

# RT-11 System Subroutine Library Manual

Order Number AA-PD6MA-TC

**August 1991**

This manual contains current reference data about the system subroutine library (SSL), a collection of routines callable from high-level languages (FORTRAN and C).

**Revision/Update Information:** This information was previously published, along with reference data about the system macro library, as part of the *RT-11 Programmer's Reference Manual*, AA-H378D-TC.

**Operating System:** RT-11 Version 5.6

**Digital Equipment Corporation  
Maynard, Massachusetts**

## Chapter 1 Using the System Subroutine Library

---

1.1	Overview	1-1
1.1.1	SYSLIB Functional Organization	1-2
1.1.2	Applicability	1-2
1.2	System Conventions	1-2
1.2.1	Naming Conventions	1-3
1.2.2	Subroutines and Functions	1-3
1.2.3	Channel Numbers	1-3
1.2.4	Completion Routines	1-4
1.2.5	Completion Routine Restrictions	1-4
1.2.6	Device Blocks	1-5
1.2.7	INTEGER*4 Support Functions	1-5
1.2.8	User Service Routine (USR) Requirements	1-6
1.2.9	Subroutines Requiring Additional Queue Elements	1-14
1.2.10	System Restrictions	1-14
1.3	Calling SYSLIB Subroutines or Functions	1-15
1.4	FORTRAN/MACRO Interface	1-23
1.4.1	Subroutine Register Usage	1-24
1.4.2	FORTRAN Programs Calling MACRO Subroutines	1-25
1.4.3	MACRO Routines Calling FORTRAN Programs	1-27
1.5	FORTRAN Programs in a Foreground/Background Environment	1-29
1.5.1	Calculating Workspace for a FORTRAN Foreground Program	1-30
1.5.2	Running a FORTRAN Program in a Foreground/Background Environment	1-31
1.6	Linking with FORLIB	1-33
1.7	SYSLIB Services Not Provided by Programmed Requests	1-33
1.7.1	Time Conversion and Date Access	1-33
1.7.2	Program Suspension	1-34
1.7.3	Two-Word Integer Support (INTEGER*4)	1-34
1.7.4	Radix-50 Conversion	1-35
1.7.5	Character String Operations	1-35
1.7.6	Control of Global Regions	1-36
1.8	Character String Functions	1-36
1.8.1	Allocating Character String Variables	1-37

1.8.2	Passing Strings to Subprograms . . . . .	1-38
1.8.3	Using Quoted-String Literals . . . . .	1-39

# Preface

---

This manual contains reference data about RT-11 system subroutines, a collection of call routines contained in system library SYSLIB.OBJ. As a FORTRAN programmer, you access RT-11 Monitor services through these call routines to the system subroutine library. Using SYSLIB subroutines, you can write almost all application programs in FORTRAN without having to write code in any assembly language. This library is also accessible from PDP-11C.

Reference data about the system macro library, previously contained in the *RT-11 Programmer's Reference Manual* is now contained in a separate manual, *RT-11 System Macro Library Manual*. See *Associated Documents*.

## Intended Audience

This information is provided for use by advanced RT-11 users, including FORTRAN IV, FORTRAN-77, and MACRO-11 assembly language programmers and C language programmers.

## Document Structure

### **Chapter 1 — Using the System Subroutine Library**

Describes implementation and effective use of subroutines contained in SYSLIB.OBJ; provides examples that demonstrate subroutine flexibility and value in working programs.

### **Chapter 2 — System Subroutine Description and Examples**

Presents all SYSLIB functions and subroutines in alphabetical order; provides a detailed description of each one. Gives examples of each call in a FORTRAN program.

## Associated Documents

The RT-11 Documentation Set consists of the following associated documents:

### Basic Books

- *Introduction to RT-11*
- *Guide to RT-11 Documentation*
- *RT-11 Commands Manual*
- *PDP-11 Keypad Editor User's Guide*
- *PDP-11 Keypad Editor Reference Card*

- *RT-11 Quick Reference Manual*
- *RT-11 Master Index*
- *RT-11 System Message Manual*
- *RT-11 System Release Notes*

#### Installation Specific Books

- *RT-11 Automatic Installation Guide*
- *RT-11 Installation Guide*
- *RT-11 System Generation Guide*

#### Programmer Oriented Books

- *RT-11 IND Control Files Manual*
- *RT-11 System Utilities Manual*
- *RT-11 System Macro Library Manual*
- *RT-11 System Subroutine Library Manual*
- *RT-11 System Internals Manual*
- *RT-11 Device Handlers Manual*
- *RT-11 Volume and File Formats Manual*
- *DBG-11 Symbolic Debugger User's Guide*

## Conventions

The following conventions are used in this manual:

---

<b>Convention</b>	<b>Meaning</b>
Black print	In code examples, black print indicates output lines or prompting characters the system displays.
Braces ( { } )	In command examples, braces enclose mutually exclusive options. You can choose only one of the options contained in braces.
Brackets [ ]	In command examples, square brackets enclose optional parameters, qualifiers or values. For example: <b>i = ISFDAT (chan,dblk[,idate][,iold])</b>
UPPERCASE characters	In command examples, uppercase characters are command elements that should be entered exactly as given.
lowercase characters	In command syntax examples, lowercase characters are command elements for which you specify a value. For example: <b>CALL POKEB (iaddr,ivalue)</b>
Command Syntax	Functions and subroutines have different formats: A function has the format: <b>i = POKEB (iaddr,ivalue)</b> A subroutine has the format: <b>CALL POKEB (iaddr,ivalue)</b> Alternative commands are shown as: <b>i = POKEB (iaddr,ivalue)</b> <b>CALL POKEB (iaddr,ivalue)</b>
<code>RET</code>	<code>RET</code> in examples and in the example installation represents the RETURN key.
<code>CTRL/x</code>	<code>CTRL/x</code> indicates a control key sequence. While pressing the key labeled Ctrl, press another key. For example: <code>CTRL/C</code>

---

## Summary of Changes

---

This section summarizes additions, deletions and changes to the system subroutine library (SYSLIB). Refer to Chapter 2 for detailed description of RT-11 system subroutines.

### Changes Between SYSLIB and FORTRAN OTS (FORLIB and F77OTS)

The following SYSLIB changes affect the relationship between SYSLIB and the FORTRAN Object Time Systems (OTS).

- Functions and subroutines DATE, IDATE, RAN, and RANDU, previously in the distributed FORTRAN subroutine libraries, are now located in SYSLIB.OBJ.
- The following functions and subroutines (see Table 1), specific to FORTRAN programming, have been deleted from the distributed RT-11 system subroutine library, SYSLIB.OBJ, because they do not work without a resident FORTRAN OTS. These functions and subroutines have been added to the FORTRAN IV distributed FORLIB and the FORTRAN-77 distributed F77OTS.

**Table 1: Functions and Subroutines Deleted from SYSLIB**

---

GETSTR	IFREEC	INTSET
IASIGN	IGETC	IQSET
ICDFN	IGETSP	PUTSTR
IFETCH	ILUN	SECNDS

---

#### NOTE

Because IQSET is no longer in SYSLIB.OBJ, FORTRAN programmers who need to add queue elements for certain other SYSLIB functions, should refer to the FORTRAN IV distributed FORLIB and the FORTRAN-77 distributed F77OTS.

### SYSLIB Subroutines

#### Changes for I-D Space

Table 2 lists subroutine changes resulting from the addition of Supervisor Mode, I-D space. One of the major features of V5.6 SYSLIB support added mapping routines that begin with letter *M*.

The *mapping* version of a routine is called in the same manner as an unmapped version, but has an added argument that specifies the type of mapping required. In

these cases, mapping is shown as an optional parameter in the generic command string. For example, ISDATW/MSDATW is shown as:

Form:

**i = ISDATW (buff,wcnt)**

**i = MSDATW (buff,wcnt[,bmode])**

**Table 2: Routines Added or Changed for I-D Space**

---

ICMAP	IUNMAP	JREADW	MREAD	MREADC	MSPFNC

# Using the System Subroutine Library

---

## 1.1 Overview

The system subroutine library is a collection of FORTRAN- and C-callable routines contained in the SYSLIB.OBJ system library which also contains overlay handlers, utility functions, a character string manipulation package, and two-word integer support routines. High-level language programmers use these subroutines to take full advantage of the latest RT-11 system features. The linker also uses this library to resolve undefined globals.

If you are not familiar with the *PDP-11 FORTRAN Language Reference Manual* and the *RT-11/RSTS/E FORTRAN IV User's Guide*, and the *Guide to PDP-11 C*, you should refer to these manuals before using the material described in this chapter. C language programmers should also refer to the *PDP-11 C Run-Time Library Reference Manual* for information about functions and macros.

The system subroutine library provides the following capabilities:

- Complete RT-11 I/O facilities, including synchronous, asynchronous, and event-driven modes of operation. FORTRAN subroutines can be activated upon completion of an input/output operation.
- Timed scheduling of completion routines, standard in the multijob and mapped monitors, is a SYSGEN option for the SB monitor.
- Facilities for communication between foreground and background jobs.
- FORTRAN language interrupt service routines for user devices.
- Complete timer support facilities, including
  - Timed suspension of execution in multijob or mapped environments
  - Conversion of different time formats, and time-of-day information
  - Timer support for facilities using either 50- or 60-cycle clocks
- Facilities for creating, attaching, detaching, and eliminating global regions in extended memory.
- All RT-11 auxiliary input/output functions: opening, closing, renaming files; creating or deleting files on any device.
- All monitor-level information functions, such as job partition parameters, device statistics, and input/output channel statistics.
- Support interface and multiterminal environment.

- Access to the RT-11 command string interpreter (CSI).
- Access to limited instruction-data (I-D) space and Supervisor mode support.
- Mapping routines, similar to unmapped routines, having added argument(s) that specify mapping required.
- Character string manipulation package supporting variable-length character strings.
- INTEGER\*4 support routines that allow two-word integer computations.

In reference to variables, unless otherwise specified, *INTEGER* means INTEGER\*2, (16-bit integer) and *REAL* means REAL\*4 (single-precision floating point). Integer and real arguments to subprograms are indicated in this section as follows:

i = INTEGER\*2 arguments  
 j = INTEGER\*4 arguments  
 a = REAL\*4 arguments  
 d = REAL\*8 arguments

### 1.1.1 SYSLIB Functional Organization

RT-11 system subroutines and functions are presented in alphabetical sequence of their generic name. For example, because READC, IREADC, and MREADC can be called as subroutines or as functions, they are presented together under \*READC to facilitate easy lookup. An I-prefixed name denotes use as a function; an M-prefixed name denotes the function or subroutine has extra arguments that specify mapping.

Functionally related calls to enable or disable functions are presented together to facilitate easy lookup. For example, LOCK and UNLOCK are presented together as LOCK/UNLOCK.

### 1.1.2 Applicability

In general, SYSLIB routines were written for use with RT-11 V2 or later and FORTRAN IV V1B or later versions for RT-11 or FORTRAN may lead to unpredictable results. SYSLIB now supports virtually all monitor requests. Do not use a SYSLIB routine on an older monitor that does not support the request implemented by the routine.

## 1.2 System Conventions

This section describes system conventions that must be followed for proper operation of calls to the system subroutine library. (For applicable restrictions, see Section 1.2.10.)

### 1.2.1 Naming Conventions

In FORTRAN, subroutine names starting with I-through-N (inclusive) are, by default, integer returns; names starting with A-through-H and O-through-Z are real returns.

SYSLIB names are the same as those used in SYSMAC except that, when names in SYSMAC start with letters other than I-through-N, the letter I is appended to the beginning. Also the following conventions apply:

- Names that start with the letter I ordinarily are functions that return a 16-bit value.
- Names that start with the letter J return a 16-bit value, but operate on a 32-bit value.
- Names that start with the letter K (such as KPEEK) are functional extensions of names beginning with I (such as IPEEK), functionally the same, except that the K-version has an optional argument.
- Names that start with the letter M (such as MRCVD) indicate that mapping or multimode mapping has been added to a function (such as IRCVD).

Names that start with the letter M might also identify multiterminal equivalents of generic functions or subroutines; for example, MTOUT and MTPRINT are multiterminal equivalents of ITTOUR and PRINT.

### 1.2.2 Subroutines and Functions

If a SYSLIB routine returns a value, it is more useful as a function than as a subroutine. If the routine does not return a value, it should only be used as a subroutine. In instances where they can function as well in either role, SYSLIB descriptions are presented for both forms. Generally, subroutines whose names start with letters other than I-through-N either do not return a useful value or return a floating-point value.

### 1.2.3 Channel Numbers

A channel number is a logical identifier for a file used to communicate with RT-11. When you open a file on a particular device, you assign a channel number to that file. When you refer to an open file, just refer to the appropriate channel number.

The FORTRAN system has 16(decimal) channels available. The call IGETC assigns a channel to your program and notifies the FORTRAN I/O system, which also uses these channels, that the channel is in use. When there is no longer need for a channel, the program should close the channel with a CLOSEC, ICLOSE, or a PURGE SYSLIB call. The channel should also be closed and returned to the FORTRAN I/O system with a IFREEC call.

The ICDFN call can activate up to 255(decimal) channels. ICDFN sets aside memory in the job area to accommodate status information for the extra channels. Use the ICDFN call during the initialization phase of your program. You can use all channels numbered higher than 15(decimal). The FORTRAN I/O system uses channels 0 through 15(decimal).

You must allocate channels in the main program routine or its subprograms. Do not allocate channels in routines that are activated as the result of I/O completion events or ISCHED or ITIMER calls.

### 1.2.4 Completion Routines

A completion routine is a subprogram that executes asynchronously with a main program and is scheduled to run as soon as possible after the completion of an associated event, such as an I/O transfer or the passing of a specified time interval. All completion routines of the current job have higher priority than other parts of the job. When a completion routine is initiated (because of its associated event), it interrupts execution of the job and continues to execute until it relinquishes control.

