returned in the X6 register. The significance of the value returned has been described earlier in the LOADCB request description.
SETCHT Request

The SETCHT request allows a task to change the application character type (ACT) of terminal messages placed in the communication block.

**NOTE**

This is an optional request; the default character type is 6-bit display code characters.

The following character types are available.

- 7-bit ASCII, seven and one-half characters per word.
- 7-bit ASCII characters, right-justified in 12-bit bytes, five characters per word.
- 6-bit display code characters, 10 characters per word.

This request causes TAF to send a change input character type supervisory message to NAM. For more information about supervisory messages, refer to the NAM/CCP Reference Manual.

**NOTE**

This request does not change the data currently held in communication blocks for the task. For example, a LOADCB request gets data in the former character type, while the next WAITINP request gets data in the new character type.

If 7-bit ASCII characters are used to originate transactions, ITASK transaction tables must be set up in terms of ASCII and not display code.

The format is:

**COBOL**

```
ENTER SETCHT USING username status act.
```

- **username** A 01-level item containing a one- to seven-character user name, left-justified with blank fill. The user name may also be specified with a computational-1 item with binary zero fill. If the item contains only binary zeros, the character type applies to the originating terminal. This user name must be a name appearing in an NCTFi file. A user name consisting of the character P with binary zero fill cannot be specified.

- **status** Computational-1 item whose value is set by TAF to indicate user name status. This value is zero if the user is not logged in and one if the request is processed normally. The task is aborted if the user name is not defined or if the data base for the specified user does not match the data base of the originating user.

- **act** A 01-level item containing one of the following words, left-justified.
  - **ASCII7** 7-bit ASCII. Seven and one-half characters per word.
  - **ASCII5** 7-bit ASCII, right-justified in 12-bit bytes, five characters per word.
  - **DISPLAY** 6-bit display code.

**Figure 2-9. LOADCB Parameter Table**

<table>
<thead>

<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- **r** If bit 59 is set to one, any message data that overflows the LOADCB buffer is released (same as RELSCB).
- **length** Length of the LOADCB buffer in words.
- **buffer** First word address of the buffer area.
CALL SETCHT(username, status, act)

username One- to seven-character user name, left-justified with zero or blank fill. If the terminal name is zero, the character type applies to the originating terminal. This user name must be a name appearing in an NCTF file.

status Unnormalized floating-point number whose value specifies the user name status. This value is zero if the user is not logged in and one if the request is processed normally.

act Parameter containing one of the following words, left-justified with binary zero or blank fill.

ASCII7 7-bit ASCII, seven and one-half characters per word.

ASCII5 7-bit ASCII, right-justified in 12-bit bytes, five characters per word.

DISPLAY 6-bit display code.

The task is aborted if the user name is not defined or if the data base for the specified user does not match the data base of the originating user.

It is not necessary to use the BLDABH request before every SEND. It is needed when a selectable parameter on the ABH for the next SEND differs from a setting on the ABH for the previous SEND. In other words, a setting of a parameter once selected by BLDABH stays in effect for that task unless changed by a subsequent BLDABH request. If a task issues a BLDABH request and then calls another task, the new task must also issue a BLDABH request because the request parameters are not passed to it. If a task is to be reusable, the task should initialize the ABH if the default values have been changed.

Default values are supplied on the ABH. If the default values are the desired values, no BLDABH request is required. Default values have been selected to remain compatible with prior versions of the transaction subsystem.

The format is:

**FORTRAN**

CALL BLDABH(field1, value1,...,fieldn, valuen)

**COMPASS**

SETCHT address

address Address of a parameter table in the form shown in figure 2-10.

**BLDABH Request**

The BLDABH request builds or modifies the application block header (ABH). This header accompanies every block passing between TAF and NAM, and thus is used during communication between TAF and terminals. It contains detailed information describing the block it accompanies.

**NOTE**

This is an optional request. The default application block header specifies 6-bit display code characters, nontransparent mode, no format effectors, and no auto input.

To use some of the NAM features, a task must use the BLDABH request to modify the ABH. Some of the features provided via the ABH are:

- Character type specification of messages sent to a terminal. Either 7-bit ASCII or 6-bit display code characters may be used.
- Transparent mode specification. Transparent mode inhibits all data transforms and allows the task direct access to the real terminal features.
- Terminal format effector specification. Format effectors control printing (or the cursor on display terminals).
- Auto-input mode specification. Auto-input mode allows a fill in the form type of transaction. This is provided since the first n characters of a message output to the terminal via the SEND request (ABT=2 only) can be used to form the first n characters of subsequent input from the terminal. If n is greater than 20, only the first 20 characters are returned, followed by the entered text.

**COBOL**

ENTER BLDABH USING field1 value1...fieldn valuen.

field1 A 01-level item containing a three-character, left-justified field for which a value is to be set. field1 can be binary zero or blank-filled. The possible values are listed in table 2-1.

value1 A computational-1 item whose value is set for the corresponding field1. The field1 and value1 parameters must appear in pairs. The possible values and descriptions are listed in table 2-1.

**FORTRAN**

CALL BLDABH(field1,value1,...,fieldn,valuen)
The following request builds the ABH with \( \text{ACT}=4, \)
\( \text{NFE}=0, \) and \( \text{AIM}=1. \)

\[
\text{CALL BLDABH(3,ACT,4,3,NFE,0,3,AIM,1)}
\]

The COMPASS user specifies changes to the ABH with the SEND request (described later in this section).

| username | One- to seven-character user name, left-justified with zero fill. If the user name is zero, the character type applies to the originating terminal. |
| status  | Address of a word in which TAF returns an unnormalized floating-point number to indicate the user status. This value is zero if the user is not logged in and one if the request is processed normally. The task is aborted if the user name is not defined or if the data base for the specified user does not match the data base of the originating user. |

</tbody>
</table>

†These are default values supplied by TAF, FORTRAN, and COBOL library routines for BLDABH and SEND. These are also the default values for the COMPASS SEND request when the task does not specify the ABH.
GETABH Request

The GETABH request allows a task to examine the ABH that accompanied the last message.

**NOTE**

This is an optional request. Terminal input and output can be done without using it.

If no SEND has been issued since the last input from the terminal, the GETABH request allows the task to obtain the ABH that accompanied the input block from the network. If a SEND has been issued, the ABH used for the SEND is obtained. This request is useful for obtaining the character type, character count, and parity error fields.

**NOTE**

The parity error indicators can also be obtained from the communication block, but it may be easier for the COBOL task to use GETABH to obtain this indicator.

The format is:

**FORTRAN**

```
CALL GETABH(username,status,field1,value1,...,fieldn,value_n)
```

- **username** Parameter whose value is a one-to-seven-character user name, left-justified with binary zero or blank fill. If the user name is binary zero, the ABH for the originating user is returned.
- **status** Unnormalized floating-point number whose value is set by TAF to indicate the user name status. Status contents is zero if the user is not logged in and greater than zero if the request is processed normally. The task is aborted if the user name is not defined or if the data base for the user name does not match the data base of the originating user.
- **field1** Variable containing a left-justified, three-character field for which a value is desired.
- **value1** Name of an unnormalized floating-point variable in which TAF returns the value of the desired field.

**COBOL**

```
ENTER GETABH USING username status field1 value1 ... fieldn value_n.
```

- **username** A 01-level item containing a one-to-seven-character user name, left-justified with blank fill. The user name may also be specified with a computational-l item with binary zero fill. If the item contains only binary zero, the ABH for the originating terminal is returned. This user name must be a name appearing in the NCVT file. A user name consisting of the character P with binary zero fill cannot be specified.
- **status** Computational-l item whose value is set by TAF to indicate the status of the user name. Status contents is zero if the user is not logged in and is one if the request is processed normally. The task is aborted if the user name is not defined or if the data base for the user name does not match the data base of the originating user.
- **field1** A 01-level item containing a three-character field for which a value is desired, left-justified with binary zero or blank fill. The possible fields and values are described in table 2-2.
- **value1** Computational-l item in which the value for the desired field is to be returned. The field1 and value1 items must appear in pairs.

**COMPASS**

```
GETABH address
```

- **address** Address of a parameter table in the format shown in figure 2-11.

**Figure 2-11. GETABH Parameter Table**

**username**: One- to seven-character user name, left-justified with binary zero fill. If the user name is zero, the ABH for the originating terminal is returned.

**status**: Address of a word in which TAF returns are unnormalized floating-point number to indicate the user name status. Status is zero if you are not logged in and one if the request is processed normally. The task is aborted if the user name is not defined or if the data base for the user name does not match the data base of the originating user.

**abh**: Application block header. The format and description of this word is listed in table 2-2.
TERMDEF Request

The TERMDEF request can be used by a task to define or modify terminal characteristics, where those of the connected real terminal differ from the assumptions made for the network's IVT model. This request can also be used to tailor the operational controls of the terminal.

This is an optional request. Terminal input and output can be done without it. Each terminal that logs into the network is associated with a default set of terminal characteristics. (Refer to appendix G.)

A complete list of terminal characteristics is provided in the NAM/CCP Reference Manual and appendix G of this manual. Characteristics that may be modified include:

- Terminal physical page width.
- Number of physical lines on a terminal page.
- Specification of a character used to cancel an input logical line in progress.
- Specification of a character to be used as a break character. User breaks are sent to the application task for processing.
- Set transparent input mode. This setting exists for only one logical input line.

The format is:

FORTRAN

CALL TERMDEF(username,status,field1, field2,...,fieldn)

username Parameter whose value is a one- to seven-character user name, left-justified with binary zero or blank fill. If the user name is zero, the terminal definition specified applies to the originating terminal. This user name must be a name appearing in an NCTFI file.

status Variable in which TAF places an unnormalized floating-point number to indicate user name status. status contents is zero if the user is not logged in and greater than zero if the request is processed normally. The task is aborted if the user name is not defined or if the data base for the user does not match the data base of the originating user.

fieldi A left-justified variable with binary zero or blank fill, containing the characteristic (for example, PW=60, PL=35, or CN=2B). A maximum of 17 non-blank, non-binary zero characters is allowed. The characteristics are described in the NAM/CCP Reference Manual and appendix G of this manual. If the NAM/CCP Reference Manual specifies x or h, a 6-bit display code alphanumeric representation is required (where x is a 7-bit ASCII character and h is a hexadecimal character).

Example:

The following request designates the page width to be 60 characters, the page length to be 40 lines, and the plus character (ASCII representation is 2B) to be the cancel character for user USERS; it then assigns the status to variable STATUS.

CALL TERMDEF(USERS,STATUS,5LPW=60, 5LPL=40,5LCN=2B)
Example:
The following statements redefine the transparent input mode text delimiter to be a slant (ASCII representation is 2F) and the character count delimiter to be 4096.

```
DATA MSG/10HDL=X2F,C40,2L96/

CALL TERMDEF(5HUSER5,STATUS,MSG)

END
```

### COMPASS

#### TERMDEF address

**address** Address of a parameter table in the format shown in figure 2-12.

### SEND Request

The SEND request sends a message to a user; that is, it performs a write operation. If the task does not specify the user to which the message should be sent, it is directed to the terminal that originated the transaction. At least one SEND request to the originating terminal must occur from the primary task chain for each message received. The task can also specify that the task be ended when the message is sent.

There is both a limit on the total output that one task can send (MAXTO),† and a limit on the output one task can send before it is rolled out, pending the transfer of the output to the terminal or terminals (MLIM).† Also, the maximum output length for one SEND request is determined by the MAXWS installation parameter.

A task can specify the status parameter in COBOL and FORTRAN or the r parameter in COMPASS so that the task will wait until the network acknowledges that the message has been delivered to the user. If recall is selected, any error detected on the output message causes the task performing the SEND request to be restarted. Therefore, tasks performing SEND requests with recall should check status and compensate for errors. Use of recall can simplify recovery since the task issuing the SEND request is informed of the problem at the first address after the SEND. When recall is selected, the task is rolled out if the message length exceeds the MLIM installation parameter. Any data manager resources held by the task, such as locked records, remain assigned for the duration of the rollout. If reserving these resources for this period of time will impact the performance of the application, tasks should release all file and record locks before executing the SEND request.

If recall is not selected, ITASK is informed of the problem, rather than the task that issued the request. ITASK is informed because the issuing task may have already terminated when the message delivering problem is detected.

---

**Figure 2-12. TERMDEF Parameter Table**

<table>
<thead>
<tr>
<th>username</th>
<th>One to seven-character user name, left-justified with binary zero fill. If the user name is binary zero, the terminal definition specified applies to the originating user.</th>
</tr>
</thead>
<tbody>
<tr>
<td>cc</td>
<td>The number of 7-bit ASCII characters (at seven and one-half characters per word) is available in string + 2. Adding two is necessary because string begins in bit 43. If no characters are specified in the string, cc should equal two.</td>
</tr>
<tr>
<td>status</td>
<td>An address of a word in which TAF returns the user name status in unnormalized floating-point format. The status contents is zero if the user is not logged in and greater than zero if the request is processed normally. The task is aborted if the user name is not defined or if the data base for the user does not match the data of the originating user.</td>
</tr>
<tr>
<td>string</td>
<td>A string of 7-bit ASCII characters, in hexadecimal notation, left-justified in the field, defining the terminal characteristic. (Refer to the NAM/CCP Reference Manual for a list of these characteristics.) As an example, to change the cancel key to a +, the string CN++ is written as 434E3D2B. string + n is the last word needed for the string.</td>
</tr>
</tbody>
</table>

†Refer to the NOS 2 Installation Handbook (refer to the preface for the publication number).
The format of the message on the terminal depends on the terminal class and the format effectors in the message. For example, on synchronous terminals the cursor for entering the next message to the host (upline) is always the first character of the line. On asynchronous terminals the cursor follows the last character of output; this assumes no format effectors are in the message. The NAM/CCP Reference Manual contains complete information on terminal protocols.

The format is:

**COBOL**

ENTER "SEND" USING messageaddress username cease-flag output-flag block status length.

The parameters are described in table 2-3.

**NOTE**

Under COBOL, SEND must be enclosed in quotation marks, because SEND is a reserved word for that compiler.

**TABLE 2-3. COBOL SEND Request Parameters (Sheet 1 of 2)**

</table>

†These parameters apply only if the a field is set to one.
RELSCB Request

The RELSCB request releases all overflow communication blocks to the system. After an RELSCB request is processed, subsequent LOADCB requests return a status word of zero.

The format is:

**COBOL**

ENTER RELSCB.

There are no parameters.

**FORTRAN**

CALL RELSCB

There are no parameters.

**COMPASS**

RELSCB

There are no parameters.

TSIM Request

The TSIM request provides limited interrogation of the terminal status table. This table, in central memory, is derived from the network file (refer to section 9). The TSIM request can search four fields in the table:

- Data base name field
- User argument field
- Communication line field
- User name field

The two-word TST entry of the users that meet a defined criterion (criterion) is returned to the user. The field specified by code is examined in each terminal table entry by taking the logical product of the field and mask to isolate a portion of the field. The logical difference of this product and criterion value is then obtained. If this result is zero, the terminal entry is placed in list. No action occurs if it is not zero; that is, the user does not meet the specified criterion. For example, an application could use this to obtain a list of the users that are allowed to use a particular data base by selecting the data base field to be searched for a certain name.

If the task data base is not the same as the one being interrogated, then the list equals zero.

The format is:

**COBOL**

ENTER TSIM USING code mask criterion rlength list length.

<table>
<thead>
<tr>
<th>Value</th>

<tr>
<td>1</td>
<td>User argument field.</td>
</tr>
<tr>
<td>2</td>
<td>Communication line field.</td>
</tr>
<tr>
<td>3</td>
<td>User name field.</td>
</tr>
</tbody>
</table>

**mask** Parameter whose value is taken as a binary mask. It is used in compiling the list of user names.

**criterion** Criterion value for the search.

**rlength** Computational-l item whose value TAF sets to indicate the number of entries found.

**list** Item in which TAF lists found entries. If zero or absent, no list is returned but rlength is given as the number of found entries.

**length** Computational-l item whose value indicates the number of words that list can hold. If zero or absent, no list is returned but rlength is given as the number of found entries. Only the lowest order 12 bits of this value are used.

†The parameters are described in table 2-5.
††Described under LOADCB Request.

CALL TSIM(code, mask, criterion, rlength, list, length)

- **code**: Integer whose value indicates which field is to be searched:
  - **Value**: 0 Data base name field.
  - **Value**: 1 User argument field.
  - **Value**: 2 Communication line field.
  - **Value**: 3 User name field.

- **mask**: Parameter whose value is taken as a binary mask. It is used in compiling the list of user names.

- **criterion**: Criterion value for the search.

- **rlength**: Integer variable whose value TAF sets to indicate the number of entries found. This value is also returned as a FORTRAN function value.

- **list**: Name of an array in which TAF places a list of found entries. If zero or absent, no list is returned, but rlength is given as the number of found entries.

- **length**: Integer variable whose value indicates the number of words that list can hold. If zero or absent, no list is returned, but rlength is given as the number of found entries. Only the lowest order 12 bits of this value are used.

---

**COMPASS TSIM address**

**address**

Address of a parameter table in the format shown in figure 2-14.

- **code**: Integer whose value indicates which field is to be searched:
  - **Value**: 0 Data base name field.
  - **Value**: 1 User argument field.
  - **Value**: 2 Communication line field.
  - **Value**: 3 User name field.

- **list**: Location of list to contain found entries. If zero or absent, no list is returned, but rlength is given as the number of found entries.

- **length**: Number of words that list can hold. If zero or absent, no list is returned, but rlength is given as the number of found entries. Only the lowest order 12 bits of this value are used.

- **rlength**: The address at which TAF returns the number of entries found.

- **mask**: Value to be taken as a binary mask. It is used in compiling the list of user names.

- **criterion**: Criterion value for the search.

---

60459500 A 2-25
TARO Request

The TARO request allows the task to manipulate the user argument field in the terminal status table entry of a particular user. (Refer to section 9 for further information.) The user argument field (24 bits) is operated on in the following manner. The logical product of the user argument field and the lower 24 bits of mask are taken; then the logical difference of this result and value is determined. This value is placed in return and replaces the old user argument field. For example, bit 1 of the user argument field may be used to establish a terminal recovery condition. The TARO request operates in the following manner.

Case 1: The request interrogates the user argument field and determines whether the recovery bit (bit 1) is set. The value of this bit in the user area is not changed and is placed in return. (Only bits 0 through 3 are shown in this example.)

<table>
<thead>
<tr>
<th>Logical</th>
<th>010 user argument field of TST</th>
</tr>
</thead>
<tbody>
<tr>
<td>Product</td>
<td>010 mask parameter</td>
</tr>
<tr>
<td>Logical</td>
<td>010 value parameter</td>
</tr>
<tr>
<td>Difference</td>
<td>000 return value = new user argument field</td>
</tr>
</tbody>
</table>

Case 2: The request sets the recovery bit.

<table>
<thead>
<tr>
<th>Logical</th>
<th>000 user argument field</th>
</tr>
</thead>
<tbody>
<tr>
<td>Product</td>
<td>010 mask parameter</td>
</tr>
<tr>
<td>Logical</td>
<td>000 value parameter</td>
</tr>
<tr>
<td>Difference</td>
<td>010 return value = new user argument field</td>
</tr>
</tbody>
</table>

Case 3: The request clears the recovery bit.

<table>
<thead>
<tr>
<th>Logical</th>
<th>010 user argument field</th>
</tr>
</thead>
<tbody>
<tr>
<td>Product</td>
<td>000 mask parameter</td>
</tr>
<tr>
<td>Logical</td>
<td>000 value parameter</td>
</tr>
<tr>
<td>Difference</td>
<td>000 return value = new user argument field</td>
</tr>
</tbody>
</table>

The format is:

**COBOL**

ENTER TARO USING value mask username return.

- **value**: Item whose value is a 24-bit value to be used to alter the user argument field.
- **mask**: Parameter whose value is taken as a binary mask. Only the lowest 24 bits are used.
- **username**: A 01-level item containing a one- to seven-character alphanumeric user name. The user name can also be a computational-1 item containing a binary zero (designating the originating user).
- **return**: Item whose value TAF sets to indicate the resultant user argument bits.

**FORTRAN**

CALL TARO(value,mask,username,return)

- **value**: Parameter whose 24-bit value is used to alter user arguments.
- **mask**: Parameter whose value is taken as a binary mask. Only the lowest 24 bits are used.
- **username**: Parameter whose value is a one- to seven-character alphanumeric user name, containing either blank or binary zero fill to a word boundary. If this parameter is omitted or is a binary zero, then the originating user is used.
- **return**: Parameter in which TAF places the resultant user argument bits. This value is also optionally returned as the value of a FORTRAN function.

**COMPASS**

TARO address

- **address**: Address of a parameter table in the format shown in figure 2-15.
The IIO request allows a task to change its own I/O limit as measured in RA+1 calls from the task. Any request given in this manual or any data manager request is considered an RA+1 call. The default value is 320 calls.

The format of the request is:

**COBOL**

ENTER IIO USING nio.

nio Computational-l item whose value specifies the new I/O limit.

**FORTRAN**

CALL IIO(nio)

nio Integer whose value specifies the new I/O limit.

**COMPASS**

IIO address

address Address of a parameter table in the format shown in figure 2-16.

The parameter table for TARO is shown in figure 2-15:

- **username**: One- to seven-character user name, left-justified with binary zero fill, for which the operation is performed. If username is a binary zero, then the originating user is used.
- **return**: Location in which to place the resultant user argument bits.
- **value**: 24-bit value to be used to alter the user argument field.
- **mask**: Value to be taken as a binary mask. Only the lowest 24 bits are used.

The parameter table for IIO is shown in figure 2-16:

- **nio**: New I/O limit.
**BEGIN Request**

The BEGIN request allows a task to specify the area where the terminal input data is to be placed, if an area other than the first word address of the task field length is desired. It supports programming languages that do not reserve the first word address of the task for the common block that is used for the communication block. The task must be installed in the appropriate task library with the (solicited) input directive, because the default is unsolicited. If task chains are involved, the calling task must issue a BEGIN request before resuming execution of the original task, because the calling task must be able to obtain the communication block containing the returned data from the called task. The returned communication block in solicited mode is in the same form as in unsolicited mode. Unless there is a specific need for this request, its use is not recommended because more execution overhead is required to support the secondary load request.

**CEASE Request**

The CEASE request provides task end processing and transaction completion processing. If a predetermined task list exists for the chain (that is, subsequent tasks have been requested for scheduling, or the CEASE is a return from a CALLRTN request), no special processing occurs on a CEASE request from a task. However, if the request is from the final task in the chain, the transaction executive releases all communication blocks and notifies the data manager that updated records should be replaced on the data base. The one exception to this procedure occurs if a task selects an abnormal CEASE by use of an optional parameter. A task that terminates in this manner is automatically the final task in the chain. After an abnormal CEASE occurs, all communication blocks are released and records updated by the task but not yet updated on the data base are not replaced on the data base.
The format is:

**COBOL**

ENTER CEASE USING a.

a Computational-l item whose value indicates the type of CEASE selected:

<table>
<thead>
<tr>
<th>a</th>
<th>Type of CEASE</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Normal CEASE.</td>
</tr>
<tr>
<td>1</td>
<td>Abnormal CEASE without memory dump.</td>
</tr>
<tr>
<td>-1</td>
<td>Normal CEASE and terminal remains locked.</td>
</tr>
<tr>
<td>217-1 &gt; a &gt; 1</td>
<td>Abnormal CEASE with memory dump.†</td>
</tr>
<tr>
<td>-1 &gt; a &gt; -(217-1)</td>
<td>Reserved for CDC.</td>
</tr>
</tbody>
</table>

Any other values produce undefined results and should not be used.

**FORTRAN**

CALL CEASE(a)

a Integer whose value indicates the type of CEASE selected:

<table>
<thead>
<tr>
<th>a</th>
<th>Type of CEASE</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Normal CEASE.</td>
</tr>
<tr>
<td>1</td>
<td>Abnormal CEASE without memory dump.</td>
</tr>
<tr>
<td>-1</td>
<td>Normal CEASE and terminal remains locked.</td>
</tr>
<tr>
<td>217-1 &gt; a &gt; 1</td>
<td>Abnormal CEASE with memory dump.†</td>
</tr>
<tr>
<td>-1 &gt; a &gt; -(217-1)</td>
<td>Reserved for CDC.</td>
</tr>
</tbody>
</table>

Any other values produce undefined results and should not be used.

**COMPASS**

CEASE a

a Integer whose value indicates the type of CEASE selected:

<table>
<thead>
<tr>
<th>a</th>
<th>Type of CEASE</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Normal CEASE.</td>
</tr>
<tr>
<td>1</td>
<td>Abnormal CEASE without memory dump.</td>
</tr>
<tr>
<td>-1</td>
<td>Normal CEASE and terminal remains locked.</td>
</tr>
</tbody>
</table>

LOGT Request (COMPASS Only)

The LOGT request logs out a terminal from TAF and returns it to nontransaction mode. The terminal can then access other interactive applications. A system task is provided using this request. (Refer to System Tasks in section 11.)

The format is:

**COBOL**

ENTER LOGT USING LOGT address.

LOGT address Address of a parameter table in the format shown in figure 2-17.

**FORTRAN**

CALL LOGT

**COMPASS**

LOGT

There are no parameters.

†Dumps are identified by the transaction subsystem user name or by the appropriate DSDUMP parameter (refer to section 6).
KPOINT Request

The KPOINT request allows a task to initiate execution of any K display command. Section 6 describes three K display commands: K.DUMP, K.DUMPLIM, and K.DSDUMP.

K display commands are normally issued from the system console to communicate with and to request specific actions of TAF. K display commands should be issued with care and then only when the results of the command are well-defined.

When a task issues a K display command, the prefix K. is omitted. For example, the entry from the console is K.DUMP., but the same command issued from a task is DUMP.

All K display commands, except K.DUMP, require that the calling task be on the system task library. Any task can issue the K.DUMP command.

The format is:

**COBOL**

ENTER KPOINT USING address.

address 01-level name of the character string (K display command). The length of the character string cannot exceed 80 characters. The string must begin on a word boundary and must be terminated by a period or a right parenthesis; the exception is the K.MESSAGE command, which must be terminated by 6 bits of zeros after either a period or a right parenthesis.

**FORTRAN**

CALL KPOINT(address)

address Address of the character string (K display command). The length of the character string cannot exceed 80 characters. The string must begin on a word boundary and must be terminated by a period or a right parenthesis; the exception is the K.MESSAGE command, which must be terminated by 6 bits of zeros after either a period or a right parenthesis.

COMPASS

KPOINT address

address Address of the character string (K display command). The length of the character string cannot exceed 80 characters. The string must begin on a word boundary and must be terminated by a period or a right parenthesis; the exception is the K.MESSAGE command, which must be terminated by 6 bits of zeros after either a period or a right parenthesis.

WAIT Request

The WAIT request allows tasks to make TAF suspend processing for a specified number of seconds (0 to 3600). The transaction must have no outstanding data manager requests at the time a WAIT request is issued.

The format is:

**COBOL**

ENTER WAIT USING time.

time A computational-2 data item indicating the number of seconds for which processing is to be suspended. If unspecified or out of range, the task is aborted. Only the integer portion is significant.

**FORTRAN**

CALL WAIT(time)

time A real number or variable indicating the number of seconds for which processing is to be suspended. If unspecified or out of range, the task is aborted. Only the integer portion is significant.
WAIT address

address The address of a word specifying the number of seconds (N) for which processing is to be suspended. The word has the form 48/0,12/N. If unspecified or out of range, the task is aborted.

TASK UTILITY REQUESTS

The following task utility requests provide capabilities for the FORTRAN and COBOL user, some of which are difficult to do because they are at the bit level.

- LOGIN
  Determine if a specified user is logged in.

- EXTRACT
  Extract a bit string from a word.

- INSERT
  Insert a bit string into a word.
LOGIN Request

The LOGIN request allows a task to determine if a specified user is logged in before it issues a SEND request to that user. TAF aborts a task that issues a SEND request without recall to a user who is not logged in.

**NOTE**

It is possible for the receiving user to log out after the task issues a LOGIN request and before the task issues a SEND request. Therefore, it is recommended that the task issue the SEND request soon after issuing the LOGIN request.

The format is:

**COBOL**

```
ENTER LOGIN USING username status.
```

- **username**: A one- to seven-character alphanumeric user name, left-justified. A binary zero specifies the user associated with the transaction that is running.
- **status**: Address of the location to contain the returned status. The format of the returned status is computational-l. Values for status are:
  0 User not logged in.
  1 User logged in.

**FORTRAN**

```
CALL LOGIN(username,status)
```

- **username**: A one- to seven-character alphanumeric user name, left-justified. Possible forms are nlf and nLf (refer to the FORTRAN Extended & Reference Manual). A binary zero specifies the user associated with the transaction that is running.
- **status**: Address of the location to contain the returned status. The format of the returned status is integer. Values for status are:
  0 User not logged in.
  1 User logged in.

EXTRACT Request

The EXTRACT request allows a task to extract a bit string from a word and move it to another word, right-justified. For instance, the EXTRACT request can be used to check fields in the terminal status table or the communication block.

In the following request formats, if n is not within the specified range, if bbp plus 1 minus n is less than 0, or if there are any other errors in the parameters, TAF aborts the task and issues the following message.

**TASK REQUEST ARGUMENT ERROR.**

The format is:

**COBOL**

```
Enter EXTRACT USING loci loc2 bbp n.
```

- **loci**: Data name of the source field. Any data type is allowed. loci must begin on a word boundary.
- **loc2**: Data name of the computational-l destination field. The bit string is right-justified in this field.
- **bbp**: Beginning bit position of field loci; this is the leftmost bit of the field. Bits are numbered 59 through 0.
- **n**: Number of bits to extract; the range of values for n is 1 to 59, inclusive. The format of n must be computational-l.

**FORTRAN**

```
call EXTRACT(loc1,loc2,bbp,n)
```

- **loc1**: Name of the integer source field.
- **loc2**: Name of the integer destination field. The bit string is right-justified in this field.
- **bbp**: Beginning bit position of field loc1; this is the leftmost bit of the field. Bits are numbered 59 through 0.
- **n**: Number of bits to extract; the range of values for n is 1 to 59, inclusive. n must be integer type.

The COBOL STRING and UNSTRING statements also provide capabilities for manipulating character-aligned data. The EXTRACT request should be used only when the use of these COBOL statements is impossible or inconvenient.
**INSERT Request**

The INSERT request allows a task to insert a bit string into a word. For instance, the INSERT request can be used to set fields in the terminal status table.

In the following formats, if n is not within the specified range, if bbp plus 1 minus n is less than 0, or if there are any other errors in the parameters, TAF aborts the task and issues the following message.

**TASK REQUEST ARGUMENT ERROR.**

The format is:

**COBOL**

ENTER INSERT USING loc1 loc2 bbp n.

- loc1: Data name of the computational-1 source field. The bit string must be right-justified in this field.
- loc2: Data name of the destination field. Any data type is allowed. loc2 must begin on a word boundary.
- bbp: Beginning bit position of field loc2; this is the leftmost bit of the field. Bits are numbered 59 through 0.
- n: Number of bits to insert; the range of values for n is 1 to 59, inclusive. The format of n must be computational-1.

**FORTRAN**

CALL INSERT(loc1,loc2,bbp,n)

- loc1: Name of the integer source field. The bit string must be right-justified in this field.
- loc2: Name of the integer destination field.
- bbp: Beginning bit position of field loc2; this is the leftmost bit of the field. Bits are numbered 59 through 0.
- n: Number of bits to insert; the range of values for n is 1 to 59, inclusive. n must be integer type.

The COBOL STRING and UNSTRING statements also provide capabilities for manipulating character-aligned data. The INSERT request should be used only when the use of these COBOL statements is impossible or inconvenient.

**APPLICATION RECOVERY REQUESTS**

The following task requests are for use in recoverable transactions. All are for use by applications tasks although some are also used by system tasks.

- **RERUN**
  Restarts a run unit using the initial terminal input.
- **RGET**
  Retrieves data from the communication recovery file (CRF).
- **RPUT**
  Places data on the communication recovery file.
- **RSECURE**
  Retrieves a message previously saved on the communication recovery file by a SECURE request.
- **SECURE**
  Signals the completion of a transaction’s work and saves a message on the recovery file to be sent to the terminal when the run unit ceases.
- **TSTAT**
  Returns the status of one or more specified objects.

Refer to section 7 for an overview of the recovery process from the applications programmer’s perspective. Refer to the applicable data manager reference manual (CDCS, TAF/CRM, or TOTAL) for requests associated with data base recovery.

**RERUN Request**

The RERUN request causes the initial terminal input for a rerunnable run unit to be resubmitted to the transaction system. The input comes from the communication recovery file. The actions that occur as a result of RERUN are:

1. The recovery status is set to zero so that the recovery task will not be scheduled.
2. The restart status (TSTAT with keyword RESTART) is set to one.
3. A termination is processed for the run unit and ITASK is called to rerun the run unit.

Transactions using this request must take care to avoid entering an infinite loop if the RERUN results from an error condition.
The format is:

**COBOL**

ENTER RERUN USING status.

status A computational-l data item whose value is set by TAF to indicate the status of the request. The values are:

- 0 No errors.
- 29 Recovery is not installed.
- 33 Run unit is not re-runnable.

**FORTRAN**

CALL RERUN (status)

status An integer variable in which TAF will return a status. The values are:

- 0 No errors.
- 29 Recovery is not installed.
- 33 Run unit is not re-runnable.

RPUT and RGET Requests

The RPUT request allows a task to put application-dependent data on the communication recovery file. The RGET request allows the task to retrieve the data placed on the recovery file by an RPUT. The length of the data in each request and the number of slots for data on the recovery file is specified at TAF initialization on the RECOVER statement in the TCF (refer to section 4). TAF maintains the data on a user name basis. TAF does not modify the user data unless the communication recovery file is initialized. These requests may be used by any task when TAF automatic recovery is installed.

The format is:

**COBOL**

ENTER "RPUT" USING message,index[.status.message-length,act].

ENTER "RGET" USING message,index,status.message-length[.act].

message An O1-level data item that contains the message. This is an input parameter for RPUT and an output parameter for RGET.

index A computational-l data item indicating the index for the recovery record. Index 1 points to the first record in user area of the communication recovery file; index 2 points to the second record in user area of the communication recovery file, and so on. This parameter is input for both RPUT and RGET. The maximum value of index is the value of the number parameter in the RECOVER statement in the TCF.

**FORTRAN**

CALL RERUN (status)

status A computational-l data item whose value is set by TAF to indicate the status of the request. The values are:

- 0 No errors.

The index is outside of the user recovery file message area (RPUT only).

- 20 No message (RGET only).

The message does not fit in the recovery file message area (RPUT only).

- 22 The message does not fit in the user message area (RGET only).

- 23 Incorrect application character type (act).

- 28 The RGET act is not equal to the RPUT act.

- 29 TAF automatic recovery is not installed.
Fortran

CALL RPUT(message,index,status,message-length [,act])

CALL RGET(message,index,status,message-length [,act])

message The name of an array that contains the message. This is an input parameter for RPUT and output parameter for RGET.

index An integer variable indicating the index for recovery record. Index 1 points to the first record in user area of the communication recovery file; index 2 points to the second record in user area of the communication recovery file, and so on. This parameter is input for both RPUT and RGET. The maximum value of index is the value of the number parameter in the RECOVER statement in the TCF.

status An integer variable whose value is set by TAF to indicate the status of the request. The values are:

0 No errors.
19 The index is outside of the user recovery area.
20 No message (RGET only).
21 The message does not fit in the recovery file message area (RPUT only).
22 The message does not fit in the user message area (RGET only).
23 Incorrect application character type (act).
28 The RGET act is not equal to the RPUT act.
29 TAF automatic recovery is not installed.

message-length An integer variable indicating the length of message in the message units specified by the act parameter. This is an input parameter for RPUT. For RGET, the user sets the message-length of the area to receive the message. Upon completion of the request, TAF returns the message-length as recorded on the communication recovery file.

act An integer variable indicating the application character type. The type is the same as for NAM. This is an input parameter. The values are:

2 7-bit ASCII characters, seven and one-half per word.
3 7-bit ASCII characters, right-justified in 12-bit bytes, five per word.
4 6-bit display code characters, 10 per word. This is the default value.

RSecure Request

The RSecure request allows a recovery task to obtain a message previously saved on the communication recovery file by a Secure request. After obtaining the message, the task would normally send the message to the appropriate terminal. Any task may use this request if automatic recovery has been installed with TAF.

The format is:

COBOL

ENTER "RSECURE" USING message,status, message-length, act, format-effector, transparent-mode.

message An O1-level data item that contains the message. This is an output parameter.

status A computational1 data item whose value is set by TAF to indicate the status of the request. The values are:

0 No errors.
20 No message.
22 The message does not fit in the user message area.
29 Recovery is not installed.
act A computational-I data item indicating the application character type. The type is the same as for NAM. Before issuing the request, the user sets the act. Upon completion of the request, TAF returns the act as recorded on the recovery file. The values are:

2 7-bit ASCII characters, seven and one-half per word.

3 7-bit ASCII characters, right-justified in 12-bit bytes, five per word.

4 6-bit display code characters, 10 per word. This is the default value.

format-effector A computational-I data item indicating format effector usage. The values are:

0 Format effectors appear in the message.

1 No format effectors appear in the message.

transparent-mode A computational-I data item indicating transparent mode usage. Default is nontransparent mode. The values are:

0 Nontransparent data. Interactive virtual terminal transforms are used.

1 Transparent data. IVT transforms are inhibited.

message-length An integer variable indicating the length of the message in message units specified by the act parameter. Before issuing the request, the user sets the message-length area in the task. Upon completion of the request, TAF returns the message length as recorded on the communication recovery file.

status An integer variable whose value is set by TAF to indicate the status of the request. The values are:

0 No errors.

20 No message.

22 The message does not fit in the user message area.

29 Recovery is not installed.

FORTRAN

CALL RSECURE(message,status,message-length,act,format-effector,transparent-mode)

message The name of an array that contains the message. This is an output parameter.

status An integer variable whose value is set by TAF to indicate the status of the request. The values are:

0 No errors.

20 No message.

22 The message does not fit in the user message area.

29 Recovery is not installed.

SECURE Request

The SECURE request tells the transaction executive that the work of the run unit is complete. All that remains is to commit the data base and end the run unit. The SECURE request includes a terminal confirmation message. This message will be sent at the run unit end time (normal CEASE). If the commit request fails, the task may RERUN the run unit or issue a CEASE request with abnormal termination. In either case, the SECURE message will not be sent.
TAF records the message associated with SECURE on permanent storage so that the message can be delivered in spite of system or terminal failures. If no failures occur, the message will be sent from the task's SECURE message area. This means that the SECURE, data base commit, and CEASE must occur in the same task. TAF assumes that the message has been acknowledged by the terminal operator when the operator enters the next transaction input. The SECURE message may appear twice if recovery is done after a failure, but it is guaranteed to appear at least once. TAF also saves the NAM application block header with the message so that it will be sent with the correct character type and mode. Only the last SECURE message is saved per run unit. Any task may use this request if recovery has been installed with TAF; however, if the run unit is not recoverable, the SECURE message will not be issued to the terminal upon recovery (only at initial CEASE time).

For a BTRAN run unit the message is recorded on the communication recovery file but no message is sent to the terminal/username. The RECOVER statement maximumsize parameter specifies the message size that can be recorded on the communication recovery file.

The format of the message on the terminal depends on the terminal class and the format effectors in the message. Refer to the SEND request description earlier in this section for more information.

The format is:

### COBOL

enenter "SECURE" USING message,status,message-length,act,format-effector,transparent-mode.