Completion routines can be written in FORTRAN or assembly language, depending on the function called. Assembly language completion routines exit with a RETURN instruction. FORTRAN completion routines exit by the execution of a RETURN or END statement in the subroutine. Names of all completion routines external to the routine being coded and passed to scheduling calls must be specified in an EXTERNAL statement in the FORTRAN program unit issuing the call:

A completion routine written in FORTRAN can have a maximum of two arguments:

Form:

```
SUBROUTINE crtn [(iarg1,iarg2)]
```

where:

- crtn** is the name of the completion routine
- iarg1** is the equivalent to R0 on entry to an assembly language completion routine
- iarg2** is equivalent to R1 on entry to an assembly language completion routine

For information on the meaning of R1 and R0 contents, see the *RT-11 System Macro Library Manual*:

If an error occurs in a completion routine or in a subroutine at completion level, the error handler traces back through to the original interruption of the main program. Thus, the traceback is shown as though the completion routine were called from the main program.

### 1.2.5 Completion Routine Restrictions

Certain restrictions apply to completion routines that are activated by the following calls:

INTSET	IREADF	ISPFNC	IWRITF
IRCVDC	ISCHED	ISPFNF	MRKT
IRCVDF	ISDATC	ITIMER	
IREADC	ISDATF	IWRITC	

When using these calls the following restrictions apply:

- No channels can be allocated by calls to IGETC or freed by calls to IFREEC from a completion routine. Channels to be used by completion routines should be allocated and placed in a COMMON block for use by the routine.

Even if the completion routine itself does not issue any programmed requests, but does perform I/O to a logical unit number through the OTS, that logical unit number must be opened from the main level. To accomplish this, either issue the first I/O access or an OPEN statement from main level. A completion routine may not call CLOSE to close a logical unit.

- FORTRAN subroutines are reusable but not reentrant. That is, a given subroutine can be used many times as a completion routine or as a routine in the main program, but a subroutine executing as main program code does not work properly if it is interrupted and then called again at the completion level. This restriction applies to all subroutines that can be invoked at the completion level while they are active in the main program.
- FORTRAN completion routines can be called only by SYSLIB functions that end in F. Conversely, MACRO completion routines cannot be called by SYSLIB functions that end in F. (SYSLIB function names ending in the letter F interface to the FORTRAN run-time system.)

## 1.2.6 Device Blocks

A device block is a four-word block of Radix-50 information that specifies a physical device and a file name. In FORTRAN, you can use one of three methods to set up this block as follows:

- Use the DIMENSION and DATA statements. For example,

```
Dimension IFILE(4)
Data IFILE /3rSY ,3rFIL,3rE ,3rXYZ/
```

- Translate the available ASCII file description string into Radix-50 format, using the SYSLIB calls IRAD50, R50ASC, and RAD50. For example,

```
Real*8 FSPEC
Call IRAD50(12, 'SY FILE XYZ', FSPEC)
```

- Use SYSLIB call ICSI to call the Command String Interpreter (CSI) to accept and parse standard RT-11 command strings.

## 1.2.7 INTEGER\*4 Support Functions

For a description of INTEGER\*4 functions for use by the MACRO programmer, see Section 1.7.3.

When you use the DATA statement to initialize INTEGER\*4 variables, you must specify both the low- and high-order parts. For example, the code that follows initializes only the first word:

```
Integer*4 J
Data J /3/
```

The following example shows the correct way to initialize an INTEGER\*4 variable to a constant, such as 3:

```
Integer*2 M(2)
Data M /3, 0/ !low order, high order
```

If you are initializing an INTEGER\*4 variable to a negative value such as -4, the high-order (second word) part must be the continuation of the two's complement of the low-order part. For example,

```
Integer*4 L
Integer*2 L2(2)
Equivalence (L, L2)
Data L2 /-4, -1/ !initialize L to -4
```

### 1.2.8 User Service Routine (USR) Requirements

The RT-11 User Service Routine (USR) is always resident in all mapped monitors; therefore, this discussion applies to unmapped monitors only. User-written routines that interface to the FORTRAN Object Time System (OTS) must account for the location of the USR. PDP-11 C user-written routines have similar requirements. USR swapping requirements for FORTRAN and C are discussed in this section.

The USR occupies 2K words. When your program calls a SYSLIB routine that requests a USR function (such as IENTER or LOOKUP) or when the USR is invoked by the FORTRAN OTS, the USR is swapped into memory if it is nonresident. The FORTRAN OTS is designed so that the USR can swap over it.

Because letting USR swap over certain kinds of data and code causes unpredictable results, you must restrict interrupt service routines and completion routines to locations outside the USR swapping area. Identify the limits of this swapping area by examining the link map and, if necessary, change the order of object modules and libraries as specified to linker.

The following subroutines require the USR:

```
CLOSEC, ICLOSE
GETSTR (only if first I/O operation on logical unit)
GTLIN
ICDFN (single job only)
ICSI
IDELET
IDSTAT
IENTER
IFETCH
IQSET
IRENAM
ITLOCK (only if USR is not in use by another job)
LOCK (only if USR is in a swapping state)
LOOKUP
PUTSTR (only if first I/O operation on logical unit)
```

### **Controlling USR Swapping**

You can control USR swapping by using the KMON commands SET USR NOSWAP and SET USR SWAP:

- SET USR NOSWAP prevents swapping and freezes the USR in memory.
- SET USR SWAP reverses this, allowing the USR to swap under program control.

Another alternative is to compile your FORTRAN main program with the /NOSWAP option if you are sure that there is space just below the foreground partition or RMON to make the USR permanent for the duration of your program. Use this option if your program does not need the 2K words of memory that the USR occupies. If the /NOSWAP option is not specified, the USR swaps over locations 1000–11000, the 2K words of your program above the base address, and the part of a FORTRAN program least likely to violate the USR restrictions.

To prevent USR swapping for part of the program execution time and to allow the USR to swap out at other times, use the LOCK, UNLOCK, and ITLOCK calls:

- LOCK call locks the USR into main memory and attaches it to the requesting job.
- The UNLOCK call lets the USR swap again and be used by another job.
- The LOCK and UNLOCK calls are used in a foreground program to prevent interference from the background during initialization and completion phases and to minimize the number of swaps.
- If ITLOCK determines another job is already using the USR, it returns an error code that lets the program try for a lock, but continue with other action if it fails.

### **Keeping the USR Resident**

For a FORTRAN main program, you can keep the USR resident by using the FORTRAN/NOSWAP command (or the /U compiler option) at compile time. This forces the USR to remain resident while the program is executing. You cannot use this option if your FORTRAN programs require the extra 2K words of memory.

### **Allowing the USR to Swap**

As with a MACRO program, the only reason to permit the USR to swap with a FORTRAN program is to gain access to an additional 2K words of memory. The USR normally swaps over the FORTRAN OTS (Object Time System). However, problems occur when the FORTRAN OTS and the program together are less than 2K words long. In this case, the USR swaps over the program's impure data area, with unpredictable results. (Since this error is frequently made by inexperienced programmers, setting the USR to NOSWAP and retrying a program is the first thing you should do when debugging a FORTRAN program that does not execute properly.) And USR swapping does not depend on your program's high limit—that is, if the USR is allowed to swap, it most definitely will swap. So, do not permit USR swapping unless your program really needs the extra memory. To enable swapping for a FORTRAN program, make sure the SET USR SWAP command is in effect, and eliminate the /NOSWAP or the /U option at compile time.

## PSECT Ordering for FORTRAN

To change the position of code or data to avoid the USR swapping area, or to move the USR itself, consider the use of program section (PSECT) ordering. PSECTs contain code and data identified by names as segments of the object program. Attributes associated with each PSECT direct the Linker to combine several separately compiled FORTRAN program units, assembly language modules, and library routines into an executable program.

The order in which program sections are allocated in the executable program is the same order in which they are presented to the Linker. Applications sensitive to this ordering typically separate those sections containing read-only information (such as executable code and pure data) from impure sections containing variables.

The main program unit of a FORTRAN program (normally the first object module in sequence presented to LINK) declares PSECT ordering as shown in Table 1–1.

The USR can swap over pure code, but must not be loaded over constants or impure data that can be used as arguments to the USR. The ordering shown in Table 1–1 collects all pure sections before collecting impure data in memory.

It is important to understand where and how the USR swaps so you can design your FORTRAN program correctly. For a FORTRAN program, the FORTRAN OTS places a value in \$UFLOA *location 46* to set up the USR swapping function. When a FORTRAN program is running, the USR will automatically start swapping at the base of OTS\$I. \$UFLOA of the *System Communication Area* contains the address where the USR will swap. If the value of \$UFLOA is zero, the USR will swap at its default location, below RMON and handlers.

The FORTRAN compiler examines the sections of your program and sorts them based on two major attributes: read-only versus read-write, and pure code versus data. Generally, program instructions are read-only, and program data is read-write. If you use assembly language routines, use the same PSECT as the FORTRAN compiler. That is, place pure code and read-only data in section USER\$I, and impure data in USER\$D. The compiler forces PSECT into the order shown in Table 1–1. PSECT attributes shown in this table are abbreviated as follows:

- RW, RO—Read/Write, Read Only
- I, D—Instructions, Data
- REL—Relocatable
- CON, OVR—Concatenated, Overlaid
- LCL, GBL—Local with overlay segment, Global across segments
- SAV—Unconditionally place PSECT in root segment.

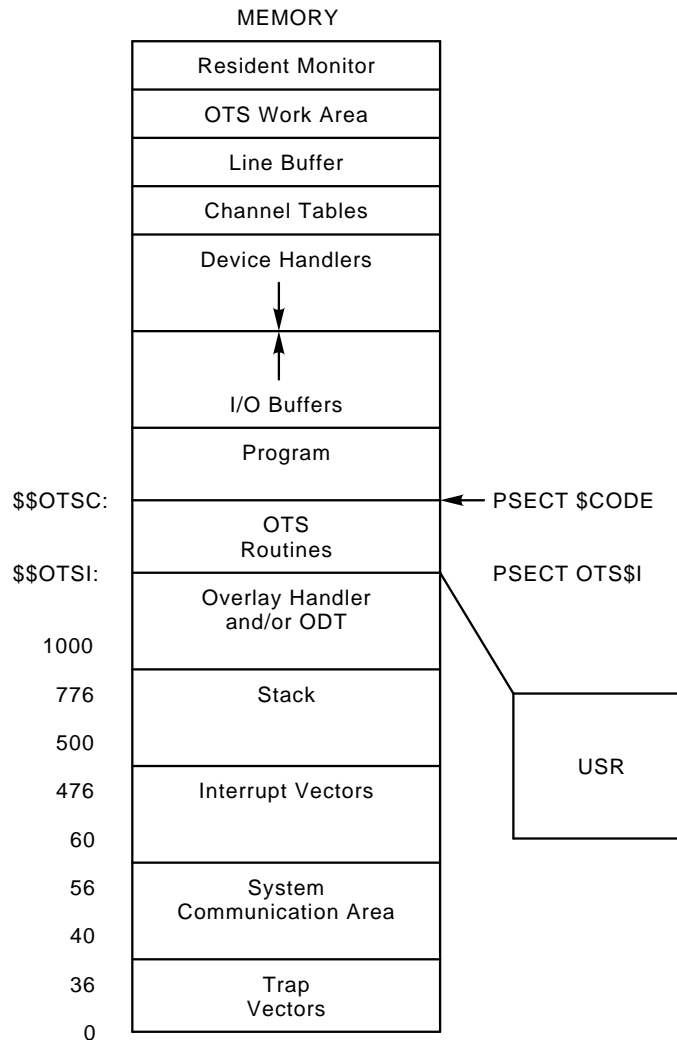

See the *RT-11/RSTS/E FORTRAN IV User's Guide* and *RT-11/FORTRAN 77 User's Guide* for more information on program sections. See also *RT-11 System Internals Manual* and *RT-11 System Utilities Manual* for information on USR swapping and PSECT ordering.

**Table 1–1: PSECT Ordering for FORTRAN Programs (Low to High Memory)**

<b>Section Name</b>	<b>Attributes</b>
<b>FORTRAN IV</b>	
OTS\$I	RW, I, LCL, REL, CON
OTS\$P	RW, D, GBL, REL, OVR
SYS\$I	RW, I, LCL, REL, CON
USER\$I	RW, I, LCL, REL, CON
\$CODE	RW, I, LCL, REL, CON
OTS\$O	RW, I, LCL, REL, CON
SYS\$O	RW, I, LCL, REL, CON
\$DATAP	RW, D, LCL, REL, CON
OTS\$D	RW, D, LCL, REL, CON
OTS\$S	RW, D, LCL, REL, CON
SYS\$S	RW, D, LCL, REL, CON
\$DATA	RW, D, LCL, REL, CON
USER\$D	RW, D, LCL, REL, CON
.\$\$\$.	RW, D, GBL, REL, OVR
Other COMMON Blocks	RW, D, GBL, REL, OVR
<b>FORTRAN 77</b>	
\$CODE1	RW, I, LCL, REL, CON
\$PDATA	RW, D, LCL, REL, CON
\$IPDATA	RW, D, LCL, REL, CON
\$VARS	RW, D, LCL, REL, CON
\$TEMPS	RW, D, LCL, REL, CON
\$SAVE	RW, D, GBL, REL, CON

This ordering collects all pure sections before impure data in memory. The USR can safely swap over sections OTS\$I, OTS\$P, SYS\$I, USER\$I, and \$CODE. Figure 1–1 shows the arrangement of components when a FORTRAN program is loaded into memory. The global symbol \$\$OTSI marks the start of the pure code area. The global symbol \$\$OTSC marks its end and the beginning of the impure data area. FORTRAN puts the value of \$\$OTSI into location 46, and the USR swaps into memory starting at that address, thus overlaying the first 2K words of your program.

**Figure 1-1: A FORTRAN Program in Memory**

As with a MACRO program, your FORTRAN program should not have certain instructions or data in the area where the USR will swap. As a general rule, the following items should not be in the USR swap area:

- Routines that request USR functions (such as IENTER and LOOKUP)
- Data structures for USR requests
- Interrupt service routines
- Completion routines
- Data areas for interrupt service routines and completion routines

The FORTRAN system itself must also be concerned with USR swapping and its inherent restrictions. For example, the PSECT OTS\$O contains the FORTRAN

OTS routines to open files. This PSECT follows \$CODE in the PSECT ordering. If the start of OTS\$O is within 2K words of \$\$OTSI, the essential information for the file operation is stored on the job stack before the USR swaps over the code in OTS\$O.