- message: A 01-level data item that contains the message. This is an input parameter.
- status: A computational-l data item whose value is set by TAF to indicate the status of the request. The values are:
  - 0: No errors.
  - 21: The message is too large to fit in TAF's communication recovery file. Refer to the RECOVER statement maximumsize parameter.
  - 23: Incorrect application character type.
  - 24: Incorrect format-effector value.
  - 25: Incorrect transparent-mode value.
  - 26: The message exceeds the maximum length for SEND.
  - 27: The message exceeds the maximum length for a run unit.
  - 29: TAF automatic recovery is not installed.
- act: A computational-l data item indicating the application character type. The type is the same as for NAM. This is an input parameter. The values are:
  - 2: 7-bit ASCII characters, seven and one-half per word.
  - 3: 7-bit ASCII characters, right-justified in 12-bit bytes, five per word.
  - 4: 6-bit display code characters, 10 per word. This is the default value.
- format-effector: A computational-l data item indicating format effector usage. This is an optional parameter. It is necessary only if format effectors are used. The default is no format effectors. The values are:
  - 0: Format effectors appear in the message.
  - 1: No format effectors appear in the message.
- transparent-mode: A computational-l data item indicating transparent mode usage. This is an optional parameter. It is necessary only if transparent mode is used. The default is nontransparent mode. The values are:
  - 0: Nontransparent data. Interactive virtual terminal transforms are used.
  - 1: Transparent data. IVT transforms are inhibited.

### FORTRAN

```
call secure (message,status,message-length [,act,format-effector,transparent-mode])
```

- message: The name of an array that contains the message. This is an input parameter.
status
An integer variable whose value is set by TAF to indicate the status of the request. The values are:

0  No errors.
21 The message is too large to fit in the communication recovery file. Refer to the RECOVER statement maximumsize parameter.
23 Incorrect application character type.
24 Incorrect format effect-or value.
25 Incorrect transparent-mode value.
26 The message exceeds the maximum length for SEND.
27 The message exceeds the maximum length for a run unit.
29 TAF automatic recovery is not installed.

TSTAT Request
The TSTAT request returns information about the current user or run unit. It is used by both system tasks and applications (user) tasks.

The format is:

```
ENTER "TSTAT" USING status,keyword1,value1,..., keywordn,value_n.
```

status
A computational-l data item whose value is set by TAF to indicate the status of the request. The values are:

0  No errors.
12 The keywords specified require TAF automatic recovery. TAF automatic recovery is not installed.
13 End of NEXT processing.
14 USER is not defined in the network file.
400+i keyword_i is invalid.

keyword_i
An 01-level item that contains a one- to seven-character keyword for which a value is desired. The keyword must be left-justified and blank-filled. Refer to table 2-7 for keyword definitions.

value_i
A data item to which TAF returns the value for the corresponding keyword. The keyword_i and value_i fields must appear in pairs. For USER, NEXT, OLDID, and NEWID usage is display. For all other TSTAT keywords, usage is computational-l.
CALL TSTAT(status,keyword1,value1,...,keywordN,valueN)

status An integer variable whose value is set by TAF to indicate the status of the request. The values are:

0 No errors.
12 The keyword specified requires TAF automatic recovery. TAF automatic recovery is not installed.
13 End of NEXT processing.
14 USER is not defined in the network file.
400+1 keyword is invalid.

keywordi A variable that contains a one-to seven-character left-justified keyword for which a value is desired. The keyword must be blank-filled. Refer to table 2-7 for keyword definitions.

valuei A variable field to which TAF returns the value of the desired keyword. The keywordi and valuei must appear in pairs. For USER, NEXT, OLDID, and NEWID, valuei is character data. For all other TSTAT keywords, valuei is an integer.

Some TSTAT keywords (both as COBOL and FORTRAN parameters) are meant for user tasks and others are meant for system tasks, such as BTASK, CTASK, and RTASK.

**TSTAT User Task Keywords**

- Keywords RESTART, OLDID, and NEWID are meant for use by application tasks that use multiple data manager begin-commit sequences to determine if the run unit is in a restarted state and, if so, where to begin processing.

- Keywords STEP, TRAN, OLDIN, NEWID, CRM, and CDCS are used by RTASK during terminal login/relogin to determine if a run unit requires rerun. The SEQ (sequence number) returned is the transaction sequence number that was first assigned to the run unit. RTASK can be either a system task or a user task.

**TSTAT System Task Keywords**

- Keywords NEXT, STEP, TRAN, OLDID, NEWID are used by BTASK to read sequentially the communication recovery file to find batch (BTRAN) run units that require rerunning. BTASK uses the SRERUN request with username to rerun BTRAN run units.

**SYSTEM TASK RECOVERY REQUESTS**

Applications programmers can skip this subsection since all the requests documented here are available only to system tasks (that is, tasks residing on the system task library). Recovery requests that are for use by both system tasks and application tasks are documented under Application Recovery Requests earlier in this section. Refer to section 8 for an overview of the recovery process from the data administrator’s perspective. Refer to the applicable data manager reference manual (CDCS, TAF/CRM, or TOTAL) for requests associated with data base recovery. The following task requests are used by system tasks for transaction recovery.

- CALLTRN
  Initiates a run unit.

- SRERUN
  Resubmits initial terminal input for a rerunnable run unit.

- TINVOK
  Returns or specifies a system identifier for begin-commit sequences in this job.

- WSTAT
  Records information needed for recovery processing.

**CALLTRN Request**

The CALLTRN request causes the initiation of a run unit. It is available only to the system task ITASK. The actions that occur as a result of CALLTRN are:

1. ITASK ceases. If an error condition is detected, an error message is issued to the terminal via MSABT.

2. The initial terminal input is logged on the CRF if the transaction is recoverable. The transaction will not be scheduled for execution until this circular input-output (CIO) operation is complete.

3. If the transaction initiated is recoverable, the commitment history of the previous recoverable run unit for this user is released.
Table 2-7. TSTAT Keyword Descriptions

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Value</th>
<th>Description</th>

<td>NEWID</td>
<td></td>
<td>Return the new (current) CRM begin-commit id from the communication recovery file.</td>
</tr>
</tbody>
</table>
**SRERUN Request**

The SRERUN request causes the initial terminal input for a rerunnable run unit to be resubmitted to the transaction subsystem. The input is retrieved from the communication recovery file. The actions that occur as result of SRERUN are:

- The recovery status is set to zero so that the recovery task will not be scheduled.
- The restart status (TSTAT with keyword RESTART) is set to one.
- The SRERUN is done without requesting run unit termination.

The format is:

**COBOL**

```cobol
ENTER SRERUN USING status[,username].
```

**FORTRAN**

```fortran
CALL SRERUN(status[,username])
```

**status**

A computational-l data item in which TAF will return a status. The values are:

- 0 No errors.
- 29 Recovery not installed.
- 31 username not in network file.
- 33 Run unit is not rerunnable.

**username**

A variable containing a one- to seven-character user name, left-justified and blank-filled. If this parameter is omitted, the rerun applies to the originating user.

**TINVOKE Request**

The TINVOKE request returns a system identifier to be used for all begin-commit sequences in the job or task. For TAF, this system identifier is the transaction sequence number. Optionally, for the recovery case, the job or task may supply an old system identifier. This establishes the task or job as a continuation of a previous task or job.

The format is:

**COBOL**

```cobol
ENTER TINVOKE USING status,new-system-id,old-system-id.
```

**FORTRAN**

```fortran
CALL TINVOKE(status,new-system-id,old-system-id)
```

**status**

An integer variable in which TAF will return a status. The values are:

- 0 Request successful.
- 32 old-system-id unknown.

**new-system-id**

A computational-l data item in which TAF will return a system identifier to be used for all begin-commit sequences in the job or task.

**old-system-id**

A computational-l data item in which the task or job supplies the old system identifier that establishes the task or job as a continuation of the old one.
WSTAT Request

The WSTAT request records information needed for recovery processing on the communication recovery file or TAF system tables. WSTAT is used by system task CTASK.

The format is:

**COBOL**

Enter "WSTAT" using status, keyword1, value1, ..., keywordn, value n.

**status**
An computational-1 item whose value is set by TAF to indicate the status of the request. The values are:

- 0 No errors.
- 29 Keyword specified requires TAF automatic recovery. TAF automatic recovery is not installed.
- 30 End of NEXT processing.
- 31 USER is not defined in the network file.
- 400+i keyword1 is invalid.

**keyword1**
An 01-level item containing a one- to seven-character keyword for which a value is specified. The keyword must be left-justified and blank-filled. Refer to table 2-8 for keyword definitions.

**value1**
A computational-1 item that contains the value for the desired keyword. The keyword1 and value1 fields must appear in pairs.

**FORTRAN**

Call WSTAT(status, keyword1, value1, ..., keywordn, value n).

- **status** An integer whose value is set by TAF to give the status of the request. The values are:
  - 0 No errors.
  - 29 Keyword specified requires TAF automatic recovery. TAF automatic recovery is not installed.
  - 30 End of NEXT processing.
  - 31 USER is not defined in the network file.
  - 400+i keyword1 is invalid.

- **keyword1** A variable containing a one- to seven-character keyword for which a value is specified. The keyword must be left-justified and blank-filled. Refer to table 2-8 for keyword definitions.

- **value1** An integer that contains the value of the preceding keyword. The keyword1 and value1 must appear in pairs.

The WSTAT keywords (both for COBOL and FORTRAN parameters) are given in table 2-8. All keywords necessary for recovery processing for a user name must be specified in the WSTAT request. For instance, CTASK makes a TSTAT request specifying NEXT, SEQ, STEP, TRAN, CRM, and CDCS followed by a WSTAT with SEQ, TRAN, CRM, CDCS, OLDID, NEWID, USER, and STEP. Any keyword not specified retains the value associated with it on the previous WSTAT request.
<table>

</tbody>
</table>
The CYBER Database Control System can be used alone or with one other data manager (CRM or TOTAL) in the same transaction. If a task is to use CDCS, the CDCS reference manuals listed in the preface should be consulted for information on how to set up the data base (schema, subschema, master directory, and files). This data base is associated with CDCS and the files will be at the control point of CDCS during execution. Tasks can use the CDCS verbs for data base access provided that they are compiled with the appropriate subschema relating them to a CDCS data base.

In the following, xx represents the two-character data base identifier.

A TAF application (known by the xx identifier in the TCF) is linked to a CDCS data base by means of the subschemas used in the tasks associated with the application (these are the tasks on xxTASKL). All tasks in a transaction must use the same subschema or a fatal task error (detected by CDCS) will occur.

A transaction will be considered to be connected to CDCS if it has successfully issued a request to CDCS and the terminate request to CDCS has not been completed. (A CDCS terminate request from other than the last task in a chain will be ignored.) If the last task in the chain does not issue a CDCS terminate request, one will be issued automatically when the last task completes.

A task will abort if it attempts to use CDCS when CDCS is not present in the system or if CDCS aborts while a transaction is connected to it. If a task aborts while it is connected to CDCS, TAF will issue an abnormal termination notice to CDCS for the task (unless the abort originated with CDCS).

Refer to sections 7 and 8 for information regarding recoverable transactions and CDCS/transaction aborts.

The following TAF files are associated with an application using CDCS:

- **TCF** | Required.
- **xxJ**
- **xxTASKL** | Required unless all tasks are on system task library.
- **xxJOR1**
- **xxJOR2** | Optional.
- **xxJOR3**

The possibility of a deadlock involving CDCS and another data manager (TOTAL or CRM) exists. For instance, if task X locks some resources under one data manager and then tries to lock other resources under another data manager that task Y initially locked, then the two tasks may be deadlocked if task Y tries to lock any of the resources locked by task X. It is the responsibility of the installation, applications programmers, and the data administrator to prevent these situations from occurring. Such deadlocks can be prevented by locking resources in a specified order only, for example, lock in data manager A resources first, then data manager B resources, and so forth.

RESTRICT clauses cause tasks to automatically request additional central memory. All of the advice and requirements relevant to a task requesting that its FL be increased apply when RESTRICT clause processing is used (refer to Memory Requests, section 2).
This section is intended for the data administrator and can be omitted by the applications programmer.

This section discusses four topics: the xxJ file, journal files, the TAF configuration file, and the communication recovery file.

An xxJ file is associated with each data base and has the following functions:

- Defines the user's user name, password, and optional user index.
- Defines optional journal files.
- Defines optional device residence for the task library and some files specific to the individual data managers (refer to the xxJ file descriptions that follow).

Up to three journal files can be specified optionally to supplement the system journalizing. A task can write to one of the journal files by using the JOURNAL request.

TCF, the TAF configuration file, defines the data bases associated with a data manager, defines the network files and communication recovery files to be used, and may contain K display commands.

A procedure file (TAFxxx) is used to initialize TAF. Commands may be added to it for recovery or to establish the operating environment. For example, commands that attach journal files (xxJORn) and data base files can be included in this file. Refer to the NOS 2 Installation Handbook for more information (refer to the preface for the publication number).

**xxJ File**

An indirect access permanent file, xxJ, where xx is the data base name, is required for each data base. If additional journal files are needed, they are defined in the xxJ file. The xxJ file is saved under the transaction subsystem user name. The file is in job command format and varies depending on the data manager used.

**NOTE**

The transaction subsystem user name should be under the control of a data administrator. The applications programmer should not have access to this name.

**CRM DATA MANAGER xxJ FILE**

If data base recovery is to be used, the user specified on the USER statement must be able to read the xxJ file. This can be done by granting read permission to that user or by making the file public.

The structure of the xxJ file (when using the CRM Data Manager) is shown as follows.

- Required.
- Optional.

### xxJ

```plaintext
USER(username,password,familyname)
BRF,number
xxJOR1,deviceType,FileType
xxJOR2,deviceType,FileType
xxJOR3,deviceType,FileType
xxTASKL,PN=packname,device
```

### CRM(xxpn,type,mode,users,locks,ml,hash,rec,fwi,packname,device)

### IXN(xxpn,naky,packname,device)

### AKY(akn,ako,akl)

### RMKDEF(xxpn1,rkw,rkp,kl,0,kf,ks,kc,nl,le,ch)

### CRM(xxpn,type,mode,users,locks,ml,hash,rec,fwi,packname,device)

### IXN(xxpn,naky,packname,device)

### AKY(akn,ako,akl)

### RMKDEF(xxpn1,rkw,rkp,kl,0,kf,ks,kc,nl,le,ch)

### CRM(xxpn,type,mode,users,locks,ml,hash,rec,fwi,packname,device)

### IXN(xxpn,naky,packname,device)

### AKY(akn,ako,akl)

### RMKDEF(xxpn1,rkw,rkp,kl,0,kf,ks,kc,nl,le,ch)
The IXN and AKY statements are necessary only for multiple indexed files. The IXN statement describes the index file; the AKY statement describes an alternate key. There is one AKY statement per alternate key. The RMKDEF statement is necessary if the file has multiple indexes and is recoverable. The RMKDEF statement in the xxJ file must be identical to the RMKDEF statement used in the initial MIPGEN creation of the data base file. There must be one RMKDEF statement for each alternate key in the xxJ file. More information on RMKDEF can be found in the CRM AAM 2 Reference Manual.

The parameters for the xxJ file are:

- **xx**: Data base name.
- **password**: Batch password.
- **number**: Number of before image recovery files for this data base.
- **devicetype**: Device type:
  - MS: Mass storage.
  - MT: Seven-track tape.
  - NT: Nine-track tape.
- **filetype**: File type (refer to figure 4-1):
  - B: Buffered write.
  - R: Nonbuffered write.
- **packname**: Pack name of the auxiliary device on which the user’s task library or data base files reside. This parameter is optional on the CRM statement.
- **device**: Type of device on which the user’s task library or data base files reside. For example, DI (for an 844) or DI3 (for a multunit 844 consisting of three devices). This parameter is optional on the CRM statement.
- **xxpfn1**: Two- to seven-character file name. **xx** is the data base name, **pfn1** is the remaining zero to five characters in the data base file name.
- **type**: CRM file type:
  - AK: Actual key.
  - DA: Direct access.
  - IS: Indexed sequential.
- **mode**: Attach mode of file **xxpfn1**:
  - M: Modify, append, or read.
  - R: Read.
  - RM: Read, with another user concurrently attaching the file in mode M.
  - W: Write, modify, append, or read.

The mode parameter controls access to the file to ensure that either TAF or a batch job can write on or modify the file at a given time. However, TAF and a batch job can read the file simultaneously. Refer to the ATTACH command in the NOS 2 Reference Set, Volume 3, for access modes granted for different combinations of multiple access.

If the TAF procedure file attaches a file that is described on a CRM statement, the mode specified in the TAF procedure file overrides the mode parameter in the xxJ file.

**NOTE**

Users Number of transactions allowed to open file **xxpfn1** concurrently. When TAF terminates, the TAF dayfile contains a message that gives the number of OPEN requests not granted because the value of the users parameter was exceeded. Each user uses 38 words plus the **pkl** parameter size (in words).

Locked Number of records the transaction can lock for file **xxpfn1**. When TAF terminates, the TAF dayfile contains a message that gives the number of locks not granted because the value of the locks parameter was exceeded. Each lock uses two words plus the **pkl** parameter size (in words).

![Figure 4-1. Journal File (Buffered and Nonbuffered Structure)](image-url)
Number specifying the maximum record length (in characters) for file xxpfxn.

Number specifying the length in characters of the primary key for file xxpfxn.

One- to seven-character indirect access file that contains the binary code of the hashing routine for file xxpfxn. This indirect access file must be stored under the username parameter on the USER statement. The entry point for the hashing routine must be this file name (hash). If this parameter is omitted, CRM uses the hashing routine supplied with CRM. This parameter applies only for CRM direct access files.

File recoverability.

This file is recoverable.

This file is not recoverable. When rec is not specified, N is assumed.

NOTE

Adding recoverable files to the data base that has a record or key length larger than any previously specified recoverable file causes recovery file validation errors during TAF initialization. Before image recovery files need to be recreated and after image recovery files need to be dumped to tape (via DMREC) and recreated. To ensure full data base recoverability, recoverable files should only be added to the data base following a normal termination of TAF.

Forced write indicator. When the forced write indicator is OFF, the modified data file buffers are written to disk when space is needed. When the forced write indicator is ON, all data file buffers that are modified in core are written to disk immediately. If fwi is not specified, the forced write indicator is set to OFF.

Sets forced write ON for this file.

Sets forced write OFF for this file.

Permanent file name of the index file; must begin with the two-letter application identifier xx.

Number of alternate keys in the index file.

Alternate key number. Alternate key description statements for one data base file must be ordered in a continuous sequence by alternate key number. For a detected key, this is the only parameter present in the statement.

Alternate key offset. The position in the record of the first character of the alternate key. This corresponds to the key offset parameter used on data manager requests accessing the record by this key. The first position in the record is character position number one (not zero).

Length of alternate key in characters.

Relative word in the record in which the alternate key begins, counting from 0; required.

Relative beginning character position within the relative key word (rkw), counting from 0; required.

Number of characters in the key, 1 to 255; required.

Required to mark position for the reserved field.

Key format; required.

Substructure for each primary key list in the index; optional.

Unique (default).

Indexed sequential; recommended for efficiency in processing.

First-in, first-out.

Length in characters of the repeating group in which the key resides.

Number of occurrences of the repeating group; zero for T-type records, and a number for a repeating group embedded within the record.

The user can specify octal numbers and decimal numbers by using a postradix of B or D, respectively. Decimal is the default.
Null suppression: a null value is all spaces (symbolic key) or all zeros (integer key):

- O Null values are indexed (default).
- N Null values are not indexed.

Include/exclude sparse control character:

- I Include alternate key value if the record contains a sparse control character.
- E Exclude alternate key value if the record contains a sparse control character.

Characters that qualify as sparse control characters; up to 36 letters and digits can be specified as a character string.

**TOTAL DATA MANAGER xxJ FILE**

The following shows the structure of the xxJ file when using the TOTAL Data Manager.

```
xxJ
USER(username,password,familyname)†
UI=n.
xxJOR1,devicetype,filetype.
xxJOR2,devicetype,filetype.
xxJOR3,devicetype,filetype.
xxTASKL,PN=packname,R=device.
NL.
LG,PN=packname,R=device.

aaa,PN=packname,R=device
.
zzz,PN=packname,R=device
```

Either the NL statement or the LG statement must be selected. PN and R parameters are optional. NL causes TOTAL to not log recovery data. LG causes TOTAL to log recovery data.

The parameters for the xxJ file are:

- **xx** Data base name.
- **password** Batch password.

**CDCS OR NO DATA MANAGER xxJ FILE**

If an application uses CDCS and one of the other data managers (CRM or TOTAL), then the xxJ file should be structured as specified for the other data manager.

If an application accesses only the CDCS Data Manager or no data manager, the structure of the xxJ file is as follows:

```
xxJ
USER(username,password,familyname)†
xxJOR1,devicetype,filetype.
xxJOR2,devicetype,filetype.
xxJOR3,devicetype,filetype.
xxTASKL,PN=packname,R=device
```

The parameters are:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>xx</strong></td>
<td>Application (data base) name.</td>
</tr>
<tr>
<td><strong>password</strong></td>
<td>Batch password.</td>
</tr>
<tr>
<td><strong>devicetype</strong></td>
<td>Device type:</td>
</tr>
<tr>
<td></td>
<td>MS Mass storage.</td>
</tr>
<tr>
<td></td>
<td>MT Seven-track tape.</td>
</tr>
<tr>
<td></td>
<td>NT Nine-track tape.</td>
</tr>
</tbody>
</table>

†TAF locates the data base using the familyname parameter in the procedure file that initializes TAF and the username and password parameters in the xxJ file. The username, password, and familyname parameters are used for validation.
<table>
<thead>
<tr>
<th>filetype</th>

<th>Pack name of the auxiliary device on which the user's task library resides.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>device</th>
<th>Type of device on which the user's task library resides.</th>
</tr>
</thead>
</table>

**CREATING AN xxJ FILE**

To enter an xxJ file, the data administrator can run a batch job to create and save the file under the transaction subsystem user name. This can also be done at a terminal through IAF. (Refer to the NOS 2 Reference Set, Volume 1, for IAF operating instructions.)
JOURNAL FILES

The two types of journal files are system and data base files.

SYSTEM JOURNAL FILE

The system journal file (a direct access file named JOURO that may be defined under the transaction sub-system user name or may be set up by the TAFxxxx procedure file at initialization) is not associated with any particular data base. All transaction data (input from terminals), errors, and transaction completion notification is automatically recorded on JOURO. The terminal status table is also journalized periodically. Data sent to terminals by tasks is not recorded on JOURO. JOURO will be created at initialization if not already present under the transaction facility user name.

DATA BASE JOURNAL FILES

The transaction subsystem allows up to three user-specified direct access journal files for each data base. The allowable names are xxJOR1, xxJOR2, and xxJOR3, where xx is the data base name. At initialization, TAF checks the xxJ files associated with all active applications to determine which xxJORnn files are needed. It will then attach any specified xxJORnn files not already at the control point and attempt to define any which it cannot find. The transaction sub-system user name must have write permission on these files. When a task makes a journal request (refer to JOURNAL request in this section), the data base for which the originating terminal is validated is used to determine the journal file on which to write. If the task is associated with a terminal validated for all data bases, the data base specified on the last data base request is used to determine the proper journal file.

JOURNAL FILE ENTRY HEADER

Each journal file entry (refer to JOURNAL request) has a header in the format shown in figure 4-2.

JOURNAL REQUEST

The JOURNAL request allows file entries to be made to supplement automatic journalizing.

The format is:

FORTRAN

CALL JOURNAL(jnum,message,length)

jnum Integer whose value indicates the number of the journal file to which the entries are to be made.

message Name of the 01-level data item containing the message to be journalized.

length Integer whose value specifies the length of the message in characters.

COBOL

ENTER JOURNAL USING jnum message.

jnum Computational-l item whose value indicates the number of the journal file to which the entries are to be made. The value of this parameter must be right-justified and zero-filled.

If a journal file is defined on magnetic tape and an end-of-reel is detected, the transaction executive unloads the tape and checks for another tape on which to write. If the operator has not preassigned a unit, the journal file is placed on mass storage. If the operator enters the K.ASSIGN command, the transaction executive copies the mass storage journal file to the tape and places all subsequent entries on the tape. If the mass storage file does not fit on the tape, the message *UNABLE TO USE TAPE* is issued.
sequence: Transaction sequence indicator.
origin: Origin indicator (octal):
0  Task origin (JOURNL request).
1  Transaction subsystem origin (input).
2  Data manager origin.
3  Transaction subsystem recovery/statistical data.
4  End-of-transaction indicator.
5  Incomplete block of terminal input data.
6  Terminal input for an interactive task.
7  Illegal intercontrol point transfer.
10 On-line LIBTASK update (TT option).
11 CDCS detected error (words following header contain error message).
12 MSG request with zero function code. Normal FORTRAN messages are logged with this function code.
length: Length of entry (equals header plus data block).
task name: Name of task if task origin requested.
hour, minute, second: Packed time (hour, minute, second).
username: User name associated with transaction, if task origin.

Figure 4-2. Journal File Entry Header

jnum: Journal file number, right-justified with binary zero fill:
0  JOURO (right-justified with binary zero fill: makes journal entries).
1 to 3  Data base journal file (xxJOR1, xxJOR2, or xxJOR3).
umwords: Length of message in words.
message: Address of message to be journalized.

Figure 4-3. JOURNL Parameter Table
TAF CONFIGURATION FILE

The TAF configuration file is a required indirect access permanent file saved under the transaction facility user name. This file is used during TAF initialization and recovery. If it is not local when the TAFREC command is reached, TAFREC will attempt to get it from TAF's user index. The TCF has the following format:

```
USER,UN,FM.
DMS,datamanager,switch,xx1,xx2,...,xxn.
NETWORK,ID=1,FM=family,
UN=username.
RECOVER,ID=i,MS=maximumsize,
NM=number.
TABCOM,n
DISPLAY,status.
K.command1=value1.
..K.commandn=valuen
```

At least one of each required.

Required or not allowed (refer to statement description).

Required for batch concurrency. Refer to the TAF/CRM Data Manager Reference Manual.

Optional.

A separate DMS statement for CDCS (OTHER) is not necessary if CDCS is to be used in conjunction with another data manager.

The TCF file must contain at least one DMS statement and each DMS statement with status set to ON must have at least one data base identifier or TAF will abort.

The maximum number of data bases that may be associated with one data manager is specified by the installation parameter MAXDB. This value is 25 unless it is altered by the user's site.

The maximum length of each DMS statement is 160 6-bit display code characters.

DMS STATEMENT

DMS statements on the TCF are used to specify the data managers to be loaded by TAF and the applications (data bases) to be associated with each data manager.

The format is:

```
DMS,datamanager,switch,xx1,xx2,...,xxn.
```

data manager Name of the data manager. Must be CRM, TOTAL, or OTHER. The same data manager can be specified on any number of DMS statements. Use the datamanager value OTHER for specifying an application that is either not associated with a data manager or is associated only with the CDCS Data Manager.

switch Data manager status. Must be ON or OFF.

ON The specified data manager (TOTAL or CRM) will be loaded. The data bases specified on the same statement are to be made available for TAF processing. These data bases are referred to as active.

OFF Data bases specified on the same statement are not made available for TAF processing.

```
xx1 Data base identifier. Must not be duplicated on the same or any other active DMS statement. For the CRM Data Manager, it is the two-letter data base name. For the TOTAL Data Manager, this parameter has the format:
```

```
xx2 Data base identifier. Must not be duplicated on the same or any other active DMS statement. For the CRM Data Manager, it is the two-letter data base name. For the TOTAL Data Manager, this parameter has the format:
```

```
```

which is the data base name (the DBMOD file name) specified in the DATA-BASE-NAME statement of the DRDLT statements. xx is the unique TAF data base name and yyyy is any combination of four alphanumeric characters.

DISPLAY STATEMENT

The DISPLAY statement on the TCF controls whether or not the TAF K display will appear at the console during initialization and recovery. However, an error in a K display command causes TAFREC to issue an error message and bring up the K display for corrections regardless of the DISPLAY statement. The format is:

```
DISPLAY,status.
```

status A variable having one of the following values.

ON K display will appear at the console during initialization and recovery to enable the operator to make changes at those times.

OFF K display will not appear at the console during initialization and recovery.

Ref to the TOTAL - CDC 2 Reference Manual for a detailed description.
NETWORK STATEMENT

The NETWORK statements on the TCF declare the network files (NCTFi) TAF uses to determine the users allowed to access TAF. There must be at least one and a maximum of eight NETWORK statements. The format is:

```
NETWORK,ID=i,FM= paramName,UN=username.
```

- **i**: An integer specifying a unique network file identifier. The range is zero to seven. This identifier is used in constructing the name of the network file (NCTFi).
- **ParamName**: The family name under which the network file exists. If the family name parameter is not specified, the default family name is used.
- **username**: The user name under which the network file exists. If the username parameter is not specified, the TAF user name is used.

RECOVER STATEMENT

The RECOVER statement on the TCF declares the set of files TAF is to use when in recovery mode. This directive is required if TAF is assembled with recovery, but it is not allowed if TAF is assembled without recovery.

The format is:

```
RECOVER,ID=i,MS=maximumsize,NN=number.
```

- **i**: An integer specifying a unique recovery file id. The range is zero to seven. This id is the id used in constructing the name of the communication recovery file (ZZCRFi). Only one id may be specified per RECOVER statement. The id must match an id specified in a NETWORK statement.
- **maximumsize**: An integer specifying the maximum size of the message, in words, that TAF will record on the communication recovery file. The default is 57. Maximum is installation parameter MAXWS. This is the maximum message size for the RPUT and SECURE requests.
- **number**: An integer specifying the maximum number of user messages that can be recorded on the communication recovery file via the RPUT request. The default is zero, the maximum is 10.

Each RECOVER statement specifies a recovery id. This id determines the communication recovery file that TAF will use. The name of the corresponding CRF is ZZCRFi. The CRF resides under the same family and user name as the corresponding network file.

K. STATEMENT

Any K display commands that can be issued under the initial K display can appear in the TCF. Values specified in the TCF become the default values in place of the installation defaults (refer to the K display utilities in the NOS 2 Analysis Handbook for the installation default values). If the operator changes any of these values during initialization, those changes remain in effect if TAF is restarted in recovery mode.

If K display commands are used in the TCF, they must appear consecutively.

USER STATEMENT

The USER statement on the TCF specifies the user name under which TAF is to run. This user name should be defined through MODVAL to have the same user index as defined by the installation parameter TRUI. Only one USER statement is allowed in the TCF. The format is as follows:

```
USER,UN,PW,FM.
```

or

```
ACCOUNT,UN,PW,FM.
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>UN</td>
<td>The user name under which TAF is to run.</td>
</tr>
<tr>
<td>PW</td>
<td>The batch password for the user name.</td>
</tr>
<tr>
<td>FM</td>
<td>The family under which TAF is to run.</td>
</tr>
</tbody>
</table>

The USER statement should be the first statement in the TCF.

COMMUNICATION RECOVERY FILE

A communication recovery file is a file TAF uses to maintain recovery information about recoverable transactions. New CRFs are created and existing CRFs are reinitialized at initialization time by using the K.INT command (refer to section 8). There can be up to eight of these files (named CRFO, CRF1,...,CRF7).

Each one corresponds to a network file having the same identifier (NCTFO, NCTFI,...,NCTF7). For every user description statement in a network file, there is a user entry in the corresponding CRF. These entries are added and deleted as follows:

- New user entries are added to a CRF by adding a user description statement to the corresponding network file.
- User entries are removed from a CRF by removing the user description statement from the corresponding network file.
## TRANSACTION FACILITY (TAF) K DISPLAYS

The following commands control operation of the TAF Subsystem. Initiate the TAF Subsystem by using the TAFffff command before issuing these commands.

### INITIATING TAF K DISPLAY

When the transaction executive is brought to a control point, the message REQUEST *K* DISPLAY appears at the control point if a DISPLAY,ON command is specified in the TAF configuration file. Respond with the entry:

```
K,TAF.
```

Any of the following initialization commands can then be entered. If no values are to be changed, enter the command:

```
K.END.
```

Values are decimal unless otherwise indicated.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>K.BFL=n.</td>
<td>Changes the starting and minimum field length allocated by TAF to CRM (200000g ≤ n ≤ 1000000g). Default is 700000.</td>
</tr>
<tr>
<td>K.CMB=n.</td>
<td>Changes the maximum number of communication blocks allowed to the TAF Subsystem (7 ≤ n ≤ 40). Default is 40.</td>
</tr>
<tr>
<td>K.ECS=n.</td>
<td>Sets the extended memory field length to be used by the transaction executive; n is octal thousands of words. Default is 0.</td>
</tr>
<tr>
<td>K.EFL=n.</td>
<td>Changes the maximum additional central memory field length made available to CRM for buffers and capsules (0 ≤ n ≤ 100000). Default is 0.</td>
</tr>
<tr>
<td>K.END.</td>
<td>Ends input of the transaction executive initialization parameters. Initialization is completed when the TAF K display appears.</td>
</tr>
</tbody>
</table>
### Command K.ER0=CRF,op.

**Description**

Specifies whether to override certain I/O and logic errors when processing the communication recovery files (CRF).

<table>
<thead>
<tr>
<th>OP</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NO</td>
<td>Aborts if I/O or logic errors are encountered while processing the communication recovery files. This is the default setting.</td>
</tr>
<tr>
<td>YES</td>
<td>I/O or logic errors encountered on a run unit header record result in the loss of that run unit with no indication to the terminal user. The loss is noted on the recovery report.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>I/O or logic errors encountered on a message record within a run unit result in a loss of that run unit. A status field is set in the run unit header, allowing TAF to inform the terminal user of the run unit loss.</td>
</tr>
<tr>
<td></td>
<td>I/O or logic errors encountered on the CRF header record result in an unconditional abort of the TAF Subsystem.</td>
</tr>
</tbody>
</table>

### Command K.GO.

**Description**

Ends input of the transaction executive initialization parameters. Initialization is complete when the TAF K display appears.

### Command K.INT=typ,fileid.

**Description**

Specifies which communication recovery files (CRF) are to be initialized. This is the only way to initialize a CRF. Files specified on a RECOVER command in the TAF configuration file and specified in this command are initialized. Files specified on a RECOVER command but not specified in this command are used for recovery.

This command also specifies whether CYBER record manager (CRM) data base recovery files are initialized or recovered. For CRM recovery files, this command is valid regardless of TAF assembly parameters.

<table>
<thead>
<tr>

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CRF</td>
<td>Communication recovery files. This parameter is valid only if the installation parameter IPTAR equals 1.</td>
</tr>
<tr>
<td>CRM</td>
<td>CYBER Record Manager after-image and before-image recovery files.</td>
</tr>
</tbody>
</table>
Command fileid Description

n  A digit from 1 to 7 that defines a CRF to be initialized. The digit corresponds to the ID parameter on the RECOVER command in the TAF configuration file. This parameter is not valid for CRM recovery files.

ALL  If typ is CRF, all communication recovery files defined by RECOVER commands in the TAF configuration file are initialized. If typ is CRM, all CRM recovery files are initialized.

NOTE

This parameter must be used with caution when typ is CRM since the CRM update history currently on the after-image recovery files is lost.

NONE  If typ is CRF, communication recovery files are initialized; all communication recovery files specified in RECOVER commands in the TAF configuration file are recovered. If typ is CRM, all CRM data bases are recovered based on information in the existing recovery files. No CRM recovery files are initialized. This fileid is the default for both typ=CRF and typ=CRM.

K.MFL=n. Sets the maximum field length to be used by the transaction executive (40000 ≤ n ≤ 376600). Default is 376600.

K.REC=n. Specifies whether to set the recovery bit in the user area of each terminal status table entry (YES or NO). If YES, the user recovery bit is set. If NO, the value of the user recovery bit is not changed from what it was before the command was issued. Default is NO.

K.SCP=n. Changes the number of subcontrol points (2 ≤ n ≤ 31). Default is 31.

K.STOP. Aborts the TAF Subsystem initialization unconditionally.

K.TFL=n. Changes the value used as the upper bound for TARGET. This is the amount of memory CRM uses for data and index blocks (100000 ≤ n ≤ 1000000). Default is 300000. For more information, refer to the CYBER Record Manager Advanced Access Methods Version 2 Reference Manual.

K.TLF=filename. Changes the name of the system task library file (any valid file name). Default is TASKLIB.
RESTARTING TAF K DISPLAY

On a level 3 recovery deadstart, or if the TAF Subsystem aborts, the TAF procedure file automatically restarts TAF by transferring control to the TAF automatic recovery program. The TAF automatic recovery program recovers the central memory pointers and variables defined during TAF initiation.

If a DISPLAY,ON command is in the TAF configuration file, the automatic recovery program brings up the K display on the left console screen. This display is identical to the initial K display, except that values specified in the TAF initiation replace any default values that were in the initial display.

TAF K DISPLAY

When the TAF Subsystem is executing, the TAF K display indicates the:

- Latest transaction sequence number.
- Number of words of unused memory.
- Maximum field length.
- Global task dump limit.
- Subsystem default values for memory dump parameters.

The TAF K display appears on the system console as shown in figure 8-31.

The subsystem default values are used to control memory dumps when parameters are not included in the CMDUMP or DSDUMP command. Any of these default values can be changed by specifying the corresponding parameter in the K.DSDUMP command.

**TAF K-DISPLAY COMMANDS**

When the transaction executive is at its control point, the following commands can be entered from the system console or submitted from tasks using the KPOINT request. Any task can issue the K.DUMP command. Only tasks that reside on the system task library can issue the other K-display commands. (Refer to the TAF Reference Manual for additional information on the KPOINT request and the system task library.)

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>K.ASSIGN,est.</td>
<td>Assigns a magnetic tape unit to be used for a journal file. est is the EST ordinal of the tape unit. The first form of the command makes unit est available for the transaction executive to assign to the next tape journal file that encounters end of reel. Two tape units may be preassigned. If a tape has not been preassigned in this manner, an end-of-reel on a journal file causes subsequent entries for that file to be placed on disk.</td>
</tr>
<tr>
<td>K.ASSIGN,est,db,n.</td>
<td></td>
</tr>
</tbody>
</table>
**Command**

The second form of the command forces journal file n (n=1, 2, or 3) for database db, defined as a tape file, from disk to tape. The transaction executive copies the data from the disk journal file to tape est and places all subsequent entries for that file on the tape. This command is necessary after the transaction executive initialization to assign tape units to the tape journal files or after an end-of-reel on a tape journal file when no tape had been preassigned to the transaction executive. All data residing on the disk for the tape journal file must fit on the tape assigned by this command or the transaction executive will unload the tape and issue the message "UNABLE TO USE TAPE".

**K.DEBUG.**

Turns on the application interface program (AIP) debug option, which logs all messages on trace file ZZZZZDN. Use this command only when TAF is installed with the DEBUG option.

**K.DROP,n.**

Drops an executing task at subcontrol point n.

**K.DS.DUMP,FW=addr, LW=addr, EP=pkg, OQ=outq, QD=qdest, DB=db.**

Allows you to modify the standard system default parameters controlling memory dumps. The command does not directly cause a dump. Rather, it sets default values to be used when a subsequent CMDUMP request is received or when abort conditions occur. Refer to TAF K Display, earlier in this section, for explanations of the parameters.

**K.DUMP,fwa,lwa.**

Dumps all or part of the field length of the Transaction Facility from the first word address (fwa) to the last word address (lwa) of the area to be dumped. The default value for fwa is 0 and for lwa is 3777777. The default base is octal. If no parameters are specified, the entire field length is dumped. The output is routed to a printer that has an ID of 0.

Unlike other K-display commands, the K.DUMP command can be issued from any task. Other K-display commands can be issued by tasks only if they are on the system task library (refer to the TAF Reference Manual).

Since secure information may be contained in a dump of the Transaction Facility, the following safeguards have been set up to protect dumped information; however, the installation must take the ultimate responsibility for the protection of dumped information.

- The global task dump limit (GTDL) can be set by the K.DUMPLIM command to limit the number of times the K.DUMP command can be issued from tasks. The initial value of the GTDL is 0 (zero), so the K.DUMP command is disabled from use by a task by default.

- For all dumps of the Transaction Facility, whether you initiated it or a task did, a one-page header precedes the dump. This header page indicates the output is secure and should be given only to the TAF central site systems analyst.

- When the Transaction Facility is dumped, the message TAF FIELD LENGTH DUMP RELEASED is issued to the system dayfile, the Transaction Facility dayfile, and line one of the control point.
<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>K.DUMPLIM,n.</td>
<td>Sets GTDL to value n ((0 \leq n \leq 9999999)). If n is not specified, the GTDL is set to 0. The GTDL is the number of times the K.DUMP command can be issued from tasks. This value is displayed on the TAF K display shown in figure 8-31. The initial value of the GTDL is 0. When the GTDL is 0, no dumps of the Transaction Facility can occur from tasks. Thus, the K.DUMP command is disabled from tasks by default. To enable the K.DUMP command for tasks, issue the K.DUMPLIM command to set the GTDL to a value greater than zero. Each time a task issues a K.DUMP command, the GTDL is decreased by one until it equals zero. When the first K.DUMP command is issued from a task with the GTDL equal to zero, the message <strong>GLOBAL TASK DUMP LIMIT EXHAUSTED</strong> is issued to the Transaction Facility dayfile, the system dayfile, and line one of the control point. Also, the message <strong>DUMPS LOST</strong> is displayed on the K display in place of the value of the GTDL. This message remains until the value of GTDL is set to a value greater than or equal to zero. The K.DUMPLIM command should be used with care in system tasks, since this might allow unauthorized users to alter the GTDL.</td>
</tr>
<tr>
<td>K.IDLE.</td>
<td>Idles down the transaction control point. Once idle down has been initiated, no new transactions will be permitted but currently executing transactions will be allowed to finish.</td>
</tr>
<tr>
<td>K.JEND,db,n.</td>
<td>Forces end-of-reel processing (writes an EOI and rewinds the file) on tape journal file n of data base db. If n is not a tape journal file, the command is ignored.</td>
</tr>
<tr>
<td>K.MAXFL,n.</td>
<td>Alters the transaction executive maximum field length. The transaction executive does not attempt to obtain more than n words of storage. This command is rejected if the value for n is more than 3766008 or less than the field length currently required for TAF.</td>
</tr>
<tr>
<td>K.MESSAGE,TN=b.</td>
<td>Directs the transaction executive to send message to a terminal specified by terminal name b.</td>
</tr>
<tr>
<td>K.NODEBUG.</td>
<td>Turns off the application interface program (AIP) debug option, which logs all messages on trace file ZZZZZDN. Use this command only when TAF is installed with the DEBUG option.</td>
</tr>
</tbody>
</table>

TAF/CRM STATUS K DISPLAYS AND COMMANDS

You can use the K display to monitor the status of CRM, CRM databases, or CRM database permanent files while TAF/CRM is running if CRMTASK is present on the system task library. To get the CRM status K display enter:

K.DIS,CRMTASK.

After the K display is assigned to the task, the display in figure 8-32 is brought to the left screen.

---

The following commands are available under CRMTASK.

<table>

For the CRM status and CRM data base status displays, if all the information does not fit on one screen, you can bring up additional pages by entering the following command.

K.+

To return to the first page of the display, enter the following command.

K.-

At any time you can return to the initial CRMTASK K display (figure 8-32) by entering the following command.

K.MENU.

To end CRM status K-display processing, enter the following command.

K.END.
Each user entry in a CRF contains space for initial transaction input, RPUT messages, and a SECURE message. Two important CRF attributes are the number of messages, number, that a recoverable run unit may record on the file and the maximum size of these messages, maximumsize. The values for these parameters are given in the RECOVER statement in the TCF.

To reduce the number of user messages and/or the message size, the CRF must be reinitialized using the K.INT command (refer to section 8).

Under certain circumstances a CRF is reformatted during recovery. Refer to section 8 for details.
The transaction subsystem interfaces with the batch subsystem in three ways. First, batch jobs can initiate tasks by using the BTRAN request. Second, tasks can route jobs to the batch input queue by using the SUBMT request. Third, batch jobs can access TAF/CRM data files using the TAF/CRM batch concurrency feature.

The BTRAN and SUBMT requests are described in this section. The TAF/CRM batch concurrency feature is described in the TAF/CRM Data Manager 1 Reference Manual.

**BTRAN REQUEST**

The BTRAN request enables a batch job to start a transaction. The transaction is passed to the transaction executive through the system control point mechanism; therefore, the user must be validated for system control point communication (AW=CUCP). The user passes a transaction to the transaction executive via the header word shown in figure 5-1.

Multiple logins under one user name are not permitted in TAF. Thus, the user name for a job issuing a BTRAN request must not be in use within TAF by a transaction terminal or another batch job. Any SEND (or DISPLAY) requests in a BTRAN-initiated transaction must explicitly specify a user name different from the one under which the batch job is being run. Unlike a terminal-initiated transaction, BTRAN-initiated transactions are not required to issue any SEND request. A transaction can use the TSTAT request with the TRAN keyword to determine whether it was initiated with BTRAN.

The format is:

**FORTRAN**

The user calls the BTRAN request in two ways. The first method is a FORTRAN function.

i=BTRAN(transaction)

i Integer variable that contains the request status after BTRAN is called. The user must declare BTRAN as an integer.

transaction Name of the array containing the header word for the transaction to be submitted.

The second method is a subroutine call.

CALL BTRAN(transaction,status)

transaction Name of the array containing the header word for the transaction to be submitted.

status Address of the variable that contains the returned status; the status is returned as an integer value.

Decimal status values are shown in table 5-1.

**COMPASS**

BTRAN transaction

transaction Address of the header word for the transaction to be submitted.

The status of the request is returned in register X6.

Decimal status values are shown in table 5-1.

Figure 5-2 demonstrates the use of BTRAN.

In the example shown in figure 5-2, LP3 is the name of the transaction to be processed by TAF. 50 is an item of data to be used by this transaction. STATUS=n goes to the OUTPUT file associated with the batch job. Output from the transaction cannot be sent to the user name under which the job is being run. Output to other user names (terminals) is permitted but not required.

Decimal status values are shown in table 5-1.

<td></td>
<td></td>
</tr>
</tbody>
</table>
**SUBMT REQUEST**

The SUBMT request allows a task to route a job to the local batch input queue. The address parameter in the call points to the area in the task field length that contains the job to be routed in control word format. This format is described in conjunction with the READCW macro in the NOS 2 Reference Set, Volume 4 (refer to the preface for the publication number). Using this format, the job may consist of multiple records.

The format is:

**COBOL**

ENTER SUBMT USING address.

*address* Name of the 01-level item containing the job data to be routed. This data is in the format shown in figure 5-3.

**FORTRAN**

CALL SUBMT(address)

*address* Name of an array containing the job data to be routed. This data is in the format shown in figure 5-3.

The first word at address must be a control word in the format shown previously. The length field must specify the number of 12-bit bytes occupied by the data in the PRU (maximum of 320 bytes, equivalent to 640 characters). The level number in the trailing control word specifies whether the PRU is an end-of-record or end-of-file. If a logical record extends over more than one PRU, the level number for the first PRU of the record must be nonzero and other than 17g.

A leading and a trailing control word must be present for each PRU of data.

Typically, the data would consist of commands which would comprise one record. Additional data to be processed by the batch job could also be present and typically constitute subsequent records.

![Figure 5-3. SUBMT Parameter Table](image-url)
Figure 5-4 shows a task using the SUBMT request.

In the example shown in figure 5-4, the first word of JOB (00390 to 00410) sets bit 42 in the header word and gives the length (75) in 12-bit bytes of the card deck images to follow. This is five times the number of 10-character (60-bit) words in the job being submitted, in this case, statements 00420 to 00590.

Each job command must be from 1 to 80 characters long. All commands to be submitted must be padded to a multiple of 10 characters and the last two characters must be binary zero (character ":" in the 63/64-character set). Thus, if a statement ends in character position 9, 10; 19, 20; and so on, a zero word must be appended. Statements 00460 to 00530 give examples of this.

At job termination, the implicit output files of the SUBMT job are not queued by the system. This is because TAF routes the submitted job using the disposition code DC=NO. To obtain output from the job, do either of the following:

- Include ROUTE commands to place the desired files in the appropriate queues.
- Include the command SETJOB,DC=DF in the submitted job. This directs that implicit output is to be queued at the end of the job.

The example in figure 5-4 uses the first method by including a ROUTE command at line 00580.

Figure 5-4. SUBMT Request
MEMORY DUMPS

A task can perform two types of memory dumps. The first type is a task dump, which is a dump of the task field length, exchange package, and associated data buffers. A task dump aids the applications programmer in debugging a task. The second type is a TAF dump, a dump of all or part of the TAF field length. A TAF dump contains pertinent information that is not contained in a task dump. This section describes the methods used to obtain both types of memory dumps.

TASK DUMP

The central memory dump (CMDUMP) request dumps central memory according to the parameters specified in the direct subsequent dumps (DSDUMP) request. Parameters specified on the DSDUMP request are used under three circumstances:

- When a fatal task error occurs.
- When a default value is requested in a CMDUMP request.
- When a parameter is in error in a CMDUMP request.

The purpose of DSDUMP and CMDUMP is to aid applications programmers in debugging their tasks. These dump requests allow users to dump any portion of their programs. The user specifies the first word address (fwa) and the last word address (lwa) of the area to be dumped. The exchange package may also be dumped by setting the proper parameter(s) to a nonzero value.

The DSDUMP request sets up default values for subsequent CMDUMP requests made by this task and all linked tasks in this transaction (those called by CALLTSK without CEASE). DSDUMP does not cause a dump; it only sets parameter values that can be defaulted as a result of a CMDUMP request.

A hierarchy of parameter values allows users to default any parameters they want on DSDUMP or CMDUMP calls. At system assembly time, default values are assembled for each parameter. These default values can be changed via a K DISPLAY command. In addition, if users want to change any default parameter values for their tasks, they may do so by using DSDUMP requests.

A hierarchy of default values works in the following manner. The CMDUMP request causes a dump according to the parameters it specifies. If a default option is requested, the system determines if a DSDUMP request has been made for this transaction. If a DSDUMP request has been made and if the corresponding parameter value has been supplied, this value is used. If DSDUMP requests have not been specified, a new default value, the system default value for this parameter, is used.

All task dumps, whether due to an aborted task, an abnormal CEASE request, or a CMDUMP request, are handled in the same manner. A job file is created containing the information to be dumped in binary format, as well as a command record. The transaction executive issues a ROUTE request releasing the job file to the input queue for batch processing. A program called KTSMDP is used, either to generate listable output from the binary file, or to transfer it to a direct access permanent file.

When dumping to an output queue, a ROUTE command is included in the command record to direct the output produced by KTSMDP to the proper queue.

A USER command is always included, thus enabling KTSMDP to attach the appropriate file if the dump is destined for a user's file. In this case, KTSMDP appends the binary information to the end of the permanent file. This method of handling dumps relieves the transaction executive of time-consuming processing that is better performed by a utility.

DS DUMP REQUEST

The DSDUMP request allows the applications programmer to change any of the default values of the CMDUMP request. The DSDUMP does not cause a dump in itself, except when the system detects an error (that is, aborts). Any default values on the DSDUMP are satisfied from the general default values. All six parameters are required. If an error occurs on any DSDUMP parameter, the task is aborted.

The format is:

```
COBOL
ENTER DSDUMP USING fwa lwa ep db oq qd.
```

- **fwa** Computational-1 item that specifies beginning address of task memory to be dumped; legal values are 0<fwa<FL (field length).

  If fwa is negative, the default value is used.

- **lwa** Computational-1 item that specifies last word of task memory to be dumped; it must be greater than fwa. If fwa is specified, no dump of task memory occurs. If lwa equals FL, the dump extends to the end of the field length. If lwa is negative, the default value is used.
ep  Computational-l item that specifies exchange package option.
    0  Do not dump exchange package.
    > 0 Dump exchange package.
    < 0 Use default value.

db  Performs no function. Retained for compatibility with previous releases.

oq  Computational-l item that specifies output queue option.
    < 0 Use default value (refer to following note).
    0 Dump to local batch output queue.
    1 Dump to remote batch output queue.
    2 Dump to user permanent file defined under data base user number.

qd  Queue destination option; value depends on oq selection.
    oq                qd
    0  Integer specifying printer id. If negative, use default value (refer to following note).
    1 User number
    2 Direct access permanent with either blank or binary zero file name.

NOTE
If either oq or qd is negative, the default value will be used for both, regardless of the option selected for the other.

FORTRAN
CALL DSDUMP(fwa,lwa,ep,db,oq,qd)

fwa  Octal integer that specifies the beginning address of task memory to be dumped; legal values are zero<fw<FL (field length).
     If fwa is negative, the default value is used.

lwa  Octal integer that specifies the last word of task memory to be dumped; must be greater than fwa.

NOTE
If either oq or qd is negative, the default value will be used for both, regardless of the option selected for the other.

COMPASS
DSDUMP address

address Address of a parameter table. The table has the form shown in figure 6-1.
CMDUMP REQUEST

The CMDUMP request allows the applications programmer to dump memory in the task's field length to a selected output queue (and logical device). The first six parameters are required. If there is an error on or a default of any parameter specified by CMDUMP, the parameter value of the DSDUMP call is used.

The format is:

**COBOL**
ENTER CMDUMP USING fwa lwa ep db oq qd.

The descriptions of the first six parameters are the same as those for the DSDUMP request.

**FORTRAN**
CALL CMDUMP(fwa,lwa, ep, db, oq, qd)

The descriptions of the first six parameters are the same as those for the DSDUMP request.

**COMPASS**
CMDUMP address

address Address of a parameter table in the form shown in figure 6-2.

**NOTE**

The manner in which the hierarchy of default values works was previously described. However, in the special case of output queue and queue destination (oq and qd parameters), if either parameter is defaulted, the next pair of output queue and queue destination parameters is obtained from the next level of the default hierarchy.

There is also a special case concerning errors in a CMDUMP request. If the parameter in error is the output queue value, the system is unable to route the dump as the user wants. If this error is on a CMDUMP request, the system attempts to dump according to the corresponding DSDUMP output queue and queue destination parameters. If that is not possible, the general system values are used.

† Default values are specified by setting the sign bit.

Figure 6-1. DSDUMP Parameter Table

<table>
<thead>
<tr>
<th>a</th>
<th>Set to one for exchange package dump.</th>
</tr>
</thead>
<tbody>
<tr>
<td>c</td>
<td>Set to one for exchange package default value.</td>
</tr>
<tr>
<td>lwa</td>
<td>Last word of task memory to be dumped; must be greater than fwa. If zero is specified, no dump of task memory occurs. If lwa equals FL, the dump extends to the end of the field length. If lwa is negative, the default value is used.</td>
</tr>
<tr>
<td>fwa</td>
<td>Beginning address of task memory to be dumped; legal values are zero through lwa-1.</td>
</tr>
<tr>
<td>qd</td>
<td>If fwa is negative, the default value is used.</td>
</tr>
<tr>
<td>oq</td>
<td>Queue destination option; the value depends on the oq selection as shown following the oq description.</td>
</tr>
</tbody>
</table>

Output queue option:

- 0 Dump to local batch output queue.
- 1 Dump to remote batch output queue.
- 2 Dump to user permanent file defined under data base user name.

Interdependency between oq and qd is defined as follows:

<table>
<thead>
<tr>
<th>oq</th>
<th>qd</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Printer id, specified as binary number, right-justified within word; if negative, use default value.</td>
</tr>
<tr>
<td>1</td>
<td>User name.</td>
</tr>
<tr>
<td>2</td>
<td>Direct access permanent file name.</td>
</tr>
</tbody>
</table>

A valid name specified in display-coded, left-justified characters with either blank or binary zero fill.
The descriptions of the first five parameters are the same as those shown in figure 6-1.

Figure 6-2. CMDUMP Parameter Table

K.DSDUMP COMMAND

The K.DSDUMP command can be used under the K display for the transaction executive control point to reset default dump parameters. The parameters can be given in any order and only those parameters to be changed need to be given.

The format when entered from the console is:

```
K.DSDUMP,FW=fwa,LW=lwa,EP=ep,0G=og,0D=qd.
```

The values of these parameters are as specified for the DSDUMP request made by a task. These system dump parameters can be examined by checking the K display for control points.

KTSDUMP UTILITY

KTSDMP can be called via a command to form listable memory dumps. The input files can be created by the transaction executive or by any other program. The following items can be listed.

- Central memory of a task or program.
- Exchange package and control point area of a task.
- Communication block of a task (always present).

The format is:

```
KTSDMP (lfn1,lfn2,P,O)
```

- `lfn1`: Input file name; if absent, default is INPUT.
- `lfn2`: Output file name; if absent, default is OUTPUT.
- `P`: If P is specified, append file `lfn1` on direct access permanent file `lfn2`. The job must be running with the proper user name and file `lfn2` must be defined. End-of-file is not copied to `lfn2`.
- `O`: If O is specified, the dump is in octal format. If O is omitted, the dump is in octal and 6-bit display code format, with the 6-bit display code format to the right of the octal format.

If the P option is used, an installation may keep a running stack of memory dumps to be listed selectively at some later time. To list all dumps on the permanent dump file, the file should be attached and KTSDMP executed. All dump records on the file are processed. To list only selected dumps, the permanent file should be attached and the selected dump records extracted using the GTR command (refer to the NOS 2 Reference Set, Volume 3). KTSDMP should be executed to process the output file from the GTR command.

The user must specify the 0 option when issuing the KTSDMP command from a terminal; if the 0 option is not specified, execution is terminated, and KTSDMP issues the following message.