The best way to make sure that the USR swaps into a safe place in your FORTRAN program is to examine the link map to determine if the USR will swap over restricted sections. That is, see if the first 2K words above \$\$OTSI can be overlaid safely. If not, relink the program and change the order of object modules and libraries you specify to the linker. One problem is caused by using SYSLIB routines that place important USR data in the lower 2K words of the job image. An example is the IFETCH routine, which uses a device block in the program. The USR swaps over the device block just before it is used, causing an error. To avoid a situation like this, do not set up device names as constants for a SYSLIB call. Instead, use DATA-initialized variables. This ensures that the information will be stored high enough in the job image to avoid being overlaid by the USR.

### PSECT Ordering for PDP-11 C

Table 1-2 lists PSECTs used by the PDP-11 Run Time Library and outlines their use. Under RT-11 if the USR is not resident, the PDP-11 C RTL will attempt to set the USR to swap at the location of the root C\$STDI and C\$OTSI PSECTs. See *PDP-11 C Guide to PDP-11 C* for more information on PSECT ordering.

**Table 1-2: PSECT Ordering for PDP-11 RTL Programs**

Section Name	Use
{ C\$CCT0 } { C\$CCT2 }	Character collating table. Used for locale-specific routines to determine the collating sequence of each character set.
{ C\$CMT0 } { C\$CMT2 }	Character mapping table. Used for locale-specific routines to determine the results of character mapping functions for each character set.
{ C\$CTT0 } { C\$CTT2 }	Character testing table. Used for local-specific routines to determine the results of character testing functions for each character set.
{ C\$END0 } { C\$END1 } { C\$END2 } { C\$END3 }	The C\$ENDx PSECTs are used for end-of-task processing. The addresses of functions to be called by the PDP-11 C RTL at task-exit time are place in the PSECT C\$END1. For instance, the address of the routine that ensures all files are closed is placed in C\$END1. This is separate from the atexit system function. The PSECTs C\$END0, C\$END1, and C\$END3 are reserved for use by the PDP-11 C RTL. The addresses of routines to be called at task exit can be placed in the PSECT C\$END2. Modules that define this PSECT may not reside in a resident library.
{ C\$INIO } { C\$INI1 } { C\$INI2 } { C\$INI3 }	Similar to the C\$ENDx PSECTs, the C\$INIx PSECTs are used to provide the addresses of routines to be called at task startup. The PSECTs C\$INIO, C\$INI1, and C\$INI3 are reserved for use by the PDP-11 C RTL. The PSECT C\$INI2 is available to place the addresses of routines to be called at task startup. Modules that define this PSECT may not reside in a resident library.

**Table 1–2 (Cont.): PSECT Ordering for PDP–11 RTL Programs**

<b>Section Name</b>	<b>Use</b>
C\$INIR	Code for initialization routines.
{ C\$MFT0 } { C\$MFT2 }	Monetary formatting table. Used for locale-specific routines to determine the results of monetary formatting functions for each character set.
{ C\$NFT0 } { C\$NFT2 }	Numeric formatting table. Used for locale-specific routines to determine the results of numeric formatting functions for each character set.
C\$OTSC	Constant data for PDP–11 C Object Time System routines.
C\$OTSD	Read data for the PDP–11 C OTS routines.
C\$OTSH	RT–11 only. Used to determine size of C\$OTSI and C\$STDI PSECTs.
C\$OTSI	Instructions for PDP–11 C OTS routines. These routines handle most of the math and conversion functions.
C\$OTSJ	RT–11 only. Used to determine size of C\$OTSI and C\$STDI PSECTs.
C\$OTSR	Constant data for PDP–11 C OTS routines.
C\$OTSW	Writable storage for PDP–11 C OTS routines. Modules that contain this PSECT may not reside in a resident library.
C\$STDC	Constant data for the Standard Library routines.
C\$STDD	Read data for the Standard Library routines.
C\$STDI	Instructions for the Standard Library routines.
C\$STDR	Constant data for the Standard Library routines.
{ C\$TIM0 } { C\$TIM2 }	Time formatting table. Used for locale-specific routines to determine the results of time formatting functions for each character set.
\$PIOXT	I/O Transfer Vector. This is used to allow PDP–11 C to easily access several low-level I/O systems. \$PIOXT contains two addresses for each low-level I/O action used by PDP–11 C. One address is for support for native I/O for that action. The other is for support for either RMS or FCS I/O for that action. Modules that define this PSECT may not reside in a resident library.
\$PRLUN	Bit mask used for reserving LUNs. The first word indicates the number of words that follow. These make up a mask. Modules that define this PSECT may not reside in a resident library.
\$\$C	The PDP–11 C OTS work area. This is read/write data space used by the RTL. Modules that define this PSECT may not reside in a resident library.
\$\$CAST	OTS work area PSECT containing structure required by asctime function.
\$\$CCLK	OTS work area PSECT containing storage required for correct use of the clock function.

**Table 1–2 (Cont.): PSECT Ordering for PDP–11 RTL Programs**

Section Name	Use
\$\$CEXI	OTS work area PSECT containing storage required to register the addresses of the functions to be called during the executions of the atexit() routine.
\$\$CGEN	OTS work area PSECT containing storage required to support the getenv () function.
\$\$CLOC	OTS work area PSECT containing storage required to support the locale functions.
\$\$CMLL	OTS work area PSECT containing storage required to support memory allocation functions.
\$\$CSIG	OTS work area PSECT containing storage required to support the signal functions.
\$\$CSIO	OTS work area PSECT containing storage required to support standard I/O operations.
\$\$CTIM	OTS work area PSECT containing storage required struct tm.

#### **USR Lockout and Timing—All Monitors**

If while one job is using the USR, another job requests it, the requesting job will be blocked until the other job releases the USR. The requesting job may be locked out for seconds or minutes at a time. Interrupt service and completion routines can run, but mainline code cannot. You can minimize or eliminate these resulting timing problems by observing the following:

- Do not use devices with slow directory operations, such as magtapes.
- Write real-time operations as completion and interrupt service routines in your foreground job so that a locked-out mainline program does not impede real-time operations.
- Separate USR and real-time operations.
- Use the ITLOCK call and avoid SYSLIB calls that request the USR while the USR is owned by another job.

A real-time foreground job has the following typical structure:

- An initialization phase that opens all required channels and begins a real-time operation
- A real-time phase that performs interrupt service and I/O operations
- A completion phase that halts real-time activity and then closes the channels.

Maintaining this structure in the foreground enables the background task to do USR operations during the real-time phase without locking out the foreground. This action simplifies USR swapping because the USR can swap over interrupt routines and I/O buffers as long as they are inactive.

### 1.2.9 Subroutines Requiring Additional Queue Elements

All subroutines in the following list require added queue elements for their proper operation. Subroutines prefixed with asterisks can be called as they are or may be prefixed with a letter I or M if they are called as functions or have added arguments for mapping. For example, \*RCVD can have the form RCVD, IRCVD or MRCVD. These subroutines are as follows:

\*RCVD, \*RCVDC, \*RCVDF, \*RCVDW  
\*READ, \*READC, \*READF, \*READW  
IWAIT  
SCHED/ISCHED  
\*SDAT, \*SDATC, \*SDATF, \*SDATW  
SLEEP/ISLEEP  
\*SPFN, \*SPFNC, \*SPFNF, \*SPFNW  
TIMER/ITIMER  
TWAIT/ITWAIT  
UNTIL/IUNTIL  
\*WRITC, \*WRITE, \*WRITEF, \*WRITW  
MRKT  
MWAIT

One queue element per job is automatically allocated. Issuing more than one request from the list requires extra queue elements. Additional queue elements can be allocated by a call to the IQSET function.

#### NOTE

IQSET is no longer contained in SYSLIB.OBJ. If you need to add queue elements for certain SYSLIB functions, refer to FORTRAN IV distributed FORLIB and to FORTRAN-77 distributed F77OTS.

### 1.2.10 System Restrictions

Consider the following system restrictions when coding a FORTRAN program that uses SYSLIB.

- Programs using IPEEK, IPOKE, IPEEKB, IPOKEB, or ISPY to access system-specific addresses, such as FORTRAN, monitor, or hardware addresses, are not guaranteed to run under future releases or on configurations other than those on which they were written. When using these functions, document their use so you can check your references against the current documentation. Also, these routines may act differently under the mapped monitor. IPEEK and IPOKE are not equivalent to programmed requests .PEEK and .POKE. Although IPEEK and IPOKE are equivalent to KPEEK and KPOKE, Digital recommends using KPEEK and KPOKE because they function better in a virtual environment.
- Various functions in SYSLIB return values that are of type *integer*, *real*, or *double precision*. To specify an implicit statement that changes the defaults for external function types, you must:

- Explicitly declare the type of those SYSLIB functions that return integer or real results.
- Be sure that the arguments to the SYSLIB routines are the correct type for the routine. Double-precision functions must always be declared to be type `DOUBLE PRECISION` (or `REAL*8`). Failure to observe this restriction leads to unpredictable results.
- Names of all completion routines external to the routine being coded and which are passed to scheduling calls (such as `ISCHED`, `ITIMER`, and `IREADC`) must be specified in an `EXTERNAL` statement in the FORTRAN program issuing the call.
- Certain arguments to SYSLIB calls must be located so that the USR is prohibited from swapping over them at execution time. This kind of swapping can occur when the `OTS$I` section (which contains the all-pure code and data for the module) is less than 2K words in length. Avoid swapping in this uncommon situation either by typing the `SET USR NOSWAP` command to make the USR resident before starting the job, or by compiling the mainline routine with a `/NOSWAP` option. You can also use the linker `/BOUNDARY` option to make `OTS$O` start at word boundary 11000(octal). (This problem generally occurs only with small FORTRAN programs.)

In FORTRAN IV, FORTRAN 77 and C Language, program sections (PSECTs) are used to collect code and data into appropriate areas of memory. If USR is needed, but not resident, it will swap over a FORTRAN program, starting at the symbol `OTS$I` for 2K words of memory.

- Unless explicitly stated, null arguments should not be used in calls to SYSLIB routines.

### 1.3 Calling SYSLIB Subroutines or Functions

SYSLIB function subprograms and subroutines are called in the same manner as user-written subroutines. In general, if SYSLIB routines return a value, they are more useful as functions than as subroutines. If they do not return a value, they should be used only as subroutines. When functions or subroutines serve equally well in either role they are called routines. Call them in whichever way they are most useful. Subroutines whose names start with letters other than I-through-N either do not return a useful value or return a floating-point value.

PDP-11 C supports SYSLIB routines described in this document. The interface used to call routines is the FORTRAN subroutine linkage.

Table 1-3 lists SYSLIB functions/subroutines and briefly describes each within several types of categories:

- File Oriented Operations
- Data Transfer Operations
- Channel Oriented Operations

- Device and File Specifications
- Timer Support Operations
- RT-11 Services
- INTEGER\*4 Support Functions
- Character String Functions
- Radix-50 Conversion Operations
- Multiterminal Operations
- Graphics (GIDCAL) Call Routines

SYSLIB entries are listed in the column that identifies their optimum use as functions, subroutines or equally well as either, depending on whether or not it is useful to return a value. Note the convention of prefixing subroutine calls with an I when called as functions; and prefixing both with an M when functions or subroutines have an added argument that specifies mapping. The *Map* column has two entries:

No SLB—Subroutine/Function cannot be used in Supervisor library.

No I-D—Subroutine/Function cannot be used in separated I-D space.

The *Restrictions* column lists restrictions to use of a function or subroutine; for example, ICNTXS can be used only in multijob environments.

SYSLIB subroutines IFREER and IGETR support mapping programmed requests, and FORTRAN virtual arrays can access extended memory.

SYSLIB descriptions in Chapter 2 present these routines as calls or functions or both, as applicable. Some subroutines and functions have an added argument that specifies mapping. In these cases, the function or subroutine has an M prefix. In the following example, *RCVD* can be called as a function or subroutine, including the M-prefix version having a mapping argument:

```

CALL RCVD (buff,wcnt)
i = IRCVD (buff,wcnt)
CALL MRCVD (buff,wcnt[,BMODE=strg])
i = MRCVD (buff,wcnt[,BMODE=strg])

```

#### Function Subprograms

A function may return an error code value or other information useful to the purpose of the calling routine. Function subprograms receive control by means of a function reference as follows:

**i = function name [(arguments)]**

### **Subroutines**

Subroutines are invoked by a CALL statement as follows:

**CALL subroutine name [(arguments)]**

### **Routines**

*Routine* is the term that describes subroutines called as function subprograms, if a return value is desired, or called as subroutines, if no return value is desired.

Some subroutines have two acceptable formats. For example, you can call the CLOSEC subroutine or specify the ICLOSE function, since the latter returns an integer error code return useful in showing either a normal return or error condition.

Quoted-string literals are useful as arguments of calls to routines in SYSLIB, especially the character string routines. These literals are allowed in subroutine and function calls (see Section 1.8.3).

## **1.4 FORTRAN/MACRO Interface**

FORTTRAN calling routines and subroutines follow a well-defined set of conventions by which MACRO programmers adhering to these conventions can write FORTRAN-callable routines such as those in SYSLIB:

- Transfer of control
- Transfer of information
- Memory usage
- Register usage

Control is transferred to a subroutine by the following assembly language syntax:

**CALL SUBR**

When control passes to the subroutine SUBR, R5 points to an argument block like that shown in the left-hand block in Figure 1-2. Null arguments in CALL statements must be entered as comma pairs ( , ). For example, CALL SUBR (A, ,B) . As shown in the right-hand block of Figure 1-2, the value -1 is stored in the argument block as the address of a null argument.

The lower byte of the first word of the argument block contains the number of arguments that are passed to the subroutine. The rest of the argument block contains the addresses of those arguments. The argument block is  $n+1$  words long for  $n$  arguments.

The program counter is the linkage register. The subroutine obtains its arguments through R5. In FORTRAN, the calling program saves the registers, and the subroutine leaves the contents of the stack pointer intact before returning to the

**Figure 1–2: Subroutine Argument Block**

Reserved	No. of Arguments	?	3
Address of Argument 1		A	
Address of Argument 2		- 1	
⋮		⋮	
Address of Argument n		B	

calling program. The RETURN statement of the subroutine is placed by the assembly language instruction *RETURN*.

The name of the subroutine must be declared *global* with the .GLOBL directive in the calling program or with the double colon (::) construction in the called program.

**NOTE**

Be sure that the called program does not modify the argument block passed by the calling program to a subprogram.

**1.4.1 Subroutine Register Usage**

A subroutine called by a FORTRAN program does not have to preserve any registers. However, each push onto the stack must be matched by a pop off the stack before exiting from the routine.

User-written assembly language programs must preserve all pertinent registers before calling FORTRAN subroutines or SYSLIB routines, then restore registers after the subroutine returns. The CALL\$F routine is provided to perform this register save and restore. See CALL\$F description in Chapter 2.

Function subroutines return a single result in a register. Table 1–4 shows the register assignments for returning the different variable types.

**NOTE**

Floating-point results are returned in the *general purpose registers* and not in the *Floating Point Unit (FPU) registers*. Assembly language subprograms that use the FP11 Floating Point Unit may be required to save and restore the FPU status.

**Table 1–4: Return Value Conventions for Function Subroutines**

Type	Result Placed In
INTEGER*2 LOGICAL*1	R0
INTEGER*4 LOGICAL*4	R0 low-order result R1 high-order result
REAL(*4)	R0 high-order result (including sign and exponent) R1 low-order result
DOUBLE PRECISION or REAL*8	R0 highest-order result (including sign and exponent) R1 next higher order R2 next higher order R3 lowest-order result
COMPLEX	R0 high-order result R1 low-order result R2 high-order imaginary result R3 low-order imaginary result

### 1.4.2 FORTRAN Programs Calling MACRO Subroutines

FORTRAN programs can call MACRO subroutines, but several rules must be followed. In the following example, the program FINITA is a MACRO subroutine that can be called from a FORTRAN program:

```

        .TITLE  FINITA
;+
;      Put INIT into the LARRY elements starting at IARRAY
;      IERR = FINITA (IARRAY, INIT, LARRAY)
;      Default INIT to 0
;
;      IERR =   0 success
;             -1 invalid LARRY (negative)
;             -2 missing argument
;-

.GLOBL  $SYSLB           ;SYSLIB version and value for $NOARG
.GLOBL  $NXADR, $NXVAL   ;routines to get args
;                               ;IN: R0 is default, R4 count
;                               ;    R5 current arg list pointer
;                               ;OUT:R0 is addr / value
;                               ;    R4 decremented count

```

```

;      R5 incremented pointer
;      Carry set if omitted arg
FINITA::
    MOV     (R5)+,R4      ;Put arg count in R4,
                        ; point R5 to first arg
    CALL    $NXADR       ;Get addr of array
    BCS     20$          ;Error, missing arg
    MOV     R0,R1        ;save first arg addr
    CLR     R0           ;use 0 for omitted value
    CALL    $NXVAL       ;Get value to init with
    MOV     R0,R2        ;save it
    CALL    $NXVAL       ;Get words in array
    BCS     20$          ;Error, missing arg
    TST     R0           ;Is the length gt 0
    BLE     30$          ;no, can't init
10$:
    MOV     R2,(R1)+     ;init array
    SOB     R0,10$      ;according to count
    RETURN                                ;done (R0 = 0)
20$:
    MOV     #-2,R0      ;indicate missing args
    RETURN
30$:
    MOV     #-1,R0      ;indicate invalid count
    RETURN
    .END

```

Call the preceding routine as follows:

Macro Call:

**CALL FINITA (IAR,IVAL,N)**

where:

**FINITA** is the name of the subroutine  
**IAR** is the name of the array to initialize  
**IVAL** is the initialized value of the array  
**N** is the number of elements to initialize

This program illustrates the rules that must be observed when calling a MACRO program. The name of the subroutine is made global by using the .GLOBL directive.

Register 5 (R5) is used to pass the arguments. For the program FINITA, the argument block would appear as shown in Figure 1-3.

Registers R0 through R4 can be freely used because the calling program saves them. When arguments have been retrieved, you can also use R5.

On completion, the subroutine returns to the calling program through a RETURN. If your MACRO program pushes data on the stack, make sure that all data is popped off the stack before the RETURN is executed.

**Figure 1–3: Argument Block for Program FINITA**

0	3
Address of IAR	
Address of IVAL	
Address of N	

The following FORTRAN program named FINITB calls the subroutine FINITA.

```

      Program FINITB
C
C      FORTRAN program to call MACRO subroutine
C
      Integer*2 Array
      Dimension Array(10)
      Data Array /-1,-2,-3,-4,-5,-6,-7,-8,-9,-10/
C
      N = 7                      !init first seven elements
      Do 10 I = 1, 10           !use 10 init values
          Call FINITA (ARRAY, I, N)
          Write (5, 100) (ARRAY(J), J = 1, 10)
10      Continue
100     Format (' ', 10I4)
      End

```

Compile and link both programs, then run the program by typing:

**.RUN FINITB** RET

The initialized array will be output to the terminal as follows:

```

1  1  1  1  1  1  1  1  -8  -9  -10
2  2  2  2  2  2  2  2  -8  -9  -10
3  3  3  3  3  3  3  3  -8  -9  -10
.
.
.
9  9  9  9  9  9  9  9  -8  -9  -10
10 10 10 10 10 10 10 10 -8  -9  -10

```

### 1.4.3 MACRO Routines Calling FORTRAN Programs

If you want to call FORTRAN subroutines from a MACRO program, create a dummy main program. For example,

```

          Program FORINT          !setup FTN environment
C
C      MAIN program to call MACRO subroutines which in turn
C      call FORTRAN subroutines.
C
          Call FMAC2F             !call first MACRO routine
          Call FMACSF             !call second MACRO routine
          End

```

where:

**FMAC2F** is the name of a MACRO program that can call FORTRAN or MACRO routines.

Creating a dummy program causes the FORTRAN main program to perform the initialization necessary for FORTRAN subroutines.

In the following example, MACRO program FMAC2F calls a FORTRAN subroutine named FMAXMN:

```

          .TITLE  FMAC2F          ;MACRO calling FORTRAN
          .GLOBL  FMAXMN         ;FORTRAN program to call
FMAC2F::          ;entry point
          MOV     #ARGBLK,R5     ;point to argument block
          CALL    FMAXMN         ;call routine
          RETURN                 ;done

ARGBLK: .WORD   2               ;two arguments
          .WORD   I               ;address of first
          .WORD   J               ;address of second

I:      .WORD   28.              ;value of first argument
J:      .WORD   76.              ;value of second argument
          .END

```

First, set up the argument block either on the stack or in a separate area in your MACRO program. Then point R5 to the top of the argument block prior to calling the FORTRAN subroutine with a CALL FMAXMN. In the FMAC2F program shown previously, the argument block is set up in an area of your program.

In the following example, a program named FMACSF performs the same operation as the FMAC2F program, except that it places the argument blockf on the stack:

```

          .TITLE  FMACSF          ;MACRO calling FORTRAN
          .GLOBL  FMAXMN         ;FORTRAN program to call
FMACSF::          ;entry point
          MOV     #J,-(SP)       ;build argument block on stack
          MOV     #I,-(SP)       ; ...
          MOV     #2,-(SP)       ; ...
          MOV     SP,R5          ;point to it
          CALL    FMAXMN         ;call routine
          ADD     #3*2,SP        ;pop argument block from stack
          RETURN                 ;done

I:      .WORD   28.              ;value of first argument
J:      .WORD   76.              ;value of second argument
          .END

```

If you set up the argument block on the stack, you must remove the arguments from the stack prior to the execution of the RETURN. Before calling the FORTRAN subroutine, you must save all pertinent registers. You do not know which registers the FORTRAN subroutine is using. The stack pointer remains unchanged across the call.

You must define the name of the FORTRAN subroutine that the MACRO program calls as a global. In the FORTRAN subroutine, execute normal FORTRAN statements and return to the MACRO program with a RETURN statement.

The following program is the FORTRAN subroutine FMAXMIN:

```
          Subroutine FMAXMN (IN1, IN2)
C
C          FORTRAN subroutine called by MACRO subroutines
C
          Integer*2 Big, Small
          If (IN1 .gt. IN2) Then
              BIG = IN1
              SMALL = IN2
          Else
              BIG = IN2
              SMALL = IN1
          End If
          Type 10, BIG
          Type 20, SMALL
10         Format (' The bigger number is ', I10)
20         Format (' The smaller number is ', I10)
          Return
          End
```

After assembling and linking the programs, type:

```
.RUN FORINT 
```

The program executes as follows:

```
The bigger number is 76
The smaller number is 28

The bigger number is 76
The smaller number is 28
STOP --
```

## 1.5 FORTRAN Programs in a Foreground/Background Environment

FORTRAN programs can be run in a foreground/background environment, which enables the efficient use of CPU execution time. (See Chapter 5 of *Introduction to RT-11* for a description of running programs in an FB environment.)

Before running your foreground program, use the LOAD command to load the device handlers required by the foreground job. These device handlers are placed in memory between RMON and the USR and KMON, causing USR and KMON to move down in memory.

Next, use the FRUN command to load your foreground program in memory between the device handlers and the USR, which causes the USR and KMON to move further down in memory. You must allocate sufficient workspace when running a FORTRAN program in the foreground. Allocate workspace by using the /BUFFER:n option of the FRUN command. Also ensure that any FORTRAN program you run in the foreground has adequate stack space. You can use one of the options supported by the linker (See the *RT-11 System Utilities Manual*).

The background area must be at least 4K words long to accommodate the USR and KMON. Until you run a background job with the RUN command, KMON is the background job.

When the USR is required (in unmapped monitors), you must set up a 2K-word area in each job for the swapping to occur correctly; that is, there must be space for at least 2K words in the background area and 2K words in the foreground area. For an explanation of USR swapping, see Section 1.2.8.

### 1.5.1 Calculating Workspace for a FORTRAN Foreground Program

Additional workspace must be allocated in memory when running a FORTRAN program in the foreground of a foreground/background environment. For a foreground job, the space is allocated by the /BUFFER:n option of the FRUN command. (A background job uses whatever space is available between its high limit and the system's low limit.) When you allocate additional workspace in memory to run a FORTRAN IV program in the foreground, calculate the space required by using the following formula:

$$n = \lceil [504 + (35 * N) + (R - 136) + A * 512] / 2 \rceil + \lceil 10 * qc\text{count} \rceil + \lceil 6 * num \rceil + \lceil 25 * INTSET \rceil + \lceil 64 + R / 2 \rceil$$

where:

- A            Specifies the maximum number of files open at one time. Each file opened as double buffered should be counted as two files.
- N            Specifies the maximum number of simultaneously open channels (logical unit numbers). This value is specified when the compiler is built and can be overridden with the /UNITS option during main program compilation.
- R            Specifies the maximum formatted sequential record length. This value is specified when the compiler is built and can be overridden with the /RECORD option during main program compilation; the default value is 136.
- qccount     Specifies queue elements.
- num          Specifies the number of channels.
- INTSET      Specifies the SYSLIB INTSET function.

Include the following optional elements in the formula if you want to use the indicated system subroutine library (SYSLIB) functions:

[10*qcount]	Specifies space for queue elements, which the IQSET function requires.
[6*num]	Specifies space for the number of channels, which the ICDFN function requires.
[25*INTSET]	Specifies space for the number of INTSET calls issued in the program, which the INTSET function requires.
[64+R/2]	Specifies space for completion routines and a second record buffer. Any functions, including INTSET, that invoke completion routines must include 64 <sub>10</sub> words plus the number of words needed to allocate the second record buffer (default is 68 decimal words).  The length of the record buffer is controlled by the /RECORD option to the FORTRAN compiler. If the /RECORD option is not used, the allocation in the formula must be 136 <sub>10</sub> bytes, or the length that was set at FORTRAN installation time.

Note that the numbers in the formula presented above are all decimal quantities for ease in computation, using a calculator. Remember, however, that in entering a decimal number in the /BUFFER:n option of FRUN, you must include the decimal point in the numeric value of *n*.

## 1.5.2 Running a FORTRAN Program in a Foreground/Background Environment

This section outlines the procedure for running two FORTRAN programs, one in the background and one in the foreground.

The background program named FBACK is as follows:

```

Program FBACK    !background demo program
Parameter JSW = "44                !JSW address
Parameter TTSPC = "010000         !TT special mode bit
Call IPOKE (JSW, TTSPC .or. IPEEK (JSW))
100 Continue
Call Print ('Hello from the background')
Call ITTOUR (ITTINR())            !echo input char
Go To 100                        !loop until killed
End

```

This program prints the message "Hello from the background" and will print the message each time you input a character at the terminal.

The foreground program named FFORE is as follows:

```

Program FFORE    !foreground demo program
Parameter JSW = "44                !JSW address
Parameter TTSPC = "010000         !TT special mode bit
Call IPOKE (JSW, TTSPC .or. IPEEK (JSW))
100 Continue
Call Print ('Hello from the foreground')
Call ITTOUR (ITTINR())            !echo input char
Go To 100                        !loop until killed
End

```

After compiling both programs, link them. Link the foreground program using the LINK command with the /FOREGROUND option. This option produces a relocatable load module with a .REL file type. For example,

```
.LINK/FOREGROUND FFORE 
```

Then you can assign the device that will be used for the output of the foreground program. You must also load into memory the peripheral device handlers needed by the foreground program.

The command FRUN loads and starts execution of a .REL program as the foreground job. At this point, typing the command:

```
.FRUN FFORE 
```

causes the following error message to display, indicating that additional workspace allocation is required and that the /BUFFER option must be used. (Refer to the previous section for the formula to calculate the additional space needed.)

```
?Err 62 FORTRAN start fail
```

The command should be typed as follows:

```
.FRUN FFORE/BUFFER:2000 
```

Execution of this command results in the following output at the terminal:

```
F>
Hello from the foreground
B>
.
```

The system first identifies the message as foreground output, then the foreground job executes and outputs its message. The background monitor next prints the characters B> and a period (.), indicating that control has returned to monitor command mode. Command input remains directed to the background job.