```
DISPLAY DUMP NOT ALLOWED TO TERMINAL.
```

TASK DUMP FORMATS

Figure 6-3 contains the formats of the dumps provided. The leftmost date and time in the header are the date and time of creation of the KTSDMP input file. The current date and time follow. The task control point area dump appears only when the exchange package dump is requested. The exchange package dump, task control point area dump, and the communication block dump all appear on the same page when the exchange package dump is requested.

TAF DUMP

A TAF dump is a dump of all or part of the TAF field length. The user initiates a TAF dump using the K.DUMP command. A TAF dump assists the systems analyst in detecting system errors that do not abort TAF. When a task detects an error in TAF, a TAF dump might be needed because there is significant information outside the task field length that is not contained in a task dump.

A task initiates a TAF dump using the KPOINT request (refer to KPOINT Request in section 2) in conjunction with the K.DUMP command. The K.DUMPLIM command sets a global limit on the number of K.DUMP commands that tasks can issue. A task uses the KPOINT request in conjunction with the K.DUMPLIM command to set the global task dump limit (GTDL). The remainder of this section describes the K.DUMP and K.DUMPLIM commands.
K.DUMP COMMAND

The K.DUMP command initiates a dump of all or part of TAF. The user can specify the first word address (fwa) and the last word address (lwa) of the memory to be dumped.

The command formats when issued from a task are:

- `DUMP,fwa,lwa`
- `DUMP,lwa`
- `DUMP`

The octal address of the first word of memory to be dumped; legal values are `0 <= fwa <= lwa`. The default is zero. This parameter cannot be used unless the `lwa` parameter is also used.

The octal address of the last word of memory to be dumped; legal values are `fwa <= lwa <= 377777`. The default is `377777`.

If both parameters are omitted, the entire field length is dumped. The output of the dump is routed to a printer that has an identifier of zero. A header page precedes the dump; it lists the date and time of the dump and the name of the task that issued the dump. Also listed are the instructions that the dump be given to the TAF central site systems analyst.

K.DUMPLIM COMMAND

The K.DUMPLIM command sets the GTDL. The GTDL specifies the number of K.DUMP commands that tasks can issue.

The command format when issued from a task is:

- `DUMPLIM,n`

The decimal number of TAF dumps that tasks can issue. The default is zero. The maximum value is 9999999. The user specifies octal by using a postradix of B.

The initial value for the GTDL is zero. When the GTDL is zero, no TAF dumps from tasks are allowed. The GTDL must be set to a value greater than zero for TAF dumps from tasks to occur. Each TAF dump (where the task does not abort) causes the GTDL to be decreased by one. This command does not affect the execution of task dumps.

Figure 6-3. KTSMP Format
This section describes automatic recovery as it affects task writing. Recovery-related information applicable to the applications programmer is covered. Additional information of interest to the system installation and maintenance personnel can be found in section 8 of this manual.

**PURPOSE**

The purpose of the TAF automatic recovery feature is to enable site personnel to design TAF transactions that can recover quickly and predictably from system failures, and maintain the data base in a consistent state across failures. Terminal operators will be able to determine the status of transactions upon recovery so the possibility of issuing a double update to the data base or of missing a data base update is greatly reduced. The recovery will be automatic in the sense that TAF and the data manager will determine which data base updates to roll back, and which transactions to restart upon initialization after a failure. Site personnel need only select recovery mode when bringing TAF back up.

**CONCEPTS**

There are two basic components to automatic recovery: data base recovery and transaction recovery. Data base recovery ensures that the data base is always in a consistent and known state, even if a failure occurs during a run unit. Transaction recovery automatically reruns recoverable run units that were active at the time of a failure. It also guarantees that the terminal operator will receive a confirmation message when the run unit completes.

**NAMED-TRANSACTIONS AND RUN UNITS**

A transaction is a task or a series of linked tasks. The linking can be internal to the tasks using the CALLTSK and/or CALLRTN requests, or external to the tasks using the LIBTASK /tname directive. Refer to section 10 for a complete description of this directive. Transactions defined using the /tname directive are referred to as named-transactions. In most discussions in this section and throughout this manual, it is not necessary to distinguish between the coding that comprises a transaction and the execution of that code. However, when the distinction is important, the execution of a transaction is referred to as a run unit. The terms executing transaction, running transaction, and run unit can be used interchangeably. A run unit is recoverable only if it is the execution of a named-transaction and the RC parameter was specified when the named-transaction was defined. There are differences in terminology between CDCS and TAF. When it is referred to as a transaction in TAF is always called a run unit in CDCS. The processing bounded by the begin statement (DB$BEG or BEGTRAN) and the commit statement (DB$END or COMMITRAN) is referred to as a transaction in CDCS. Each of these transactions has an id supplied within the application.

**DATA BASE RECOVERY**

Automatic data base recovery is available to transactions using the CDCS and/or the TAF/CRM Data Managers. Data base recovery is based on the concept of a begin-commit sequence. A begin-commit sequence is a portion of a transaction, designated by the programmer, that contains one or more data base updates that are to be treated as a unit. Should a failure occur during a recoverable run unit, data base recovery ensures that the updates within a begin-commit sequence are performed or that none of them are. It also provides a means by which the transaction can determine which begin-commit sequences had successfully completed prior to failure so that on restart, the transaction can avoid performing those updates a second time.

Data base begin-commit sequences are identified in a transaction by placing a data base BEGIN request at the beginning of the sequence and a data base COMMIT request at the end of the sequence. (The BEGIN and COMMIT requests have different forms depending on the data manager and source language being used.) The data base BEGIN request includes a parameter for assigning an identifier to the begin-commit sequence. The identifier (selected by the programmer) is preserved across failures and can be retrieved upon restart to enable the transaction to determine how far processing had gone prior to failure. The data base COMMIT request tells the data manager that the updates are to be made permanent. A failure before a data base COMMIT causes all updates for this sequence to be rolled back. This means that the data base is returned to the state it was in at the time the BEGIN for this sequence was issued. If a failure occurs after a data base COMMIT, all updates for the committed sequence are retained. A transaction can terminate an update sequence without committing the updates by issuing a data base FREE request.

**TRANSACTION RECOVERY**

Transaction recovery restarts recoverable run units that were active at the time of a system or terminal failure. Transaction recovery also uses the concept of a begin-commit sequence. With transaction recovery, the BEGIN is implicit in the initiation of any recoverable run unit. The transaction COMMIT is specified with a SECURE request indicating that the work of the transaction is complete. The SECURE request should immediately precede the last data base commit request in the transaction.

When a recoverable run unit is initiated from a terminal or a batch job (via a BTRAN request), TAF logs the initial input on the communication recovery file. If a failure occurs during the run unit, automatic recovery takes place when TAF is subsequently brought back up. At that time the data base recovery routine is called in to restore the data base to a consistent state.
Then, the transaction recovery routine examines all run units that were active at the time of failure to determine which should be rerun. For run units initiated from a terminal, a flag is set in the terminal status table and the decision is postponed until the terminal logs back in. For run units initiated by BTRAN, the decision and restart, if necessary, are made immediately. This decision process is summarized in the following steps.

1. Is this transaction designated as recoverable?
   - YES
     Go to step 2. Do not rerun.
   - NO
     Go to step 4.

2. Does this transaction use CDCS?
   - YES
     Rerun. Go to step 3.
   - NO
     Go to step 4.

3. Was the transaction SECURE at the time of failure?
   - YES
     Go to step 4.
   - NO
     Rerun.

4. Did an incomplete begin-commit sequence exist at the time of failure?
   - YES
     Rerun.
   - NO
     Send SECURE message. Do not rerun.

CODING STRUCTURES FOR DATA BASE RECOVERY ONLY

Transactions Using CRM

A transaction that uses the CRM Data Manager may be structured as follows. In addition, the recovery parameter must be specified on the XXJ file CRM statement for any file to be updated by this transaction. Although only one begin-commit sequence is shown, actual transactions can contain as many separate (nonnested) begin-commit sequences as desired. Multiple data base updates are permitted within a begin-commit sequence.

- OPEN request(s).
- Record lock request(s).
- DBBEGIN request.
- (data base processing/updating)
- DBCOMIT or DBFREE request.
- CLOSE request.

TAF Transactions Using CDCS

TAF transactions using the CDCS data management system may be structured as follows to take advantage of data base recovery. Although only one begin-commit sequence is shown, actual TAF transactions can contain as many separate (nonnested) begin-commit sequences as desired. Multiple data base updates are permitted within a begin-commit sequence.

In all the CDCS outlines in this section where a FORTRAN request name is different from the equivalent COBOL request name, the FORTRAN name is given in parentheses.

- OPEN file request(s).
- DB$BEG (BEGINTRAN) request.
- (data base processing/updating)
- DB$CMT (COMMITTRAN) or DB$DROP (DROPTRAN) request.
- CLOSE file request(s).
CODING STRUCTURES FOR TRANSACTION RECOVERY

Transactions Using CRM

Recoverable transactions using the CRM Data Manager can be divided into two categories: single begin-commit sequence transactions and multiple begin-commit sequence transactions. A single begin-commit sequence transaction needs only to include a SECURE request immediately before the COMMIT request. If a failure occurs before the COMMIT request is successfully executed, the database will automatically be rolled back and the transaction rerun at recovery time. A multiple begin-commit sequence transaction must first determine if recovery is in progress. If it is, the transaction must then discover which was the last successfully committed begin-commit sequence and begin processing with the following begin-commit sequence. For this purpose, the database BEGIN requests require a user-supplied identifier to be included as part of the request. All identifiers used within a single transaction must be unique for the restart point to be unambiguous.

Single Begin-Commit Sequence Transaction

OPEN files.
Record lock request(s).
DBEGIN request.
( DATABASE PROCESSING )
SECURE request.
DBCOMIT request.
CLOSE request.
transaction CEASE — SECURE message is sent to terminal.

In the preceding transaction, if a failure interrupts processing any time prior to the DBCOMIT request, TAF automatic recovery reruns the transaction from the beginning. If a failure interrupts processing after the DBCOMIT request, automatic recovery only sends the SECURE message to the terminal.

Multiple Begin-Commit Sequence Transaction

OPEN files.
TSTAT request using keywords RESTART, OLIDID.
If RESTART value is zero or OLIDID value is blank, begin processing at SEQN1.
If OLIDID is SEQN1
begin processing at SEQN2.

If OLIDID IS SEQN(n-1)
begin processing at SEQNn.

Processing Module(s)

TAF Transactions Using CDCS

A recoverable TAF transaction using CDCS must first determine if recovery is in progress. If it is, the TAF transaction must determine the last successfully committed begin-commit sequence. This is necessary even for single begin-commit sequence transactions because all recoverable run units using CDCS are rerun during recovery regardless of whether the last begin-commit sequence was successfully committed. The failure may have occurred after the COMMIT request and before the transaction CEASE. Rerunning from the start would cause a double update for the transaction. The transaction must begin processing at the first begin-commit sequence following the last successful COMMIT. If the final begin-commit sequence was successfully committed prior to failure, the transaction need only retrieve and send the SECURE message to the terminal.

Figure 7-1 shows the structure of a recoverable, multiple begin-commit sequence transaction that uses CDCS. The decision process that determines where to begin during recovery is shown in expanded form for clarity. The use of subscripted variables for begin-commit ids would allow for condensed code in the case of a large number of begin-commit sequences.

CDCS applications programmers should be aware of some terminology differences between TAF automatic recovery documentation and CDCS automatic recovery documentation. The term transaction in CDCS documentation refers to what TAF documentation calls a begin-commit sequence; that is, all processing starting with a database begin request and ending with the corresponding database commit request. Similarly, CDCS documentation uses the term transaction-id to refer to what TAF documentation calls the begin-commit id.
OPEN file(s).
TSTAT request, Keyword RESTART.
If RESTART value is zero
   DBGET (ASSIGNID) request
   RPUT request
   begin processing at SEQN1.
ELSE
   DBGET request.
   DB$ASK (FINDTRAN) request.
   If the begin-commit id is blank
      begin processing at SEQN1.
   If the begin-commit id is SEQN1
      begin processing at SEQN2.
   If the begin-commit id is SEQN2
      ...
   If the begin-commit id is SEQN(n-1)
      begin processing at SEQNn.
   If the begin-commit id is SEQNn or **********
      begin processing at WRAP-UP.

Processing Module(s)
   ...
   (data base processing/updating)
   ...

SEQN1.

(Get id of last committed begin-commit
sequence. This also assigns the old
sequence. This also assigns the old
RESTART-id to this transaction.)
RESTART-id to this transaction.)

Figure 7-1. Recoverable TAF Transaction Using CDCS

TERMINAL RECOVERY CONSIDERATIONS

If a communication subsystem, TAF, or system failure occurs, an application cannot assume that the termi-
nal contains any particular set of data. The last
message may not have been transferred to the termi-
nal, or the terminal operator may not have noticed
the message. Also, login procedures or terminal
failures may destroy the screen.

Terminal recovery is also dependent upon the type of
terminal and the form used on the terminal. On hard
copy terminals, the terminal may not need all the
data resent. In fact resending the data may spoil
the form. On cathode ray tubes (CRTs), the data
entered by the operator may need to be sent after
recovery to indicate what still needs specification.

Applications must design their terminal dialog so
that the operator has no doubts about the state of
the run unit by sending a final message via SECURE
indicating unmistakably that the run unit was suc-
cessfully completed. The transaction system guaran-
tees that the operator will see this message in all
cases when the run unit completed successfully;
otherwise, the operator might reenter the transaction
causing a double update of the data base.

Applications that require many terminal interactions
must reconstruct the screen from the data base upon
recovery.
CALLTSK WITHOUT CEASE AND RECOVERY

A CALLTSK without CEASE starts a new run unit. This new run unit is not recoverable. It will be restarted only if the calling task is part of a recoverable run unit and the task makes the CALLTSK request again upon restart.

Care is necessary when using SECURE, RSECURE, RPUT, and RGET from run units initiated by CALLTSK without CEASE. Such run units may write or read the same recovery data being written or read by the originating run unit.

MULTIPLE DATA MANAGER USE

Correct recovery cannot be assured for nested or overlapping begin-commit sequences using both CDCS and CRM. A transaction may use both CDCS and CRM provided that begin-commit sequences are neither nested nor overlapping.

TOTAL DATA MANAGER USE

The TOTAL Data Manager does not use the concept of begin-commit for data base recovery. Applications using this data manager, however, may implement data base recovery using current TOTAL features and TAF automatic recovery. If TAF automatic recovery is installed, such tasks may use any of the requests described in section 2 of this manual, including the application recovery requests.

During recovery, transactions that do not use CRM or CDCS and that were active at the time of failure are rerun unless the SECURE request data resides on the communication recovery file. If the SECURE message is present, the transaction is not rerun but the SECURE message is sent to the terminal.
This section contains recovery information of interest to persons responsible for the installation and maintenance of the transaction subsystem.

RECOVERY OVERVIEW

The TAF recovery package consists of two major components: transaction recovery and data base recovery. Data base recovery can be further subdivided into the automatic component and the batch component. The integrated system works like this:

A transaction is declared to be recoverable when it is added to the application task library. The data managers (CRM and CDCS) provide methods of declaring data files recoverable. Upon initiation of a recoverable transaction, ITASK schedules the transaction via a CALLTRN request. Then the original input (that is, the transaction name and all unsolicited data) is logged to the communication recovery file before the transaction begins execution. The transaction must indicate to the data manager that it wishes to open a begin-commit sequence by making a data base BEGIN request. When the transaction requests to update a data file, the following occurs.

- The record as read from the data file (the record in this state is called the before image) is logged to a before image recovery file, also known as the before image log file.
- The record is processed by the transaction.
- The updated record (called the after image) is logged to an after image recovery file when the program makes a write, rewrite, or delete request. The updated record is also written to the data file at this time.

After an update or a series of updates, the transaction indicates to the data manager that it wishes to close the begin-commit sequence by making a data base COMMIT request. If the transaction does not intend to open another begin-commit sequence, it indicates to TAF that its work is done by issuing a SECURE request just prior to the COMMIT request. TAF logs a message associated with the SECURE request to the CRF and sends this message to the terminal when the final transaction CEASE request is processed.

If a failure occurs after the COMMIT request, the database is not rolled back, all updates become permanent when the COMMIT is processed. Whether the transaction is restarted depends upon the data manager being used. CDCS transactions are restarted if a failure occurs any time prior to the final transaction CEASE request. CRM transactions are rerun unless both a COMMIT and SECURE request have been successfully issued. The applications tasks must be designed to handle cases where restart can occur after a COMMIT has been successfully executed. Refer to section 7 for some suggested transaction structures.

A BRF file is used repeatedly by the application. Only the before images for the current begin-commit sequence need to be saved so each new begin-commit sequence can overwrite the previous one.

An after image recovery file (ARF) is continuous. New after images are written sequentially until the file is full. At that time, logging is switched to a second ARF while the after images from the first ARF are dumped to tape.

The ARF files are not used for automatic recovery. They provide a backup in case a CRF, BRF, or data file becomes damaged. If this happens, the data administrator can use batch recovery to reload the data file(s) from the dump tape and apply, after images from an ARF dump, thus restoring the data base to a correct state as of any desired point in time.

The function performed by each of the recovery components are as follows.

- **Transaction recovery**
  - Logs the initial input to the CRF.
  - Logs and sends the SECURE message.
  - Restarts recoverable transactions after a failure.
- **Data base recovery**
  - **Automatic component**
    - Rolls back updates in uncommitted begin-commit sequences.
    - Logs before images to the BRF.
    - Logs after images to the ARF.
    - Switches after image logging when an ARF is full and submits a batch job to dump the full ARF to tape.
  - **Batch component**
    - Dumps full ARFs to tape.
    - Dumps data files to tape upon request.
- Restores data base files from data file and ARF tapes.
- Maintains a directory of dumped files.

The nomenclature used here is specific to the TAF/CRM Data Manager. CDCS automatic recovery uses similar concepts but different terminology. The details associated with data base recovery are documented in the respective data manager reference manuals. The remainder of this section covers the details of transaction recovery.

HARDWARE CONFIGURATION CONSIDERATIONS

Recovery cannot succeed if failures affect more than one component of the recovery system. For example, if a single hardware failure destroys both the recovery files and the data base, there is no recovery other than to restore the data base from a backup copy (file dump). For this reason, the data base files, the communication recovery files, the before image recovery files, and the after image recovery files should be assigned to physically separate devices. Also, the backup directory file for batch recovery should not reside on the same device as the ARFs.

The dump tape storage area should be physically separate from the area housing the disk drives.

Automatic recovery also depends on the integrity of single input/output operations. An on-line motor-generator is essential to ensure that disk operations underway at the time of a power failure have time to complete correctly.

Performance improvements through the use of multiple CRFs and BRFs (TAF/CRM only) will be realized only if each additional file resides on a separate device.

INSTALLATION

A procedure file for TAF initialization and recovery is presented in the NOS 2 Installation Handbook.

Transaction recovery is enabled or disabled by the installation parameter IPTAR. If IPTAR is set to one, transaction recovery is enabled; if IPTAR is set to zero, transaction recovery is disabled.

If recovery is disabled, these requests will not be honored in recovery mode:

CALLTRN For logging of input on CRF.
RERUN
RGET
RPUT
RSECURE
SECURE
TINVOKEL
TSTAT
WSTAT

A number of other installation parameters have an effect on recovery. Refer to the NOS 2 Installation Handbook for details.

TAF K DISPLAY

INITIAL K DISPLAY

Three K display commands are available to perform recovery-related functions: K.INT, K.ERO, and K.REC.

K.INT Command

The K.INT command specifies which recovery file(s) are to be initialized. This is the only means of initializing a CRF. Files listed on a RECOVER statement in the TCF and on this command will be initialized. Files listed on a RECOVER statement but not on this command will be used for recovery. The INT command also specifies whether CRM data base recovery files (ARFs and BRFs) are to be initialized or recovered. When used for CRM recovery files, this command is valid regardless of TAF installation options.

The format is:

K.INT=type,fileid

type File type. The options are:

CRF Command relates to the communication recovery file. This option valid only if installation parameter IPTAR = 1.

CRM Command relates to CRM recovery files.

fileid File identifier. The options are:

digits Each digit in the string specifies a CRF to be initialized. The digit corresponds to the id parameter on the RECOVER statement in the TCF. This option is not valid if type is CRM.

ALL If type is CRF, all CRFs listed in TCF RECOVER statements are to be initialized. If type is CRM, all CRM after image recovery files are to be initialized.

NONE If type is CRF, no CRFs are to be initialized (all CRFs listed in TCF RECOVER statements are to be recovered). If type is CRM, no CRM recovery files will be initialized. NONE is the default for both values of type.

NOTE

This option must be used with caution as the CRM data base update history currently residing on the recovery files will be lost.

A number of other installation parameters have an effect on recovery. Refer to the NOS 2 Installation Handbook for details.
The K.ERO command specifies whether to override certain I/O or logical errors encountered during processing of the communication recovery file(s). The format is:

\[ \text{K.ERO} = \text{CRF}, \text{option} \]

- **option** Error override option. Must be **NO** or **YES**.
  - **NO** Abort if I/O or logical errors are encountered when processing the communication recovery file(s). This is the default.
  - **YES** I/O or logical errors encountered on a run unit header record will result in the loss of that run unit with no indication to the terminal user. The loss will be noted on the recovery report.

I/O or logical errors encountered on a message record within a run unit will result in a loss of that run unit. However, a status indicator would be set in the run unit header that would enable the terminal user to be informed.

I/O or logical errors encountered on the CRF header record will result in unconditional abort of TAF.

The K.REC command sets the user recovery bit in the terminal status table. The format is:

\[ \text{K.REC} = \text{nnn} \]

- **nnn** Recovery option. Must be **YES** or **NO**.
  - **YES** Set the user recovery bit in the terminal status table.
  - **NO** Do not change the present setting of the user recovery bit.

If DISPLAY,ON is selected in the TCF, the K display is issued. This display is identical to the initial K display except that if any values were changed at initialization, the changed values are retained on the restarted K display. This does not apply to K.INT and K.ERO commands. Changed values for these commands are not retained after TAFREC completes. (This prevents inadvertent initialization of recovery files in a recovery situation).

**TCF/CRF RECOVERY CONSIDERATIONS**

**TAF CONFIGURATION FILE**

The TCF contains several recovery-related items.

- The **RECOVER** statement indicates the CRF identifier (zero to seven) and the size and number of messages that can be written to the CRF.
- Default K display values can be changed by placing K display commands in the TCF.
- The **DISPLAY** statement provides the option of having the K display brought up at initialization and recovery to allow the operator to override any of the default values.

Details on these statements are given with the TCF description in section 4.

The use of multiple CRFs is indicated by multiple **RECOVER** statements in the TCF. Each **RECOVER** statement corresponds to a separate CRF. For each **RECOVER** statement there must be a corresponding **NETWORK** statement. Refer to Use of Multiple Communication Recovery Files in this section and Communication Recovery File in section 4.

**COMMUNICATION RECOVERY FILE**

**Error Override**

Certain errors on the CRF file(s) can be overridden by using the K.ERO K display command (refer to Initial K Display in this section). Input/output errors on the CRF encountered during the running of transactions cause TAF to abort and TAFREC to attempt recovery of all readable data from the CRF.

**File Reformatting**

TAF recovery processing reformat the CRF under the following circumstances.

- If the number of user messages per recovery unit is increased in the number parameter on the **RECOVER** statement.
- If the size of user messages per recovery unit is increased in the maximize parameter on the **RECOVER** statement.
- If a new user is added to or deleted from the corresponding network file.
The RECOVER statement cannot be used to reduce the number or size of the user messages. The only way to reduce either of these is to reinitialize the CRF using the K.INT command.

To reformat ZZCRF1, TAF creates a permanent file named ZZCRF1A and writes the reformatted CRF to it. When the reformat is complete, the old CRF (ZZCRF1) is purged and the new CRF (ZZCRF1A) has its permanent file name changed to ZZCRF1.

Multiple Communication Recovery Files

Up to eight CRFs may be active simultaneously. Each CRF must have a unique identifier. Once a CRF has been initialized with a given id, it must be brought up with the same id. If this is not done, recovery will fail. Advantages of using multiple CRFs are:

- The input/output associated with the CRFs is spread out across several disks. This improves performance.
- Multimainframe recovery becomes possible. Refer to Multimainframe Recovery in this section.

MULTIMAINFRAME RECOVERY

The guidelines in this subsection pertain to sites running TAF on several mainframes. These guidelines are applicable if the ability to recover transaction processing for a downed mainframe on an alternate mainframe is desired.

- Make certain that the network (NCTFI) and CRF (CRFI) file identifiers (i) on each mainframe are unique among all mainframes.
- Allocate unique data base names to all applications across all mainframes.
- Allocate recovery-related files to shared mass storage.
- Define unique terminal user names across all mainframes.
- When a mainframe goes down, IDLE TAF on the mainframe that is to run the downed applications.
- Restart TAF with a TCF file that contains RECOVER statements for the recovery ids of both mainframes.
- When the downed mainframe is repaired, IDLE TAF on the recovery mainframe. Then bring TAF up independently on the two mainframes with the original TCFs.

RECOVERY PROCESSING FLOW

TAF AND SYSTEM FAILURE

Following a TAF or operating system failure, the TAF initialization procedure brings TAF up in recovery mode. During recovery mode initialization, TAFREC and TAF perform the following functions:

- Sets the K display values to those in effect prior to failure.
- Identifies the users that were active at the time of failure. Active users will have the recovery flag (word 1, bits 0 and 53) set in the terminal status table (TST).
- Reformats the CRF if necessary (refer to File Reformating under Communication Recovery File in this section).
- Prepares the TAF automatic recovery report.
- Initializes the transaction sequence number count.
- Schedules CTASK to move begin-commit ids from BRF to CRF.

BTASK is scheduled to determine which users active at the time of failure were running recoverable BTRAN-initiated transactions. BTASK calls CTASK to recover these transactions.

Recovery for transactions being run from interactive terminals is postponed until the terminal logs in. When a terminal logs in, TAF checks the recovery flag (word 1, bit 53) in the terminal status table. If the recovery flag is set, RTASK is scheduled instead of ITASK. RTASK performs these functions:

- If the run unit is not recoverable, RTASK sends READY to the terminal and ceases.
- If a recoverable transaction is no longer rerunnable, RTASK sends a message telling the terminal operator
  1. that recovery has occurred,
  2. that the recoverable transaction will not be rerun automatically, and
  3. to enter the next input.

This situation occurs when an input/output error occurred on the communication recovery file. Terminal operators should be instructed to inform the data administrator if this occurs since batch recovery will be necessary to restore the data base.

- If the transaction SECURE request and a TAF/CRM COMMIT request have been successfully executed, RTASK sends the terminal confirmation message, and ceases. The terminal confirmation message was stored on the CRF as a result of the transaction SECURE request.
- If none of the preceding is true, RTASK calls CTASK.

CTASK requests a new transaction sequence number and returns the begin-commit history to TAF/CRM. CTASK then makes a RERUN request. The RERUN request turns off the recovery status, retrieves terminal input from the CRF, and schedules ITASK using the new sequence number and original terminal input. ITASK processes the input as if it had come from the terminal.

If CDCS has been running on both mainframes and interfacing with TAF, CDCS must be dropped on the functional mainframe or recovery of CDCS data bases will not be possible.
NAM FAILURE

If NAM fails, TAF continues running. The rollout table is searched to suspend transactions that were initiated by an interactive terminal and are waiting for input (the wait time in the rollout table is set to zero). All other active transactions continue to run. When a running transaction issues a network request, it is suspended if recoverable and the request is issued to the original terminal (without recall in the case of SEND). If the transaction is not recoverable, it is terminated. Suspended transactions are processed as follows:

- A terminal-login-delay flag is set in the terminal status table to prevent terminal login until the next step is completed.
- CTASK is scheduled to recover the data base associated with the transaction and to issue a WSTAT request to clear the delay flag.
- At the time the terminal logs in, RTASK is scheduled either to send the SECURE message or to rerun the transaction.

TAF will periodically attempt reconnection to NAM. When NAM becomes available, terminal operators will have to go through the login dialog required for the terminal. Upon terminal reconnection to TAF, TAF issues an appropriate message to tell the terminal operator the current state of the terminal work.

TERMINAL FAILURE

Processing for an individual terminal failure is the same as described for NAM abort.

CDCS FAILURE

If CDCS fails, TAF continues running. When TAF detects a CDCS abort, it does the following to run units using CDCS:

- If the run unit is recoverable, its processing is suspended and an informative message is issued. The terminal operator may wait for the run unit to be automatically rerun when CDCS becomes available, or may enter a new transaction. In the latter case, the run unit will not be rerun when CDCS becomes available.
- If the run unit is not recoverable, it is aborted and an error message is issued to the originating terminal.

TAF sets a flag in the CRF for suspended run units waiting to use CDCS.

TAF, on a periodic basis, will check to see if CDCS is running and ready for transaction processing.

When CDCS is again accepting requests, TAF will rerun those recoverable run units whose processing was suspended, as previously described.

TASK FAILURE

TAF does the following when a task fails:

- TAF sends a failure or end run unit message to the data manager. The data manager rolls back updates in any incomplete being-commit sequences.
- TAF logs the reason for the failure in the journal file.
- TAF calls system task MSABT. The Control Data-furnished version of MSABT sends a message explaining the error condition to the terminal. Sites may modify MSABT to meet special requirements.
- TAF reloads the task if the task has other run units queued on it or is central memory-resident.
- Run units aborted because task failures are not rerun. Failure of the logged in terminal, NAM, or CDCS does not cause a task failure for a recoverable run unit.

TAF TERMINATION

TAF goes through termination processing when:

- The computer operator or terminal operator forces execution of a K.IDLE request.
- The computer operator enters IDLE,TAF.
- TAF (including any data manager in its field length) fails.
- A level 3 deadstart occurs.

When TAF receives a K.IDLE or IDLE,TAF command, TAF tells ITASK with an idle message. ITASK then:

- Tells terminal users entering a new transaction that shutdown is occurring.
- Prohibits new transactions from starting.

When no more transactions are running (no communication blocks are reserved), TAF does an ENDRUN to give control to TAF2. TAF2 tells the data manager(s) about shutdown and records a shutdown status on the CRF. When TAF is subsequently brought up, no recovery takes place since all users were inactive at termination.
TAF AUTOMATIC RECOVERY REPORT

This report is produced by TAFREC and placed on local file ZZIRRF. A site may save the report on permanent storage and/or route the report to a printer by including appropriate statements in the TAF procedure file. The report consists of four parts.

- Part one is a copy of the TAF configuration file. Each directive is printed. If a directive error occurs, a message is printed on the following line.

- Part two is an image of the initial K-display. If the same command is used repeatedly, only the last image of that command is listed.

- Part three is a report on each CRF processed. The format of this part is shown in figure 8-1.

- Part four is a summary consisting of the total number of terminals recovered, initialized, and deleted, and the number of concurrent batch and BTRAN requests recovered.

* terminal: Terminal/user name.
* tseq: Transaction sequence number of the last run unit.
* type: Transaction type (refer to TSTAT request).
* step: Transaction step (refer to TSTAT request).
* date: Date of last recorded run unit.
* time: Time of last recorded run unit.

Figure 8-1. Format of Part Three of the TAF Automatic Recovery Report.
Applications programmers should determine whether an analyst is preparing the network files. If so, applications programmers can skip this section.

Before any transaction processing can be done, the terminal configuration must be defined to the transaction executive. This is done by the terminal network description file (network file).

The NAM local configuration file is also needed to describe the terminal configuration. This file is described in the Network Products NAM 1 Network Definition Language Reference Manual.

**TERMINAL NETWORK DESCRIPTION FILE**

A terminal network description file consists of directives that describe users and their data bases. The directives needed consist of the //DIAL directive and user directives.

The format is:

//DIAL.

User directives must follow the //DIAL directive.

User directives have the form:

/username,parameter-string.

username A user name that is used to log into the network and TAF (or is specified in the local configuration file for automatic login). User names must be unique across all network files, even if they reside on different families.

The possible elements of the parameter string, separated by commas, are:

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TT=*ID</td>
<td>Transaction terminal type.</td>
</tr>
<tr>
<td>DB=aa</td>
<td>Two-character name of the data base to be accessed by the user. Only one data base can be associated with a user name.</td>
</tr>
<tr>
<td>UA=n</td>
<td>Contents of the user argument area in the communication block. n ranges from 0 through 16777215. Default is zero. User area contents can be examined and changed by tasks. The appropriate initial value is site dependent. Bit 0 is the default task recovery bit.</td>
</tr>
</tbody>
</table>

A simple set of terminal network file directives follows:

//DIAL.
/AJOHNSN,TT=*ID,DB=BC,
   UA=16117711B.
/BJOHNSN,TT=*ID,DB=BC,
   UA=00007700B.
/XYZ1,TT=*ID,DB=BC.

**NETWORK FILE ORIGINATION**

When an error-free network description is ready, an analyst should create a system file called NCTFi (where i is the network file identifier) from the terminal network description file.

A typical way to originate an NCTFi file follows. First, the user establishes a set of network description statements as a local file.

NCTF.
USER,username,password,familyname.
CHARGE,charge,projectnumber. or (*)
COPYBR,INPUT,NET.
SAVE,NET.
end-of-record
Network description statements
end-of-file

Then the user enters the following at the system console.

X.DIS.
USER,username,password,familyname.
CHARGE,charge,projectnumber.
GET,NET.
SUI,377777.
DEFINE,NCTFi/CT=PU.
COPY,NET,NCTFi,V.
RETURN,NCTFi,NET.

This creates a direct access public file called NCTFi under the system user index 377777. NCTFi is used to generate terminal status table entries.

Figure 9-1 illustrates a terminal status table entry. Each line gives the user name and its associated data base, read and update securities, and user area value.

When a run unit originates from a terminal, the transaction executive uses the appropriate entry in the terminal status table to construct words 0 and 1 of the communication block.

After the network file is originated, it must be updated to reflect changes, and the transaction executive must be reinitialized to recognize the new information.
### Terminal Status Table Entry

</tbody>
</table>

#### Word 0
- **Base**: Database
- **User area**: User name
- **Sequence number**: Message count

#### Word 1
- **Id**: User name
- **Function**: User active.
  - A: Terminal active.
  - L: Terminal logged in.
  - D: Terminal down.
  - C: Connection requested from network or terminal off.
  - R: Recovery required.
  - N: Recoverable transaction run.
  - ACN: Application connection number.

#### Word 2
- **Id**: Message count
- **Function**: Multiple block input being sent.
  - M: Multiple block input being sent.
  - I: Input wanted.
  - F: Last message block sent.
  - P: Connection to be postponed.
  - C: CDCS abort.
  - NT: Number of transactions received from terminal.

---

**Figure 9-1. Communication Between a Terminal Status Table and a Communication Block**
A task library contains all of the named-transactions and tasks that may be requested by a user group within the transaction subsystem. The task library is created by the LIBTASK utility.

A task library file is a direct access permanent file with no password that must be created with a DEFINE command before a library creation run occurs. However, it does not have to be attached by the user unless the DA option is specified (refer to LIBTASK command). The transaction subsystem simultaneously supports one system task library and, optionally, one task library for each data base.

The system task library, called TASKLIB by default, may be renamed at the site's option. It is defined under the transaction subsystem user name and given write permission to that user name. The name TASKLIB may also be changed using the K DISPLAY command K.TLF. (Refer to the NOS 2 Operator/Analyst Handbook.)

A user task library must be named xxTASKL where xx is the name of the data base with which the library is associated. It must be defined under the data base user name, and explicit write permission must be granted to the transaction subsystem user name to access the file.

During initialization, TAF attempts to attach a library for each initialized data base. The xxJ file is accessed to determine the user name needed to attach the library. When a scheduling request is received, the transaction subsystem searches for the named-transaction or task first in the associated data base library, if one exists, and then in the system library. Transaction and task names, therefore, need be unique only within a given task library. The only exception to this procedure is the initial task, ITASK, which is always loaded from the system library.

LIBTASK UTILITY

The LIBTASK utility creates a new library, adds new named-transactions and tasks to an existing library, deletes named-transactions and tasks from an existing library, replaces tasks in an existing library, and compacts an existing library by removing inactive records. Named-transactions and tasks may be added or deleted while the transaction subsystem is running, because tasks are added as a new file at the end of the library. The library is a multifile file. The transaction executive attempts to read a new library directory if the LIBTASK command contains the TT option. Thus, online update of any task library is allowed.

If the library is modified while the transaction subsystem is running and the user wants the new directory used, the user number and password of the LIBTASK user are passed to the transaction subsystem for validation. This is done by intercontrol point communication, which is also used to check if the transaction subsystem is running if the CR or PR option is selected. Therefore, the first USER command in the job must have permission to do intercontrol point communication. (Refer to the NOS 2 System Maintenance Reference Manual for the use of MODVAL to alter permissions.) The LIBTASK run issues an error message and does not update the library if the validation fails. The task binaries to be added or replaced are in ABS or OVL format produced by the CYBER Loader.

TASK RESIDENCY AND TYPE

An important option of LIBTASK enables the user to specify the residency and type of tasks on the task library. A task can reside on central memory, extended memory, or mass storage. This can be specified with the C and E options on LIBTASK directives.

A task can be of either reusable or nonreusable type. A reusable task must be written so that it is reinitializing. A reinitializing task (program) does not modify program areas that the program considers constant; if it does, it resets (reinitializes) these areas upon reentry. Multiple requests for a reusable task can be queued together; this is partly under the control of the person who sets up the task library and partly under the control of the transaction executive. The queuing of multiple requests occurs in an internal list, the requested task list (RTL). Each entry in this list represents a scheduling request for a copy of a task. There may be multiple entries in the RTL list for a given task. The LIBTASK queue limit input directive can be used to specify the maximum number of transactions that can be queued against one entry. When the transaction executive schedules a copy of a task from the RTL list, it picks an RTL entry and forces all of the multiple requests queued for that RTL entry to use the same copy of the task.

It is generally possible to have multiple copies of a given task in execution at the same time (note that this does not apply to CM-resident tasks). Additional application control of task scheduling is provided by the Q LIBTASK option in the input directives.

A nonreusable task is not a reinitializing task; a new copy of the task must be loaded from the task library for each transaction.
The task type can be specified with the D option on L I B T A S K directives. The queue limit can be specified with the QL option.

If a task is specified as central memory-resident and reusable, it is loaded to a subcontrol point when TAF is initialized and, unless the task aborts, remains at that subcontrol point to service transactions as long as TAF is running. If the task aborts, another copy of it will be loaded. It is a single copy task. No additional copies of this task are loaded to process requests after queue limit has been reached.

LIBTASK COMMAND

The LIBTASK command has two formats. The first format allows specification of the file containing input directive statements; this format is:

LIBTASK(p1,p2,...,pn)

The second format specifies that input directive statements are included in this LIBTASK command. This format is:

LIBTASK(p1,p2,...,z,...,pn);d1;d2;...;dn.

; Unique delimiter that does not occur in any di input directives. This delimiter does not have to be a semicolon.

di Input directive statement (refer to Input Directives in this section).

The input directives on a LIBTASK command remain in effect for a task in an existing task library until the task is specified in a subsequent LIBTASK command; that is, the most recent input directives (including default input directives) for a task take precedence over earlier input directives. However, this is not true for a task that is not in a task library; in this case, the first input directives (including default input directives) take precedence.

For example, you specify the following command:

LIBTASK(p1,p2,p3,...,pn);=T1 DL.

This command logically deletes task T1. If you specify task T1 in a subsequent LIBTASK command and do not specify DL, the task is activated (by default).

The LIBTASK command cannot exceed 80 characters.

The parameters (pi) for either format can be in any order and are:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>Specifies the file containing input directives. The file is not rewound before processing. All directives that do not refer to a task name present on the B file or P file are ignored. Options are:</td>
</tr>
<tr>
<td>I=1fn</td>
<td>File is COMPile.</td>
</tr>
<tr>
<td>I=0</td>
<td>No directive file exists.</td>
</tr>
<tr>
<td></td>
<td>Omitted Default file is INPUT.</td>
</tr>
<tr>
<td>B</td>
<td>Specifies the file containing task binaries to be added to the library. These may be tasks already existing in the library or they may be new ones. The file is rewound before processing. Options are:</td>

<tr>
<td></td>
<td>TN=tname</td>
</tr>
<tr>
<td></td>
<td>omitted</td>
</tr>
<tr>
<td>DA</td>
<td>Disables all attaches and returns of the library files in the LIBTASK program. With this option selected, the N file and the file specified by P must be attached prior to the LIBTASK call. If a library is attached in the proper mode from another user name, the DA option must be selected so that LIBTASK does not try to attach the appropriate libraries under the user name from which the update is being run.</td>
</tr>
<tr>
<td>CR</td>
<td>Creates a new task library. LIBTASK reads one task at a time from the B file, checks for an input directive for the task, constructs a directory entry, and inserts the entry in alphabetical order in the library directory. The directory is written at the end of the library. This option applies only if LIBTASK was able to attach the task library (specified by the N option) in write mode.</td>
</tr>
<tr>
<td>PR</td>
<td>Removes inactive task binaries and old directories from the task library. LIBTASK processes the B file and the input directives normally and, if N is not specified, copies the entire library to a scratch file. The current binary for each task in the library is then transferred from the scratch file to the library file, and the directory is updated and written at the end. Therefore, only one copy of each task and one directory remain in the library. If N is specified, no scratch file is written, and P is not purged. The new library file contains only the latest copy of each active task and one directory.</td>
</tr>
<tr>
<td>TT</td>
<td>Instructs the transaction executive to update the TAF-resident copy of the task library directory while TAF is running. If not specified, TAF will not become aware of the update until the next time it is initialized.</td>
</tr>
</tbody>
</table>

The installation parameters TLDMN and TRDMN are used to specify the amount of space to be reserved for adding tasks and transactions for each of the TAF-resident task library directories. The default allows 10 additions for each. Although further additions can be made to your task library, they will not be recognized by TAF until TAF is reinitialized. There is no limit to the number of times existing tasks can be replaced.

The user name from which LIBTASK is being run must be the same as the user name in the WXL file associated with the library being modified, and TAF must be able to attach the library in write mode in order for the update of TAF’s copy of the TLD to take place. You must be validated for intercontrol point communication (the CSTP bit in user’s access word must be set) to use the TT option. Each time you use the TT parameter with the LIBTASK command, a file is added to your task library. |

</table>

tnamei Transaction name.
taski Task names. If any task does not exist in this library, its name is enclosed in parentheses.
data-manager The data managers used by the named-transaction. May be either or both:

- C Transaction uses CRM.
- D Transaction uses CDCS.

Use of the indicated data manager is allowed if the letter appears.
rc Recovery indicator. For recoverable transactions, RC appears in this position.

Figure 10-1. Task Library Report
NAMED-TRANSACTION INPUT DIRECTIVE

The named-transaction input directive is used to create and delete named-transactions.

The format is:
/tname,T1=task1,T2=task2,T3=task3,T4=task4,T5=task5,RC,DM=datamanager,DL.

tname  Transaction name. Must be one to seven alphanumeric characters.

taski  Name of the task(s) in the named-transaction, tname. The tasks will be executed in the order listed. If a task issues a CALLTSK with CEASE, the remaining tasks in the original transaction will not be executed.

RC  Recovery indicator. When this parameter is specified, this transaction is recoverable. If not specified, this transaction is not recoverable.

datamanager  The data manager(s) that may be used by this named-transaction. If a recoverable transaction attempts to use CDCS or CRM and its usage was not declared via this parameter, the run unit will be aborted. This parameter is valid only if the RC parameter is also specified. The options are:
   C  The transaction uses CRM.
   D  The transaction uses CDCS.
   DL  Causes the deletion of transaction tname from the task library. If specified, this parameter must be the only parameter in addition to the tname parameter on the directive.

Additional tasks can be made part of the execution of a named-transaction if they are initiated via a CALLRTN or CALLTSK with CEASE. A CALLTSK with CEASE, however, will prevent any remaining tasks in the original transaction from being executed.

A task may be part of more than one named-transaction.

Declaring the named-transaction recoverable is necessary but not sufficient to ensure correct recovery from failures. The transaction must also be constructed to support recovery as specified in section 7 of this manual.

Tasks specified in this directive do not have to exist in the data base task library. This allows system tasks to be included in the named-transaction definition. Named-transactions with tasks that do not exist in the data base task library are enclosed by parentheses in the report generated by using the LIBTASK LO parameter.

TASK INPUT DIRECTIVE

To alter task characteristics, directive statements may be entered in the directive file. Only one statement should appear for each task. These characteristics are kept in the directory for use by the transaction executive when the task is to be executed.

The directive statement format is:
*name P1,P2,...,Pn.*

name is the task name and pi is any of the following input directives in any order.

<table>
<thead>
<tr>
<th>Directive</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>B=nn</td>
<td>Beginning scheduling priority of task.</td>
</tr>
<tr>
<td>BP</td>
<td>Beginning priority defaults to 25g.</td>
</tr>
<tr>
<td>BP omitted</td>
<td>Beginning priority defaults to 20g.</td>
</tr>
<tr>
<td>C</td>
<td>Specifies a memory-resident task. The default is a disk-resident task.</td>
</tr>
<tr>
<td>D</td>
<td>Specifies a destructive code (non-reusable) task that is removed from the subcontrol point when the task is completed. The default is a reusable task. This option is recommended when debugging a task.</td>
</tr>
<tr>
<td>DL</td>
<td>Specifies that a task (name) is logically deleted. All logically deleted tasks are physically deleted from the task library when the LIBTASK command contains the PR option.</td>
</tr>
<tr>
<td>E</td>
<td>Specifies an extended memory-resident library copy of the task. The default is mass storage-resident.</td>
</tr>
</tbody>
</table>

If tasks are specified as extended memory-resident, the transaction executive loads as many as will fit into its available extended memory during initialization and leaves the remaining tasks on the mass storage file. If no extended memory is available, all tasks are loaded from mass storage.

If a LIBTASK command specifying the TT option is issued while the transaction executive is running, no tasks are replaced or added to extended memory, and one of the following situations occurs.

- Old copy of task in extended memory and new copy in extended memory. The new copy is ignored, and the old copy remains on the library in extended memory.
<table>
<thead>
<tr>
<th>Directive</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>• O l d c o p y n o t i n e x t e n d e d memory and new copy in extended memory. The new copy is used but is read from mass storage.</td>
<td></td>
</tr>
<tr>
<td>• Old copy in extended memory and new copy not in extended memory. The new copy is loaded from mass storage.</td>
<td></td>
</tr>
<tr>
<td>EF=efl</td>
<td>Specifies the maximum amount by which a task will be allowed to increase its initial field length. efl is assumed to be octal unless it contains an 8 or 9 or is followed by a trailing D. The default value is zero. EF will be increased to the next multiple of 100g if it is not already such a multiple. The maximum field length allowed for the task is (initial task FL) + efl. The value of efl can range from 0 to 300000g.</td>
</tr>
<tr>
<td>IG</td>
<td>Specifies that a task (name) in the file specified with the B option is ignored.</td>
</tr>
<tr>
<td>MP=mn</td>
<td>Maximum scheduling priority of task (for future use in aging tasks).</td>
</tr>
<tr>
<td>MP omitted</td>
<td>Maximum priority defaults to 50g.</td>
</tr>
<tr>
<td>Q</td>
<td>Sets task to OFF; requests for the task are routed to the OFFTASK routine (refer to OFFTASK in section 11). The default is ON.</td>
</tr>
<tr>
<td>QL=n</td>
<td>Specifies the number of requests, up to a maximum of five, that can be queued for an RTL entry for a task. If a task uses a large amount of memory and executes rapidly, performance is not degraded if requests are queued. In this case, multiple copies of the task require too much memory. If a task does a large amount of I/O, then performance is degraded if requests are queued. In this case, multiple copies of the task enhance performance.</td>
</tr>
<tr>
<td>QL omitted</td>
<td>Queue entry limit defaults to three.</td>
</tr>
<tr>
<td>R</td>
<td>Specifies that the FL assigned to a CM-resident task is to be reduced to the initial load value each time the transaction is run. The default is no reduce. Non-CM-resident tasks are always started with their initial load value.</td>
</tr>
<tr>
<td>SC</td>
<td>Sets the task communication block load status to solicited. This means you must request the communication block and supply a valid address (using the BEGIN request) after the task is initiated. The default is unsolicited.</td>
</tr>
</tbody>
</table>

All directives for one task must appear on the same line. The following situation will result in only P1 being recognized as an input directive for TASKI.

```plaintext
*TASK1 P1.
*TASK1 P2.
*TASK1 Pn.
```

Improper way to specify input directives.

If a LISTASK function specifying the TT parameter is issued while the transaction executive is running and an attempt is made to change the Q attribute of a task on a library in use by TAF, then the Q attribute change will not affect TAF scheduling until the executive is reinitialized.

This parameter is not applicable to CM-resident tasks.
SCHEDULING PRIORITY

When the tasks are queued, the scheduler will attempt to load the task with the highest current priority. If there are several tasks with the highest priority, the task with the lowest field length requirement will be selected for loading. When a task enters the queue, the beginning priority (BP) is used as the task's current priority. The current priority is then aged (incremented by one) every second up to the maximum priority (MP). Tasks in the queue having identical current priorities and field length requirements normally will be scheduled in the order they entered the queue.

With these directives, classes of tasks can be created. For example, if two classes were created (X and Y) their priorities could be:

\[ XBP = 25 \quad XMP = 40 \quad YBP = 30 \quad YMP = 45 \]

In this case, no tasks in X could be scheduled until all tasks in Y having a current priority greater than 40 had been scheduled.

CREATING A NEW TASK LIBRARY

The following examples show how you can create a new task library. An explanation is provided after each LIBTASK command.

```
LIBTASK(P=0,N=lfn1,CR,B=lfn2,I)
```

LIBTASK copies file lfn2 to file lfn1 according to input directives in the COMPILE file and adds a new sorted task library directory at the end of file lfn1.

```
LIBTASK(P=lfn2,N=lfn1,Z);*name P1,P2,...,Pn
```

LIBTASK copies file lfn2 to file lfn1 and adds a new sorted task library directory at the end of file lfn1 according to input directives on the LIBTASK command.

```
LIBTASK(P=lfn2,N=lfn1,PR,Z);*name P1,P2,...,Pn
```

LIBTASK copies all active (not logically deleted or replaced) task binaries from file lfn2 to file lfn1, and adds a new sorted task library directory at the end of file lfn1 according to input directives on the LIBTASK command. This command is not valid when TAF is up and has attached file lfn1.

```
LIBTASK(P=lfn1,B=lfn2,Z);*name P1,P2,...,Pn
```

LIBTASK copies file lfn2 to the end of file lfn1 according to input directives on the LIBTASK statement. LIBTASK adds a new sorted task library directory to the end of file lfn1.

```
LIBTASK(P=lfn1,B=lfn2,PR,I=lfn3)
```

LIBTASK copies all active (not logically deleted or replaced) tasks from file lfn1 onto a scratch file, copies the scratch file back onto file lfn1, and adds a new sorted task library directory at the end of file lfn1.

DELETING A TASK FROM A TASK LIBRARY

With the DL input directive on the LIBTASK command, you can logically delete a task from the task library if TAF is up and has attached the task library as follows:

```
LIBTASK(P=lfn1,TT,Z);*name DL
```

In this example, LIBTASK logically deletes a task (name) from file lfn1. The TT option is required when TAF is up. The DL input directive is the only input directive allowed for the named task.

With the PR option on the LIBTASK command, you can delete inactive tasks from the task library when TAF is not up and when TAF is up but has not attached the task library.

```
LIBTASK(P=lfn1,PR,Z);*name DL
```

In this example, LIBTASK physically deletes a task (name) from file lfn1. TAF must not have the file attached when this command is executed.

UPDATING AN EXISTING TASK LIBRARY

The following examples show how you can update (add new tasks and delete and replace existing tasks) an existing task library without supplying any binaries. An explanation is provided after each LIBTASK command.

```
LIBTASK(P=lfn1,Z);*name P1,P2,...,Pn
```

LIBTASK adds a new sorted task library directory at the end of file lfn1 according to input directives on the LIBTASK command.

```
LIBTASK(P=lfn1,PR,Z);*name P1,P2,...,Pn
```

LIBTASK copies all active (not logically deleted or replaced) tasks from file lfn1 onto a scratch file, copies the scratch file back onto file lfn1, and adds a new sorted task library directory to the end of file lfn1 according to the input directive on the LIBTASK command.
IGNORING A TASK IN THE REPLACEMENT FILE

With the IG input directive on the LIBTASK command, the user can tell LIBTASK to ignore a task binary in the replacement file specified with the B option as follows:

\[ \text{LIBTASK}(P=\text{lfn}_1,B=\text{lfn}_2,Z);*\text{name IG}. \]

In this example, LIBTASK skips a binary task (*name) on file lfn2 when copying file lfn2 to file lfn1. The IG input directive is the only input directive allowed for the named task.
REQUIRED SYSTEM TASKS AND TRANSACTIONS

The applications programmer should be aware of the functions of these tasks but may omit the detailed information contained in this and section 12.

Several system tasks are required with every application: BTRAN recovery task (BTASK), data base recovery task (CTASK), initial task (ITASK), K display director (KDIS), logout transaction terminal (LOGT), message abort (MSABT), inactive task (OFFTASK), CDCS rerun task (RCTASK), run unit recovery task (RTASK), system message (SYSMSG), and execute named tasks (XTASK). Each must reside on the system task library of every transaction system. Limited versions of these system tasks are supplied by Control Data; however, modifications to these tasks are often necessary for specific applications. One additional system task, CRMTASK, is required if the TAF/CRM Data Manager is used. Refer to the TAF/CRM Data Manager 1 Reference Manual for information on CRMTASK.

Directions for installing these tasks are contained in the TAF Installation section of the NOS 2 Installation Handbook.

BTRAN RECOVERY TASK (BTASK)

BTASK recovers rerunnable BTRAN run units. BTASK must be installed on the TAF system library.

DATA BASE RECOVERY TASK (CTASK)

CTASK helps TAF/CRM recover the data base during TAF initialization, terminal failure, and network failure. CTASK must be installed on the TAF system library.

INITIAL TASK (ITASK)

The primary functions of ITASK are analyzing terminal input and TAF-originated transactions. If the TAF-originated transaction field is set in the communication block (figure 2-1), ITASK uses a table to initiate the processing routine associated with that type of transaction. Otherwise, ITASK examines three characters, starting with the first character of the input message. The first of these three characters is the transaction code; the other two comprise the subtransaction code entered from a terminal.

ITASK recognizes the transaction code EX., which is used to call the system transaction XTRAN. This special transaction code is reserved for XTRAN.

NOTE

Because ITASK schedules tasks, care must be taken to avoid entering an infinite loop when a task calls ITASK.

ITASK is described in more detail in section 12.

K DISPLAY TASK (KDIS)

KDIS is a system task scheduled by the transaction executive when the K.SWITCH command is entered by the console operator. KDIS requests the K display and displays a complete list of K display commands. The K display commands are discussed in the NOS 2 Analysis Handbook.

LOGOUT TASK (LOGT)

This task logs a terminal out of TAF. However, the task does not log the terminal off the computer system. The task sends a message, END OF TRANSACTION SESSION; performs a LOGT request; and performs a CEASE request. The terminal is then available for login to TAF or other network applications.

MESSAGE ABORT (MSABT)

Message abort (MSABT) is a system task that sends error messages to the originating terminal when a transaction is terminated due to a system-detected error. MSABT checks for error codes that were placed in the communication block by the transaction executive or the initial task. When an error code is detected, MSABT sends the appropriate error message and initiates an abnormal CEASE function.

MSABT is scheduled in the same manner as other tasks.

If the TOTAL Data Manager is used, MSABT must be modified to perform a FREEX command. This ensures that TOTAL records are released if a task aborts.

Error messages issued by MSABT are described in appendix B.
INACTIVE TASK (OFFTASK)

This task is provided to give you control over an internal condition that might be the result of operational error. OFFTASK is scheduled by the transaction executive when a request has been received for an inactive task. The task may be inactive or off due to the use of the K.OFFTASK command or use of a LIBTASK directive when the task was placed in the library. OFFTASK sends an error message to the originating terminal and ceases abnormally. It is expected that you will expand the task to handle any specific conditions that may exist when a transaction is interrupted by an inactive task.

SEND MESSAGE TASK (STASK)

This task sends a message to the terminal and then terminates. STASK is called into ITASK only when ITASK is to terminate after sending a message to the terminal.

SYSTEM MESSAGE TASK (SYSMSG)

This task sends K.MESSAGE-entered messages and K display diagnostic messages to terminals. It calls the subroutine in COMKCBT passing the user argument bits. The word returned is sent after the message is sent.

EXECUTE NAMED TASK (XTASK)

The execute named task (XTASK) is a special task scheduler used to execute most named tasks. It will not execute tasks by the names ITASK, KDIS, MSABT, OFFTASK, SYSMSG, and XTASK. These are the names of required system tasks. XTASK can be used to schedule LOGT as a means of logging a terminal out of transaction mode. XTASK is initiated via system transaction XTRAN, described following the XTASK description.

EX.task

Special three-character transaction code which causes ITASK to schedule XTRAN via a CALLTRN request. XTRAN specifies XTASK as its only task.

task

One- to seven-character alphanumeric task name, left-justified (no space between EX. and task) with a nonalphanumeric character terminator.

A site may want to delete the TRANS table entry of STRAN (X.), XTASK in the TRANT table of ITASK, or the system task XTASK altogether for security reasons. XTASK was provided as a means of scheduling tasks, and as an example of how a site might use such a task. However, it may provide too much flexibility, and therefore should be used with discretion.

XTRAN TRANSACTION

Transaction XTRAN must be defined when the system task library is created. XTRAN will be scheduled when the three-character code EX. is entered from a terminal. This transaction allows scheduling any task in the local or system task library as described under XTASK.

The characteristics of XTRAN are:

- Task name is XTASK.
- No data managers.
- Not recoverable.
This section describes some of the features, options, and requirements of ITASK.

MACROS
ITASK contains three tables. These tables are set up for the following codes.

- Time a task is to be run
- Transaction code
- Subtransaction code

A macro is used to set up each type of ITASK table. These three COMPASS macros, TIMCNT, TRAN, and STRAN, are discussed here.

TIMCNT MACRO
The TIMCNT macro makes an entry in the table of time-originating tasks (TTOT). TTOT contains the time a transaction or task is to be initiated and an address.

One TTOT contains all of the entries, regardless of the application that is to use them. This feature allows tasks to be run at predetermined times without specific task requests or terminal input to initiate the run.

The format is:

```
TIMCNT hr, min, sec, address
```

hr Hour.
min Minute.
sec Second.
address Routine address.

The TTOT table format is:

```
Word 1: TTOT, number of entries in the table.