For example, when you type:

```
.RUN FBACK 
```

the background job will display the following message:

```
Hello from the background
```

Each time you type a character to the terminal, say an "L", the message will be repeated, as follows:

```
LHello from the background
```

Use the CTRL/F command to direct terminal input to the foreground job. The system prints F> to remind you that you are now directing input to the foreground job. When you type a character, such as "Y", the foreground job message will be displayed.

```
F>
YHello from the foreground
```

Type a CTRL/B to return to the background job or a CTRL/C to return to monitor command mode. If you are returning to a background environment, you should unload the foreground job and any handlers to reclaim memory space for background use. To stop these two example programs, enter CTRL/C to each one.

## 1.6 Linking with FORLIB

Normally, default system library file SYSLIB.OBJ also includes the overlay handlers and the appropriate FORTRAN run-time system routines.

To add FORLIB.OBJ modules to the default library SYSLIB.OBJ, use the following command:

```
.LIBRARY/INSERT/REMOVE SYSLIB FORLIB RET
Global? $ERRS [RET]
Global? $ERRTB [RET]
Global? $OVRH [RET]
Global? [RET]
```

## 1.7 SYSLIB Services Not Provided by Programmed Requests

SYSLIB provides many services that are not handled by single programmed requests, for example:

- Time conversion and date access
- Program suspension
- Two-word integer support (INTEGER\*4)
- Radix-50 conversion
- Character string manipulation
- Control of global regions in extended memory

### 1.7.1 Time Conversion and Date Access

Use the following calls to perform time conversions:

- CVTTIM** Converts a two-word internal format time to hours, minutes, seconds, and ticks.
- JTIME** Converts a time given in hours, minutes, seconds, and ticks into the internal two-word time format.

Use the following calls to print out the time:

- TIMASC** Converts the time in internal two-word format into an eight-character ASCII string.
- TIME** Returns the current time of day as an eight-character ASCII string.

Access the current system date by issuing the DATE/IDATE call:

where:

- DATE** Returns date as a string value.
- DATE4Y** Returns the date as a string value with a four-digit year value.
- IDATE** Returns date as an integer value.

### 1.7.2 Program Suspension

You can suspend execution of a program with ITWAIT, ISLEEP, and IUNTIL calls, where:

- ITWAIT** Suspends program execution for a specified number of ticks.
- ISLEEP** Suspends running program for a specified number of hours, minutes, seconds and ticks.
- IUNTIL** Suspends job execution until a specific time of day, in hours, minutes, seconds, and ticks.

### 1.7.3 Two-Word Integer Support (INTEGER\*4)

This support is primarily for FORTRAN IV. It also can be used from MACRO, but FORTRAN-77 has INTEGER\*4 functionality built in. You can make calls to SYSLIB to manipulate a 32-bit integer that uses two words of storage. The first word contains the low-order part of the value and the second word contains the sign and the high-order part of the value. The range of numbers that is represented is  $-2^{31}$  to  $2^{31}-1$ . This format differs from the two-word internal time format that stores the high-order part of the value in the first word and the low-order part in the second word. Table 1-5 shows the calls you use to convert from one format to another.

**Table 1-5: SYSLIB Conversion Calls**

From	To	Call
INTEGER*4	REAL*4	AJFLT/AJFLT
INTEGER*4	REAL*8	DJFLT/IDJFLT
INTEGER*4	INTEGER*2	IJCVT
REAL*4	INTEGER*2	JAFIX
REAL*8	INTEGER*4	JDFIX
INTEGER*2	INTEGER*4	JICVT

INTEGER\*2 are 16-bit integers; INTEGER\*4 are 32-bit integers; REAL\*4 are 2-word, single-precision floating-point numbers; REAL\*8 are 4-word, double-precision floating-point numbers.

Calls are also available for you to perform arithmetic operations on INTEGER\*4 values, move a value to a variable, and convert a two-word internal time format to and from an INTEGER\*4 value.

## 1.7.4 Radix-50 Conversion

You can convert ASCII characters to or from Radix-50, using RAD50, IRAD50, and R50ASC,

where:

- IRAD50** Converts a specified number of characters of Radix-50 and returns the number of characters converted as a function result.
- RAD50** Encodes RT-11 file descriptors in Radix-50 notation.
- R50ASC** Converts a specified number of Radix-50 characters to ASCII.

## 1.7.5 Character String Operations

SYSLIB provides character string functions that perform string operations such as:

- Concatenating strings
- Comparing strings
- Copying strings
- Replacing strings
- Computing the number of characters in a string

The following example is a program that demonstrates calling a SYSLIB character-string subroutine from a macro program:

```
.TITLE  FEGT2;2          ;calling SYSLIB from MACRO
.GLOBAL CONCAT CALL$F    ;SYSLIB routines
.MCALL  .PRINT  .EXIT    ;macros

START:  :
MOV     #STRCON,R2       ;Point to final buffer
MOV     #ARGBLK,R5       ;Point to argument block
MOV     #CONCAT,R0       ;Point to routine to call
CALL    CALL$F           ;Call it, saving registers R1-R4
.PRINT  R2               ;Print resulting string
.EXIT   ;and away

ARGBLK: .WORD  3          ;3 arguments
        .WORD  STRNG1     ;first input string address
        .WORD  STRNG2     ;second input string address
        .WORD  STRCON     ;output string buffer address

STRNG1: .ASCIZ  "Research and"
STRNG2: .ASCIZ  " Development"
STRCON:  .BLKB  31

        .END  START
```

Running this program concatenates string 1 and string 2, producing the following terminal output:

```
Research and Development
```

For detailed description of character string functions, see Section 1.8.

## 1.7.6 Control of Global Regions

Global regions are areas in extended memory which can be used independently from the program that created them; that is, they are shareable among programs. Use the IGETR/MGETR and IFREER system subroutines to create, attach to, detach from, and eliminate global regions in extended memory. All facilities for global region control are available, using the MGETR and IFREER subroutines:

- MGETR creates or attaches to a global region. (IGETR obsolete; retain for compatibility.)
- IFREER detaches from or eliminates a global region.

For a complete description of global region support, see the *RT-11 System Internals Manual*.

## 1.8 Character String Functions

SYSLIB character string functions and routines provide variable-length string support for RT-11 FORTRAN and for MACRO programs. SYSLIB calls that perform character string operations are listed in Table 1-6.

**Table 1-6: Character String Functions**

Call	Operation
CONCAT	Concatenates variable-length strings
INDEX	Returns the position of one string in another
INSERT	Inserts one string into another
LEN	Returns the length of a string
REPEAT	Repeats a character string
SCOMP	Compares two strings
SCOPY	Copies a character string
STRPAD	Pads a string with blanks on the right
SUBSTR	Copies a substring from a string
TRANSL	Performs character modification
TRIM	Removes trailing blanks
VERIFY	Verifies the presence of characters in a string

### String Storage

Strings are stored in BYTE or LOGICAL\*1 arrays that you define and dimension. These arrays store strings in ASCII format as one character per array element, plus a zero element to indicate the current end of the string.

### ASCII Code

The ASCII code used in this string package is the same as that employed by FORTRAN for A-type FORMAT items, ENCODE/DECODE strings, and object-time format strings. Whenever quoted strings are used as arguments in the CALL statement, ASCIZ strings are generated for these routines by the FORTRAN compiler. Note that a null string (a string containing no characters) can be represented in FORTRAN by a variable or constant of any type that contains the value zero or by a LOGICAL variable or constant with the .FALSE. value.

### String Length

The length of a string can vary at execution time from zero characters to one less than the size of the array that stores the string. The maximum size of any string is 32767 characters.

Strings can contain any of the seven-bit ASCII characters except null(0), since the null character is used to mark the end of the string. The inclusion of a terminating zero byte constitutes an *ASCIZ format*, the format set up by a MACRO assembler directive .ASCIZ. This directive automatically sets up strings with a terminating zero byte. Bit 7 of each character must be cleared; therefore, valid characters have a decimal representation range from 1 to 127, inclusive.

In many routines, it is difficult to predict the length of the string produced. To prevent a string from overflowing the array that contains it, you can specify an optional integer argument to the subroutine. This argument, called *len* limits the length of an output string to the value specified for *len plus one* (for the null terminator), so that the array receiving the result must be at least *len-plus-one* elements in size.

### NOTE

If the string is larger than the array, and you do not specify a correct *len* argument, other data may be destroyed and cause unpredictable results.

When *len* is specified, you can also include optional argument *err*. *Err* is a logical variable that should be initialized by the FORTRAN program to .FALSE. If a string function is given the arguments *len* and *err*, and *len* is actually used to limit the length of the string result, then *err* is set to the .TRUE. value. If *len* is not used to truncate the string, *err* is unchanged; that is, it retains a .FALSE. value.

The argument *len* can appear alone; however, *len* must appear if *err* is specified.

Several routines use the concept of character position in which each character in a string is assigned a *position number*, where the first character in the string is at position one.

## 1.8.1 Allocating Character String Variables

A one-dimensional BYTE array can contain a single string whose length can vary from zero characters to one fewer than the dimensioned length of the array. In the following example, array A is used as a string variable that can contain a string of 44 or fewer characters.

```
Byte A(45)           !allocate 1 string
```

Similarly, a two-dimensional BYTE array can be used to contain a one-dimensional array of strings, each of which can have a length up to one less than the first dimension of the BYTE array. There can be as many strings as the number specified for the second dimension of the BYTE array. The program in the following example creates string array W that has ten string elements, each of which can contain up to 20 characters. String I in array W is referenced in subroutine or function calls as W(1,I).

```
Byte W(21,10)       !Allocate an array of 10 strings
```

In the following example, the program allocates a two-dimensional string array.

```
Byte T(14,5,7)      !Allocate a 5 by 7 array of  
                   !13 character strings
```

Each string in array T may vary in length to a maximum of 13 characters. String I,J of the array can be referenced as T(1,I,J). Note that T is the same as T(1,1,1). This dimensioning process can create string arrays of up to six dimensions (represented by BYTE arrays of up to seven dimensions).

## 1.8.2 Passing Strings to Subprograms

BYTE arrays that contain strings can be placed in a COMMON block and referenced by any or all routines with a similar common declaration. However, when you place a BYTE array in a common block, make sure that one of the following is true:

- Array is even in length
- Odd-length arrays are paired to result in an overall even length.
- Strings are together as the last elements in the COMMON block; otherwise, all succeeding variables in the COMMON block may be assigned odd addresses.

A BYTE array has an odd length only if the product of its dimensions is odd. For example,

```
Byte B(10,7)        !10*7 = 70, even length  
Byte H(21)          !21, odd length
```

These might be handled as shown in the following example:

```
Common A1, A2, A3(10), H           !odd size at end
```

or

```
Byte HPAD                !odd length  
Common A1, A2, H, HPAD, A3(10) !Pair H and HPAD for even
```

These restrictions apply only to BYTE variables and arrays.

A single string can be passed by using its array name as an argument. In the following example, the program passes string R to subroutine SUBR.

```
Byte R(21)              !20 char string variable  
Call Subr (R)
```

If the calling program has declared a multidimensional array, and only one string of that array is to be passed to a subroutine, then the subroutine call should specify the first element of the string to be passed (this requires that the first dimension of the array equals the maximum length of each string).

For example,

```
Byte NAMES(81,20)      !20 names max 80 chars each
Do 10 NAMNUM=1, 20      !get 20 lines of input
    Call GTLIN (NAMES(1, NAMNUM)) !from terminal/command file
10 Continue
```

If the maximum length of a string argument is unknown in a subroutine or function, or if the routine is used to handle many different lengths, the dummy argument in the routine should be declared as a `BYTE` array with a dimension of one, such as `BYTE ARG(1)`. In this case, the string routines correctly determine the length of `ARG` whenever it is used, but it is not possible to determine the maximum size of any string that can be stored in `ARG`. If a multidimensional array of strings is passed to a routine, it must be declared in the called program with the same dimensions that were specified in the calling program.

#### NOTE

The length argument specified in many of the character string functions refers to the maximum length of the string, excluding the necessary null byte terminator. The length of the `BYTE` array to receive the string must be at least one greater than the length argument.

### 1.8.3 Using Quoted-String Literals

You can use quoted strings as input arguments to any of the string routines invoked as functions or with the `CALL` statement. In the following example, the program compares the string in the array `NAME` to the constant string `SMYTHE`, `R` and sets the value of the integer variable accordingly.

```
Call SCOMP (NAME, 'SMYTHE', R', M)
```

## System Subroutine Description and Examples

---

This chapter presents all SYSLIB functions and subroutines in alphabetical order by generic name. For example, because READ, IREAD, and MREAD can be called either as subroutines or functions, presenting them together under \*READC will simplify lookup. An I-prefixed name indicates its use as a function; an M-prefixed name indicates that mapping is specified.

Each description briefly defines the subroutine or function; gives its argument list, and defines each parameter and argument contained in the argument list. Function results and errors are listed for each, as appropriate. Descriptions include specific examples for each function or subroutine or refer you to examples elsewhere in the chapter.

---

## ABTIO/IABTIO

ABTIO/IABTIO aborts I/O on a specified channel.

Form:

```
CALL ABTIO (chan)
i = IABTIO (chan)
```

where:

**chan** is the channel number for which to abort I/O

Errors:

Value	Meaning
i = 0	Success.

Error message *TRAP \$MSARG* will display if *chan* argument is missing.

Example:

```
Program FABTIO !demo ABTIO
C
C Pump out 9 buffers to LP using non-wait mode I/O.
C Abort the I/O. This should cause the printout to
C be truncated.
C
C NOTE: using LS7 as a trick to bypass SPOOLING, since
C spooling is normally applied to LP, LP0, LS and LS0.
C
Integer*2 DBLK(4)
Data DBLK /3rLS7, 3rTES, 3rTXX, 3rTMP/ !LS7 to sneak around SP
Integer*2 BUFFER(256,9), CHARS, CRLF
C
CHARS = '11' !begin at 1
CRLF = '015'o + ('012'o * '400'o) ! CR / LF pair in word
ICHAN = IGETC ()
Call IQSET (20) !get more queue elements
Call ENTER (ICHAN, DBLK, 0)
Do 300, J = 1, 9
    Do 200, I = 1, 256
        BUFFER(I,J) = CHARS
        If (IMOD (I, 60 * 2) .eq. 0) BUFFER(I,J) = CRLF
    200 Continue
    CHARS = CHARS + '400'o + 1 !then 2 ... 9
    Call WRITE (256, BUFFER(1,J), J - 1, ICHAN)
300 Continue
C
C Comment out the call to ABTIO and observe the difference
C
Call ABTIO (ICHAN) !stop it in midstream
Call CLOSEC (ICHAN)
End
```

---

## AJFLT/IAJFLT

AJFLT/IAJFLT converts an INTEGER\*4 value to a REAL\*4 value and returns that result as the function value.

Form:

```
ares = AJFLT (jsrc)
i = IAJFLT (jsrc,ares)
```

where:

**jsrc** is the INTEGER\*4 variable to be converted  
**ares** is the REAL\*4 variable or array element to receive the converted value

Function Results:

i = -1 Normal return; result is negative.  
= 0 Normal return; result is 0.  
= 1 Normal return; result is positive.

Errors:

Value	Meaning
i = -2	Significant digits were lost during the conversion.

Unpredictable results will occur if the *jsrc* argument is omitted.

Example:

```
Program FIAJFL !FORTRAN IV
Integer*4 JVAL, J5
Integer*2 IVAL(2), I5(2)
Equivalence (IVAL(1), JVAL), (I5(1), J5)
Real*4 RESULT
C
IVAL(1) = 123 !initial value
IVAL(2) = 1 !really 65536+123 (65659)
I5(1) = 5 !constant value
I5(2) = 0 ! ...
100 Continue
IERR = IAJFLT (JVAL, RESULT)
Type 101, RESULT
101 Format (' ', '!FIAJFL-I-Results', f16.0)
IERR = JMUL (JVAL, J5, JVAL)
If (IERR .eq. -2) Go To 200
Go To 100
200 Continue
Type 102
102 Format (' ', '!FIAJFL-I-Overflow')
End
```

## AJFLT/IAJFLT

The following example converts the INTEGER\*4 value in JVAL to single precision (REAL\*4), multiplies it by 3.5, and stores the result in VALUE:

```
Real*4 VALUE, AJFLT, THREE5  
Data THREE5 / 3.5/  
Integer*4 JVAL  
JVAL = 123456789  
VALUE = AJFLT (JVAL) * THREE5
```

---

# CALL\$F

CALL\$F can be called only from a MACRO-11 program.

The CALL\$F routine saves the contents of general registers R1 through R4 across a call to another routine that might destroy the contents of those registers. CALL\$F saves the contents of R1 through R4 on the stack, calls the other routine, and then restores the saved register contents.

Form:

```
MOV    #rtn,R0
MOV    #arg,R5
CALL   CALL$F
```

where:

**rtn** is the address of the routine you want to call. The current contents of registers 1 through 4 are preserved during execution of the called routine

**arg** is the starting address of the argument list for the routine you want to call

Errors:

None. Any errors are returned by the routine called by CALL\$F.

Example:

```
.GLOBL  GTLIN, CALL$F    ;routines from SYSLIB
.PSECT  CODE,I          ;program code fragment
MOV     #GTLIN,R0        ;routine to call (ultimately)
MOV     #PARMS,R5        ;argument list to use
CALL    CALL$F           ;call GTLIN, save R1-R4

.PSECT  DATA,D         ;program data fragment
PARMS:  .WORD  2          ;number of arguments
        .WORD  BUF        ;response buffer
        .WORD  PROMPT     ;prompt string

BUF:    .BLKB  81.        ;buffer
PROMPT: .ASCII  "Enter username>" ;prompt
        .BYTE  200        ;without terminating cr/lf
```

---

## CHAIN

The CHAIN subroutine lets a background program transfer control directly to another background program and pass specified information to it. CHAIN cannot be called from a completion or interrupt routine. The FORTRAN impure area is not preserved across a chain. Therefore, when chaining from one program to another, the information must be reset in the program being chained to. When chaining to any other program, you should explicitly close the opened logical units with calls to the CLOSE routine. Any routines specified in a FORTRAN USEREX library call are not executed if a CHAIN is accomplished. (See Appendix B in the *RT-11/RSTS/E FORTRAN IV User's Guide*.)

Form:

**CALL CHAIN (dblk,var,wcnt)**

where:

- dblk** is the address of a four-word Radix-50 descriptor of the file specification for the program to be run (See device block discussion in Chapter 1) for the format of the file specification
- var** is the first variable (which must start on a word boundary) in a sequence of variables with increasing memory addresses to be passed between programs in the chain parameter area (absolute locations 510 to 777). A single array or a COMMON block (or portion of a COMMON block) is a suitable sequence of variables
- wcnt** is a word count specifying the number of words (beginning at var) to be passed to the called program. The argument wcnt may not exceed 60. If no words are passed, then a word count of 0 must be supplied.

If the size of the chain parameter area is insufficient, it can be increased by specifying the /B (or /BOTTOM) option to LINK for both the program executing the CHAIN call and the program receiving control.

The data passed can be accessed through a call to the RCHAIN routine. For more information on chaining to other programs, see the .CHAIN programmed request.

Errors:

Error message *TRAP \$MSARG* will display if any argument is missing.

Example:

The following example transfers control from the main program to FRCHAI.SAV on BIN and passes it variables (See also RCHAIN for FRCHAI.FOR):

## CHAIN

```
Program FCHAIN !demonstrate CHAIN routine
C
C Chain to BIN:FRCHAI.SAV passing 100,200,301
C
Integer*2 DBLK(4)
Data DBLK /3rBIN, 3rFRC, 3rHAI, 3rSAV/
COMMON /CHAIND/ I, J, K !force order
Data I /100/, J /200/, K / 301/ !initialize
C
Call CHAIN (DBLK, I, 3)
End
```

---

# CHCPY/ICHCPY

## Multijob Only

CHCPY/ICHCPY opens a channel for input, logically connecting it to a file that is currently open by another job for either input or output. CHCPY/ICHCPY is used in a multijob situation to gain shared access to a file already opened by another job. It substitutes for an OPEN (or LOOKUP or ENTER) in your program, instead obtaining the parameters of the file from the other job. An ICHCPY must be done before the first read or write on *ochan*.

Form:

```
CALL CHCPY (chan,ochan[,jobblk])  
i = ICHCPY (chan,ochan[,jobblk])
```

where:

- chan** is the channel the job will use to read the data. You must obtain this channel through an IGETC call, or you can use channel 16 or higher if you have done an ICDFN call
- ochan** is the channel number of the other job that is to be copied
- jobblk** is a pointer to a three-word ASCII job name

## Notes

- If the other job's channel was opened with an IENTER function or a .ENTER programmed request to create a file, your channel indicates a file that extends to the highest block that the creator of the file had written at the time the CHCPY was executed.
- A channel that is open on a sequential-access device should not be copied, because requests can become intermixed.
- Your program can write on a copied channel to a file that is being created by the other job, just as your program could if it were the creator. When your channel is closed, however, no directory update takes place.

Errors:

Value	Meaning
i = 0	Normal return.
= 1	Specified job does not exist. Or specified channel ( <i>ochan</i> ) open.
= 2	Channel ( <i>chan</i> ) is already open.

Error message *TRAP \$MSARG* will display if *chan* or *ochan* argument is missing.

## Example:

```

Program FCHCPB !BG program for CHCPY
Parameter SUCCS = '001'o
Parameter FATAL = '010'o
Integer*2 BUFFER(513)
Integer*2 FCHCPF(3)
Byte CHCPF(6)
Data CHCPF /'F', 'C', 'H', 'C', 'P', 'F'/
Equivalence (FCHCPF(1), CHCPF(1))
C
BUFFER(513) = 0          !null just in case
ICHAN = 14
JCHAN = 15
IERR = ICHCPY (ICHAN, JCHAN, FCHCPF)
If (IERR .ne. 0) Go To 100
IERR = IREADW (512, BUFFER, 0, ICHAN)
If (IERR .ne. 512) Go To 200
Call PRINT (BUFFER)
Call Exit (SUCCS)
C
100  Type *, '?FCHCPB-F-ICHCPY failed with code ', IERR
      Call Exit (FATAL)
200  Type *, '?FCHCPB-F-IREADW failed with code ', IERR
      Call Exit (FATAL)
      End

Program FCHCPF !FG program for ICHCPY
Integer*2 DBLK(4)
Data DBLK /3rSRC, 3rFCH, 3rCPB, 3rFOR/
C
ICHAN = 15
IERR = LOOKUP (ICHAN, DBLK)
If (IERR .lt. 0) Go To 100
Call SUSPND      !sleep (forever)
C
100  Type *, '?FCHCPF-F-LOOKUP failed with code ', IERR
      End

```

---

## CLOSEC/ICLOSE

The CLOSEC subroutine terminates activity on the specified channel and frees it for use in another operation.

Form:

```
CALL CLOSEC (chan[,i])
CALL ICLOSE (chan[,i])
i = ICLOSE(chan)
```

where:

- chan** is the channel number to be closed. This argument must be located so that the USR cannot swap over it
- i** is the error returned if a protection violation occurs

### Notes

Under certain conditions, a handler for the associated device and USR must be available when issuing a .CLOSE for a channel opened with a .ENTER or .LOOKUP:

- .CLOSE requires a handler and USR, if it is:
  - A special directory device (magtape).
  - An RT-11 standard directory device, and the file was opened with a .ENTER.
- All other RT-11 operations do not require either handler or USR.

A CLOSEC or PURGE must eventually be issued for any channel opened for input or output. A CLOSEC call specifying a channel that is not open is ignored.

A CLOSEC performed on a file that was opened via an IENTER causes the device directory to be updated to make that file permanent. If the device associated with the specified channel already contains a file with the same name and type, the old copy is deleted when the new file is made permanent. If the file name is protected, then a protection error is generated and two files will exist with the same name. A CLOSEC on a file opened via LOOKUP does not require any directory operations.

When an entered file is closed, its permanent length reflects the highest block of the file written since the file was entered; for example, if the highest block written is block number 0, the file is given a length of 1; if the file was never written, it is given a length of 0. If this length is less than the size of the area allocated at IENTER time, the unused blocks are reclaimed as an empty area on the device.

Use ICLOSZ, rather than CLOSEC or ICLOSE, to set file size at closure. ICLOSZ has no effect on the file size when the file was opened by a LOOKUP. (See CLOSZ /ICLOSZ.)

Errors:

**Value    Meaning**

i = 0    Normal return.

= -4    A protected file with the same name already exists on a device. The CLOSEC is performed, resulting in two files on the device with the same name.

Error message *TRAP \$MSARG* will display if any argument is missing.

Example:

The following example creates a file which becomes a 0-block permanent file:

```

Program FCLOSE  !demo CLOSEC / ICLOSE
C
C   Create and close DK:TEST.TMP w/o I/O.
C   Note that this makes a permanent file of 0 length.
C   Compare with FCLOSZ.
C
Integer*2 DBLK(4)
Data DBLK /3rDK , 3rTES, 3rT  , 3rTMP/
Parameter SUCCS = '001'o, FATAL = '010'o
C
ICHAN = IGETC()
If (ICHAN .lt. 0) Go To 100
IERR = IENTER (ICHAN, DBLK, 100)
IF (IERR .lt. 0) Go To (110, 120, 130) IABS(IERR)
CALL CLOSEC (ICHAN, IERR)
If (IERR .eq. -4) Go To 200
Call IFREEC(ICHAN)
Call Exit (SUCCS)
100 Type *, ' ?FCLOSE-F-No channel available'
Call Exit (FATAL)
110 Type *, ' ?FCLOSE-F-Channel in use'
Call Exit (FATAL)
120 Type *, ' ?FCLOSE-F-Not enough room'
Call Exit (FATAL)
130 Type *, ' ?FCLOSE-F-Device in use'
Call Exit (FATAL)
200 Type *, ' ?FCLOSE-F-Protected file already exists'
Call Exit (FATAL)
End

```

---

## CLOSZ/ICLOSZ

CLOSZ/ICLOSZ terminates activity on the specified channel and frees it for use in another operation. ICLOSZ closes any file opened on that channel by an IENTER and sets the file size to a value you specify. Use ICLOSZ, as opposed to CLOSEC or ICLOSE, when you want to set the file size at closure. ICLOSZ has no effect on the file size when the file was opened by a LOOKUP. See also CLOSEC/ICLOSE.

Form:

```
CALL CLOSZ (chan,size)
i = ICLOSZ (chan,size)
```

where:

**chan** is the INTEGER\*2 channel number to be closed. If the specified channel is not open, no action is taken

**size** is the size of the file in blocks at closure

**i** is a returned INTEGER\*2 result of the function

If the handler for the device associated with the channel is marked FILST\$ (supports the RT-11 file structure) and the file is opened with IENTER, the value you specify for the file size at closure must be equal to or less than the current allocated file size. If the handler is marked SPECL\$ (supports the special directory file structure), RT-11 enforces no size constraints when the file is closed. However, the handler may impose constraints.

The handler for the device associated with the channel must be in memory if the channel was opened with the IENTER subroutine or if the handler is marked SPECL\$ (supports the special directory structure).

An ICLOSZ performed on a file that was opened with IENTER causes the device directory to be updated to make that file permanent. If the device associated with the specified channel already contains a file with the same name and type, the old copy is deleted when the new file is made permanent. If the file name is protected, then a protection error is generated. An ICLOSZ on a file opened using a LOOKUP does not require the USR for RT-11 directory devices, but does require the USR for special directory devices.

Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return
= -2	Size too big
= -3	Invalid operation
= -4	A protected file with the same name already exists on the device.
= -257	Required argument missing

## Example:

```

Program FCLOSZ !demo ICLOSZ
C
C Create DK.TEST.TMP with 100 blocks, and
C make permanent at that size w/o I/O.
C
Integer*2 DBLK(4)
Data DBLK /3rDK , 3rTES, 3rT , 3rTMP/
Parameter SUCCS = '001'o
Parameter FATAL = '010'o
C
ICHAN = IGETC()
If (ICHAN .lt. 0) Go To 100
IERR = IENTER (ICHAN, DBLK, 100)
IF (IERR .lt. 0) Go To (110, 120, 130) IABS(IERR)
IERR = ICLOSZ (ICHAN, IERR)
If (IERR .eq. -4) Go To 200
Call IFREEC(ICHAN)
Call Exit (SUCCS)
100 Type *, ' ?FCLOSZ-F-No channel available'
Call Exit (FATAL)
110 Type *, ' ?FCLOSZ-F-Channel in use'
Call Exit (FATAL)
120 Type *, ' ?FCLOSZ-F-Not enough room'
Call Exit (FATAL)
130 Type *, ' ?FCLOSZ-F-Device in use'
Call Exit (FATAL)
200 Type *, ' ?FCLOSZ-F-Protected file already exists'
Call Exit (FATAL)
End

```

---

# CMAP/ICMAP

## Full Mapping

CMAP/ICMAP, available only under fully mapped monitors, is a routine that controls mapping for Supervisor mode and I-D space. CMAP establishes CMAP status in Supervisor data space, distinct from User data space.