Word 2 and following: Table entries.
```

The format of a TTOT entry is shown in figure 12-1.

TRAN MACRO
The TRAN macro sets up entries for the table of transaction codes (TRANT). TRANT contains the address of the table of subtransaction codes for that particular transaction code. ITASK assumes that the TRANT table is set up in 6-bit display code order. It uses the 6-bit display code value of the transaction code you enter to locate the proper entry in TRANT.

The format is:

```
TRAN code
```

code One-character transaction code.

The format of an entry in TRANT is shown in figure 12-2.

STRAN MACRO
The STRAN macro makes entries in the table of subtransaction codes (TRANS). TRANS contains the subtransaction code and the corresponding transaction name.

The format is:

```
STRAN sc, tname
```

sc Two-character subtransaction code.
tname Name of the transaction to be called.

The format of an entry in TRANS is shown in figure 12-3.

![Figure 12-1. Format of a TTOT Table Entry](image)
Each group of entries relating to the same transaction is placed immediately following the TRANT entry for that code, although the subtransaction table is assembled elsewhere. This is an example of the TRANT and TRANS tables.

**TRANT**

<table>
<thead>
<tr>
<th>BSS</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>TRAN</td>
<td>A</td>
</tr>
<tr>
<td>STRAN</td>
<td>02,TRNAME</td>
</tr>
<tr>
<td>STRAN</td>
<td>03,TRANN</td>
</tr>
</tbody>
</table>

A is the transaction code, 02 and 03 are the subtransaction codes, and TRNAME and TRANN are the respective transactions to be requested.

A site may want to delete the TRANS table entry of STRAN (X.), ITASK in ITASK for security reasons. ITASK is described in more detail in section 11.

**ITASK DESCRIPTION**

Entries in all ITASK tables, as well as the user subroutines for TIMCNT entries in TTOT, should be inserted in the designated places within the program before assembly. TRANT and TRANS entries must be in alphabetical or numerical order according to 6-bit display codes.

Initial terminal input, while TAF is running normally, results in execution of a transaction as follows:

- If the first three characters of input are recognized by ITASK as a transaction code that is associated with a transaction, then ITASK attempts to schedule the transaction. Transaction codes can be associated with transaction units through the STRAN macro, previously described.
- If no transaction was associated with the transaction code, then ITASK interprets the string of characters starting with the first character input and terminating with the first nonalphanumeric character as a transaction name. If this string is null or more than seven characters long, an error message is issued; otherwise, ITASK will attempt to schedule the named-transaction. If the named-transaction does not exist in the task library corresponding to the terminal application or in the system task library, an error message is issued via MSABT.

**Initial terminal input while TAF is idling down** (following an IDLE,TAF or K.IDLE command) is processed as follows:

- If the input is EX.LOGT, the logout is processed normally.
- If the input is anything else, ITASK issues the message TAF IDLING DOWN to the terminal and ceases without trying to schedule the requested transaction.

TTOT entries must be accompanied by user-written subroutines to set up and call the task, as follows:

- The system time is retrieved from the appropriate word in the communication block. TTOT is then searched for any entries that were to be run by that time.
- If such an entry is found, ITASK jumps to the user's subroutine to set up and call the task. This subroutine must set up the communication block required by the task that is to be run. It must perform a CALLTSK without the cease option set to ensure that control is returned to ITASK.
TAF-ORIGINATED TRANSACTIONS

TAF recognizes certain conditions not normally noted or processed by user applications. Some of these conditions are:

- Exceeding a length of time as specified by an assembly option (TACTL).
- K.IDLE command telling the transaction subsystem to idle down.
- Transaction executive recovery.
- Terminal login.
- Network and terminal failures.

When any of these conditions occur, a TAF-originated transaction may be processed. Code in common deck COMKSTC identifies the condition. ITASK examines the communication block (figure 12-4) to determine the condition and jumps to a subroutine which sets up and calls the proper task or sequence of tasks to respond properly to the identified condition. Although the Control Data-supplied ITASK contains code to process each of the conditions, sites may want to modify ITASK and provide transactions to suit their individual needs.

To provide TAF-originated tasks that properly respond to the NAM conditions, the analyst should refer to the NAM/CCP 1 Reference Manual.

A number of common decks aid in processing the TAF-originated transactions as follows:

- COMKSTC gives the values for the condition field of the communication block.
- COMKNWF describes the fields for the NAM message word of the communication block.
- COMSNCD gives values to fields in the NAM message word.

### CONDITIONS REQUIRING TAF-ORIGINATED TRANSACTIONS

The conditions that require TAF-originated transactions and possible methods of processing are described here. Limited versions of routines needed to process these transactions are available in ITASK. To change the existing routines, ITASK must be modified to include the necessary code or call the necessary tasks. It may be advisable to include short procedures as subroutines in ITASK, but long or frequently updated transactions should be maintained as separate programs apart from ITASK and merely called from the ITASK subroutine. The recovery situations described in this subsection apply to sites not using TAF automatic recovery.

#### Time Activation

This might be processed by ITASK as follows:

1. ITASK retrieves the system time from the appropriate word in the communication block.
2. ITASK then searches the TTOT for any transactions that are to be run at that time.
3. If such an entry is found, ITASK jumps to the user-supplied subroutine that must set up and call the next task for that transaction. This subroutine must set up the communication block required by the task that is to be run.

#### K.IDLE Console Operator Command

Same as IDLE, TAF command. Refer to ITASK Description earlier in this section.

---

message from terminal, terminated by 12 bits of zero in last word of message; meaningless data follows

available to user

0 yr mo day hr min sec
Terminal Login

The application may want to prompt the terminal user, set application character type, or go through recovery procedures if the user has the recovery field set in the user area of the terminal status table. Upon terminal login, the NAM message word of the communication block (figure 12-4) contains the following information:

<table>
<thead>
<tr>
<th>Bits</th>
<th>Significance</th>
</tr>
</thead>
<tbody>
<tr>
<td>35-25</td>
<td>Block size of terminal.</td>
</tr>
<tr>
<td>24</td>
<td>Signifies a hardwired terminal if set.</td>
</tr>
<tr>
<td>23-16</td>
<td>Terminal class.</td>
</tr>
<tr>
<td>15-8</td>
<td>Page width of terminal.</td>
</tr>
<tr>
<td>7-0</td>
<td>Page length of terminal.</td>
</tr>
</tbody>
</table>

Terminal Break Conditions

If some tasks perform SENDs without the recall flag set, breaks can occur because of the following:

- User break keys.
- Output device not ready.
- Incorrectly formatted data.

For a user to resume processing after a terminal break, the following must occur.

1. Terminal communication with NAM must be reestablished. When the break occurs, NAM places the supervisory message associated with the break in the NAM message word of the communication block. To restart terminal communications, TAF must send a reset supervisory message to NAM. The individual application need not provide this function. Upon the user task SEND request, TAF issues the reset supervisory message prior to honoring the SEND.

2. The user must resume interaction with the application. The user application must provide this break recovery. The following description suggests one method.

ITASK and any recovery tasks can communicate through the terminal status table user area. For instance, when ITASK initiates a transaction, it could set a series of fields in the TST to indicate important events in the transaction. The recovery task could examine the fields to determine what events had occurred. Nonrecovery tasks could watch a recovery field in the TST and CEASE to allow the recovery task to proceed in a quiet environment. (TAF sets the recovery field in the TST before calling ITASK.)

Terminal Connection Broken

A connection may be broken because a line has been disconnected. If a SEND with recall was active, the task issuing the SEND rather than ITASK is notified of the error. It may be desirable for the application to process these incomplete transactions. TAF sets the recovery field in the terminal status table user area. The application can save terminal output on a data manager file and send it when the user logs in again. The outstanding block limit specified in the local configuration file determines how many messages must be saved. (Refer to the Network Products NAM 1 Network Definition Language Reference Manual.)

Network Normal Shutdown

TAF monitors task activity on communication blocks generated by terminal input. When all tasks have been completed and no tasks are performing WAITINF requests, TAF sends end connection supervisory messages to NAM for each logged-in user and performs a NETOFF to end processing with the network. To initiate this condition, it may be desirable for ITASK to notify users of the pending shutdown and begin rejecting new transactions.

Network Failure

TAF sets the recovery field in the user area of the terminal status table for all logged-in users. All tasks performing WAITINF requests are scheduled. The application, through ITASK, may want to begin database recovery.

Network Immediate Shutdown

TAF performs a NETOFF and sets the recovery field in the user area of the terminal status table. The application may want to begin recovery by processing only transactions from batch input.

Terminal Inactive

NAM issues a terminal inactive supervisory message when it detects that 10 minutes have elapsed without message traffic over a connection. TAF passes the transaction sequence number of any running task using that user name to ITASK. The application may want to log out the user after a period of time to reduce line connect costs.

Logical Error

One of the application's tasks may have set up an application block header or message block incorrectly. If the task performed a SEND request with recall set, the task, rather than ITASK, is notified of the error.
Block Not Delivered

This occurs because of a system error. If the task performed a SEND request with recall set, the task, rather than ITASK, is notified of the error. Before scheduling ITASK, TAF sets the recovery field in the user area of the TST. It may be desirable for the application to recover by sending the lost block. The application block number of the block that was lost is returned in the NAM message word of the communication block. Tasks may specify a block number on the SEND or obtain the block number used by TAF. Resending the lost block may cause the block to be delivered out of sequence, if further blocks had been sent following the lost block.

Terminal Characteristic Change

A NAM terminal characteristic supervisory message is sent to ITASK when the terminal operator has redefined the terminal class, page width, or page length.

Terminal Input Too Large

The terminal operator sent a message longer than the maximum input message size. TAF will not have journalized the input.

Terminal Type Ahead

The network allows terminal operator type-ahead. In other words, the terminal operator can enter several transactions without waiting for the response from the first. The network ignores all type-ahead when the terminal operator enters a user break 1 or user break 2.

User Status

The network allows a terminal user to make a status request by typing:

```
ct (alpha) ®
```

ct  The network control character.

(alpha) Any alphabetic character.

TAF will right justify the character in word 3 of the communication block and initiate ITASK. At this point a user-written routine in ITASK must take over to perform whatever action is desired. The ITASK reason code will indicate a user status message.
Table A-1 lists the character codes for the ASCII 63/64-character sets. Users should check with a site analyst to see which character set is being used.

This appendix contains an alphabetical listing of messages which may be important to the TAF programmer. Each message is followed by an explanation of the message and/or the circumstances causing it to be issued, the recommended action, and the routine which issued the message.

Lowercase letters are used within a message to identify variable fields. All messages beginning with lowercase (variable) fields are listed alphabetically according to the first nonvariable field after the messages that begin with nonvariable fields.

</table>
**MESSAGE**

ATTACH ERROR ON PF xxxxxxx.

ATTACH MODE MUST BE W, M, R, OR RM.

n.nnn AVERAGE ACTIVE SUBCONTROL POINTS.

n.nnn AVERAGE OUTSTANDING CDCS REQUESTS.

BACKUP DIRECTORY - xxxxxxx has been reconstructed.

BATCH CONCURRENCY DISABLED.

BATCH RECOVERY ACTIVE ON DATA BASE

BEGIN CRM TASK RECOVERY.

BFL = xxxxxxxB, MINIMUM REQUIRED = zzzzzzzB.

BINARY RECORD WAS LESS THAN 64D WORDS LONG.

BINARY RECORD WAS NEITHER ABSOLUTE NOR OVERLAY FORMAT.

BLOCK BUFFER OVERFLOW.

BLOCK BUFFER TOO SMALL.

BLOCK LOAD ERROR.

BLOCKAGE AMONG CM RESIDENT TASKS.

BOTH AFTER IMAGE FILES ACTIVE.

BRF PARAMETER TOO LARGE OR INVALID.

BTASK - TAF AUTOMATIC RECOVERY NOT INSTALLED.

BTASK - TASK LOGICAL ERROR.

**SIGNIFICANCE**

When attempting to attach a permanent file xxxxxxx, an error was encountered.

The mode parameter on the CYBER Record Manager (CRM) statement must be one of the specified values.

n.nnn is the average number of simultaneously active subcontrol points when TAF is not rolled out. An active subcontrol point is one which is in recall, is waiting to use the CPU, or is currently assigned the CPU. The sampling rate is once per second.

n.nnn is the average number of outstanding (uncompleted) System Control system requests per second. The sampling rate is once per second.

No directory file for the specified data base. A new directory was generated from the information on the xxJ file.

TAF was brought up without BATCH concurrency enabled. CTBCON=Q).

Self-explanatory

TAF/CRM has received a recovery indication from TAF.

Information on the actual value of the beginning field length and the minimum value TAF/CRM requires for the Common Memory Manager Buffer.

The task binary file contains records in the wrong format.

The task binary file contains records in the wrong format.

When attempting a record load operation, the data block buffer was found to be too small.

Tape block on ARF was too large for buffer.

Block load of a file failed because no header was found on dump tape. Or, the targeted file or the tape does not match request file name.

The sum of initial field lengths for the CM resident tasks exceeds the minimum size of total task area.

Both after image recovery files for a data base are active. The after image files must be dumped by DMREC, if not already dumped.

The parameter on the BRF statement is nonnumeric, the value is greater than the installation parameter BMAX, or too many parameters were specified.

A keyword specified in a TSTAT request requires TAF automatic recovery to be installed.

An unexpected error status was returned.

**ACTION**

Check for valid directive file name and presence of a direct access permanent file by that name.

Correct the mode parameter on the CRM statement or inform the data administrator.

None.

Inform data administrator.

Ask data administrator to bring up TAF with BATCH concurrency enabled.

Wait for the completion of batch recovery, then reinitialize the transaction subsystem.

None.

None.

Inform data administrator.

Increase the length of the working buffer WBUF. Inform the data administrator.

Increase size of buffer and try again.

Load from previous dump tape.

Correct error.

Dump the after image recovery files.

Correct BRF statement or reassemble TAF and related decks with a larger value for BMAX (if possible).

Inform the data administrator.

Inform the data administrator.

**MESSAGE**

**BTASK - xxxxxxx TRANSACTION NOT RUNNABLE NOW.**
This occurs when an I/O error is detected and the data base cannot be recovered for the user xxxxxxx.

**BTASK - USER NOT DEFINED IN NETWORK FILE.**
The user is not defined in the NETWORK file on a TSTAT request.

**C. B. NOT AVAILABLE TO SCHEDULE CTASK.**
Communication block not available to schedule CTASK.

**CALLRTN NESTED CALL LIMIT EXCEEDED.**
A task error. An attempt was made to nest CALLRTN requests more than 16 levels.

**CANNOT DEFINE REFORMATTED FILE - filename.**
A reformat of the TAF COMMUNICATIONS recovery file was necessary, but when attempting to DEFINE the reformatted file (ZICRFAi), an error occurred.

**CDCS ABORTED PLEASE WAIT.**
A TAF transaction was using CDCS while CDCS aborted. The transaction will be rerun after CDCS comes back up.

**CDCS CONNECTION ESTABLISHED.**
Informative message. The connection between TAF and CDCS has been established.

**CDCS INVOKE FAILURE.**
CDCS files are not available.

**CDCS NOT AVAILABLE.**
Your TAF transaction attempted to use CDCS when it was not present in the system, CDCS aborted while your transaction was waiting for completion of a CDCS request (SSC), or CDCS aborted while your transaction was rolled out.

**CDCS REQUESTED ABORT.**
TAF aborted the TAF transaction as a result of a request by CDCS. The detailed error message returned by CDCS is available in the JOURO file and will be sent to the terminal.

**CHANGED TLD DETECTED - filename, username.**
An unrecognizable library directory format was encountered during a library directory update attempt.

**CIO ERROR ON RECOVERY FILE**
A CIO error was encountered while trying to position the ARF or BRF correctly.

**CMM* ERROR.**
A *CMM* error occurred. Memory cannot be granted to load *OPEN* routine.

**CMMBFL IS NOT LARGE ENOUGH.**
The size of the beginning field length (BFL) for the Common Memory Manager Buffer is not large enough to contain CMMFL and CMMLAP and the user's FIT-S and FSTT-S.

**CONFLICTING LIBTASK OPTIONS - p1,p2.**
The user specified an incorrect combination of LIBTASK command options. Possible incorrect combinations of p1 and p2 are:
- CR, PR
- CR, TT
- PR, TT
- TT, N
Another possible incorrect combination gives P=0,-N for p1,p2. This means that the user specified P=0 but did not specify N.

**CONTROL CARD ARGUMENT ERRORS.**
Errors exist in the parameters on the LIBTASK command.

**CWF HEADER ERROR - filename.**
I/O errors or logical errors were encountered in the header record of the named CRF. The file is unusable. filename File name

**SIGNIFICANCE**

This occurs when an I/O error is detected and the data base cannot be recovered for the user xxxxxxx.
The user is not defined in the NETWORK file on a TSTAT request.
Communication block not available to schedule CTASK.
A task error. An attempt was made to nest CALLRTN requests more than 16 levels.
A reformat of the TAF COMMUNICATIONS recovery file was necessary, but when attempting to DEFINE the reformatted file (ZICRFAi), an error occurred.
A TAF transaction was using CDCS while CDCS aborted. The transaction will be rerun after CDCS comes back up.
Informative message. The connection between TAF and CDCS has been established.
CDCS files are not available.
Your TAF transaction attempted to use CDCS when it was not present in the system, CDCS aborted while your transaction was waiting for completion of a CDCS request (SSC), or CDCS aborted while your transaction was rolled out.
TAF aborted the TAF transaction as a result of a request by CDCS. The detailed error message returned by CDCS is available in the JOURO file and will be sent to the terminal.
An unrecognizable library directory format was encountered during a library directory update attempt.
A CIO error was encountered while trying to position the ARF or BRF correctly.
A *CMM* error occurred. Memory cannot be granted to load *OPEN* routine.
The size of the beginning field length (BFL) for the Common Memory Manager Buffer is not large enough to contain CMMFL and CMMLAP and the user's FIT-S and FSTT-S.
The user specified an incorrect combination of LIBTASK command options. Possible incorrect combinations of p1 and p2 are:
- CR, PR
- CR, TT
- PR, TT
- TT, N
Another possible incorrect combination gives P=0,-N for p1,p2. This means that the user specified P=0 but did not specify N.
Errors exist in the parameters on the LIBTASK command.
I/O errors or logical errors were encountered in the header record of the named CRF. The file is unusable.

**ACTION**

Inform the data administrator.
Inform the data administrator.
Increase the number of communication blocks at initialization time using the K.MCB command.
Correct task or inform data base administrator.
Purge the existing file indicated by filename.
Operator can log off by typing in EXLOGT, or wait for CDCS.
None.
Inform site analyst or data administrator. The transaction should be rerun after the problem is fixed.
Inform data administrator.
Inform data administrator.
Inform data administrator.
Inform site analyst.
Reinitialize the transaction subsystem or inform the site analyst.
Inform data base administrator.
Data base administrator can either 1) increase the size of CMMBFL, or 2) decrease the size of CMMLFL, or 3) decrease the size of CMMLAP.
The user must choose either p1 or p2. For the P=0,-N combination, the user must specify N if no old task library (P=0) exists.
Correct and rerun.
Inform data base administrator.
Inform site analyst.
Initiate the file using the K.INT initial K display command.
MESSAGE

CRF RECOVERY/INITIALIZATION ABORTED.

CRF RECOVERY/INITIALIZATION COMPLETE.

CRF RECOVERY UNIT ERROR - filename.

CRM(...parameter-list...)

CRM DATA MANAGER NOT LOADED.

CRM DATA MANAGER SUCCESSFULLY LOADED.

CRM ERROR nnnB IGNORED ON OPEN OF filename.

CRM ERROR ENCOUNTERED.

CRM ERROR xxx IN UPDATE PROCESSOR.

CRM ERROR IN ZZdbOIR (GET).

CRM TASK RECOVERY IMPOSSIBLE.

CRMTASK - DATA BASE DOWNED BY OPERATOR.

CRMTASK - DATA BASE/FILE BEING IDLED.

CRMTASK - DATA BASE/FILE CANNOT BE UPPED.

CRMTASK - DATA BASE/FILE NAME UNKNOWN.

CRMTASK - INCORRECT REQUEST.

CRMTASK - INCORRECT REQUEST FORMAT.

SIGNIFICANCE

Informative message.

Informative message.

I/O errors or logical errors were encountered in a run unit of the named CRF.

This is a copy of a CRM statement that is in error. A subsequent message follows.

An AAM request for CRM was issued by a task and the CRM Data Manager was not loaded into TAF at initialization time.

Self-explanatory.

A non-fatal CRM error, nnnB, was returned to the TAF/CRM data manager while issuing CRM requests associated with opening a recoverable CRM file, filename, for the first time. This error is ignored.

A CRM error occurred while processing the directory. The CRM error is either an incorrect key or end of file when this is the only output message.

A CRM error has occurred during the application of the after image to a data file.

A CRM error was encountered when trying to retrieve a VSN record from the directory on a file load.

Recovery is not possible when the recovery file structure is found to be inconsistent with TAF/CRM tables and parameters specified on xxJ files.

DMREC notified TAF that the data base was recovered. But AAMI was not able to access it because it had been downed by the operator.

AAMI will not process any requests on an idle data base/file.

CRM task was not able to bring up the data base or file.

DMREC request had an incorrect data base or file name.

CRMTASK was not called correctly by DMREC.

AAMI rejected this request.

ACTION

The action depends on the message preceding this one in the dayfile.

None.

Attempt to recover any good information using the K.ERRYES Initial K display command, or initialize the file using the K.INT Initial K display command.

Inform the data administrator.

Check the DMS statements in the TCF which specify which data managers are to be loaded by TAF. For CRM users, you need a DMS statement such as:

\[ 
\text{DMS,CRM,ON,xx,xx,...,xx} 
\]

where \( xx \) is any data base identifier.

Inform the data administrator.

Note which error has occurred and locate references to the error in the CRM/AAM Reference Manual for appropriate action.

Inform data administrator.

The last reported BRF must be corrected or reallocated.

Only an operator may up the data base that he/she downed. It cannot be upped automatically.

After the cause of the data base/file being idle has been fixed, the operator must bring it up.

Data administrator must investigate the cause of AAMI inability to bring file/data base up.

Call the data administrator to investigate the cause.

There may be a transaction in the system attempting to use functions reserved for DMREC.

An analyst should investigate the reason for this rejection.

MESSAGE               SIGNIFICANCE                                                                 ACTION                  ROUTINE
FIELD LENGTH EXCEEDED FOR RECORD.  TAF does not have enough field length to allocate the space for the record buffer. Decrease the record size specified in the xxJ file or increase the TAF initialization field length. TAF
FIELD LENGTH EXCEEDED FOR USERS.  TAF does not have enough initialization field length for allocating file control tables. Decrease the users parameter on the CRM statement, increase the TAF initialization field length, or inform site analyst. TAF
FILE ATTACH/DEFINE ERROR
An error was detected in attaching or defining an ARF or BRF. Check the ARFs and the BRFs for attach mode and processing mode and correct if necessary. TAF1
xxfilen - FILE, ERROR ON LOCK FUNCTION.  An error occurred while attempting to lock the specified file. Possible causes are: - No free file lock table entry (TKOK). - Another task has file locked. - Another task has record locked. Rerun the job at another time. If problem persists, increase the number of lock table entries. AAMI
xxfilen - FILE, ERROR ON OPEN FUNCTION.  An error occurred while attempting to open the specified file. Possible causes are: - No free file control table entry (TFCB). - *CRM* error on OPEN function. - Incorrect key length. - Incorrect record length. Correct error. If not possible, contact site analyst. AAMI
FILE xxJ NOT FOUND.  Transaction subsystem aborts. Data base in TCF file has no xxJ file, or a PFM error occurred. Inform TAF data administrator or site analyst. TAF
FILE NAME CONFLICT.  The input file name specified on the KTSOMP command is the same as the output file name specified. Correct error and rerun. KTSOMP
FILE NAME MISMATCH ON TAPE HEADER RECORD.  File name on ARF tape and attached ARF don't match. Check file name on ARF tape being used. DMREC
FILE NAME MUST BE 2-7 CHARACTERS.  The xxpfn1 parameter on the CRM statement must be two to seven characters, the first two (xx) being the data base name. Correct the xxpfn1 parameter on the CRM statement or inform data administrator. TAF
FILE NOT ATTACHED - filename.  Either the P or the N parameter file was not attached when the DA option was used; filename is the permanent file name. Ensure that the file is defined or attached prior to entering the LIBTASK statement. TAF or LIBTASK
FILE hash NOT FOUND.  The indirect file named hash containing the binary code of the hashing routine was not found under the username parameter on the USER statement in the xxJ file or a PFM error occurred. Ensure that file hash is saved under the username parameter or inform data administrator. Consult the CYBER Loader Reference Manual (listed in the preface). TAF
FILE ORGANIZATION IS NOT IS, DA OR AK.  The file organization parameter on the CRM statement was not specified as either IS, DA, or AK. Correct the CRM statement and try again. DMREC
FILE TCF EMPTY.  An empty TCF exists under the TAF user name. Place the necessary information on TCF. TAF
FILE TCF NOT FOUND.  The TCF was not found under the user name of the Transaction Facility. Create a TCF file under the TAF user name. TAF
FILE TYPE MUST BE AK, DA, OR IS.  The type parameter on the CRM statement must be AK (actual key), IS (indexed sequential) or DA (direct access). Correct the type parameter on the CRM statement or inform the data administrator. TAF
FILE TYPE NOT ARF OR BRF.  On a create function a file name was used that does not conform to the ARF/BRF naming conventions. Check file name on create directive. DMREC
FL TOO LARGE- nnnnnB, taskname,tasklibrary.  The initial load field length, nnnnnB, for task taskname on task library tasklibrary exceeds the minimum size of the transient task area (potential space available to contain transient tasks). Thus a situation could arise in which it would not be possible to load the task. Correct error. TAF

</table>
**MESSAGE**

n.nnn KILO TASK RECALLS FOR OUTPUT.

Upon transaction facility termination, this message indicates the number of times tasks were put in recall because the network block limit (NBL parameter on a TERMINAL statement) for the terminal in use was reached.

**SIGNIFICANCE**

Refer to the Network Access Method Network Definition Language Reference Manual (listed in the preface).

**ACTION**

TAF

**ROUTINE**

TAF

n.nnn KILO TASK RELOADS.

Upon transaction facility termination, this message indicates how many reloads of tasks occurred. TAF reloads tasks that have fatal errors if one of the following is true:
- The task is central memory resident.
- There are queued transactions waiting to use the task.

**SIGNIFICANCE**

Inform site analyst.

**ACTION**

TAF

**ROUTINE**

TAF

n.nnn KILO TASK ROLLOUT COMPLETES.

Upon transaction facility termination, this message indicates the number of times TAF rolled out tasks. This statistic excludes the number of times the rollout operation did not complete.

**SIGNIFICANCE**

None.

**ACTION**

TAF

**ROUTINE**

TAF

n.nnn KILO TASK ROLLOUT STARTS.

Upon transaction facility termination, this message indicates the number of times TAF initiated a rollout operation. Rollout includes writing a task to disk and releasing the task subcontrol point space. In some cases, the task is allowed to stay central memory resident for a while before it is rolled out.

**SIGNIFICANCE**

None.

**ACTION**

TAF

**ROUTINE**

TAF

n.nnn KILO TRANSACTION ABORTS.

Upon transaction termination, this message indicates how many transaction tasks have aborted.

**SIGNIFICANCE**

None.

**ACTION**

TAF

**ROUTINE**

TAF

n.nnn KILO TRANSACTIONS PROCESSED.

Upon TAF termination, this message indicates the number of TAF transactions processed.

**SIGNIFICANCE**

None.

**ACTION**

TAF

**ROUTINE**

TAF

KL PARAMETER OR CRM CARD NOT SPECIFIED PROPERLY.

The KL parameter or the CRM statement was specified improperly or specified as zero length.

**SIGNIFICANCE**

Correct the CRM statement and try again.

**ACTION**

DMREC

**ROUTINE**

DMREC

KTSMDP COMPLETE.

Dump completed normally.

**SIGNIFICANCE**

None.

**ACTION**

KTSMDP

**ROUTINE**

KTSMDP

LIBRARY DIRECTORY EMPTY - filename.

The task library file indicated does not contain a directory.

**SIGNIFICANCE**

Inform site analyst.

**ACTION**

TAF

**ROUTINE**

TAF

LIBRARY DIRECTORY ERROR - filename.

The task library file indicated contains a nonrecognizable directory.

**SIGNIFICANCE**

Inform site analyst.

**ACTION**

TAF

**ROUTINE**

TAF

LIBRARY DIRECTORY TOO LONG - filename.

The directory record on the task library file indicated exceeded the maximum length allowed by the transaction executive (398 entries).

**SIGNIFICANCE**

Inform site analyst.

**ACTION**

TAF

**ROUTINE**

TAF

LIBRARY FILE TIME OUT.

The library file was busy for the length of time specified by an assembly constant, so LIBTASK was unable to attach it. Another user apparently has the file attached and will not allow modification.

**SIGNIFICANCE**

Retry at a later time.

**ACTION**

LIBTASK

**ROUTINE**

LIBTASK

LIBTASK ERROR CONDITION UNKNOWN.

The error condition for the error processing routine ERR within LIBTASK was unknown.

**SIGNIFICANCE**

Inform data base administrator.

**ACTION**

LIBTASK

**ROUTINE**

LIBTASK

LIBTASK PFM ERROR DETECTED.

A permanent file error other than FILE BUSY was received when the library file attach was attempted.

**SIGNIFICANCE**

Correct and rerun.

**ACTION**

LIBTASK

**ROUTINE**

LIBTASK

LIST COMPLETE.

Informative message.

**SIGNIFICANCE**

None.

**ACTION**

DMREC

**ROUTINE**

DMREC

LOAD ERROR IN HASHING ROUTINE.

When attempting to load the hashing routine on a record load operation, a load error or no entry point in the hashing routine was found.

**SIGNIFICANCE**

Check for valid hashing routine, inform analyst.

**ACTION**

DMREC

**ROUTINE**

DMREC

LOADING ECS taskname.

Informative message. The transaction subsystem is loading task taskname.

**SIGNIFICANCE**

None.

**ACTION**

TAF

**ROUTINE**

TAF

LOG ENTRY TABLE OVERFLOW.

Too many recoverable data base file names exist on ARF.

**SIGNIFICANCE**

Increase size of table (TLOG).

**ACTION**

DMREC

**ROUTINE**

DMREC

(BLT)

MESSAGE

NO TERMINALS IN NETWORK FILE - filename.

NO TRANSACTION NAME IS DEFINED IN TASK
LIBRARY.

NOT ALL DATA BASE FILES UPPED.

NOT AVAILABLE.

filename NOT FOUND.

xxxxxx NOT FOUND IN DIRECTORY.

xxxxxx NOT IN DIRECTORY.

xxxxxx NOT INITIALIZED BY TOTAL.

STATUS IS yyyy.

NOTE FAILURE, THEN TYPE IN CFO, JSN. GO.

NULL DESCRIPTION FILE.

OFF TASK taskname-LIBRARY libraryname.

ONLY *BLOCK* or *RECORD* CAN FOLLOW FILE
NAME.

OPEN ERROR ON COPY OF THE DIRECTORY.

OPERATOR OVERRIDE.

OPERATOR TERMINATION.

PACKED DATE/TIME CONVERSION ERROR.

PARAMETER FORMAT ERROR.

PARITY ERROR IN TAPE WITH VSN=vsn.

nnnn PER CENT CPU USAGE.

PERCENT PARAMETER NOT SPECIFIED PROPERLY.

PF x x x x x x x - NOT ON xxJ FILE.
MESSAGE

PF xxxxxx - READ ONLY.

POSSIBLE BLOCKAGE AMONG CM RESIDENT TASKS.

The sum of the maximum field lengths (MFLs) for the CM resident tasks exceeds the minimum size of the total task area (potential space available to contain tasks). Thus one or more CM resident tasks could be blocked from completing.

POTENTIALLY BLOCKED TASKS DETECTED.

During TAF initialization, potentially blocked tasks were detected. Preceding error messages contain additional details.

RA+1 CALL ERROR.

There was an unrecognizable task request.

RA+1 CALL PARAMETER ADDRESS OUTSIDE FL.

A parameter in a task request was outside the field length of the task.

RA+1 CALL WITH ILLEGAL FUNCTION CODE.

There was an unrecognizable task request for system action.

READ ERROR ON TAPE.

Error in attempting to read an after image dump tape.

READ/WRITE ERROR ON TAPE.

A tape error has been encountered. If possible, use another tape.

RECORD NUMBER ERROR.

No header or an incorrect header or a missing header has been found on an ARF when updating a file.

xx - RECOVERABLE DATA BASE.

TAF/CRM is beginning task recovery process for recoverable data base xx.

RECOVERABLE FILE PARAMETER MUST BE *R* OR *N*.

The recovery parameter of the *CRM* statement in the *xxJ* file is incorrect.

RECOVERABLE RUN UNIT DELETED - username.

The recoverable run unit for username which appeared on the CRF has been deleted because username did not appear in the corresponding NCTFI file.

RECOVERY COMPLETE.

The transaction executive or interactive subsystem has successfully completed recovery.

RECOVERY FILE INCONSISTENT

The ARF or BRF table header information does not match the buffer header information.

RECOVERY FILE INITIALIZATION ERROR

An error has occurred during initialization because of the ARF or BRF file.

RECOVERY IMPOSSIBLE.

A fatal error occurred during transaction executive initialization or the recovery file prepared by the TAF initialization routine does not exist or could not be read.

RECOVERY NOT POSSIBLE NOW BECAUSE DATA BASE FILE IS DOWN. SELECT DESIRED OPTION FROM FOLLOWING LIST BY ENTERING LETTER.

A WAIT 5 MINUTES AND TRY AGAIN. TAF WILL WAIT 5 MINUTES BEFORE ATTEMPTING RERUN OF TRANSACTION.

B LOG OFF. THE PREVIOUS RECOVERABLE INFORMATION WILL REMAIN INTACT. LOG IN AT A LATER TIME TO ATTEMPT RERUN.

C ALLOW ENTRY OF NEXT TRANSACTION. THE PREVIOUS RECOVERABLE INFORMATION WILL BE LOST.

SIGNIFICANCE

An attempt has been made to write on a file defined in the *xxJ* file as read only.

ACTION

Change the *xxJ* file access mode.

Correct error.

Correct error.

Correct task or inform data base administrator.

Correct error.

Correct task or inform data base administrator.

Correct task or inform data base administrator.

Inform the data administrator.

Inform the data administrator.

Correct task or inform data base administrator.

Inform the data administrator.

None.

Fix the *CRM* statement.

None.

Inform data base administrator.

Self-explanatory.

None.

None.

Dump the database associated with the inconsistent ARF or BRF using DMREC. Re-create the ARF or BRF using DMREC and reinitialize the transaction subsystem.

Refer to the error message following this one for the error condition description.

Check dayfile for a specific error message or inform the site analyst.

Inform data base administrator. The data base file must be brought up for recovery.

</table>
MESSAGE

TAF ERROR CODE NOT DEFINED.
TAF or TAF/CRM has returned an error code that the routine RQS was not programmed to handle.

SIGNIFICANCE
Inform responsible individual for maintaining system.

ACTION
ROUTINE

TAF FUNCTION CODE NOT VALID.
TAF cannot process the request issued because it is an unrecognizable function code. This is an internal error.

TAF IDLE.
Informative message. This message appears only on the B display when TAF is idle.

TAF IDLE (GO OR DROP).
Access to TAF denied because it is idling down.

TAF IDLING DOWN.
TAF is idling down only EXLOGT will be accepted by TAF.

TAF INTERNAL ERROR.
TAF has found internal data to be inconsistent.

TAF NOT PRESENT (GO OR DROP).
The TAF subsystem was not present when a batch job tried to connect to it.

TAF RECOVERY REQUEST ERROR.
TAF cannot recover a batch user because of an internal TSTAT error.

TAF SUBSYSTEM NOT DEFINED AS A SCP
TAF was not defined as a system control point when it was brought up.

TAF TERMINATE.
The transaction subsystem was dropped via DSD command IDLE,TAF and was not restarted.

TAF TRANSACTION NAME UNKNOWN.
The transaction name requested for scheduling was not found in either the data base or system task library in TAF.

TAF TRANSACTION NOT RERUNNABLE.
There was an attempt to rerun a transaction and an error occurred.

TAF TWO OUTSTANDING REQUESTS.
TAF received another request from a user program before the previous request was satisfied. This is an internal error.

TAF USER NOT VALID FOR TAF ACCESS.
The batch job tried to access TAF (via a BTRAN) and the user name under which the job was run was not validated in the network file of TAF.

TAF USER NUMBER ACTIVE.
Another batch or terminal job is currently accessing TAF/CRM under this user name.

TAPE NOT READABLE.
On a record load of a file the dump tape was found incomplete - no trailer record.

TASK CEASE WITH REQUESTED ABORTED.
The task requested on abnormal CEASE with or without memory dump.

TASK EDITING COMPLETE.
Dayfile message indicating that the run has terminated. Normal LIBTASK output consists of four lists - the input directives, the tasks on the current library, the tasks added to the library, and the tasks replaced on the library. After these lists, the time and date of the last library modification are given. If errors occurred during processing of the task binary file, a list of error messages also appears. If the LIBTASK run was initiated from a terminal, the directive and current library lists do not appear.

TASK LIBRARY DIRECTORY EMPTY.
The last record of the library file is empty.

ACTION
Inform responsible individual for maintaining system.
Inform data base administrator.
None.
Log off by typing EXLOGT.
Perform a dump of TAF or inform site analyst.
Operator: Type GO,jsn. or drop job with DROP,jsn. Others: Informative message only.
Inform data base administrator.
Inform data base administrator.
None.
Enter correct transaction name or define the unknown transaction name in the task library or check to see whether nonexistent tasks are defined in the transaction.
Inform the data administrator. The administrator may check the TAF dayfile for the possible cause of the error.
Inform the data administrator.
Inform TAF data administrator to enter the user name in the network file of TAF.
Resubmit job at a later time.
Load from previous dump.
Refer to next dayfile message.
Ensure that the correct file has been specified; if so, the library must be recreated.

MESSAGE          SIGNIFICANCE          ACTION            ROUTINE
TOO MANY DATA BASE NAMES.       The number of data base names associated with one data manager via DMS statements exceeds the value of MAXDB.         Decrease the number of data base names associated with the data manager.          TAF
TOO MANY FILE NAMES OR VSN-S SPECIFIED.       The VSN or file name limit was exceeded on a directive.         Check the installation parameters TVSNL and TDFNL for maximums.          DMRREC
TOO MANY FILES IN TOTAL DATA BASE.       Self-explanatory.         Reduce the number of entries in the TCF file or increase TMAXFIL.          TAF
TOO MANY NEW TRANSACTIONS ON TRANSACTION DIRECTORY - filename.       Informative message. During an on line update of a task library, TAF detected that the transaction directory (TRD) was longer than allowed (the number of new additions exceeds installation parameter TRDMN). Excess named TAF transaction definitions will be discarded.         None.  When TAF is next initialized, the new transaction definitions will be included.          TAF
TOO MANY RA+1 CALLS.       Only n monitor requests are allowed; more than n occurred, where n is an assembly constant.         Inform site analyst.  Possibly a task is in a loop.          MSABT
TOO MANY TAF JOURNAL FILES IN xxJ FILE.       More than three TAF journal files per data base were specified, causing the transaction subsystem to abort.         Examine xxJ file for xxJOR entries. Inform the TAF data administrator.          TAF
TOTAL DATA MANAGER NOT LOADED.       TOTAL data manager was called but has not been loaded.         Inform data base administrator.          MSABT
TOTAL DATA MANAGER SUCCESSFULLY LOADED.       Self-explanatory.         None.          TAF
TOTAL DID NOT RECOVER PROPERLY STATUS IS yyyy.       An error status yyyy was returned on a TOTAL FINAL call. Refer to Diagnostics in the TOTAL Reference Manual for yyyy.         Correct error and reinitialize transaction executive.          TAF
TRAN. SEQ. zzzzzzzzzB with ID xxxxx MIGHT BE BAD.       A BRF disk error has occurred and the transaction sequence numbers listed in the dayfile might contain errors.         Inform data base administrator of the error.          DMRREC
TRANSACTION DIRECTORY EMPTY.       Probable corruption of task library file.         Regenerate task library.          LIBTASK
TRANSACTION DIRECTORY EMPTY - filename.       Probable corruption of task library file.         Regenerate task library.          TAF
TRANSACTION DIRECTORY ERROR.       Probable corruption of task library file.         Regenerate task library.          TAF
TRANSACTION DIRECTORY ERROR - filename.       Probable corruption of task library file.         Regenerate task library.          TAF
TRANSACTION DIRECTORY TOO LONG - filename.       Error -- Too many transaction definitions exist in the transaction directory.         Regenerate task library. Make sure the number of transactions does not exceed installation parameter TRDMT or reassemble TAF and LIBTASK increasing the size of the installation parameter TRDMT.          LIBTASK
TRANSACTION DIRECTORY TOO LONG.       Too many transactions exist in named-transaction directory.         Either reduce number of named-transactions declared or contact TAF site analyst.          LIBTASK
TRANSACTION SESSION ENDED.       Option B was selected and TAF logged the terminal off leaving the previous recoverable information intact.         Log in at a later time to attempt rerun.          RTASK
TT OPTION REQUIRES USER NUMBER.       When updating a task library on-line (TT option is specified on LIBTASK command), the user name must be specified prior to the LIBTASK command so the library associated with that user name can be found.         Specify user name via USER or CHARGE command before LIBTASK command and rerun job.          LIBTASK
UN=username NOT VALID ON FM=family.       Username on the specified familyname is not valid. The user name and familyname may not be defined or are incorrect in xxJ file.         Inform site analyst.          TAF
UNABLE TO ATTACH TOTAL BINARIES.       File of TOTAL binaries is not under the user index of the transaction subsystem or a PFN error occurred.         Correct error and reinitialize transaction executive, or inform site analyst.          TAF

MESSAGE

ZZdbBnn - BRF RECOVERY FILE.

ZZdbOIR UNREADABLE.

SIGNIFICANCE

TAF/CRM is beginning to roll back data base updates from file ZZdbBnn.

When trying to expand a data file, an attempt to read the directory file failed.

ACTION

File name entry can be restored by adding an appropriate CRM statement to the xxJ file.

Inform data administrator.

ROUTINE

AAMI

DMREC
GLOSSARY

AAM
Refer to Advanced Access Methods.

ABH
Refer to Application Block Header.

ABN
Refer to Application Block Number.

Absolute code
Code in which all required external references have been satisfied. All addresses refer to specific locations within the job field length.

ABT
Refer to Application Block Type.

ACN
Refer to Application Connection Number.

ACT
Refer to Application Character Type.

Actual Key
The primary key for a record in a file with actual key organization; indicates the storage location of the record.

Actual Key (AK) File
A mass storage file in which each record is stored at the location indicated by the primary key. For initial actual key files, the primary key must specify the block and record slot number in which the record is stored. For extended actual key files, the primary key is a record number that AAM converts to the storage location of the record. Access is random or sequential.

Address
The location of a word in memory. The location is designated by number or symbolic name.

Advanced Access Methods (AAM)
A file manager that processes indexed sequential, direct access, and actual key file organizations, and supports the Multiple Index Processor. Refer to CYBER Record Manager.

After Image
A copy of a DMS-170 data base record after it has been modified.

After Image Recovery File (ARF)
A file upon which TAF writes after images of records in recoverable files when a request to update such a record is processed within a begin-commit sequence.

AK File
Refer to Actual Key File.

Alias
A data name used in a subschema in place of a schema data name.

Alphabetic Character
A character belonging to the set of letters A through Z and the space.

Alphanumeric
Consisting of alphabetic and/or numeric characters only.

Alternate Key
A key, other than the primary key, by which an indexed sequential, direct access, or actual key file can be accessed.

ANSI
American National Standards Institute. An organization that establishes standards for the benefit of its member organizations.

Application
In TAF, a set of data files and the set of tasks associated with those files.

Application
A program resident in a host computer that provides an information storage, retrieval, and/or processing service to a remote user via the data communication network. IAF is an example of an application.

Application Block Header (ABH)
A single 60-bit word description accompanying every block passing between an application and NAM.

Application Block Number (ABN)
A field in the application block header. An application-assigned number used to identify a particular data message block.
Application Block Type (ABT)
A field in the application block header defining the accompanying block as either data or supervisory, null or not null, and indicating if this is the last block of a message.

Application Character Type (ACT)
A field in the application block header defining the byte size of text characters.

Application Connection Number (ACN)
A number assigned by the communications supervisor program to identify a particular logical connection within an application.

Application Switching
The process of leaving the control of one application and entering the control of another, without going through another complete login sequence.

Backup Directory
A direct access file automatically allocated and maintained by DMREC. It contains information about the data base, index and after image recovery files for an application. The file name is ZxxDIR where xx is the application identifier.

Backup Dump
A copy of all or selected portions of a data base, which is produced on a regularly scheduled basis for the explicit purpose of data base recovery.

Batch Job
Instructions and data submitted as a complete unit without further user intervention. The job can be punched on cards or created and submitted from a terminal.

Batch Mode
The state of a mode 4A terminal during which batch data is transmitted from the terminal's card reader to central files and/or from central files to the terminal's line printer. Also, the state of an asynchronous terminal during which input transmission occurs on a block-by-block basis.

Batch Test Facility
An absolute program residing on the CDCS system library that allows CDCS to run at the same control point as a user program.

Before Image
A copy of a DMS-170 data base record before it has been modified.

Before Image Recovery File (BRF)
A file to which TAF/CRM writes the before images of records in recoverable files when a request to read such a record is processed from within a begin-commit sequence.

Begin-commit sequence
A series of data base updates beginning with a data base begin request and ending with a data base commit or data base free request.

Beginning-of-Information (BOI)
The start of the first user record in a file. Tape labels and system-supplied information, such as an index block or control word, do not affect beginning-of-information.

Binary File
Usually a noneditable file containing a pre-compiled program.
Bit

An abbreviation of binary digit. It is a single digit, 0 or 1, in a binary number. Also used to represent the smallest unit of information. A central memory word (one storage location) contains 60 bits.

Block

In the context of network communications, a portion or all of a message. A message is divided into blocks to facilitate buffering, transmission, error detection, and correction for variable length data streams.

During input from a terminal, a block is a single transmission comprising one or more lines of one or more messages.

During input to an application, a block is a single line comprising part or all of a message. Terminal transmission blocks are divided into as many application input blocks as needed to provide one block of input per terminal input line, until the message is completed.

During output to a terminal, a block is one or more lines comprising one message.

BOI

Refer to Beginning-of-Information.

BP

Beginning Priority.

BRF

Refer to Before Image Recovery File.

Called Task

A task which is the object of a CALLTSK or a CALLRTN request.

Calling Task

A task which executes a CALLTSK or a CALLRTN request.

Carriage Control

The control exercised over the format of printed output. The leftmost character of the data line to be printed is the carriage control character. Carriage control is also called format control.

CB

Communication Block.

CCP

Communications Control Program.

CDCS

Refer to CYBER Database Control System.

Central Memory (CM)

The main storage device whose storage cells (words) can be addressed by a computer program and from which instructions and data can be loaded directly into registers from which the instructions can be executed or from which data can be manipulated.

Character

Any alphabetic, numeric, or special symbol that can be encoded. This term applies to the graphic characters for an input or output device, and to uniquely encoded control characters used by a terminal. Unless specified otherwise, characters are ASCII 8-bit byte characters.

Charge Number

An alphanumeric identifier the installation uses to allocate charges to individual users for system usage.

CIO

Circular Input/Output.

Close

A set of terminating operations performed on a file when input and output operations are complete. All files processed by the CYBER Record Manager must be closed.

CM

Refer to Central Memory.

CMM

Common Memory Manager.

COBOL

Common Business-Oriented Language. This higher level language simplifies the programming of business data applications.

Command

A sequence of words and characters that call a system routine to perform a job step. The command must conform to format specifications and end with either a period or a right parenthesis. A command is sometimes called a control statement.

Communication Recovery File (CRF)

Files used for the automatic recovery feature.

Compile

To translate a program from a higher level programming language (for example, FORTRAN or BASIC) into machine instructions called object code.
Concurrency

Simultaneous access to the same data in a data base by two or more applications during a given span of time.

Console

A terminal devoted to network control processing. There may be three such terminals: the network operator's (NOP) terminal, the local operator's (LOP) terminal, and the network processing unit console.

CRF

Refer to Communication Recovery File.

CRM

Refer to CYBER Record Manager.

CRT

Cathode Ray Tube.

CYBER Database Control System (CDCS)

The DMS-170 controlling module that provides the interface between an application and a data base.

CYBER Loader

The utility that prepares programs for execution by placing program instruction and data blocks in central memory.

CYBER Record Manager (CRM)

A software product that allows a variety of record types, blocking types, and file organizations to be created and accessed. Products like COBOL 5, FORTRAN Extended 4, FORTRAN 5, Sort/Merge 4, Sort/Merge 5, ALGOL 5, and DMS 170 use the CYBER Record Manager to manage execution time input/output. Neither the input/output of the operating system nor that of most of the system utilities such as COPY or SKIPF is implemented through the CYBER Record Manager. All CYBER Record Manager file processing requests ultimately pass through the operating system input/output routines.

DA

Refer to Data Administrator.

Data Administrator (DA)

The individual who leads the design, programming, implementation, and maintenance efforts associated with a DMS-170 controlled data base.

Data Base

A systematically organized, central pool of information; organization is described by a specific schema.

Data Base Status Block

An area of memory defined within an application to which CDCS returns information concerning the status of operations on data base files and relations. The status block is updated after each CDCS operation.

Data Block

A block in which user records are stored in an indexed sequential or actual key file. Data block structure is defined by the user, or AAM defaults are accepted. Contrast with Index Block for indexed sequential files.

Data Description Language (DDL)

The language used to structure a DMS-170 schema and subschema.

Data Management System

Refer to Database Management System.

Database Management System

A generalized computer program which handles the mechanics of storing, updating, and accessing data for multiple applications.

Dayfile

A chronological file created during job execution which forms a permanent accounting and job history record. Dayfile messages are generated by operator action or when commands are processed. A copy of the dayfile is printed with the output for each job. You must explicitly request it in an interactive job.

DBREC

Utility used to prepare files for transaction recovery using CDCS.

DDL

Refer to Data Description Language.

Deadlock

A situation that arises in concurrent data base access when two or more applications are contending for a resource that is locked by one of the other ones, and none of the programs can proceed without that resource.

Deadstart

The process of initializing the system by loading the operating system library programs and any of the product set from magnetic tape or disk. Deadstart recovery is reinitialization after system failure.

Default

A system-supplied option used when you do not supply the option.
Delimiter
A character used to separate statement elements, such as words and literal constants, or other strings of text.

Device
The physical recording medium of random mass storage, such as a disk pack.

Device Set
A group of rotating mass storage devices. No device can belong to more than one device set. Every file must be contained within one device set, but can be on different devices in that device set.

Direct Access File
A CYBER Record Manager file containing records stored randomly in home blocks according to the hashed value of the primary key in each record. Files must be mass storage-resident. All allocation for home blocks occurs when the file is opened on its creation run. Access is random or sequential. It may be attached to your job and all changes are made on the file itself rather than a temporary copy of the file.

Directives
The instructions that supplement processing defined by a command or by a program call for execution of a utility function or member of a product set. Directives do not appear in the command record; they are usually in a separate record of the file INPUT or a file referenced in a command. Directives are required for execution of FORM, the CREATE utility, and EDITLIB, among others.

Disk
A unit composed of one or more flat, circular plates with magnetic material on both sides that is used to store large amounts of data or programs.

Display Code
A 6-bit-display code set used to represent alphanumeric and special characters.

Displays
Two console screens or a split screen used to display system and job information, operator messages, and contents of central memory. Through the console keyboard, the operator can control the operation of the system. The displays are identified by alphabetic characters; some used frequently are: job status (B), system files (H), and dayfile messages (A).

Dump
A printed listing of the contents of the central processor registers and a predetermined number of words within central memory that pertain to a job.

Dynamic Access
Access mode that allows a nonsequential file on mass storage to be accessed randomly or sequentially, depending on the format of the access statement.

ECS
Refer to Extended Core Storage.

End-of-File (EOF)
A boundary within a sequential file, but not necessarily the end of a file, that can be referenced by name. The actual end of a named file is defined by EOI. For labeled tape, EOF and EOI (denoted by the EOF1 label) are the same. For multifile tape files, EOF and EOI do not correspond. In the product set manuals, an end-of-file is also referred to as an end-of-partition.

End-of-Information (EOI)
An indicator that marks the physical end of a named file.

End-of-Record (EOR)
The terminator of a logical record. On a PRU device, a short PRU or a zero-length PRU with a level designator of 0 indicates EOR. On tapes that are not PRU devices, an interrecord gap indicates EOR.

EOF
Refer to End-of-File.

EOI
Refer to End-of-Information.

EOR
Refer to End-of-Record.

ESM
Extended Semiconductor Memory.

Exchange Package
A table that contains information used during job execution. It is printed as part of the output when a job aborts.

Extended
A term used in conjunction with indexed sequential, direct access, and actual key files to denote a specific type of internal processing by AAM and MIP. Processing is indicated by setting the ORG FIT field to NEW.

Extended Core Storage (ECS)
Optional additional memory. ECS contains 60-bit words; it has a large amount of storage and fast transfer rates. ECS can be used only for program and data storage, not for program execution. Special hardware instructions exist for transferring data between central memory and ECS.
Extended Memory

An extension to central memory which is physically located outside of the machine. Formerly referred to as extended core storage (ECS) or large central memory (LCM).

Family Name

Name of the permanent file storage device or set of devices on which all of your permanent files are stored. When you request a permanent file, the system looks for it on this family (group) of devices. Usually a system has only one family of permanent file devices but it is possible to have alternate families in the system. You specify which family you are using when you log in. Your family name is given to you by your employer, instructor, or computer personnel.

FAST Dynamic Loader (FDL)

A facility that provides fast loading and unloading of specially formatted code called capsules. The amount of memory required for job execution can be greatly reduced because capsules can be easily loaded and unloaded as needed, freeing memory for other uses.

FDL

Refer to Fast Dynamic Loader.

FE

Refer to Format Effector.

FET

Refer to File Environment Table.

Field Length (FL)

The area in central memory allocated to a particular job; the only part of central memory that a job can directly access. Also the number of central memory words required to process a job.

FILE Command

A command that supplies file information table values after a source language program is compiled or assembled but before the program is executed. Basic file characteristics such as organization, record type, and description can be specified in the FILE command.

FILE Environment Table (FET)

A table within a program's field length through which the program communicates with operating system input/output routines. One FET exists for each file in use by the program.

File Information Table (FIT)

A table through which a user program communicates with the CYBER Record Manager. For direct processing through CRM, a user must initiate establishment of this table. All file processing executes on the basis of information in this table. The user can set FIT fields directly or use parameters in a file access call that sets the fields indirectly. Some product set members set the fields automatically for the user.

File Organization

Defined by ORGANIZATION clause. Can be sequential, indexed, relative, direct, actual-key, or word-address. Established at the time the file is created and cannot change as long as the file exists. Affects access mode, open mode, and formats of statements that can be used to manipulate file records.

File Statement

Command for the CYBER Record Manager that specifies parameters for the FIT at the time the file is opened.

File Statistics Table (FSTT)

A table generated and maintained by the CYBER Record Manager to collect statistics about each direct access, indexed sequential, and actual key file. The FSTT is a permanent part of a file and contains information such as organization type, size of blocks and the number of current accesses.

FIT

Refer to File Information Table.

FL

Refer to Field Length.

Flag

A character or bit that signals the occurrence or presence of a particular condition.

FORM

A general purpose file management utility for manipulating records and creating and converting files.

Format Effector (FE)

A control symbol used by certain protocols (for instance, the HASP protocol).

FORTRAN

FORmula TRANslatiOn. A language that solves algebraic and scientific problems using symbols and statements that closely resemble mathematical notation.

FSE

Refer to Full Screen Editor.
Refer to File Statistics Table.

Full Screen Editor

The editing facility that enables you to edit files in a screen format or a line-by-line format.

Global Task Dump Limit.

Host availability display.

Hashing

The method of using primary keys to search for relative home block addresses of records in a file with direct access storage structure.

Header

A word or set of words at the beginning of a block, record, file, or buffer which contains control information for that unit of data.

Host

A computer that executes applications.

Interactive Access Facility (IAF)

An application that provides a terminal operator with the interactive processing capability. The interactive facility makes terminal input/output and file input/output appear the same to an executing program.

Input/Output.

Refer to Indexed Sequential File.

Itemize

A utility routine that produces a listing of the contents of a file or library.

Interactive Virtual Terminal.

Job

All computer-related activity associated with a terminal session from login to logout. A batch job consists of instructions and data submitted as a complete unit.

Key

A group of contiguous characters or numbers the user defines to identify a record in a CRM file.

Large Central Memory Extended.

The loader directive used to control the load process under a variety of conditions.

The default name of the file to which language processors write executable code during program assembly or compilation.

A sequence of load operations which encompasses all of the loader's processing from the time that nothing is loaded until the time execution begins. It includes initialization, specification of specified loader requests, and the completion of the load.
Loader
A software product that prepares programs for execution by placing program instructions and data blocks in central memory and linking references in the program to the appropriate external routines.

Local
Refers to data that exists only during the processing of a single job and that can only be accessed by that job.

Local Operator (LOP)
The network operator who monitors line, terminal, and application activities in the network.

Login
The procedure used at an interactive terminal to gain access to the system.

Logout
The procedure by which you end terminal session. You type BYE.

LOP
Refer to Local Operator.

Macro
A sequence of source commands that are saved and then assembled whenever needed through a macro call.

Mass Storage
Magnetic disk or extended memory that can be accessed randomly as well as sequentially.

Master Directory
A file containing information used by CDCS in processing. This information consists of schema and subschema tables, media parameters, and data base procedure library and logging specifications.

MFL
Maximum Field Length.

MIP
Refer to Multiple Index Processor.

MP
Maximum Priority.

Multifile Set
A tape file set having more than one tape file.

Multimainframe Operation
Operation that provides mechanisms by which more than one computer can share mass storage devices.

Multiple Index File
An indexed sequential, direct access, or actual key file that has alternate keys defined.

Multiple Index Processor (MIP)
A processor that allows AAM files to be accessed by alternate keys.

NAM
Refer to Network Access Method.

NCT
Network Communication Table.

NCTF
Refer to Network Description File.

NDL
Refer to Network Definition Language.

Network Access Method (NAM)
A software package that provides a generalized method of using a communications network for switching, buffering, queuing, and transmitting data. NAM is a set of interface routines used by a terminal servicing facility for shared access to a network of terminals and other applications, so that the facility program does not need to support the physical structures and protocols of a private communication network.

Network Definition Language (NDL)
The compiler-level language used to define the network configuration file and local configuration file contents.

Network Description File (NCTF)
File that must be present if the transaction facility is used. The file is prepared by the site analyst.

NOS
Network Operating System.

Numeric Character
Digits 0 through 9.

Object Code
The machine language version of a program that has been translated (compiled) from source code written in a higher level language.

Open
A set of preparatory operations performed on a file before input and output can take place; required for all CRM files.
Operating System

The set of system programs that controls the execution of computer programs and provides scheduling, error detection, input/output control, accounting, compilation, storage assignment, and other related services.

Operation

A particular function performed on units of data; for instance, opening or closing an area, or storing or deleting a record.

Order Dependent

Used to describe items which must appear in a specific order.

Order Independent

Used to describe items which need not appear in any specific order. Parameters, particularly those with keywords, may be order independent.

Output

Information flowing downline from host to terminal.

Output File

The file on which the system writes information to the user. Unless another file name is specified, the output file is printed at the terminal.

Pack Name

A one- to seven-character name that identifies the auxiliary device to be accessed in a permanent file request.

Parameter

A variable that is given a specific value for a particular purpose or process.

Parity

In writing data, an extra bit is either set or cleared in each byte so that every byte has either an odd number of set bits (odd parity) or an even number of set bits (even parity). Parity is checked on a read for error detection and possible recovery.

Password

A name or word entered during login to provide extra security for your user name. A unique password ensures that no one else can log into the system using your user name and access your files.

Permanent File

A file stored on mass storage. This file is cataloged by the system so that its location and identification are always known to the system. Permanent files cannot be destroyed accidentally during normal system operation. They are protected by the system from unauthorized access according to privacy controls specified by the file owner.

Physical Record Unit (PRU)

The amount of information transmitted by a single physical operation of a specified device. For mass storage files, a PRU is 64 central memory words (640 characters); for magnetic tape files, the size of the PRU depends upon the tape format. A PRU that is not full of user data is called a short PRU; a PRU that has a level terminator but no user data is called a zero-length PRU.

Primary Key

A key whose value uniquely identifies a record and determines the location of the record in a file. The primary key for a file must be defined when the file is created and must be used to update the file. Contrast with Alternate Key.

Procedure

A user-defined set of instructions that are referenced by name. The instructions consist of procedure directives and system commands.

Procedure File

A file containing one or more procedures.

PRU

Refer to Physical Record Unit.

PSN

Packet-Switching Network.

Purge

To delete a permanent file from the system. This enables releasing its mass storage space, erasing its catalog entries, and so forth.

Queue

A sequence of blocks, tables, messages, and so forth. Most NPU queues are maintained by leaving the queued elements in place and using tables of pointers to the next queued element. Most queues operate on a first-in, first-out basis. A series of worklist entries for a specific terminal is an example of an NPU queue.

RA

Refer to Reference Address.

RAE

Refer to Reference Address.

Record

A unit of information. In the CYBER Record Manager and its language processors, a record is a unit of information produced by a single read or write request. Eight different record types exist within CRM. The user defines the structure and characteristics of records within a file by declaring a record format.

Other parts of the operating system and its products might have additional or different definitions of records.
Record Slot Number

The position of a record within a block in an actual key file; specified by the low-order bits of the primary key.

Record Type

The term record type can have one of several meanings, depending on the context. The CYBER Record Manager defines eight record types established by an RT field in the file information table. Tables output by the loader are classified as record types such as text, relocatable, or absolute, depending on the first few words of the tables.

Recovery

A process that makes a data base useful after some type of software or hardware failure has occurred.

Reference Address (RA and RAE)

RA is the absolute central memory address that is the starting, or zero, relative address assigned to a program. Addresses within the program are relative to RA. RA+1 is used as the communication word between the user program and monitor. RAE is the absolute extended memory starting address assigned to the file.

Release System

A software system delivered to a customer. In installing a system, the customer, but not an individual applications programmer, can use default values or parameters that differ from the released system.

Relocatable Code

Code that can be loaded into any region of the job field length. External references have not yet been satisfied.

Request

A statement that identifies a function to be performed. Often there are items used by or resulting from the function that are required as parameters in the request.

Reserved Word

An identifier that has a predefined meaning to a compiler and must not appear in a source program as a user-defined word or name.

Restart Identifier File

Random permanent file used for a start identifier in recovery by CDCS.

Returned Value

The value returned from a procedure invoked as a function, or the value returned by a built-in function.

Rewind

An operation that positions a file at beginning-of-information.

RMS

Refer to Rotating Mass Storage.

Rollback

The process of restoring a data base to a previous state.

Rotating Mass Storage (RMS)

A disk storage device.

RTL

Requested Task List.

Satisfying External References

The process of searching one or more libraries and loading programs that contain entry points matching external references that are currently unsatisfied.

Schema

A detailed description of the internal structure of a data base.

Separator

A character used to separate parameters in a command.

Sequential (SQ) File

A file in which records are accessed in the order in which they occur. Any file can be accessed sequentially. Sequential files must be accessed sequentially because no key or address is associated with each record in the files.

Source Code

Code input to the computer for later translation into executable machine language instructions (object code).

SQ File

Refer to Sequential File.

Stimulator

A collection of central memory and peripheral processor programs which enters a hypothetical work load into the system to analyze the effects of such a load on response time and system reliability.

String

A sequence of contiguous characters or bits treated as a unit.
Subschema

A detailed description of the portion of a data base to be made available to one or more applications.

Supervisory Message

A message block in the host not directly involved with the transmission of data, but which provides information for establishing and maintaining an environment for the communication of data between the application and NAM, then through the network to a destination or from a source. Supervisory messages may be transmitted to an NPU in the format of a service message.

TAF Configuration File (TCF)

A file created and maintained by the data administrator specifying which data managers are active and the applications to be associated with each.

Task

A program to be executed under the transaction subsystem. Tasks are stored in absolute binary format on libraries which must be available to the transaction subsystem.

Task Library Directory (TLD)

The directory on each task library which contains information on the tasks in the library. TAF makes its own copy of each TLD at initialization and uses this copy to locate requested tasks.

Transaction

A task or a series of tasks executed as a unit under the transaction subsystem. All tasks in a transaction have the same transaction sequence number. In CDCS, the term data base transaction refers to the process which this manual calls a begin-commit sequence.

Transaction Library Directory (TRD)

The directory on each task library which contains information on the transactions in the library. TAF makes its own copy of each TRD at initialization and uses this copy to locate requested transactions.

Transaction Name

The one to seven alphanumeric character name given to a transaction created with the \tname input directive from the LIBTASK utility.

Transaction Recovery File

Random permanent file used for before image records necessary for recovery by CDCS.

Transaction Sequence Number

A unique number assigned by TAF to each transaction. It is used by TAF for task identification.

Transparent Mode

A software feature provided by the Network Access Method and the network processing unit (NPU). When transparent mode transmission occurs between an application and a terminal the Network Access Method does not convert data to or from 6-bit display code, and the NPU does not edit the character stream or convert the characters to or from 7-bit ASCII code. When no parity is in effect for the terminal and transparent mode transmission occurs, all seven bits of the character byte can be used to represent characters in character sets (such as EBCDIC).

TRD

Refer to Transaction Library Directory.

TST

Terminal Status Table.

TTOT

Table of Time-Originating Tasks.

UEM

Unified Extended Memory.

UJN

User Job Name.
User Index

A unique 17-bit identifier that is associated with each user name. The user index is used by the permanent file manager to identify the device and catalog track for the user's files.

User Name

A system access word that must be supplied by the user for validation purposes at login.

Utility

A program designed to help the user perform specific functions such as permanent file maintenance, library maintenance, and file editing.

Virtual Terminal

A software concept for CCP that converts all types of upline messages to one of two formats: batch virtual terminal or interactive virtual terminal. By this method, applications in the host need only to be able to process data in IVT or BVT format rather than in the multiplicity of formats which real terminals use. Downline messages from the host to real terminals are converted from IVT or BVT to real terminal format. The IVT/BVT processors are a part of the NPU's network communications software.

Volume Serial Number (VSN)

A one- to six-character identifier that identifies the volume of magnetic tape for the operator.

VSN

Refer to Volume Serial Number.

Word

A group of bits (or 6-bit characters) between boundaries imposed by the computer system. A word is 60 bits in length. The bits are numbered 59 through 0, starting from the left. It is also composed of five 12-bit bytes, numbered 0 through 4, from the left.

Working Storage Area

An area within the user's field length intended for receipt of data from a file or transmission of data to a file.

Write Mode

Allows a user to write, modify, append, read, execute, or purge the file (modify permission applies only to direct access files).

XXJ Files

Files created and maintained by the data administration which associates a particular user with a particular application.

Zero-Length PRU

A PRU that contains system information, but no user data. Under the CYBER Record Manager, a zero-length PRU level of 17 is a partition boundary. Under NOS, a zero-length PRU defines EOF.
The sample command list structures in this appendix demonstrate the use of various parameters that are available. The default input and output files can be used to reduce the number of control language statements needed to bring about a compile, load, and LIBTASK sequence, because the default binary output files are the binary input files for subsequent processors.

For example:

COBOL5,TAF,UC1.
LOAD,LGO.
NOGO,LGOB.
LIBTASK,P=RLTASKL,TT.

It is assumed that each of the following lists is preceded by job and USER commands. Some sites may require a CHARGE command.

### COMPASS TASK COMMAND LIST STRUCTURE

A sample command list that assembles a COMPASS application program and loads it onto a task library, RLTASKL, is illustrated in figure D-1.