Form:

```
CALL CMAP (ival [,iold][,ierr])
ierr = ICMAP (ival [,iold])
```

where:

<b>ierr</b>	Error return
<b>ival</b>	New value for CMAP status
<b>iold</b>	Previous CMAP status

Errors:

<b>Value</b>	<b>Meaning</b>
0	Success.
-257	Required argument ( <i>ival</i> ) argument is omitted.

Example:

```

```

---

## CMKT/ICMKT

CMKT/ICMKT cancels one or more scheduling requests (made by an ISCHED, ITIMER, or MRKT routine). Support for CMKT in SB requires that you select timer support during SYSGEN.

Form:

```
CALL CMKT (id[,itime])  
i = ICMKT (id[,itime])
```

where:

**id** is the identification integer of the request to be canceled. If *id* is equal to 0, all scheduling requests are canceled

**itime** is the name of a two-word area in which the monitor returns the amount of time remaining in the canceled request

For further information on canceling scheduling requests, see the .CMKT programmed request in the *RT-11 System Macro Library Manual*.

Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return.
= 1	The value of <i>id</i> was not equal to 0 and no scheduling request with that identification could be found.

Error message *TRAP \$MSARG* will display if *id* argument is missing.

Example:  
See MRKT.

---

# CNTXS/ICNTXS

## Multijob Only

CNTXS/ICNTXS establishes a list of locations to be saved when a transition is made from one running job to another. CNTXS preserves locations that are not preserved automatically by the monitor. Refer to the *RT-11 System Macro Library Manual*.

Form:

```
CALL CNTXS (addr)
i = ICNTXS (addr)
```

where:

**addr** is the pointer to the list of addresses to be preserved. The list is terminated with a zero word

**i** is a returned INTEGER\*2 result of the function.

Errors:

Value	Meaning
i = 0	Normal return
= -1	One or more of the conditions specified by <i>addr</i> was violated
= -257	Required argument missing.

Example:

```
Program FCNTXS !demo ICNTXS
C
C Setup swapping of vectors 400 through 406
C
Parameter SUCCS = '001'o, FATAL = '010'o
Integer*2 LIST(5), NOLIST
Data LIST /'400'o, '402'o, '404'o, '406'o, 0/
Equivalence (NOLIST, LIST(5))
C
IERR = ICNTXS (LIST) !swap 400--406
If (IERR .ne. 0) Go To 1000
C
C ...
C
Call CNTXS (NOLIST) !stop swapping
Call PRINT ('!FCNTXS-I-Success')
Call Exit (SUCCS)
C
1000 Call PRINT ('?FCNTXS-F-Failed')
Call Exit (FATAL)
End
```

---

## CONCAT

The CONCAT subroutine concatenates two character strings.

Form:

```
CALL CONCAT (a,b,out[,len[,err]])
```

where:

- a** is the array containing the left string. The string must be terminated with a null byte
- b** is the array containing the right string. The string must be terminated with a null byte
- out** is the array into which the concatenated result is placed. This array must be at least one element longer than the maximum length of the resultant string (that is, one greater than the value of *len*, if specified)
- len** is the integer number of characters representing the maximum length of the output string. The effect of *len* is to truncate the output string to a given length, if necessary
- err** is the logical error flag set if the output string is truncated to the length specified by *len*.

You must specify *err* as LOGICAL\*1 in FORTRAN 77. It can be any logical type in FORTRAN IV and any integer type in PDP-11C.

CONCAT sets the string in *out* to the value of the string in *a*, immediately followed by the string in *b*, followed by a terminating null character.

### NOTE

Any combination of string arguments is allowed, so long as *b* and *out* do not specify the same array.

Concatenation stops when a null character is detected in *b* or when the number of characters specified by *len* has been moved.

If either the left or right string is a null string, the other string is copied to *out*. If both are null strings, then *out* is set to a null string. The old contents of *out* are lost when this routine is called.

Errors:

Error conditions are indicated by *err*, if specified. If *err* is given and the output string would have been longer than *len* characters, then *err* is set to .TRUE.; otherwise, *err* is unchanged.

Error message *TRAP \$MSARG* will display if argument *b* or *out* is missing.

**Example:**

The following example concatenates the string in array STR and the string in array IN and stores the resultant string in array OUT. OUT cannot hold a string longer than 29 characters:

```
      Program FCONCA !demo CONCAT
C
C      Show concatenation and truncation
C
      Byte IN(22), OUT(30), STR(10)
C
      Call SCopy ('abcdefghijklmnopqrstu', IN)
      Call SCopy ('123456789', STR)
      Call CONCAT (STR, IN, OUT, 29)
      Call Print (OUT)
      End
```

---

# CRAW/ICRAW

## Mapping

CRAW/ICRAW are memory mapping routines which create an address window into an existing memory region. It can be used in both User and Supervisor modes, and can access both I and D space. See also .CRAW in the *RT-11 System Macro Library Manual*.

Form:

```
CALL CRAW (iwdb [,ierr])
i = ICRAW (iwdb)
```

where:

<b>iwdb</b>	Address of Window Descriptor Block
<b>ierr</b>	Error return

Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Function completed successfully.
= -1	Window alignment error.
= -2	Attempt to define more than 7 windows.
= -3	Invalid region identifier.
= -5	Combination of offset into region and size of window to be mapped is invalid.
= -16	Mode/space not available.
= -257	Required argument missing.

Example:

```
C      RDBDF.FOR -- FORTRAN equivalent of .RDBDF
      Parameter RGID = 0          !region id subscript
      Parameter RGSIZ = 2/2      !region size subscript
      Parameter RGSTS = 4/2      !region status subscript
      Parameter RGLLN = 6/2      !local RDB size
      Parameter RGNAM = 6/2      !global region name words subscript
      Parameter RGBAS = 10/2     !global region base addr subscript

## CRRG/ICRRG

### Mapping

CRRG/ICRRG (Create Region) is a mapping routine for Supervisor mode, I-D space. The function allocates or attaches to a region in physical memory for use by the requesting job. See .CRRG and .RDBDF macros in the *RT-11 System Macro Library Manual*.

Form:

```
CALL CRRG (irdb [,ierr])
ierr = ICRRG (irdb)
```

where:

<b>ierr</b>	Error return
<b>irdb</b>	Address of Region Descriptor Block

Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Function completed successfully.
= -7	No region control blocks available.
= -10	Insufficient memory to allocate region of requested size.
= -11	Invalid region size was specified.
= -13	Global region not found.
= -14	Too many global regions.
= -16	Global region privately owned.
= -17	Global region already exists with different base address.
= -257	Required argument missing.

Example: See CRAW.

---

## CSI/ICSI

CSI/ICSI calls the RT-11 Command String Interpreter in special mode to parse a command string and return file descriptors and options to the program. In this mode, the CSI does not perform any handler IFETCH, CLOSEC, IENTER, or LOOKUP. This subroutine requires the USR.

Form:

```
CALL CSI (filspc,deftyp[,cstring][,option],n)
i = ICSI (filspc,deftyp[,cstring][,option],n)
```

where:

- filspc** is the 39-word area to receive the file specifications. The format of this area (considered as a 39-element INTEGER\*2 array) is:
- Word 1–4 output file number specification
  - Word 5 output file number 1 length
  - Word 6–9 output file number 2 specification
  - Word 10 output file number 2 length
  - Word 11–14 output file number 3 specification
  - Word 15 output file number 3 length
  - Word 16–19 input file number 1 specification
  - Word 20–23 input file number 2 specification
  - Word 24–27 input file number 3 specification
  - Word 28–31 input file number 4 specification
  - Word 32–35 input file number 5 specification
  - Word 36–39 input file number 6 specification
- deftyp** is the table of Radix-50 default file types to be assumed when a file is specified without a file type:
- deftyp(1) is the default for all input file types
  - deftyp(2) is the default file type for output file number 1
  - deftyp(3) is the default file type for output file number 2
  - deftyp(4) is the default file type for output file number 3
- cstring** is the area that contains the ASCIZ command string to be interpreted; the string must end in a zero byte. If the argument is omitted, the system prints the prompt character (\*) at the terminal and accepts a command string. If input is from a command file, the next line of that file is used

**option** is the name of an INTEGER\*2 array dimensioned (4,x) where x represents the number of options defined to the program. This argument must be present if the value specified for *n* is non-zero. This array has the following format of the *j*th option described by the array:

- option(1, *j*) is the one-character ASCII name of the option
- option(2, *j*) is set by the routine to 0, if the option did not occur; to 1, if the option occurred without a value; to 2, if the option occurred with a value
- option(3, *j*) is set to the file number on which the option is specified
- option(4, *j*) is set to the specified value if option(2, *j*) is equal to 2

**n** is the number of options defined in the array option. The *n* is not optional. If the *n* is omitted, specify *n* as 0.

**Notes**

The array option must be set up to contain the names of the valid options. For example, use the following to set up names for five options:

```
INTEGER*2 SW(4,5)
DATA SW(1,1)/'S'//,SW(1,2)/'M'//,SW(1,3)/'I'//
DATA SW(1,4)/'L'//,SW(1,5)/'E'//
```

Multiple occurrences of the same option are supported by allocating an entry in the option array for each occurrence of the option. Each time the option occurs in the option array, the next unused entry for the named option is used. When there are identical options, they are placed in the *option array* in reverse order. The last occurrence of *option* in the command line is placed in the first matching entry in *option*. You may want to consider putting both upper and lower case versions of the options in the table, because options might be entered either way.

The arguments of ICSI must be positioned so that the USR cannot swap over them. For more information on calling the Command String Interpreter, see the .CSISPC programmed request.

**Errors:**

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return.
= 1	Invalid command line passed by <i>cstring</i> in memory; no data was returned.
= 2	Invalid device specification occurred in the command string <i>cstring</i> in memory.

= 3 Invalid option specified; specified option exceeded number allowed in the option array.

Error message *TRAP \$MSARG* will display if *filpc*, *deftyp*, or *n* argument is missing.

Example:

The following example causes the program to loop until a valid command is typed at the terminal:

```

      Program FCSI !demo CSI
C
C      Accept a command line, parse it into file specifications
C      and switches. Display the results of this parsing.
C      Note that input files use a trick to allow selection of
C      a default type dynamically. The value of the /I switch is
C      used as the default type for all input files.
C      Switches that are accepted are /S/M/I/L/E.
C
      Parameter OPTNUM = 5      !number of options allowed

      End If
300  Continue
      Go To 50
    End
```

---

## CSTAT/ICSTAT

CSTAT/ICSTAT obtains information about a channel.

Form:

```
CALL CSTAT (chan,addr[,strng])  
i = ICSTAT (chan,addr[,strng])
```

where:

<b>chan</b>	is the channel whose status is desired												
<b>addr</b>	is a six-word area to receive the status information. The area, as a six-element INTEGER*2 array, has the following format:  <table><tr><td>Word 1</td><td>channel status word</td></tr><tr><td>Word 2</td><td>starting absolute block number of file on this channel</td></tr><tr><td>Word 3</td><td>length of file</td></tr><tr><td>Word 4</td><td>highest block number written since file was opened</td></tr><tr><td>Word 5</td><td>unit number of device with which this channel is associated</td></tr><tr><td>Word 6</td><td>Radix-50 of device name with which the channel is associated</td></tr></table>	Word 1	channel status word	Word 2	starting absolute block number of file on this channel	Word 3	length of file	Word 4	highest block number written since file was opened	Word 5	unit number of device with which this channel is associated	Word 6	Radix-50 of device name with which the channel is associated
Word 1	channel status word												
Word 2	starting absolute block number of file on this channel												
Word 3	length of file												
Word 4	highest block number written since file was opened												
Word 5	unit number of device with which this channel is associated												
Word 6	Radix-50 of device name with which the channel is associated												
<b>strng</b>	is the 3-character area to receive the ASCII device name and unit number associated with the specified channel.												

Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return.
= 1	Channel specified is not open.

Error message *TRAP \$MSARG* will display if *chan* or *addr* argument is missing.

Example:

The following example obtains channel status information about channel I.