```plaintext
ATTACH,OPL/UN=username.
COMPASS.
LDSET,LIB=TRANLIB,LIB=TRANF5.
LOAD,LGO.
NOGO,LGOB.
LIBTASK,P=RLTASKL,TT,I=0.
end-of-record
IDENT TASK
ENTRY TASK
OPL XTTEXT COMMACOM
COMBL BSS 69
   ← COMPASS task appears here
END
end-of-file
```

Figure D-1. COMPASS Command List Structure

### NOTE

The system OPL must be attached for COMMACOM to be called in the COMPASS program. Consult site personnel for the appropriate command.

### FORTRAN TASK COMMAND LIST STRUCTURE

A sample command list that compiles a FORTRAN application program and loads it onto a task library, RLTASKL, is illustrated in figure D-2.

```plaintext
FTN, DB=0.†
LDSET,LIB=TRANLIB,LIB=TRANF5.
LOAD,LGO.
NOGO,LGOB.
ATTACH,RLTASKL/M=W.
LIBTASK,P=RLTASKL,TT,I=0.
end-of-record
OVERLAY,ABS,0,0.
PROGRAM TASK2 ††
   ← FORTRAN task appears here
end-of-file
```

†The SEQ, TS, and OPT=0 options are not allowed.
††TASK2 is the name of the task.

Figure D-2. FORTRAN Command List Structure

### COBOL TASK COMMAND LIST STRUCTURE

A sample command list that compiles a COBOL application program and loads it onto a task library, RLTASKL, is illustrated in figure D-3.

```plaintext
COBOL5,TAF,UC1.
LDSET,LIB=TRANLIB,LIB=TRANC5.
LOAD,LGO.
NOGO,LGOB.
LIBTASK,P=RLTASKL,TT,I=0.
end-of-record
   ← COBOL task appears here
end-of-file
```

Figure D-3. COBOL Command List Structure

### NOTE

Under COBOL, the PROGRAM-ID name is used for the task name. Only alphabetic names can be used as task names.
Table E-1 lists files used by TAF.

INTRODUCTION

The network, through which terminals access a host and its applications (like TAF), can support many types of terminals. All supported terminals are grouped by the network into 18 standard terminal classes. Each terminal class has specific operating characteristics, also referred to as terminal characteristics. These terminal characteristics, taken together, make up a terminal definition and are predefined by the network to closely match the operating characteristics of actual terminals. The network accepts changes to any of these terminal definitions through terminal definition commands. These commands specify one or more parameters, each of which may give a new value to a terminal characteristic. Tables G-1 and G-2 list these terminal definitions, the default values, and possible values for each of the 18 classes.

The tables use the following abbreviations when identifying the terminal types for each terminal class:

<table>
<thead>
<tr>
<th>Abbreviation</th>
<th>Terminal</th>
</tr>
</thead>
<tbody>
<tr>
<td>HASP</td>
<td>Terminals using the Houston Automatic Spooling Program communication protocol.</td>
</tr>
<tr>
<td>HAZ</td>
<td>Hazeltine.</td>
</tr>
<tr>
<td>POST</td>
<td>HASP terminals that only support postprint format control.</td>
</tr>
<tr>
<td>PRE</td>
<td>HASP terminals that only support preprint format control.</td>
</tr>
<tr>
<td>Tek</td>
<td>Tektronix (teletypewriter emulation).</td>
</tr>
<tr>
<td>TTY</td>
<td>Teletype.</td>
</tr>
<tr>
<td>UT</td>
<td>User Terminal.</td>
</tr>
<tr>
<td>X.25</td>
<td>Terminals connected to a packet switching network (PSN) using the X.25 communication protocol.</td>
</tr>
<tr>
<td>X3.64</td>
<td>Terminals conforming to the ANSI X3.64 standard.</td>
</tr>
</tbody>
</table>

When a terminal logs in to the network, either the network assumes it to be of a certain terminal class or assigns it a terminal class that resembles the terminal's actual characteristics. If you do not know the terminal class in use, you can enter the CH command (described in this appendix) to ascertain the terminal class and some of the characteristics of your terminal. In either case, if the characteristics of your terminal do not match those of its assigned terminal class, you can change the values of the terminal characteristics or even change the terminal class by using the terminal definition commands described in this appendix. You can enter terminal definition commands any time the terminal is connected to the network (refer to appendix J for information on how to access a host).

When you use a terminal definition command to change a value, that change remains in effect until the terminal is disconnected from the network or another terminal definition command is used to change the value. Even application switching and logout do not change the values of the terminal characteristics if the terminal has not been disconnected from the network. Disconnecting your terminal from the network (that is, disconnecting the phone and redialing on dial-up terminals or turning a dedicated terminal off and then on again) causes all terminal characteristics to be reset to site-defined default values. The site defines these values using the Network Definition Language (NDL).

You can also reset your terminal's characteristics by entering the TC command. The TC command resets your terminal characteristics to the default values specified by the Communications Control Program (CCP). Note that CCP-defined values may differ from the site-defined NDL values.

It is also possible to change terminal definitions using the TRMDEF command or by using control byte 16 from an interactive job. The TRMDEF command is described under Terminal Control Commands in the NOS Reference Set, Volume 3, System Commands. Refer to NOS Reference Set, Volume 4, Program Interface, for information on control bytes.

TERMINAL DEFINITION COMMAND FORMAT

This section describes the general format of a terminal definition command. The specific format of each command appears later in this appendix.

General formats:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ct keyword=value†</td>
<td>Represents the network control character for your terminal as defined by the CT terminal definition command. Table G-1 gives</td>
</tr>
<tr>
<td>ct keyword1=value1 ct keyword2=value2 ...ct keywordn=value†</td>
<td></td>
</tr>
</tbody>
</table>

†The spaces shown are for clarity only. Do not include spaces when you enter a terminal definition command.
The default network control character for your terminal.

- **keyword**
  - Represents a mnemonic associated with a terminal characteristic.

- **value**
  - Specifies a particular value associated with the terminal definition mnemonic. Table G-2 gives the range of values for each terminal definition keyword. On some commands the value portion of the command is optional and defaults to `-Y`.

- **keyword**
  - Same as keyword.

- **value**
  - Same as value.

The second format allows you to make multiple terminal definitions in one line. If the line exceeds beyond character position 34, the results are unpredictable. Also, if you change the network control character ct in a concatenated group of commands, the CT command does not take effect until the remaining commands in the group have been processed.

As with all commands described in this manual, you must press the message transmission key in order for the system to process your command. Appendix K of the NOS Reference Set, Volume 3, System Commands, shows the default message transmission keys for the various terminal classes. This appendix describes how you can change the message transmission key (refer to the EB and EL commands).

**Example:**

To change the page width of a 200 User Terminal, enter these characters

```
   ZPW-50
```

and press the SEND key. The `Z` character is the network control character, `PW` is the keyword associated with page width, 50 is the new page width for the terminal, and the SEND key is the message transmission key for a 200 User Terminal.

**Restrictions**

You should not enter terminal definition commands while output is in progress. The network may not be able to perform such commands immediately.

The network presets all user-adjustable terminal characteristics any time you establish a connection to the network. The site administrators choose these preset values. Additionally, when a terminal is disconnected from the network and then reconnected, the network resets any terminal characteristics you have changed to their preset values.

To enter a terminal definition command at asynchronous terminals from which you can enter more than one line before transmitting (IN=BK is specified), the terminal definition command must be the last input line in the transmission. If the input is from paper tape (IN=PT is specified), the tape reader must stop. Unpredictable results can occur if more input follows the terminal definition command in the transmission block.

Characters or character codes you specify for the value portion of terminal definition commands are subject to the following restrictions:

- You cannot use the following ASCII characters (or their character codes) in the value portion of the AB, CN, BS, BI, B2, CT, EB, or EL commands:
  - any lowercase or uppercase alphabetic character
  - any digit 0 through 9
  - NUL
  - SOH
  - STX
  - DEL
  - space
- The ASCII characters or character codes you specify for the AB, BS, BI, B2, CN, CT, EB, and EL terminal definitions must all be different, except that AB and CN can have the same value and EB and EL may have the same value.
- If output flow control is used, do not use DC1s and DC3s in the AB, CN, BS, BI, B2, CT, EB, or EL commands.

**Terminal Definition Commands**

This subsection describes the function and format of each terminal definition command. The headings consist of the command name (a two-character mnemonic) followed by the terminal attribute it defines. Generally, the format descriptions do not show the default values or ranges of values since they vary with terminal class. Tables G-1 and G-2 show this information. If you are unable to find the key on your keyboard that corresponds to a particular character given in table G-1, consult the documentation for your terminal.

This section refers to categories of terminal classes to which commands apply. The categories are as follows:

<table>
<thead>
<tr>
<th>Category</th>
<th>Terminal Classes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Asynchronous</td>
<td>1 through 8</td>
</tr>
<tr>
<td>Mode 4</td>
<td>10, 11, 12, 13, 15</td>
</tr>
<tr>
<td>HASP</td>
<td>9, 14</td>
</tr>
<tr>
<td>Baysynchronous</td>
<td>16, 17, 18</td>
</tr>
<tr>
<td>X.25 PSN</td>
<td>1, 2, 3, 5, 6, 7, 8</td>
</tr>
<tr>
<td>3270</td>
<td>18</td>
</tr>
</tbody>
</table>

†You must press the ATTN key on a 2741-compatible terminal before entering this character.
(AB) - ABORT OUTPUT BLOCK CHARACTER

The AB command specifies the character used to abort an output block. When you enter this character from the terminal as the only character in a line, the current transmission block of output to the terminal is discarded.

Format:

ct AB=ab

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ct</td>
<td>Represents the network control character for your terminal as defined by the CT terminal definition command.</td>
</tr>
<tr>
<td>ab</td>
<td>Specifies the new abort output block character. This character must differ from the characters defined for BS, BI, B2, CT, EB, and EL.</td>
</tr>
</tbody>
</table>

This command only applies to asynchronous terminals and is not valid for X.25 PSN terminals.

(BF) - BLOCKING FACTOR

The BF command sets the size of intermediate data blocks that will be delivered to the host.

Format:

ct BF=bf

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ct</td>
<td>Represents the network control character for your terminal as defined by the CT terminal definition command.</td>
</tr>
<tr>
<td>bf</td>
<td>Specifies the blocking factor. You can specify the following values for bf:</td>
</tr>
<tr>
<td></td>
<td>0 Selects a line feed character and a character count of 100 as data-forwarding signals.</td>
</tr>
<tr>
<td></td>
<td>1 Selects a character count of 100 as a data-forwarding signal.</td>
</tr>
<tr>
<td></td>
<td>2 Selects a character count of 200 as a data-forwarding signal.</td>
</tr>
</tbody>
</table>

Regardless of the blocking factor, an end-of-line character (carriage return) forwards data to the host.

(BR) - BREAK KEY AS USER BREAK 1

The BR command determines if the BREAK key (interruption key for interactive output) also functions as the interruption sequence (user break 1 sequence) when entered during output and as the cancel character when entered during input.

Format:

ct BR=option

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ct</td>
<td>Represents the network control character for your terminal as defined by the CT terminal definition command.</td>
</tr>
<tr>
<td>option</td>
<td>Determines if this feature is enabled or disabled. A value of Y enables and a value of N disables this feature.</td>
</tr>
</tbody>
</table>

This command only applies to asynchronous terminals. For X.25 PSN terminals, the BREAK key can only
function as the interruption sequence whether entered
during input or output.

**BS - BACKSPACE CHARACTER**

The BS command specifies the character used to
delete the previous input character.

**Format:**

```plaintext
ct BS=bs
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ct</td>
<td>Represents the network control character for your terminal as defined by the CT terminal definition command.</td>
</tr>
<tr>
<td>bs</td>
<td>Specifies the new backspace character. This character must differ from the characters currently defined for AB, BS, B1, CN, CT, B2, and EL.</td>
</tr>
</tbody>
</table>

It is possible to backspace only to the beginning of the current physical line; additional backspaces are disregarded. When a page width of 0 is selected, the network assumes a page width of 100 characters for backspacing. If the page width is in the range 20 through 56, backspacing into previous physical lines is sometimes permitted.

This command only applies to asynchronous terminals only.

**B1 - INTERRUPTION OR USER BREAK 1 CHARACTER**

The B1 command specifies the character that, when entered as the only character in a logical line (interruption character followed by the message transmission key), causes program interruption.

**Format:**

```plaintext
ct B1=ub1
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ct</td>
<td>Represents the network control character for your terminal as defined by the CT terminal definition command.</td>
</tr>
<tr>
<td>ub1</td>
<td>Specifies the new user break 1 character. This character must differ from the characters currently defined for AB, BS, B1, CN, CT, B2, and EL.</td>
</tr>
</tbody>
</table>

The interruption sequence is discussed in section 17. This command does not apply to bisynchronous 2780 and 3780 terminals.

**B2 - TERMINATION OR USER BREAK 2 CHARACTER**

The B2 command specifies the character that, when entered as the only character in a logical line (termination character followed by the message transmission key), causes program termination.

**Format:**

```plaintext
ct B2=ub2
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ct</td>
<td>Represents the network control character for your terminal as defined by the CT terminal definition command.</td>
</tr>
<tr>
<td>ub2</td>
<td>Specifies the new user break 2 character. This character must differ from the characters currently defined for AB, BS, B1, CN, CT, EB, and EL.</td>
</tr>
</tbody>
</table>

The termination sequence is discussed in section 17. This command does not apply to bisynchronous 2780 and 3780 terminals.

**CH - DISPLAY TERMINAL CHARACTERISTICS**

The CH command displays some of the terminal’s current characteristics.

**Format:**

```plaintext
ct CH
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ct</td>
<td>Represents the network control character for your terminal as defined by the CT terminal definition command.</td>
</tr>
</tbody>
</table>

The CH command produces a display in the following format:

```plaintext
TC=tc,BS=bs,CN=cn,AB=ab,B1=ub1,B2=ub2,EL=el,EB=eb
```

where the variable portions appear as ASCII characters if printable, mnemonics (for example, STX) if nonprintable, or N/A if the attribute is not applicable.

**CI - CARRIAGE RETURN IDLE COUNT**

The CI command specifies the number of idle characters to be inserted into the output stream after a carriage return.

**Format:**

```plaintext
ct CI=ci
```

This command does not apply to bisynchronous 2780 and 3780 terminals.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ct</td>
<td>Represents the network control character for your terminal as defined by the CT terminal definition command.</td>
</tr>
<tr>
<td>cn</td>
<td>Specifies the new carriage return idle count. This value can be from 0 to 99 or the string CA. A value of CA restores the carriage return idle count to the default value.</td>
</tr>
</tbody>
</table>

When the network produces a carriage return, the network outputs the specified number of idle characters before outputting the next line. This allows time for the carriage return function and ensures that characters are not lost because of printing attempts during the carriage return operation.

This command only applies to asynchronous terminals.

(CN) - CANCEL CHARACTER

The CN command specifies the character used to cancel the logical line currently being input.

Format:

```
ct CN=cn
```

(CT) - NETWORK CONTROL CHARACTER

The CT command specifies a network control character for the terminal. When you enter this character as the first character of a logical line, it signals that what follows is a terminal definition command or a special command that the network forwards to your application with a preemptive status.

Format:

```
ct CT=char
```

(DL) - DELIMITERS FOR SINGLE-MESSAGE TRANSPARENT INPUT MODE

The DL command specifies the delimiters that terminate single-message transparent input mode. When you initiate transparent input mode (IN=X, IN=KK, or IN=XP), the network reads your input and sends it to the system without translation until it encounters a delimiter. If your terminal's parity is set to even, odd, or zero (PA=E, 0, or Z), the parity bit is stripped (set to zero) before the characters are sent to the host, although no
translation occurs. If your terminal's parity is set to none or ignore (PA=N or I), the parity bit is not stripped. See the NAM/CCP Terminal Interfaces Reference Manual for more information on transparent input and parity. The first delimiter encountered terminates transparent input mode.

Format:
ct DL=Xxx, Ccount, TO

Parameter | Description
---|---
ct | Represents the network control character for your terminal as defined by the CT terminal definition command.
Xxx | Specifies the 2-digit hexadecimal code (xx) of the character you want as a delimiter. The network does not send the character as part of the input data. When you specify a hexadecimal code above 7F, you must have previously set your terminal's parity to none (PA=N) or ignore (PA=I); otherwise the network cannot detect the code when it occurs in a transparent mode message. If the terminal's parity is set to none, the 8-bit hexadecimal code input from the terminal is matched against the 8-bit hexadecimal code specified as the delimiter (xx). If the terminal's parity is set to ignore, the bottom 7 bits of the terminal input are matched against the bottom 7 bits of the specified delimiter (xx).
Ccount | Specifies a decimal value (count) from 1 to 4095 that functions as a character count delimiter.
TO | Specifies that a timeout of between 200 and 400 milliseconds will be a transparent mode delimiter.

You can select any of the three types of delimiters: character delimiter (specify Xxx), character count delimiter (specify Ccount), and timeout delimiter (specify TO). The parameter values for DL are order-independent and optional. However, you must specify at least one of the parameter values. You can omit trailing commas if you do not specify all three types of delimiters.

Entering this command with any number of new delimiters cancels all transparent mode input delimiters already in effect, including those specified with the XL command.

The DL command applies only to asynchronous and mode 4 terminals. Terminal class 4 is configured with the RETURN key as the only transparent mode terminator and mode 4 terminals are configured with the SEND or ETX key as their only transparent mode terminator. For X.25 devices, the PAD forwarding signal always acts as a transparent mode terminator in addition to any other options selected.

(EB) - END-OF-BLOCK CHARACTER

The EB command defines the end-of-block character and defines the cursor-positioning response to that character. The EB character acts as the message transmission key for terminals operating in block mode (refer to the IN command).

Format:
ct EB=eb, cpr

Parameter | Description
---|---
ct | Represents the network control character for your terminal as defined by the CT terminal definition command.
eb | Specifies the new end-of-block character. You can specify the following values for eb:
char | Selects the new EB character. This character must differ from the characters currently defined for AB, BS, BI, B2, CN, and CT.
EB | Selects the default end-of-block character or character sequence.
EL | Selects the current logical end-of-line character.
cpr | Specifies the cursor-positioning response to the EB character. You can specify the following values for cpr:
CR | Send a carriage return to the terminal.
LF | Send a line feed to the terminal.
CL | Send a carriage return and a line feed to the terminal.
NO | Send no response.

The two EB parameters (EB=eb and cpr) are optional and order-independent. If you omit one, the system retains its previous value.

† These values are valid within the network. However, unless changed during installation, the maximum logical input line length in IAF (160 characters) limits you.
This command is valid only for asynchronous terminals, except for paper tape devices and 2741 terminals. The end-of-block character for mode 4 terminals is ETX and is not changeable. The X.25 PAD forwarding signal is the default for X.25 PSN terminals and always acts as an end-of-block. If you specify the char form of the eb parameter, it is only effective if it occurs as the last character in a packet sequence.

The CP command enables or disables the cursor-positioning response specified by the cpr parameter.

(EL) - END-OF-LINE CHARACTER

The EL command defines the logical end-of-line character (carriage return) and defines the cursor-positioning response to that character. It also defines the message transmission key for asynchronous terminals not operating in block mode (refer to the IN command).

Format:
```
ct EL=el, cpr
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ct</td>
<td>Represents the network control character for your terminal as defined by the CT terminal definition command.</td>
</tr>
<tr>
<td>el</td>
<td>Specifies the new logical end-of-line character. You can specify the following values for el:</td>
</tr>
<tr>
<td></td>
<td>el Description</td>
</tr>
<tr>
<td></td>
<td>char</td>
</tr>
<tr>
<td></td>
<td>EB</td>
</tr>
<tr>
<td></td>
<td>EL</td>
</tr>
<tr>
<td></td>
<td>cpr</td>
</tr>
<tr>
<td></td>
<td>cpr Description</td>
</tr>
<tr>
<td></td>
<td>CR</td>
</tr>
<tr>
<td></td>
<td>LF</td>
</tr>
</tbody>
</table>

The two EL parameters (el and cpr) are optional and order-independent. If you omit one, the system retains its previous value.

This command does not apply to 2741, HASP, 3270, and bisynchronous 2780 and 3780 terminals; the cpr parameter does not apply to mode 4 or X.25 PSN terminals; and the char specification does not apply to mode 4 terminals.

The CP command enables or disables the cursor-positioning response specified by the cpr parameter.

(EP) - ECHOPLEX MODE

The EP command enables or disables the echoing of input characters back to the terminal.

Format:
```
ct EP=option
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ct</td>
<td>Represents the network control character for your terminal as defined by the CT terminal definition command.</td>
</tr>
<tr>
<td>option</td>
<td>Specifies whether to enable (Y) or disable (N) input echoing.</td>
</tr>
</tbody>
</table>

Some terminals can perform their own character echoing, such as terminals with a HALF/FULL duplex switch. If the switch is in the HALF position, set the EP value to N, and the terminal echoes the input. If the switch is in the FULL position, set the EP value to Y and the network echoes the input.

You can use the EP command and full-duplex mode as a security measure. If you are in full-duplex mode and EP is Y during login, the system echoes all of your input except your password. This is not true, however, if you enter your user name and password on the same line.

This command only applies to asynchronous terminals (except 2741a) but is not valid for X.25 PSN terminals.

(FA) - FULL ASCII INPUT MODE

The FA command enables or disables the full-ASCII input mode.

Format:
```
cf FA=option
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ct</td>
<td>Represents the network control character for your terminal as defined by the CT terminal definition command.</td>
</tr>
<tr>
<td>option</td>
<td>Specifies whether to enable (Y) or disable (N) input echoing.</td>
</tr>
</tbody>
</table>
### Parameter Description

- **ct**: Represents the network control character for your terminal as defined by the CT terminal definition command.

- **option**: Specifies whether to enable (Y) or disable (N) the full-ASCII input mode.

In full-ASCII input, all 128 ASCII characters, including NUL, DEL, STX, LF, and all BLK and message-forwarding signals (which are normally discarded), are sent to the host. Exceptions to this are the following characters:

- NULs, DELs and LFs when encountered as the first character of an input line or as the character following a message-forwarding signal
- CRs that follow LFs when inputting from paper tape
- DC3s that follow the EL character when inputting from paper tape
- DC1s and DC3s when output control (OC-Y) is selected

In full-ASCII mode, the network does not recognize the terminal functions associated with the mnemonics B1, B2, CN, A8, and BS. The network does recognize terminal definition commands and other commands beginning with the CT character.

If SE is in effect when you select FA or if FA is in effect when you select SE, FA takes precedence and SE will not be effective until FA is turned off. If full-ASCII mode is enabled when you select transparent input mode, the network suspends the full-ASCII mode until the transparent input mode terminates.

This command only applies to asynchronous and mode 4 terminals.

### (HD) - DISPLAY OF HOST NODES

The HD command controls when the system displays the host availability display (HAD), which shows all paths you can select to connect your terminal to a host. If your computer system is a multihost system, your site may choose to show the HAD whenever you disconnect from a host unless you inhibit the display.

**Format:**

```plaintext
cMDHD-option
```

**Parameter**

- **ct**: Represents the network control character for your terminal as defined by the CT terminal definition command.
- **option**: Represents Y or N. Y enables and N disables the automatic displaying of the HAD.

If you specify HD=Y, you get a display of the HAD immediately and at any time you disconnect from the host (for example, after you enter the TM command or after you log out of an application without switching to another application). You also get a header and trailer line along with the HAD (refer to the TM command).

The HAD has the following format:

```plaintext
message CONTROL CHARACTER=ct
NPU NODE=npu TERMINAL NAME=terminal
HOST NODE SELECTED/CONNECTED STATUS
host₁ node₁ condition₁ status₁
host₂ node₂ condition₂ status₂
...
hostₙ nodeₙ conditionₙ statusₙ
```

The variable items in the display have the following descriptions.

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>message</td>
<td>A message describing the status of your current host connection.</td>
</tr>
<tr>
<td>ct</td>
<td>Network control character currently defined for your terminal.</td>
</tr>
<tr>
<td>npu</td>
<td>The node number of the Network Processing Unit (NPU) your terminal is connected to.</td>
</tr>
<tr>
<td>terminal</td>
<td>The name of your terminal.</td>
</tr>
<tr>
<td>hostₙ</td>
<td>Represents the 1- to 7-character name of a host. The field may be blank.</td>
</tr>
</tbody>
</table>

The host selected is used until either you change it or until your terminal is disconnected from the host.

### (HC) - HOST CONNECTION

The HC command sets or changes the host connected to your terminal. The host availability display (HAD) shows the available hosts (refer to the HD command for more information on the HAD). This command disconnects you from your current host and establishes a new host connection. This command is equivalent to HS or HN followed by TM.

**Format:**

```plaintext
cMDHC=hostname
```

**Parameter**

- **ct**: Represents the network control character for your terminal as defined by the CT terminal definition command.
- **hostname**: specifies the name of the host to which you want your terminal connected. The valid entries appear in the HAD.
**Item** | **Description**
--- | ---
node<sub>1</sub> | Represents a node number (1-31).
condition<sub>1</sub> | Indicates that you have selected node<sub>1</sub> (S), that you are connected to the host using node<sub>1</sub> (C), or that node<sub>1</sub> has been automatically selected and the connection to the host is in progress (SA).
status<sub>1</sub> | Represents AVAILABLE or NOT AVAILABLE.

**Item** | **Description**
--- | ---
ct | Represents the network control character for your terminal as defined by the CT terminal definition command.
node | Specifies a node number. The default is the node the network processing unit is presently using to access its supervisor (CS).

The host availability display (HAD) lists all nodes your terminal can use. Refer to the HD command for a description of the HAD.

**HS - HOST SELECTION**

The HS command selects a host which is connected to your terminal. The host availability display (HAD) shows the available hosts (refer to the HD command).

Format:

```
ct HS=hostname
```

**Parameter** | **Description**
--- | ---
ct | Represents the network control character for your terminal as defined by the CT terminal definition command.
hostname | Specifies the name of the host to which you want your terminal connected. The valid entries appear in the HAD.

Your terminal uses the path to host with the least traffic. The path selected is used until either you change it or until your terminal is disconnected from the host.

**IC - FLOW CONTROL FOR INPUT DEVICES**

The IC command specifies whether the terminal recognizes DC3s as a stop signal and DC1s as a resume signal for terminal input.

Format:

```
ct IC=option
```

**Parameter** | **Description**
--- | ---
ct | Represents the network control character for your terminal as defined by the CT terminal definition command.
option | Specifies whether to enable (Y) or disable (N) input control.

Input control applies to asynchronous terminals, including paper tape devices (except 2741 and X.25 PSN terminals).

**IN - INPUT DEVICE AND TRANSMISSION MODE**

The IN command identifies the input device and the transmission mode of the device. As the input device, you can specify one of the following:
- A keyboard.
- A paper tape reader.

As the input transmission mode, you can specify either:
- Normalized line mode (one message or logical line per terminal transmission block).
- Normalized block mode (one or more logical lines or messages collected into a block before it is transmitted).
- Transparent mode (input is not edited or translated by the network).

Format:

```
ct IN=in
```

**Parameter** | **Description**
--- | ---
ct | Represents the network control character for your terminal as defined by the CT terminal definition command.
in | Specifies the input device and transmission mode. You can specify the following values for in:
<table>
<thead>
<tr>
<th>IN</th>
<th>Description</th>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BK</td>
<td>Selects block mode as from a form terminal and normalized input mode.</td>
<td>value</td>
<td>Specifies the new line feed idle count. This value can be from 0 to 99 or the string CA. A value of CA restores the line feed idle count to the default value.</td>
</tr>
<tr>
<td>KB</td>
<td>Selects a keyboard in character or line mode and normalized input mode.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>PT</td>
<td>Selects paper tape and normalized input mode.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>X</td>
<td>Selects the current input device and transparent input mode.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XK</td>
<td>Selects the keyboard and transparent input mode.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>XP</td>
<td>Selects paper tape and transparent input mode.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

When the IN value is XK, XP, or X, terminal input is sent to the host in transparent mode blocks. Transparent mode continues until the system encounters a previously defined transparent mode terminator.

When the IN value is XK and transparent mode terminates, the IN value automatically reverts to KB. When the IN value is XP and transparent mode terminates, the IN value automatically reverts to PT. When the IN value is X and transparent mode terminates, the IN value automatically reverts to the value that was previously in effect.

When the IN value is PT or XP, the network sends the X-ON code to start the paper tape reader automatically after the end of a message is output to the terminal and the message empties the terminal's output queue.

The IN command is not applicable to HASP, 3270 or bisynchronous 2780 and 3780 terminals. 2741 terminals can only select IN=KB, IN=X, and IN=XX. Mode 4 terminals, which are always in block mode, and X.25 PSN terminals cannot select PT or XP mode.

(II) - LINE FEED IDLE COUNT

The LI command specifies the number of idle characters to be inserted into the output stream following a line feed.

Format:
```
ct LI=value
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ct</td>
<td>Represents the network control character for your terminal as defined by the CT terminal definition command.</td>
</tr>
</tbody>
</table>

If you are having problems with the network (such as difficulty connecting to IAF), you can communicate these problems to the network operator using the MS command.

(LK) - LOCKOUT OF UNSOLICITED MESSAGES

The LK command determines whether unsolicited messages from the network operator appear at your terminal.

Format:
```
ct LK=option
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ct</td>
<td>Represents the network control character for your terminal as defined by the CT terminal definition command.</td>
</tr>
<tr>
<td>option</td>
<td>Specifies whether to lock out unsolicited messages. A value of Y locks out the messages and a value of N allows the messages to appear.</td>
</tr>
</tbody>
</table>

This command is not valid for bisynchronous 2780 and 3780 terminals.

(MS) - MESSAGE TO NETWORK OPERATOR

The MS command sends a message to the network operator.

Format:
```
ct MS=message
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ct</td>
<td>Represents the network control character for your terminal as defined by the CT terminal definition command.</td>
</tr>
<tr>
<td>message</td>
<td>Specifies your message to the operator. You can use any string of 50 characters or less.</td>
</tr>
</tbody>
</table>

If you are having problems with the network (such as difficulty connecting to IAF), you can communicate these problems to the network operator using the MS command.
(OC) - FLOW CONTROL FOR OUTPUT DEVICES

The OC command specifies whether the terminal generates DC3s as a stop signal to the network and DC1s as a resume signal for terminal output.

Format:

```
ct OC«option
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ct</td>
<td>Represents the network control character for your terminal as defined by the CT terminal definition command.</td>
</tr>
<tr>
<td>option</td>
<td>Specifies whether to enable (Y) or disable (N) output control.</td>
</tr>
</tbody>
</table>

If the network receives a DC3 while output control is enabled, it suspends output until it receives a DC1 or until you send another block of input.

Output control applies to asynchronous terminals, including paper tape devices (except 2741s).

(OP) - OUTPUT DEVICE SELECTION

The OP command specifies the type of output device.

Format:

```
ct OP«op
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ct</td>
<td>Represents the network control character for your terminal as defined by the CT terminal definition command.</td>
</tr>
<tr>
<td>op</td>
<td>Specifies the output device. You can specify the following values for op:</td>
</tr>
<tr>
<td></td>
<td>Description</td>
</tr>
<tr>
<td>op</td>
<td>Description</td>
</tr>
<tr>
<td>DI</td>
<td>Specifies a display device.</td>
</tr>
<tr>
<td>PR</td>
<td>Specifies a printer.</td>
</tr>
<tr>
<td>PT</td>
<td>Specifies a paper tape punch.</td>
</tr>
</tbody>
</table>

You can punch a tape in any mode, but the network does not provide the proper X-OFF characters unless OP has a value of PT.

If you select OP=PR, the network does line folding and page bounding for asynchronous and X.25 PSN terminals. If OP=DI, the network assumes the terminal performs these functions itself.

This command only applies to asynchronous terminals (except 2741s). OP=PT does not apply to X.25 PSN terminals.

(PA) - PARITY PROCESSING

The PA command specifies the parity processing to be performed by the network.

Format:

```
ct PA«pa
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ct</td>
<td>Represents the network control character for your terminal as defined by the CT terminal definition command.</td>
</tr>
<tr>
<td>pa</td>
<td>Specifies the type of parity processing. You can specify the following values for pa:</td>
</tr>
<tr>
<td></td>
<td>Description</td>
</tr>
<tr>
<td>pa</td>
<td>Description</td>
</tr>
<tr>
<td>E</td>
<td>Set parity bit for even parity during output, and check for even parity and set parity bit to zero on input.</td>
</tr>
<tr>
<td>N</td>
<td>In transparent mode, do not set or check the parity bit because it is part of the input or output data. In normalized mode, set the parity bit to zero on input and output.</td>
</tr>
<tr>
<td>O</td>
<td>Set parity bit for odd parity during output, and check for odd parity and set parity bit to zero on input.</td>
</tr>
<tr>
<td>Z</td>
<td>Set parity bit to zero on output and check parity bit against zero on input.</td>
</tr>
<tr>
<td>I</td>
<td>In transparent mode, do not set or check the parity bit because it is part of the input or output data. Ignore the parity bit when checking for transparent input mode delimiters. In normalized mode, set the parity bit to zero on input and output.</td>
</tr>
</tbody>
</table>

This command only applies to asynchronous terminals (except 2741s). For X.25 PSN terminals, the parity bit is set to 0 and not checked for input.
The PG command enables or disables page waiting at the terminal during output. If you enable page waiting, the terminal stops at the end of each output page for your acknowledgement (a null input line) before output continues.

Format:
```plaintext
c|t PG<option>
```

Parameter | Description
---|---
ct | Represents the network control character for your terminal as defined by the CT terminal definition command.
option | Specifies whether to enable (Y) or disable (N) page waiting.

When you enter a null input line to get the next page of output, the null input line has no other meaning.

Page waiting does not apply to bisynchronous 2780 or 3780 terminals or to HASP terminals.

The PL command establishes the maximum number of physical lines that can be printed as one page. If OP has a value of PR, the network automatically positions the carriage to the top of the form after PL lines have been output.

Format:
```plaintext
c|t PL=pl
```

Parameter | Description
---|---
ct | Represents the network control character for your terminal as defined by the CT terminal definition command.
pl | Specifies the page length. You can specify 0 or any value from 8 to 255. PL=0 selects an infinitely long page.

The PL value must be nonzero if you want to enable page waiting, since page waiting only occurs after the number of lines defined by pl-1 are output.

The PW command establishes the maximum number of characters that the terminal prints on one output line. If OP has the value PR, the system automatically starts a new line after pw characters have been output.

Format:
```plaintext
c|t PW=pw
```

Parameter | Description
---|---
ct | Represents the network control character for your terminal as defined by the CT terminal definition command.
pw | Specifies the page width. You can specify a value of 0 or any value from 20 to 255. PW=0 selects an infinitely long line.

The SE command enables or disables the special editing variant of normalized input mode.

Format:
```plaintext
c|t SE<option>
```

Parameter | Description
---|---
ct | Represents the network control character for your terminal as defined by the CT terminal definition command.
option | Enables (Y) or disables (N) special editing operations.

When special editing is in effect, any backspace character entered is stored for transmission to the host. Similarly, a line feed entry produces a normal line feed operation at the terminal and the network stores the line feed character code for transmission to the host. A backspace followed by a line feed causes the system to output a bell and an exclamation point on an ASCII terminal or an inverted caret (v) on an APL terminal below the last character entered.

This command is only valid for asynchronous terminals but not for X.25 PSN terminals.

The TC command specifies a terminal class for your terminal. The terminal class associates your terminal with a predefined set of terminal characteristics. To effectively use a terminal class, choose a terminal class whose default terminal definition corresponds to the characteristics of your terminal.

Format:
```plaintext
c|t TC=tc
```

Parameter | Description
---|---
ct | Represents the network control character for your terminal as defined by the CT terminal definition command.
tc | Specifies the terminal class. The value tc can be from 1 to 17.
The following list associates terminal class values with terminal types:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tc</td>
<td>Represents the network control character for your terminal as defined by the CT command.</td>
</tr>
</tbody>
</table>

You can use the TM command if your application does not respond to your input. The system responds to the TM command in the following manner:

- **host status** CONTROL CHARACTER=ct
- **had** prompt

The variable items have the following descriptions:

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>host status</td>
<td>Indicates the status of the host you have just specified or to which you are/were connected. You can get any one of the following messages:</td>
</tr>
<tr>
<td></td>
<td>HOST AVAILABLE</td>
</tr>
<tr>
<td></td>
<td>HOST BUSY</td>
</tr>
<tr>
<td></td>
<td>HOST CONNECTED</td>
</tr>
<tr>
<td></td>
<td>HOST DISCONNECTED</td>
</tr>
<tr>
<td></td>
<td>HOST UNAVAILABLE</td>
</tr>
<tr>
<td></td>
<td>NO HOST AVAILABLE</td>
</tr>
<tr>
<td></td>
<td>NO HOST CONNECTED</td>
</tr>
<tr>
<td></td>
<td>NO HOST SELECTED</td>
</tr>
<tr>
<td>ct</td>
<td>Represents the network control character for your terminal as defined by the CT command.</td>
</tr>
<tr>
<td>had</td>
<td>Represents the host availability display (HAD). The HAD appears only if you have enabled its automatic display (refer to the HD command).</td>
</tr>
<tr>
<td>prompt</td>
<td>Represents an action the system wants you to take or a status message. You can get any one of the following prompts:</td>
</tr>
</tbody>
</table>

### (TM) - TERMINATING A TERMINAL-HOST CONNECTION

The TM command severs the connection between your terminal and a host.

Format:

```plaintext
tc TM
```

A terminal that is not shown as belonging to a terminal class may still be operational. The terminal can be assigned to a terminal class having similar characteristics and the terminal’s definition can be modified as necessary to correctly define the operational characteristics of the terminal.

If your terminal is on an auto-recognition line and its terminal class is other than 1, 4, 10, or 13, you can use the TC command to change its terminal class to ensure proper operation.

If you include a TC command in a sequence of terminal definition commands, enter the TC command first as it resets all other terminal characteristics.

### (XL) - MULTIMESSAGE TRANSPARENT MODE

The network provides a transparent mode that allows you to remain in transparent input mode even after message blocks have been forwarded to the application. The XL command specifies the multimeessage-forwarding signal and the terminator for transparent input mode. If your terminal’s parity is set to even, odd, or zero (PA=E, O, or Z), the parity bit is stripped (set to zero) before the characters are sent to the host, although no translation occurs. If your terminal’s parity is set to none or ignore (PA=N or I), the parity bit is not stripped. See the NAM/CCP Terminal Interfaces Reference manual for more information on transparent input and parity.
Format:
ct XL=XXX,COUNT,TO,Yyy

Parameter | Description
--- | ---
ct | Represents the network control character for your terminal as defined by the CT terminal definition command.
XXX | Selects the character with the two-digit hexadecimal representation xx as the message-forwarding signal. If you do not specify a value yy, the occurrence of two successive characters defined by xx acts as a terminator for transparent input mode. When you specify a hexadecimal code above 7F, you must have previously set your terminal's parity to none (PA=N) or ignore (PA=I); otherwise the network cannot detect the code when it occurs in a transparent mode message.
COUNT | Selects a decimal value from 1 to 4095† as a character count that functions as a message-forwarding signal.
TO | Selects timeout as a transparent input mode terminator.
Yyy | Selects the character with the two-digit hexadecimal representation yy as a terminator for transparent input mode when it follows xx. When you specify a hexadecimal code above 7F, you must have previously set your terminal's parity to none (PA=N) or ignore (PA=I); otherwise the network cannot detect the code when it occurs in a transparent mode message.

Yyy, if specified, must follow the XXX parameter; otherwise, it is ignored. The parameters are otherwise order-independent. You must specify at least one of XXX or TO to select a transparent mode terminator. When it immediately follows the character defined by XXX on input, the character defined by yy terminates transparent input mode. The characters defined by XXX and Yyy can be identical or you can omit Yyy. In either case, two successive input characters defined by XXX are required to terminate transparent mode.

The message-forwarding signals and mode terminators are not sent to the host.

This command cancels all transparent mode terminators and delimiters defined by the DL command or a previous XL command. You can select multimessage transparent input mode by using the XL command in conjunction with the IN command and selecting IN=X, IN=XX, or IN=XP.

This command does not apply to HASP and bisynchronous terminals.

†These values are valid with the network. However, unless changed during installation, the maximum logical input line length in IAF (160 characters) limits you.

**Table G-1. Default Terminal Definitions**

- (1) Terminal class is the same as for the terminal if it were not connected via a packet-switching network.
- (2) End-of-record sequence CR-bit is reset to zero.
- (3) Output is ignored on input and is generated for output vs. for the basic terminal type.
- (4) ETS (resulting from the EOM key).
- (5) ESC-1 (resulting from the CARRIER RETURN key).
- (6) Page attention key 1 is a valid user break 1.
- (7) Page attention key 2 is a valid user break 1.

(1) Any character in the ASCII 128-character set except any lowercase or uppercase alphabetic character, any digit 0 through 9, SPACE, or a space.
(2) Same as for the terminal if it were not connected by a packet-switching network.
(3) X, Y, X, Y, X, Y, X, Y.
(4) Parity ignored on input and is generated for output.
(5) Same as for the terminal if it were not connected by a packet-switching network.
(6) Any character except any lowercase or uppercase alphabetic character, any digit 0 through 9, Natürlich, SPACE, or a space.
You can transmit input to an application in normalized mode (also called character mode) or transparent mode (also called binary mode). In transparent input mode, the network does not convert any of your input but sends it directly to your application. Characters like LF and BS, which the network normally strips from the input stream, become part of the data sent to your application. Appendix G describes how you delimit and transmit input in transparent mode (refer to the DL and XL commands). The default input mode for all supported terminal classes is normalized mode, however. The remainder of this appendix describes how to delimit and transmit terminal input in normalized mode under the default conditions of the various terminal classes. (Appendix G also describes how you can change these defaults.)

LOGICAL END-OF-LINE (CARRIAGE RETURN)

You terminate a logical line of input with a carriage return key. A logical line can consist of one or more physical lines but not vice versa. The network may respond to the carriage return by advancing the cursor or carriage to the next line (refer to the EL command in appendix G).

MESSAGE TRANSMISSION

You transmit your input to the network with the message transmission key. For non-blockmode devices, the message transmission key is the carriage return key. Hence, for these terminal classes, logical lines are transmitted separately. When the delimiter for the logical terminal classes, logical lines are transmitted separately. When the delimiter for the logical end-of-line and transmission key are different (as with block mode devices, including PSN and mode 4 terminals), the terminal stores logical lines until you press the transmission key. It then sends the single transmission consisting of multiple logical lines to the network. The network sends each logical line separately to your application.

Table H-1 shows the keys used by the various terminal classes to perform the three functions just described.

†If in block mode, refer to terminal documentation for terminal key equivalences. Those listed are for character and line modes. ††Terminals operating under HASP protocol use different keys for this purpose.
TAF prevents situations from occurring in which the execution of a task is blocked because it is impossible under the circumstances to obtain the needed central memory space for the task, whether for an initial load or a memory increase. Several terms will be defined to aid in the description of how potentially blocked tasks are detected:

- **Minimum size of the total task area**

  The total task area is the CM in which TAF will schedule tasks. It includes the space occupied by CM-resident tasks. The area extends from the first word address into which tasks can be loaded to the maximum field length of TAF. The size of this area fluctuates if the TAF/CRM Data Manager is used. The minimum size of this area occurs when the TAF/CRM buffer takes on its maximum size.

- **Minimum size of the transient task area**

  The transient task area is that portion of the total task area not occupied by CM-resident tasks. The minimum size of this area is defined to be the minimum size of the total task area minus the sum of the MFLs of all CM-resident tasks.

One or more tasks will be considered to be potentially blocked under the following circumstances:

- If the initial field lengths of the CM-resident tasks are so large that they all couldn't be loaded together.
- If the sum of the MFLs for the CM-resident tasks exceeds the minimum size of the total task area.
- If the MFL of a non-CM-resident task exceeds the minimum size of the transient task area.

Following are the situations when potentially blocked tasks are detected and the actions that are taken:

- At TAF initialization. Potentially blocked tasks result in TAF being aborted.
- When TAF is informed, via the LIBTASK TT option, of the update of a task library attached by TAF and the library contains potentially blocked tasks, the update will be rejected.
- When an attempt is made to reduce the MFL of TAF via the K.MAXFL command to a value that results in potentially blocked tasks, the command will be rejected.

The preceding checking assumes that the maximum field length of TAF is set (by default, via K.MFL, or via K.MAXFL commands) to a value that can be attained.
This appendix describes the steps used to access a host and to use CDC network software. The login procedure can be divided into eight steps.

- Gathering information.
- Setting up your terminal.
- Connecting your terminal to the network.
- Identifying your terminal to the network.
- Selecting a host.
- Connecting to the selected host.
- Identifying yourself and your terminal to the host.
- Selecting a network application.

The first part of this appendix gives a brief description of the eight steps. The second part of the appendix gives a more detailed description of the same eight steps followed by additional general information. You may find the brief description of the steps sufficient to accomplish login at your site. If not, consult the detailed description. In addition to more detail, it provides shortcuts, the various options that are available at any given step, and failure conditions.

**BRIEF DESCRIPTION OF ACCESS**

**STEP 1 - GATHERING INFORMATION**

Find the answers to the following questions.

- Is your terminal hardwired to the system?
- Which key is the data transmission key for your terminal?
- If you have a dialup terminal, what telephone number must you dial?
- Into which of the following categories does your terminal fall?

**STEP 2 - SETTING UP YOUR TERMINAL**

- Turn power switch on.
- Load and initialize any software or controlware needed by your terminal.
- Set the terminal's duplex or echoplex switch to the correct position (typically HALF if your keyboard entries appear unduplicated on your console's screen or printer).
- Set the terminal's parity switch to its proper position.
- Set the line speed switch to its proper setting.
- Set the transmission mode to either the character or line mode position.
- Set the online/offline switch to the online position.

**STEP 3 - CONNECTING YOUR TERMINAL TO THE NETWORK**

Skip this step if your terminal is hardwired. Otherwise, determine which of the configurations in figures J-1, J-2, J-3, and J-4 most closely matches your terminal and follow the instructions in the figure.
1. Turn on coupler.
2. Pick up receiver.
3. Dial phone number.
5. Fit receiver into coupler. Be sure you put the cord end of the receiver into the correct cup, as indicated on the coupler.

Figure J-1. Separate Acoustic Coupler

1. Pick up receiver.
2. Push button, such as ORIG button on Teletype model 33 or 35.
3. Dial phone number.
5. Push button, such as ORIG button on Teletype model 33 or 35.
6. Replace receiver.

Figure J-2. Data Set Built into the Terminal

1. Pick up receiver.
2. Set switch to TALK or push TALK button.
3. Dial phone number.
5. Set switch to DATA or push DATA button.
6. Replace receiver.

Figure J-3. Data Sets with Switches and Buttons
1. Pick up receiver.
2. Dial phone number.
4. Fit receiver into coupler. Be sure you put the cord end of the receiver into the correct cup, as indicated on the coupler.

Figure J-4. Terminal with Built-in Acoustic Coupler

STEP 4 - IDENTIFYING YOUR TERMINAL TO THE NETWORK

If the network does not prompt you within a few seconds after you are connected to it (there might be a light on the terminal that indicates when your terminal is connected), perform the appropriate following steps.

- For asynchronous terminals not using X.25 protocol:
  a. Press the key that transmits a carriage return. The network responds with two line feeds when it recognizes your line speed.
  b. Type a closing parenthesis (not required if the terminal uses the ASCII character set and code) and press the carriage return key. When the network recognizes your character code set, it responds with a line feed.
- For asynchronous terminals using X.25 protocol:
  Get the information from your site.
- For mode 4 synchronous terminals:
  Press the data transmission key.
- For HASP and 2780/3780 bisynchronous terminals:
  Send a /*CONFIG card image.

- For 3270 bisynchronous terminals:
  No identification is necessary.

STEP 5 - SELECTING A HOST

If you have a choice of hosts or host paths (multi-host), the network displays a list of the hosts and host paths that are available and prompts you to make a selection. Otherwise, you can enter:

ct HD
to get a list of hosts. ct is your terminal's network control character (refer to the NOS Reference Set, Volume 1, System Commands).

Make your selection with one of the following commands.

cr HN=node
or
cr HS=hostname

node is the number of a host path; and hostname is the name of a host.

STEP 6 - CONNECTING TO THE SELECTED HOST

If your terminal was not automatically connected to a host, the network prompts you to connect. Enter a carriage return to make the connection.
STEP 7 - IDENTIFYING YOURSELF AND YOUR TERMINAL TO THE HOST

Once your terminal is connected to the host, the host displays a banner similar to:

WELCOME TO THE NOS SOFTWARE SYSTEM.
COPYRIGHT CONTROL DATA 1978, 198X.

date \hspace{1cm} time \hspace{1cm} terminal name
site identification \hspace{1cm} NOS 2 PSR level number

Following this banner, you may be prompted for a family name, then a user name, then a password, and finally an application name (if there is no default). For each prompt, enter the appropriate information followed by a carriage return.

STEP 8 - SELECTING A NETWORK APPLICATION

If your login is successful, your terminal is placed under the control of the requested or default application, which then prompts you for a command.

DETAILED DESCRIPTION OF ACCESS

The following description covers in more detail the eight steps briefly described earlier. Although each of the steps is always performed when a terminal accesses the system, you might find that your network's administrators can make many of these steps unnecessary by having the software perform the steps for you.

STEP 1 - GATHERING INFORMATION

If you know the answers to the following questions, or can get the answers from people at your site, the text following each question will tell you which steps and corresponding subsections of this appendix you can skip. If you cannot answer the questions, read all of the subsections; each procedure description contains hints for answering the questions.

1. Is the terminal hardwired, or is it a dial-up terminal?

A hardwired terminal is connected directly to the network through a device called a modulator/demodulator (modem). A modem can be either a separate box, or built into the terminal. A dial-up terminal temporarily connects to the network through a telephone line and either an acoustic coupler or a telephone data set (a coupler or data set does the same things as a modem).

If you do not need to dial a telephone number to use the network, then your terminal is hardwired. (A nearby telephone does not necessarily mean the terminal is dial-up.)

2. Is your network configured for automatic recognition?

Your site can ask the network software to determine certain things about your terminal when the terminal joins the network. This process is called automatic recognition. [Terminals using X.25 packet-switching networks (PSN) cannot use automatic recognition.]

If your network is configured for automatic recognition, you must perform an extra step each time you connect your terminal to the network. If your terminal is not so configured, you may skip questions 3 and 4.

3. What protocol does your terminal use?

Your terminal must fit into one of the following categories.

- Asynchronous terminals that work like teletypewriters or IBM 2741 terminals.
- Asynchronous using an X.25 PSN through a packet assembly/disassembly (PAD) service; these terminals work like teletypewriters.
- CDC mode 4 synchronous; mode 4A terminals work like the CDC 200 User Terminal, while mode 4C terminals work like CDC 711 or 714 terminals.
- HASP terminals.
- Bisynchronous terminals that work like IBM 2780, 3270 or 3780 terminals.

If your terminal operating manual does not tell you what protocol your terminal uses, question 4 and the terminal classes shown in the NOS Reference Set, Volume 3, System Commands might help you answer this question. If your network is not configured for automatic recognition, skip question 4.

4. What class of terminal is it?

Many different kinds of terminals exist. The network software assigns terminals it supports to classes. If you know what the terminal class is, that will tell you the protocol, as follows:

<table>
<thead>
<tr>
<th>Class</th>
<th>Protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 thru 8</td>
<td>Asynchronous or X.25 asynchronous</td>
</tr>
<tr>
<td>9 and 14</td>
<td>HASP bisynchronous</td>
</tr>
<tr>
<td>10 and 15</td>
<td>CDC mode 4A synchronous</td>
</tr>
<tr>
<td>11 thru 13</td>
<td>CDC mode 4C synchronous</td>
</tr>
<tr>
<td>16 and 17</td>
<td>IBM 2780 and 3780 bisynchronous</td>
</tr>
<tr>
<td>18</td>
<td>IBM 3270 bisynchronous</td>
</tr>
<tr>
<td>Other</td>
<td>Site-defined</td>
</tr>
</tbody>
</table>

60459500 C
Terminals in classes 1 through 8 sometimes are called interactive terminals. A console has an input and output device that can be used for dialog with the network. Most consoles use a television-like screen or a typewriter-like mechanism to convey output information. Almost all consoles have a keyboard for entering information to the network. Some consoles might also use mechanisms such as magnetic tape cassettes or paper tape reader/punches for input or output.

Terminals in classes 9 through 18 sometimes are called remote batch terminals or remote job entry terminals. Such terminals have an interactive console and can also have batch devices the network can use for input only or for output only.

Figure J-5 shows a console with a display screen and a keyboard. Figure J-6 shows a console with a printer and a keyboard. Figure J-7 shows a remote batch terminal with a console, card reader, and a batch printer device.
5. What key ends a line of data? What key sends data? (Does the terminal use block mode?)

You should know when data leaves your terminal so that you know when to expect a response from the network or the host computer. Your terminal operator's guide should tell you what key or keys send data from your terminal.

Terminals transmit information in one of the following ways.

- A character at a time (transmission occurs as you enter each character).
- A line at a time (transmission might occur when you end each line).
- Several lines at a time, called a block (transmission occurs when you direct the terminal to transmit).

Terminals that send data a character at a time are treated by the network as if they sent characters a line at a time. Until you end the line by entering a character or set of characters called an end-of-line character, you can backspace within the line and change data. When you enter the end-of-line character, the network processes the data.

The end-of-line character used can be changed by you, by a site administrator, or by an application. We represent the end-of-line character for such terminals by a carriage return.

This appendix assumes you enter an end-of-line character after each command.

Terminals that send data a character at a time usually send the end-of-line character when you use a key called the end-of-line key (remember, the character can be changed). The end-of-line key might be labeled CARRIAGE RETURN, RETURN, RET, NEWLINE, NEXT, ATTN, or CR.

Terminals that transmit a line at a time usually send the end-of-line character and transmit the line when you use the end-of-line key. If the character is changed, then you must enter the character as the last entry on the line before pressing the end-of-line key. The end-of-line key might be labeled CARRIAGE RETURN, RETURN, RET, NEWLINE, NEXT, ATTN, or CR.

Terminals that send data a block at a time do not transmit your data to the network when you press an end-of-line key. Until you press a key called the end-of-block key, you can position the cursor anywhere within...
any unsent line and change data. This key might be labeled SEND, ETX, EOT, or XMIT. When you press the end-of-block key, the network processes each line of data as if it had been transmitted one line at a time.

The network expects each block from a block mode terminal to end with a character or set of characters called the end-of-block indicator. The end-of-block indicator used can be changed by you, by a site administrator, or by an application program. We do not show the end-of-block indicator in the examples.

Terminals that transmit a block at a time usually send the end-of-block character and transmit all lines in the block when you use the end-of-block key. If the character is changed, then you must enter the character at the end of the last line before pressing the end-of-block key.

Terminals that transmit blocks are sometimes said to work in batch mode; do not confuse this kind of batch mode operation with remote batch data transmissions. Remote batch data transmissions are simply transmissions of files from or to the host using batch devices, bypassing the terminal.

6. What telephone number is appropriate?
   If your terminal is hardwired, you may skip questions 6 and 7.
   Your network might use a specific telephone number for terminals that communicate at a certain speed, for terminals operating in block mode, or for all terminals using certain protocols.

   The telephone number you use determines whether you need to complete some of the procedures. If you do not know what numbers you should use, get help from a site administrator.

7. Is your terminal automatically connected to a host?
   If it is, skip question 8.

8. What is the name or node number for the host you need to use?

9. Will your terminal be automatically logged in?
   If so, skip question 10.

10. What is the family name, user name, and password appropriate for you on the host system you will be using?

You can get this information from site administrators.

11. Is your terminal automatically connected to a network application?
   If so, you will not have to select an application at login.

STEP 2 - SETTING UP YOUR TERMINAL

If your terminal is hardwired, you can probably skip most of this subsection; hardwired terminals are usually set up once and left in the appropriate condition. Before using this subsection, review the applicable terminal operator's manual, which describes the procedures for setting up your terminal. If you are using an X.25 terminal, follow the PAD access procedures supplied by the packet-switching network service.

Switch settings are important. The number, type, settings, and names of switches vary from terminal to terminal. Some terminals use buttons or toggles for switches; others use software option selections as switches.

If other people have used your terminal to connect to the network, the switches should be set correctly; do not change them. Directions for setting the switches may be posted near your terminal.

Here is a suggested procedure to follow when setting up your terminal:

1. Turn on the power switch.

2. Load and initialize any software or control-ware needed by your terminal. You will find detailed information on this task in your terminal's operator manual.

3. Set the terminal's duplex or echoplex switch to the correct position (use HALF if you are not sure). If you wish to have the display of your login password suppressed, you must use full duplex. If nothing you enter appears on your console after you connect to the network, the network must display characters for your console. The NOS Reference Set, Volume 3, System Commands describes how to enable and disable character echoing by the network (refer to the EP command).

4. Set the terminal's parity switch to the proper position. If garbled output appears at your console after you connect to the network, the network must use a different parity choice for your terminal. The NOS Reference Set, Volume 3, System Commands describes how to change parity use by the network (see the PA command).

5. Set the line speed switch to a speed that matches one associated with the telephone numbers you were given. If you do not know the line speed you should use, set the switch to any position for X.25, mode 4 synchronous, or bisynchronous terminals; set the switch to 30 characters per second (300 bits per second) for asynchronous terminals.

6. Set the transmission mode switch to either the character or line mode position (you can change it later if you have a block mode terminal). For example: on a Viking 721, select the CHAR option; on a CDC 751, set the switch to the CHAR position; on a CDC 200 User Terminal, set the switch to the LINE position.
To begin communication, your terminal must be physically connected to the network. If your terminal is hardwired, skip the remainder of this subsection; this subsection applies only to dial-up terminals.

A dial-up terminal uses either an acoustic coupler (asynchronous terminal) or a data set (asynchronous, X.25, asynchronous, or synchronous terminal) to connect itself to the network.

An acoustic coupler can be built into the terminal. Figure J-3 shows a terminal with a built-in acoustic coupler and gives directions to connect the terminal to the network.

An acoustic coupler can also be separate from the terminal. Figure J-1 shows an acoustic coupler separate from a terminal and gives directions to connect the terminal to the network.

A data set can be built into the terminal. Figure J-2 shows a terminal with a data set built in and gives directions to connect the terminal to the network.

A stand-alone data set can have either a switch labeled TALK and DATA or individual buttons labeled TALK and DATA. Figure J-3 shows both a data set with switches and a data set with buttons and gives directions to connect the terminal to the network.

After you dial the phone number, either you get a high-pitch tone or an operator answers. If an operator answers, ask for your terminal to be connected, wait for the tone, and then place the receiver in the coupler or set the data set switch or button to the on or data position. If you get a busy signal, wait and redial or try another number.

If your terminal has an indicator (sometimes marked DSR, DATA SET READY, or SYSTEM ACTIVE), it lights to let you know that the terminal is connected to the network. Wait approximately 2 seconds after the light comes on before entering data.

You are now ready for the next step. You might need to do one or all of the following:

- Identify your terminal to an X.25 network (this appendix does not describe this procedure).
- Identify your terminal to the CDC network.
- Select a host.
- Connect to the selected host.
- Identify yourself and your terminal to the host (log in).
- Select a network application.

The software usually sends you a message that helps you decide which step comes next. If nothing appears at your terminal within a few seconds, you probably need to identify the terminal to the network.

**STEP 4 - IDENTIFYING YOUR TERMINAL TO THE NETWORK**

Once you have established physical connection to the network hardware, you might need to identify the terminal to the network software.

This identification procedure, called automatic recognition, is not always needed. It does not apply to X.25 terminals. It does not apply if the communication line used by your terminal is not configured for automatic recognition.

If your terminal does not display any information within a few seconds of physical connection, you should complete one of the identification procedures described in the following subsections. The procedure you use depends on the terminal protocol, which you can determine if you know the terminal's type and/or class.

If you do not complete the identification procedure within the allowed time, the network disconnects a dial-up terminal. Hang up the phone and redial the number if you are using a dial-up terminal. You must restart the procedure for a hardwired terminal.

**Procedure for Asynchronous Terminals**

For an asynchronous terminal, which belongs in terminal classes 1 through 8, complete this procedure within 1 minute:

1. Wait about 2 seconds after the light that indicates your terminal is connected to the network comes on.
2. Press the carriage return key to identify the line speed used by your terminal. The network software responds with two line feeds.
3. If your terminal uses an APL, EBCD, or correspondence code character set, type a closing parenthesis; if your terminal uses an ASCII character set, you need not type in anything.
4. Press the carriage return key to identify the character and code set used by the terminal. The network software responds with a line feed.

The software sends you a message that helps you decide which step comes next. Turn to the subsection appropriate for the next step you must perform.
Procedure for HASP Terminals

HASP terminals belong either to terminal class 9 or 14. For automatic recognition of your HASP terminal, you might need to modify the signon block or enter a special statement.

The first information transmitted by a HASP terminal after it is connected to the network is called a signon block. A terminal might handle signon block transmission in one of several ways.

- Some terminals automatically transmit a signon block that begins with the characters:
  /*SIGNON

  These eight characters and the information following them imitate the card required by some IBM host systems for terminal identification. This transmission can occur without your knowledge or intervention if the information is built into the firmware or hardware.

- Some terminals require you to enter information for the signon block before they will transmit anything to the network; however, they only allow the block to contain information beginning with the eight characters /*SIGNON. These characters and other information might be required as:
  - A command from the console.
  - A card read from any card reader.
  - A card read from a specific card reader.

- Some terminals require you to enter signon block information before they will transmit anything to the network, but the content of the signon block is left up to you. Whether the information can be entered from the console or from a card reader depends on the terminal.

The network software cannot use information from a /*SIGNON card image. When such a card image is received in a signon block, the signon block contents are discarded.

Instead, the network software uses a /*CONFIG statement for the automatic recognition procedure. You can send the /*CONFIG statement in the signon block when your terminal permits you to provide the contents of that block.

If the signon block does not contain the /*CONFIG statement and the terminal must use automatic recognition, a prompt requesting that statement is sent to the terminal console. When a prompt for the statement appears, enter the statement through a card reader.

The format of the /*CONFIG statement is:

/*CONFIG, ti, CO=co, CR=x, LP=x, CP=y, PL=z

Blanks are not allowed within the statement; a blank ends parameter processing. The parameters, which you can specify in any order, are:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ti</td>
<td>Terminal type:</td>
</tr>
<tr>
<td></td>
<td>POST HASP postprint (default); this is terminal class 9.</td>
</tr>
<tr>
<td></td>
<td>PRE HASP preprint; this is terminal class 14.</td>
</tr>
<tr>
<td>CO=co</td>
<td>Configuration ordinal, a decimal integer from 1 to 255; the default is 1. Use the configuration ordinal to select one of several terminal definitions defined for the line that describes a specific combination of additional characteristics. Site administration personnel can tell you the correct number to use.</td>
</tr>
<tr>
<td>CR=x</td>
<td>Identifies available card readers. The default is 1.</td>
</tr>
<tr>
<td>LP=x</td>
<td>Identifies available line printers. The default is 1.</td>
</tr>
<tr>
<td>CP=y</td>
<td>Identifies available card punches; y cannot equal z. The default is 1.</td>
</tr>
<tr>
<td>PL=z</td>
<td>Identifies available plotters; y cannot equal z. No default exists for z; you cannot omit PL=z if you have a plotter.</td>
</tr>
</tbody>
</table>

x, y, or z is a list of numbers specified by either:

1/2/.../7

or:

ALL (all numbers from 1 through 7)

The numbers you use for x, y, and z must match the HASP stream numbers used for the corresponding devices within the workstation. Site administration personnel should have this information if you do not know what numbers to use.

For example:

/*CONFIG,PRE,CO=2,CR=2,LP=2/3,CP=4,PL=5

identifies your terminal as the second preprinting workstation defined for the communication line, having:

- A card reader and line printer on stream 2.
- Another printer on stream 3.
- A card punch on stream 4.
- A plotter on stream 5.

If no prompt for a /*CONFIG statement appears, you are ready for the next step.

The software sends you a message that helps you decide which step comes next. Turn to the subsection appropriate for the next step you must perform.
Procedure for Mode 4 Terminals

Mode 4 terminals belong to terminal classes 10 through 13 and 15. For automatic recognition, press the end-of-block key within 1 minute of physical connection.

You are ready for the next step. The software sends you a message that helps you decide which step comes next. Turn to the subsection appropriate for the next step you must perform.

Procedure for Bisynchronous Terminals

Bisynchronous terminals belong to terminal classes 16, 17, and 18. Enter a /*CONFIG statement to specify the type of terminal and the devices available at it.

The format of the /*CONFIG statement is:

/*CONFIG,ti,C0=co,CR,LP,CP=y

Blanks are not allowed within the statement; a blank ends parameter processing. The parameters, which you can specify in any order, are as follows:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ti</td>
<td>Terminal type:</td>
</tr>
<tr>
<td>2780</td>
<td>IBM 2780 (default); this is terminal class 16.</td>
</tr>
<tr>
<td>3780</td>
<td>IBM 3780; this is terminal class 17.</td>
</tr>
<tr>
<td>3270</td>
<td>IBM 3270; this is terminal class 18.</td>
</tr>
<tr>
<td>C0=co</td>
<td>The configuration ordinal, a decimal integer from 1 through 255; the default is 1. Use the configuration ordinal to select one of several terminal definitions defined for the line that describes a specific combination of additional characteristics. Site personnel can tell you the correct number to use.</td>
</tr>
<tr>
<td>CR</td>
<td>Indicates an available card reader; assumed if not specified.</td>
</tr>
<tr>
<td>LP</td>
<td>Indicates an available line printer; assumed if not specified.</td>
</tr>
<tr>
<td>CP=y</td>
<td>Indicates an available card punch; assumed not to exist if not specified. The y portion is required and can be either 2 or 3 to correspond to the device selection character DC2 or DC3.</td>
</tr>
</tbody>
</table>

For example:

/*CONFIG,3780,C0=4,CR,LP,CP=2

identifies your terminal as a 3780 terminal having:

- A card reader and line printer.
- A card punch, which is selected by the character code DC2.

If no prompt for a /*CONFIG statement appears, you are ready for the next step.

The software expecting the next step sends you a message which helps you decide which procedure comes next. Turn to the subsection appropriate for the next step you must perform.

STEP 5 - SELECTING A HOST

You might need to select the host, which runs the software you want to use. This is not necessary if your installation personnel select a host path for your terminal when the network is configured.

You can select or change a site-defined host path after you connect your terminal to the network. The host path selected is used until either you change it or until your terminal is disconnected from the network.

More than one host path can be available to each host from a terminal. If one host path fails, you can select an alternate route to the host.

Selecting a Host

You can select a host or override a site-defined host selection with the following terminal definition command.

```
ct HS=hostname
```

c
t represents the network control character for your terminal. For most asynchronous terminals this is ESC or X.

Each host may be configured with a unique name. This name (1 through 7 characters) is indicated by hostname.

For example:

```
% HS=ARHNOS
```

would select the path with the least traffic to the host called ARHNOS (Z represents your terminal's network control character).

If you specify the name, your terminal uses the host path with the least traffic.

If you do not know the name you need, the host availability display (HAD) can show you what names are available. That display is described later in this appendix.

Once you have selected your host, you are ready for the next step.
Selecting a Specific Host Path

Use the following terminal definition command to select your own host path or to override the site-defined host path.

\[ \text{ct HN=nn} \]

c\(t\) represents the network control character for your terminal. For most asynchronous terminals this is ESC or \%.

Each access has a unique number, called a node number. The host node number (1 through 31) is indicated by \(\text{nn}\).

For example:

\[ \text{%HN=2} \]

would select access 2 (% represents your terminal's network control character).

If you omit the node number, your terminal uses the host path the network is using to communicate with its supervising host.

If you do not know the node number you need, the host availability display (HAD) can show you what numbers are available. That display is described in the following subsection. Each node number may have a name for its host, provided by your site to help you identify the corresponding host system on the HAD.

Once you have selected the host path, you are ready for the next step.

The software sends you a message that helps you decide which step comes next. Turn to the subsection appropriate for the next step you must perform.

Controlling the Display of Host Paths

The host availability display (HAD) (figure J-8) lists all host paths your terminal can currently use to gain access to the host and all hosts in the network. You can turn display of the HAD on and off or request the display with the following terminal definition command.

\[ \text{ct HD=option} \]

c\(t\) represents the network control character for your terminal. For most asynchronous terminals this is ESC or \%.

If the display mode is N (no), you receive only two lines at your terminal (the host status message and the prompt message) instead of the full display when you disconnect your terminal from a host.

If you enter \(\text{HD=Y} \) or \(\text{HD} \), the full display is issued immediately when you disconnect your terminal from the host. You then have a choice of hosts and/or host paths to which you can request connection.

If you have a multihost system, typically the HAD appears when you first access the network. This appearance is controlled by site installation.

### Field

**host status message**

Status of a given host, which can be one of the following:

<table>
<thead>
<tr>
<th>Message</th>
<th>Meaning</th>
<th>You Also See:</th>
</tr>
</thead>
<tbody>
<tr>
<td>HOST CONNECTED</td>
<td>You are connected to the host.</td>
<td>prompt message d or e</td>
</tr>
<tr>
<td>NO HOST SELECTED</td>
<td>Host is available; you have not selected a host.</td>
<td>prompt message b</td>
</tr>
<tr>
<td>NO HOST AVAILABLE</td>
<td>No hosts are available.</td>
<td>prompt message a</td>
</tr>
<tr>
<td>HOST UNAVAILABLE</td>
<td>You have selected a host that is not up.</td>
<td>prompt message a</td>
</tr>
<tr>
<td>HOST BUSY</td>
<td>Connection rejected by host.</td>
<td>prompt message a</td>
</tr>
<tr>
<td>HOST DISCONNECTED</td>
<td>Connection to host terminated.</td>
<td>prompt message c or e</td>
</tr>
<tr>
<td>HOST AVAILABLE</td>
<td>You have selected host that is up.</td>
<td>prompt message c</td>
</tr>
<tr>
<td>NO HOST CONNECTED</td>
<td>You are not connected to a host.</td>
<td>prompt message c</td>
</tr>
</tbody>
</table>

- **ct**: Network control character currently defined for your terminal.
- **xx**: The number of the host node you are connected to.
- **yyyyyy**: The terminal number of your terminal.
- **host**: The 1- to 7-character name of a host; if the network only has one host, this can be blank.
- **node**: The host node number used in selecting a path through the network; \(1 \leq \text{node} \leq 31\).
- **condition**: \(S = \text{selected, not connected}\), \(C = \text{connected, not selected}\), \(SC = \text{selected and connected}\), \(SA = \text{selected, attempting connection}\).
- **status**: Either \(\text{AVAILABLE}\) or \(\text{NOT AVAILABLE}\); a host is only available when it is connected to the network.

### Action to take in response to a host status message

- **prompt message a**: ENTER \(ct\) \(HD\) TO SEE HOST STATUS
- **prompt message b**: ENTER \(ct\) \(HN=nn\) TO SELECT HOST
- **prompt message c**: ENTER INPUT TO CONNECT TO HOST
- **prompt message d**: READY FOR INPUT
- **prompt message e**: TERMINAL DISABLED BY NOP
- **prompt message f**: INPUT DISCARDED

---

**Figure J-8. Host Availability Display (Sheet 2 of 2)**
STEP 6 - CONNECTING TO THE SELECTED HOST

Your site personnel might have configured your terminal so that it is automatically connected with a host. If so, the network continues to attempt connection indefinitely either until the connection is completed or until you stop it by entering CT TM. You can tell the network is attempting to connect you when the HAD shows a SA status for any host. If your terminal is automatically connected to a host, you may skip this subsection. If not, you will have to ask for the connection to be made.

You can ask to be connected to the selected host by entering a carriage return. If the carriage return is not preceded by an empty line, the information is discarded (unless it is a valid terminal definition command).

If your connection is rejected, you are notified. If you select another host path you must make another entry to complete a connection. The network software physically disconnects dial-up devices if you do not attempt connection to a host within 2 minutes of completing the previous step.

Once you are connected to a host, you are ready for the next step.

STEP 7 - IDENTIFYING YOURSELF AND YOUR TERMINAL TO THE HOST

The step that identifies you and your terminal to the host system is called login. Your terminal is identified to the host system by assigning it a family name, a user name, and a password. The host can prompt you for each of these things.

Your site can set up your terminal connection so that part or all of your login is done automatically. If so, you might not see the corresponding prompt and you need not enter the information.

Your site might also require use of a secure login initiation sequence, prior to login, to ensure that you send your user identification to the correct host software. If required, the sequence contains a site-selected security character and the sequence will be recognized by the system at any time. Depending on your terminal type, the secure login initiation sequence is entered in one of the following ways.

- At an asynchronous terminal (not 2741), press the interactive interrupt key (BREAK or ATTN) and type the character at a 2741 terminal, press the NL key twice. Then enter the ATTN key, the character, and press the NL key.
- At an X.25 terminal, press the interactive interrupt key, type the character, and press the message transmission key.
- At a mode 4 terminal, clear the screen, press SEND, clear the screen again, type the char-acter, and press the end-of-block key.
- At a HASP terminal, type the character and press the end-of-line key.
- At a 2780 or 3780, enter /* and the character from the console or a card reader.

This action momentarily disconnects you from the host. You might need to reconnect your terminal to the host (if connection is not automatic). Now you are guaranteed that you are sending your login entries to the correct host software.

Refer to figure J-9 for a sample login from an asynchronous terminal. In the example, the terminal has not been configured by site personnel for automatic login. Everything you would typically enter is shown in lowercase.

![Figure J-9. Sample Login from an Asynchronous Terminal](image-url)
Automatic Login

The family name or user name assigned to your terminal for an automatic login can be:

- A mandatory value.
- A default value.
- A primary value.

If a mandatory value is assigned, you do not receive a prompt and cannot use any other value.

If a default value is assigned, you are prompted and you can either: enter an empty line as a response to the system prompt if you want either the default family or user name to apply, or respond to the prompt with another value.

The default family name value assigned to your terminal for automatic login can be different from the default value used by the host for a family name. You can override the login default even when you do not know the system default; this procedure is described in the following subsection.

If a primary value is assigned, you do not receive a prompt the first time login occurs while you are connected to the host. Subsequent logins (refer to Restarting Login Identification) do prompt you. You can override a primary value for user name by entering a different value during an abbreviated login. Abbreviated login is described in a later subsection.

Login Dialog

Login begins when the system displays the following lines.

WELCOME TO THE NOS SOFTWARE SYSTEM.
COPYRIGHT CONTROL DATA 1978, 198X.

Then a line appears with the date, time, and terminal name; for example:

83/12/28. 15.23.58. TERM201

Next is a line your site supplies that identifies the host system used; something similar to:

CDC NETWORK OPERATING SYSTEM NOS 2

The next line is either of the following prompts.

FAMILY:

This indicates that no mandatory or primary family name has been assigned to your terminal. Enter the 1- to 7-character name of the storage device that contains your permanent files and press the carriage return. If you want to use the default login family name, just press the carriage return after the FAMILY prompt appears. You can also enter a value of 0 to override a preassigned login default family name and use the system default family name. If you have no preassigned default family name, carriage return selects the system default family name.

USER NAME:

This indicates that no mandatory or primary user name has been assigned to your terminal. Enter the user name you were given. The user name, which can contain any combination of digits, letters, and asterisks, identifies you as the terminal operator.

The next prompt appears only after a USER NAME prompt has appeared. This final prompt is either:

PASSWORD:

or

PASSWORD: XXXXXXX

The system attempts to preserve your password's secrecy. If you have set your terminal at full duplex (refer to the NOS Reference Set, Volume 3, System Commands), your password will not be displayed when you enter it. You will not see what you type in. At some terminals, the network overprints several characters on a line and asks you to type your password on that line, as shown by the second PASSWORD prompt. After creating this row of overstruck characters, the cursor moves back to the first character.

Enter the password currently associated with your user name. If you must enter the user name, you also must enter the password. No default exists for a password.
You must respond to each prompt within 2 minutes. If you take too long to respond, this message is displayed at your terminal.

TIMEOUT.

Your terminal is then disconnected from the host.

If you enter an unacceptable family name, user name, or password, you receive either the following message:

IMPROPER LOGIN, TRY AGAIN.
FAMILY:

If no mandatory family name is assigned to your terminal, or:

IMPROPER LOGIN, TRY AGAIN.
USER NAME:

If a mandatory family name is assigned. Reenter all needed login information, beginning with the requested parameter, regardless of when the error occurred.

You must spell each login entry correctly. If you make a mistake, such as typing the letter 0 for the numeral 0 or the number 1 for the letter l, your login will not be successful. Try again when the prompting sequence restarts.

You are allowed four consecutive chances to complete the login procedure. If you make four unsuccessful attempts to complete login, this message appears at your terminal:

USER RETRY LIMIT.

Your terminal is then disconnected from the host. If this happens, check the spelling of all of the entries. If you spelled everything correctly, contact a site administrator.

When the family name, user name, and password are accepted by the host, you must next connect your terminal to an application, if there is no default network application.

STEP 8 - SELECTING A NETWORK APPLICATION

Your site may be set up so that your terminal is connected to the IAF application automatically. Or your site may connect your terminal automatically to another application, depending on the installation. If so, you might not see the corresponding prompt. If not, you must complete this step yourself.

You are allowed several chances to make a correct entry. However, if you fail to connect successfully after four consecutive attempts, your terminal is automatically disconnected from the host. If this happens, check the spelling of the name you used. If the spelling was correct, contact a site administrator.

Automatic Connection

Your host may permit you access only to one network application, or an application can be connected automatically. Your host site can configure your connection for either possibility by preassigning an automatic connection application name.

A preassigned automatic application connection can be either mandatory or primary for the connection or it can be mandatory for the user. If either you or your connection has a preassigned mandatory application, you are not prompted, you are automatically connected to that application, and you cannot use any other applications. If a mandatory application program is not running in the host, you are logged out and disconnected from that host.

If a primary value is assigned, you are not prompted for the initial connection request after identifying your terminal to the host, and connection to that program occurs automatically. If that connection is not successful or if you disconnect from that application program, you have a choice of actions; you can select another application or disconnect from the host.

To override a primary automatic application connection on the first attempt to select an application, name a different application in an abbreviated login entry (described later in this appendix) following a login prompt.

When a primary value is assigned, you are prompted on subsequent attempts to select an application, such as when you are switching applications. When you are prompted to enter an application name and you want to be connected to your primary application, enter an empty line as a response.

Manual Connection

This procedure begins when you see the following prompting message.

    terminalname - APPLICATION:

The terminalname variable on this line is the same terminal name as the one on the first line of your login sequence. If your terminal is automatically logged into a network application, you do not receive this prompt.

When you receive the APPLICATION prompt, enter the letters and digits that identify the network application you want to access; for example, IAF for the Interactive Facility. You can access CDC-written applications from the following list that are installed at your site:

- Remote Batch Facility (enter RBF).
- Interactive Facility (enter IAF).
- Transaction Facility (enter TAF).
- Terminal Verification Facility (enter TVF).
- Message Control System (enter MCS).
- PLATO (enter PNI, which stands for the PLATO-NAM Interface).

Other applications, written at your site, might be available.
You must respond to the prompt within 2 minutes. If you take too long to respond, this message is displayed at your terminal.

TIMEOUT.

Your terminal is then disconnected from the host.

You must spell your entry correctly. If you make a mistake, such as typing the letter 0 for the numeral 0 or the letter l for the number 1, you receive the following error message:

ILLEGAL APPLICATION, TRY AGAIN.

terminatename - APPLICATION:

The terminal name is indicated by terminatename. You can also receive this message if your user name is not permitted access to the application you named. If you did not spell the name correctly, try again. If you did spell the name correctly, disconnect your terminal and contact a site administrator.

If you make four unsuccessful attempts to enter an application name, this message appears at your terminal.

APPLICATION RETRY LIMIT.

Your terminal is then disconnected from the host.

This step is complete when the application you request connects to your terminal. The application you asked to use might print an identification line next.

Whether the program sends such a message or not, you can use commands recognized by that application. If you need to disconnect your terminal from the application, the application probably has a command for that purpose. If the program has no such command, the subsection called Disconnecting from a Host describes a command you can use.

ABBREVIATED LOGIN AND APPLICATION CONNECTION

You can shorten the standard login and application connection procedures by entering all of the required information at once. For example, in response to the FAMILY prompt, you can enter the following information on the same line.

FAMILY: familyname,username,password,application

Separate all entries with a comma. The entries are order-dependent. Use a comma to indicate any default or unused entries.

You do not receive any of the remaining login selection prompts if you use this abbreviated login procedure, unless you omit a required entry or supply an entry that is not recognized. Your password entry is not protected by the system when you use an abbreviated login procedure.

Here are some examples. To log in and connect to the Interactive Facility application IAF with a family name of SYSTEMA, a user name of RLS4525, and a password of PASS123, enter:

SYSTEMA,RLS4525,PASS123,IAF

To use the site-defined login default family name, enter:

,RLS4525,PASS123,IAF

To override your site-defined login default family name with the host's default family name, enter:

0,RLS4525,PASS123,IAF

To use a login default family name and user name defined by the site for your terminal, enter:

---,IAF

To also use a default application name defined by the site for your terminal, enter:

---

You can supply combined entries in response to the FAMILY, USER NAME, and PASSWORD prompts. Although you do not need to complete the remaining sequence on the same line, you must enter the information in the correct order: family name, user name, password, and application (if there is no default). For example:

FAMILY: systema
USER NAME: rls4525,pass123
terminatename - APPLICATION: iaf

If you supply a user/password combination that is overridden by a mandatory specification, this message is displayed.

VOLUNTEERED USER/PASSWORD IGNORED.

If you offer an application name that is overridden by a preassigned mandatory application, the following message is displayed.

VOLUNTEERED APPLICATION IGNORED.

SWITCHING TO A DIFFERENT APPLICATION

Unless you have a mandatory network application assigned for your terminal, you can transfer your terminal's connection from the current application to another application. There are two ways to do this, depending on the commands used by the current application.

Direct Switches

You can switch in one step by entering a switch command recognized by the current application. The following switch commands are recognized by CDC-written network applications:

<table>
<thead>
<tr>
<th>Application</th>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>RBF</td>
<td>IAF</td>
</tr>
<tr>
<td>IAF</td>
<td>BYE,application</td>
</tr>
<tr>
<td>MCS</td>
<td>LOGIN,application</td>
</tr>
</tbody>
</table>

For example, if your terminal is connected to RBF, you can gain access to IAF by entering the IAF command.
Do not enter any more input until the application acknowledges it has processed your switch command. Otherwise, you may lose the input.

Indirect Switches

If your current application does not have a command for a direct switch, you must disconnect your terminal from the current application with a command recognized by that application. Then you must request another application connection from the host. The following disconnection commands are recognized by CDC-written network applications:

<table>
<thead>
<tr>
<th>Program</th>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>RBF</td>
<td>END</td>
</tr>
<tr>
<td>IAF</td>
<td>BYE,</td>
</tr>
<tr>
<td>MCS</td>
<td>END</td>
</tr>
<tr>
<td>TAF</td>
<td>EX.LOGT</td>
</tr>
<tr>
<td>TVF</td>
<td>END</td>
</tr>
</tbody>
</table>

For example, you can switch your terminal connection from RBF to an application other than IAF by entering the END command. You then receive a prompt for a new application name. Do not enter any more input until the application acknowledges it has processed your disconnection command. Otherwise, you might lose the input.

Dialog for Direct and Indirect Switches

After disconnecting the application, the system indicates that a connection switch is in progress by issuing this message:

application - CONNECT TIME hh.mm.ss.

The application that was just disconnected is indicated by application and the time that passed while the terminal was connected to the program is indicated by hh.mm.ss.

If you used a switch command, you receive an identifying message from your new application. If you used a disconnection command, you receive another prompt for an application name.

terminalname - APPLICATION:

unless the terminal is permitted access to only one application. If so, you are disconnected from the host.

If you enter the name of another application in response to the APPLICATION prompt, you are connected to that application.

RESTARTING LOGIN IDENTIFICATION

There are many reasons why you might want to restart login identification and the subsequent application connection. Perhaps you have several user names available to you, each with permission to use different host resources. Or perhaps someone else left the terminal connected to an application you do not need, and you do not want to use their user name.

There are three ways to restart login, depending on the commands recognized by the current application and installation options.

Direct Restarts

You can restart host identification by entering a login command recognized by the current application. The following login commands are recognized by CDC-written network applications:

<table>
<thead>
<tr>
<th>Application</th>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>RBF</td>
<td>LOGIN</td>
</tr>
<tr>
<td>IAF</td>
<td>HELLO</td>
</tr>
<tr>
<td>MCS</td>
<td>LOGIN</td>
</tr>
</tbody>
</table>

For example, if your terminal is connected to IAF, you can restart login by entering the HELLO command.

Do not enter any more input until the application acknowledges it has processed your command. Otherwise, you may lose the input.

Indirect Restarts

If your current application does not have a command for a direct switch, you must disconnect your terminal from the current program with a command recognized by that application. Then you must request restart of login from the host. The disconnection commands recognized by CDC-written network application are described earlier in this section under Switching to a Different Application.

For example, you can restart your terminal login from RBF by entering the END command. You then receive a prompt for a new application name. Do not enter any more input until the application acknowledges it has processed your disconnection command. Otherwise, you might lose the input.

Secure Login Restarts

If your site has selected the secure login initiation option and defined a security character, the sequence may be entered at any time to immediately disconnect from the current application and initiate the user login procedure.

After entering the disconnection command, you receive another prompt for an application name:

terminalname - APPLICATION:

unless the terminal is permitted access to only one application program. If so, you are disconnected from the host and can restart login by reconnecting.

If you receive the APPLICATION prompt, you use one of the following commands to ask the host system to restart login:

HELLO
LOGIN
DISCONNECTING FROM A HOST

You might want to disconnect your terminal from a host for several reasons, for example:

- You want to disconnect from the network properly, without leaving behind an indication that something went wrong; disconnecting from a host is the first step in disconnecting from a CDC network.
- You are allowed access to more than one host system, and you want to transfer your terminal's connection from the current host to another host.

There are four ways to do this, depending on the commands used by the current application.

Disconnecting with Application Commands

You can disconnect in one step by entering a host disconnection command recognized by the current application. The following host disconnection commands are recognized by CDC-written network applications:

<table>
<thead>
<tr>
<th>Program</th>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>RBF</td>
<td>LOGOUT or LOGOFF</td>
</tr>
<tr>
<td>IAF</td>
<td>BYE or LOGOUT or GOODBYE</td>
</tr>
<tr>
<td>MCS</td>
<td>BYE or LOGOUT</td>
</tr>
</tbody>
</table>

For example, if your terminal is connected to IAF, you can disconnect from the host by entering the BYE command.

Disconnecting with Host Commands

If your current application does not have a command for direct disconnection, you must first disconnect your terminal from the current program with a command recognized by that application. Then you must request host disconnection from the host. Application disconnection commands are described earlier in this section under Switching to a Different Application.

After disconnecting the application, the system indicates that a connection switch is in progress by issuing this message:

application - CONNECT TIME hh.mm.ss.

The application that was just disconnected is indicated by application and the time that passed while the terminal was connected to the program is indicated by hh.mm.ss.

You then receive another prompt for an application program name:

terminalname - APPLICATION:

unless the terminal is permitted access to only one application. If so, you are disconnected from the host anyway.

Disconnecting with a Network Software Command

You normally end a connection with a host by using a command to disconnect you from an application and/or a command to log out of the host. Events might make it impossible for you to do either. When this happens, you can end your terminal's connection to the host by entering this terminal definition command.

cT TM

cT represents the network control character. For most asynchronous terminals this is ESC.

The network responds to your TM command with a new host availability display. You can use the TM command if an application does not respond to your entries.

Reconnecting to a Host or Connecting to a Different Host

For a single host system, after your terminal is disconnected from the host, this message is printed.

HOST DISCONNECTED. CONTROL CHARACTER = ct

cT is the network control character. This message is followed by the prompting message.

ENTER INPUT TO CONNECT TO HOST

You can then attempt another connection to the same host by sending any input you want. If you have a multihost system, typically the HAD will be displayed between these two messages. To reach a different host, you must complete the procedures for Selecting a Host and Connecting to the Selected Host described earlier in this appendix.

Disconnecting from One Host and Connecting to a Different Host

You can disconnect from one host establish a connection with another host using the single command

ct HC = hn

cT is the network control character, and hn is the name of the desired host.
INTERRUPTIONS

Events can sometimes interrupt your input or output. These interruptions fall into two categories:

- Interruptions for communication with the network operator.
- Temporary suspensions in communication.

Communicating with the Network Operator

The term network operator includes any operator who has access to the network, including the host operator. Any network operator can send and receive messages that involve you.

Receiving Messages

The network operator can send short messages to a terminal. The message appears at your terminal in this format:

```
FROM NOP . . . message text
```

These messages can appear at any time a new line of output is possible at your terminal. For example, the network operator might want to inform all connected terminals that communication is going to be suspended intentionally with this message:

```
FROM NOP . . . SHUTDOWN IN 5 MIN
```

Sending Messages

You can respond to such messages by entering the following terminal definition command.

```
ct MS=message
```

c represents the asynchronous terminals this is ESC.

The message text must not exceed 50 graphic characters. Because the network operator can be located at a terminal that does not support many special characters, you should avoid characters not in the ASCII 63-character subset described in appendix A of the NOS Reference Set, Volume 2, Guide to System Usage.

You can also begin dialog with the network operator. For example, if you need to use a remote batch printer that has been logically disabled, the entry:

```
IMS=PLEASE ENABLE LP=M4C555
```

causes the message PLEASE ENABLE LP=M4C555 to appear at the network operator’s terminal, prefixed by the terminal name of your terminal. The X character represents the network control character for your terminal.

Preventing Messages

Sometimes it is important that output to your terminal does not include unplanned messages from the network operator. You can prevent delivery of messages from the network operator by locking them out with the following terminal definition command.

```
ct LK=option
```

c represents the network control character. For most asynchronous terminals this is ESC.

After you enter this command with the option Y, any message to your terminal from the network operator is discarded by the network software. Messages are discarded until you again allow delivery by using the command with the option N.

Site administrators can configure your terminal so that messages are discarded as soon as the terminal is connected to the network. A network application can also change the LK option in use.

Suspensions of Communication

Sometimes, message traffic in the network is so heavy that all storage is temporarily used up. Also, a host may be too busy to accept data. During these times, the network software takes steps that temporarily stop input until enough output has occurred to free additional storage.

Although storage may be low, sometimes the network cannot prevent you from entering data. Therefore, the network discards each message from your terminal and sends this message to your terminal.

```
WAIT . .
```

When the following message appears, you can reenter any information that was previously discarded.

```
REPEAT . .
```

If your terminal transmits more than one message at a time, you must determine which information you need to reenter. The application might have commands that can help you determine which messages it received.

Communication Failures

Events can occur that:

- Cause your application to fail.
- Disconnect your terminal from an application.
- Disconnect your terminal from the host.
- Disconnect your terminal from the network.
Application Failures

If an application fails after your terminal is connected, this message is displayed.

APPLICATION FAILED.
application CONNECT TIME hh:mm:ss.
terminalname - APPLICATION:

The length of time your terminal was connected to the application is specified by hh:mm:ss; application is the name of the application; and terminalname represents the terminal name the network uses to identify the terminal. You either can select another application or log out.

Disconnection from the Network

The network informs you that it has lost communication with the host software by displaying the host status message:

HOST DISCONNECTED. CONTROL CHARACTER = ct

followed by the prompting message:

ENTER INPUT TO CONNECT TO HOST

If you have a multihost system, the HAD will be displayed between these two messages.

If you are at a dial-up terminal and you do not attempt to connect to the same or a different host within 2 minutes, your terminal is disconnected from the network.

If communication between the network and the host software resumes, you must connect to the host and log in again but you do not need to access the network again (perform dial-up and auto-recognition procedures). These host communication failures occur either when the host has been shut down or when hardware fails in the communication path between the network and the host.

All network software conditions (that is, parameters that may be set with terminal definition commands) are retained across host disconnection except for transparent, full ASCII, and special edit input modes. Refer to the NOS Reference Set, Volume 3, System Commands for a discussion of these commands.

Failures in the communication path between the network hardware and your terminal are treated by the network software as if you your terminal had failed. These failures can occur because of hardware problems, or maybe because you entered an input character during output. If you hold the interactive output interrupt key down for too long, a communication failure can occur. This key is identified in the NOS Reference Set, Volume 3, System Commands.

There are several tests for communication failures. If your terminal has a CTS, ON-LINE, or CARRIER indicator, the light goes out when a failure occurs. If you hold the interactive output interrupt key down for too long, a communication failure can occur. This key is identified in the NOS Reference Set, Volume 3, System Commands.

Batch input and output devices associated with the failed console stop running, and batch device connections are ended. The network software does not distinguish between dial-up and hardwired terminals when processing terminal failures.

Terminal failures require you to complete new access and login procedures to resume communication with the network. Terminal failures always cause disconnection when the terminal is on a dial-up line.

DIAL directive 9-1
Disable transaction recovery 8-2
DISPLAY statement 4-7
DMS statement 4-7
DSUUMP request 6-1
Dump
Communication block 6-4
Exchange package 6-4
TAF field length 6-4
Task field length 6-3, 4

ECS 5
End task 2-28
Entering transaction subsystem 1-4
Entry header, journal file 4-5
ERO command 8-3
Error messages B-1
Establish system identifier 2-40
Examine ABH 2-14
Execute named task 11-2
Executing transaction 7-1
Extend field length 2-3; 10-6
Extended core storage 1-5
Extended memory 5; 1-5
Extract bit string from word 2-31
EXTRACT request 2-31

File
CRM type 4-2
Definitions E-1
Descriptions E-1
Index 4-2

Files
Journal 4-5
JOURO 4-5
NCTFI 4-8
Network 4-8; 9-1
Procedure 4-1
Recoverable 8-1
Recovery 4-8; 8-1
Reserved E-2
System 4-1
TCF 4-1; 7-2; E-1
xxJ 4-1; 2,4
xxJORM 4-4
xxTASKL 10-1
Forced write indicator 4-3
Format effectors 2-12,15
Free requests 7-1
FSE C=6

GETABH request 2-14
Global task dump limit 6-5
GTDL 6-5

Hardware configuration 8-2

Ignore task in replacement file 10-8
II0 request 2-28
Implement application 1-5
Index file 4-2
Initiate a run unit 2-38
Initial task 1-3; 11-1; 12-1
Initialize recovery files 8-2
Initiate new transaction chain 2-6
Input/output
Limit 2-28
Requests 2-8
Input overflow 2-10,23
Insert bit string into word 2-31
INSERT request 2-32
Installing TAF F-1
INT command 8-2
Interactive virtual terminal 1-3; 2-16
Interrogate TST 2-23
ITASK 1-4; 11-1; 12-1
ITL request 3-29
IVT 1-3; 2-16
IXN statement 4-2

Journal files 4-5
JOURNAL request 4-5
JOURO file 4-5

K display commands 2-30; 4-8; 6-1,4; 8-2,3
K.DSDUMP command 6-4
K.DUMP command 6-5
K.DUMPLIM command 6-5
K.ERO command 8-3
K.INT command 8-2
K.REC command 8-3
K. statement 4-8
KDIS 11-1
KPOINT request 2-30
KTSMDP utility/request 6-4

Libraries 10-1
LISTASK command 10-2
LISTASK input directives 10-5
LISTASK utility/command 10-1
Line feed and transmission keys R-1
List tasks on library 10-3
Load overflow blocks 2-10
LOADCB request 2-10
Lock conflict 7-2
LOGIN request 2-31
Login terminal to TAF 1-4
Logout task 11-1
Logout terminal from TAF 2-29; 11-1
LOGT request 2-29
LOGT system task 11-1

Macros 12-1
Manipulate user area of TST 2-26
Memory
Changing from tasks 2-3; 10-5
Dump requests 6-1
Dumps 6-1
Requests 2-3
Message abort 11-1
Modify ABH 2-12
Modify terminal characteristics 2-16
Move data from terminal to task 2-28
MSABT 11-1
Multimainframe 1-5
Multimainframe recovery 8-4
Multiple indexed files 4-2
Multiple RECOVER statements 8-3

NAM 1-3; 12-3