```
Program FCSTAT !demo CSTAT  
C  
C This program opens a file on a FORTRAN unit and then  
C uses CSTAT to find out about the associated RT-11 channel.  
C  
C Parameter CSW = 1, BGNBLK = 2, LENGTH = 3  
C Parameter HIH2O = 4, UNIT = 5, R50DEV = 6  
C Integer*2 REPLY(6) !reply area for CSTAT  
C Character*3 NAME !device name  
C  
C Open (Dispose='SAVE', File='SY:SWAP.SYS', Readonly,  
1 Status='OLD', Unit=1)
```

## CSTAT/ICSTAT

```
Open (Dispose='DELETE', File='DK:TEST.TMP',  
1 Status='NEW', Unit=2)  
Do 200, I = 0, 15  
    If (ICSTAT (I, REPLY, NAME) .eq. 0)  
1      Type 1, REPLY(BGNBLK), REPLY(LENGTH), NAME, I  
        Format (' ', ' Beginning block=', I6,  
1          ' File length=' , I6,  
2          ' Device=' A3,  
3          ' Channel=' I2)  
200      Continue  
End
```

---

## CVTTIM

The CVTTIM subroutine converts a two-word internal format time to hours, minutes, seconds, and ticks.

Form:

**CALL CVTTIM (time,hrs,min,sec,tick)**

where:

**time** is the two-word internal format time to be converted. If time is considered as a two-element INTEGER\*2 array, then:  
time (1) is the high-order time  
time (2) is the low-order time

**hrs** is the integer number of hours

**min** is the integer number of minutes

**sec** is the integer number of seconds

**tick** is the integer number of ticks (1/60 of a second for 60-Hz clocks; 1/50 of a second for 50-Hz clocks)

Errors:

Error message *TRAP \$MSARG* will display if any required argument is missing.

Example:

```
Program FCVTTI !demo CVTTIM
C
C Get current time of day and display appropriate greeting
C
Integer*4 TIME
C
Call GTIM (TIME) !Get current time
Call CVTTIM (TIME, IHRS, IJUNK, IJUNK, IJUNK) !"parse" it
If ((IHRS .ge. 0) .and. (IHRS .lt. 8)) Type *, 'Good Grief'
If ((IHRS .ge. 8) .and. (IHRS .lt. 12)) Type *, 'Good Morning'
If ((IHRS .ge. 12) .and. (IHRS .lt. 17)) Type *, 'Good Afternoon'
If ((IHRS .ge. 17) .and. (IHRS .lt. 22)) Type *, 'Good Evening'
If ((IHRS .ge. 22) .and. (IHRS .lt. 24)) Type *, 'Good Night'
End
```

---

## DATE/DATE4Y

The DATE and DATE4Y subroutines display current (system) date or format a date you specify.

Previously, the DATE subroutine was located in the distributed FORTRAN subroutine libraries, FORLIB and F77OTS.

DATE stores the date as a 9-byte string as **dd-mmm-yy**. DATE4Y stores the date as an 11-byte string as **dd-mmm-yyyy**.

where:

- dd** is the 2-digit day of the month (with leading zero if necessary)
- mmm** is the 3-character month (all capital letters)
- yy** is the last two digits of the year (DATE subroutine)
- yyyy** is the 4-digit year (DATE4Y subroutine)
- is the separating character

Form:

```
CALL DATE (array[,opdate])  
CALL DATE4Y (array[,opdate])
```

where:

- array** is a predefined array for receiving the date string.
  - For DATE, the array must contain at least nine bytes. The 9-byte string is set to blanks if the date is invalid.
  - For DATE4Y, the array must contain at least eleven bytes. The 11-byte string is set to blanks if the date is invalid.
- opdate** is an optional RT-11 date word to be formatted. Specifying a 0 value for *opdate* returns the current system date.

The format of the date word is:

Bits	Contents		
0-4	Year minus the base (base specified by bits 14,15)		
5-9	Day (1-31)		
10-13	Month (1-12)		
14,15	Age bits. Age bits extend the directory date by 32(decimal) year increments and have the following meaning:		
	15	14	Meaning When Set
	0	0	Base year 1972
	0	1	Base year 2004
	1	0	Base year 2036
	1	1	Base year 2068

DATE4Y is included within DATE. DATE4Y is functionally the same as DATE, except that it stores a 4-character year rather than a 2-character year.

Errors:

Error message *TRAP \$MSARG* will display if *array* argument is missing.

Example:

For DATE4Y, see GTDIR/IGTDIR.

For DATE:

```

          Program FDATE    !demo DATE & IWEEK
C
C          Display current date and day of week
C
          Byte DAYSTR(9)
          Integer*4 DAYS(7)
          Data Days /'Sun', 'Mon', 'Tue', 'Wed', 'Thu', 'Fri', 'Sat' /
C
          Call IDATE (MONTH, IDAY, IYEAR)
          IWD = IWEEKD (MONTH, IDAY, IYEAR)
          Call DATE (DAYSTR)
          Type 100, DAYS(IWD), DAYSTR
100      Format (' ', 'Today''s date: ', 6x, a4, 1x, 9a1)
          End

```

---

## DELET/IDELET

DELET/IDELET deletes a named file from an indicated device. DELET requires the USR. It is not supported for magtape handlers supplied by Digital.

Form:

```
CALL DELET (chan,dblk[,seqnum])  
i = IDELET (chan,dblk[,seqnum])
```

where:

- chan** is the channel to be used for the delete operation. You must obtain this channel through an IGETC call, or you can use channel 16(decimal) or higher if you have done an ICDFN call
- dblk** is the four-word Radix-50 specification (dev:filnam.typ) for the file to be deleted
- seqnum** is the file number for magtape operations

### Notes

The arguments of DELET must be located so that the USR cannot swap over them.

The specified channel is left inactive when the DELET is complete. DELET requires that the handler to be used be resident (via an IFETCH call or a LOAD command from KMON) at the time the DELET is issued. If the handler is not resident, a monitor error occurs.

For further information on deleting files, see the .DELETE programmed request.

Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return.
= 1	Channel specified is already open.
= 2	File specified was not found.
= 3	Device in use.
= 4	The file is protected and cannot be deleted.

Error message *TRAP \$MSARG* will display if *chan* or *dblk* argument is missing.

## Example:

```
Program FDELETE !Demo DELET
C
C Delete the file DK:TSTDEL.TMP
C
Parameter SUCCS = '001'o, FATAL = '010'o
Integer*2 DBLK(4)
Data DBLK /3rDK , 3rTST, 3rDEL, 3rTMP/
C
If (IDELET (IGETC (), DBLK) .ne. 0) Then
    Call Print ('?IDELET-F-Delete failed')
    Call Exit (FATAL)
Else
    Call Print ('!IDELET-I-File deleted')
    Call Exit (SUCCS)
End If
End
```

---

## DEVICE/IDEVICE

DEVICE/IDEVICE sets up a list of addresses to be loaded with specified values when the program is terminated. If a job terminates or is aborted with a CTRL/C from the terminal, this list is used up by the system to set the specified addresses to the corresponding values.

This function is primarily designed to allow user programs to load device registers with necessary values. In particular, it is used to turn off a device's interrupt enable bit when the program servicing the device terminates.

Unless *link arg1* is used, only one address list can be active at any given time. If multiple DEVICE calls are issued, only the last one has any effect. The list must not be modified by the program after the DEVICE call has been issued, and the list must not be located in an overlay or an area over which the USR swaps.

The second argument of the call *link* provides support for a linked list of tables. The link argument is optional and causes the first word of the list to be processed as the link word. With linked lists, each call adds the new list to the previous lists, rather than replacing the previous lists.

Form:

```
CALL DEVICE (ilist[,link])
i = IDEVICE (ilist[,link])
```

where:

- ilist** is an integer array that contains two-word elements, each composed of a one-word address and a one-word value to be put at that address, terminated by a zero word. On program termination, each value is moved to the corresponding address.
- link** is an optional parameter of any value that indicates a linked list table is to be used.

If the linked list form is used, the first word of the array is the link list pointer.

For more information on loading values into device registers, see the .DEVICE programmed request.

Errors:

Error message *TRAP \$MSARG* will display if the *ilist* argument is missing.

Errors:

Value	Meaning
i = -1	Value specified for <i>ilist</i> is above 160000 (octal)

Example:

```
Integer*2 IDR11(3)      !DEVICE argument list
Data IDR11 /"167770, 0, 0/ !addr, value, end of list
C
Call    DEVICE (IDR11)  !setup for job abort
```

---

## DJFLT

The DJFLT function converts an INTEGER\*4 value into a REAL\*8 (DOUBLE PRECISION) value and returns that result as the function value. See IDJFLT.

Form:

**d = DJFLT(jsrc)**

where:

**jsrc** specifies the INTEGER\*4 variable to be converted

### NOTES

If DJFLT is used, it must be defined in the FORTRAN program, either explicitly (REAL\*8 DJFLT) or implicitly (IMPLICIT REAL\*8 (D)). Without a definition, DJFLT is assumed to be REAL\*4 (single precision).

The function result is the REAL\*8 value that is the result of the operation.

Errors:

Unpredictable results will occur if the *jsrc* argument is omitted.

Example:

```
Program FDJFLT !FORTRAN IV
Real*8 VALUE, DJFLT, THREE5
Data THREE5 / 3.5d0/
Integer*4 JVAL
Integer*2 IVAL(2)
Equivalence (IVAL(1), JVAL)
C
IVAL(1) = 2      !00002
IVAL(2) = 1      !65536
VALUE = DJFLT (JVAL)
VALUE = VALUE * THREE5
Type 101, VALUE
101 Format (' ', f16.0)
End
```

---

## DSTAT/IDSTAT

DSTAT/IDSTAT obtains information about a particular device.

Form:

```
CALL DSTAT (devnam,cbk)
i = IDSTAT (devnam,cbk)
```

where:

**devnam** is the Radix-50 device name

**cbk** is the four-word area used to store the status information. The area, as a four-element INTEGER\*2 array, has the following format:

Word 1	Device status word (See .DSTAT)
Word 2	Size of handler in bytes
Word 3	Entry point of handler (non-zero implies that the handler is in memory)
Word 4	Size of the device (in 256-word blocks) for block-replaceable devices; zero for sequential-access devices, the smallest-sized volume for variable-sized devices. The last block on the device is the device size -1

### Notes

The arguments of IDSTAT must be positioned so that the USR cannot swap over them.

IDSTAT looks for the device specified by *devnam* and, if found, returns four words of status in *cbk*.

Errors:

Error message *TRAP \$MSARG* will display if any required argument is missing.

Value	Meaning
i = 0	Normal return.
= 1	Device not found in monitor tables.

Example:

The following example determines whether the line printer handler is in memory. If it is not, the program stops and prints a message to indicate that the handler must be loaded:

C

```
Program FDSTAT !demo DSTAT
Integer*2 DEVNAM
Data DEVNAM /3rLP /
Integer*2 REPLY(4)
Data REPLY /4*0/

Call DSTAT (DEVNAM, REPLY)
If (REPLY(3) .eq. 0) Then
    Call Print ('!FDSTAT-I-LP is not in memory')
Else
    Call Print ('!FDSTAT-I-LP is in memory')
End If
End
```

---

## ELAW/IELAW

### Mapping

ELAW/IELAW (eliminate window) eliminates a virtual address window. An implied unmapping of the window occurs when its definition block is eliminated.

Form:

```
CALL ELAW (iwdb [,ierr])  
i = IELAW (iwdb)
```

where:

**iwdb** is the address of Window Definition Block (WDB)  
**ierr** is address of location to return error information

Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return.
= -4	Invalid window identifier specified.
= -257	Required argument missing.

Example:  
See CRAW.

---

## ELRG/IELRG

### Mapping

ELRG/IELRG (eliminate region) eliminates a dynamic region of physical memory and returns the memory to the free list where it can be used by other jobs.

Form:

```
CALL ELRG (irdb [,ierr])  
ierr = IELRG (irdb)
```

where:

<b>ierr</b>	Error return
<b>irdb</b>	Address of Region Definition Block (RDB)

Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return.
= -3	Invalid region identifier specified.
= -12	Deallocation failure.
= -257	Required argument missing.

Example:  
See CRAW.

---

## ENTER/IENTER

ENTER/IENTER allocates space on the specified device and creates a tentative directory entry for the named file. If a file of the same name already exists on the specified device, it is not deleted until the tentative entry is made permanent by issuing either CLOSEC/ICLOSE or CLOSZ/ICLOSZ. The file is attached to the channel number specified. This routine requires the USR.

Form:

```
CALL ENTER (chan,dblk,length[,seqnum])  
i = IENTER (chan,dblk,length[,seqnum])
```

where:

- chan** is the integer specification for the RT-11 channel to be associated with the file. You must obtain this channel through an IGETC call, or you can use channel 16 or higher, if you have done an ICDFN call.
- dblk** is the four-word Radix-50 descriptor of the file to be operated upon.
- length** is the integer number of blocks to be allocated for the file. If 0, the larger of either one-half the largest empty segment or the entire second largest empty segment is allocated. If the value specified for length is -1, the entire largest empty segment is allocated (See the .ENTER programmed request).
- seqnum** is a magtape file sequence number that can have the values listed below. (*Seqnum* is also a file number for cassette.) If this argument is blank, a value of 0 is assumed.

<b>Value</b>	<b>Meaning</b>
--------------	----------------

- |    |   |
|----|---|
| -2 | Rewind the magtape and space forward until the file name is found, or until logical-end-of-tape is detected. The magtape is now positioned correctly. A new logical-end-of-tape is implied.                 |
| -1 | Space to the logical-end-of-tape and enter file.  |
| 0  | Rewind the magtape and space forward until the file name is found or the logical-end-of-tape is detected. If the file name is found, an error is generated. If the file name is not found, then enter file. |
| n  | Position magtape at file sequence number n if n is greater than zero and the file name is not null.   |

### Notes

- ENTER requires that the appropriate device handler be in memory.
- The arguments of ENTER must be positioned so that the USR does not swap over them.

For further information on creating tentative directory entries, see the .ENTER programmed request.

Errors:

Value	Meaning
i = n	Normal return; number of blocks actually allocated (n = 0 for non-file-structured IENTER).
= -1	Channel ( <i>chan</i> ) is already in use.
= -2	In a fixed-length request, no space greater than or equal to length was found.
= -3	Device in use.
= -4	A file by that name already exists and is protected.
= -5	File sequence number not found.
= -6	File sequence number is invalid.
= -7	Invalid unit number on a special directory device.

Error message *TRAP \$MSARG* will display if *chan*, *dblk* or *length* argument is missing.

Example:

The following example allocates a channel for file TEMP.TMP on SY0. If no channel is available, the program prints a message and halts:

```

Program FENTER ! demo ENTER
Parameter SUCCS = '001'o, FATAL = '010'o
Integer*2 DBLK(4)
Data DBLK /3rDK , 3rTEM, 3rT , 3rTMP/
C
    ICHAN = IGETC ()
C
C   Create temp work file
C
    If (IENTER (ICCHAN, DBLK, 20) .ne. 20) Then
        Call Print ('?FENTER-F-ENTER failed')
        Call Exit (FATAL)
    End If
C
C   use temp file
C
C   ...
C
    Call PURGE (ICCHAN)
    Call IFREEC (ICCHAN)
    Call Print ('!FENTER-I-ENTER ok')
    Call Exit (SUCCS)
End

```

---

## FPROT/IFPROT

FPROT/IFPROT sets or removes file protection for a file.

Form:

```
CALL FPROT (chan,dblk[,prot])  
i = IFPROT (chan,dblk[,prot])
```

where:

**chan** is the channel number to be used for the protect operation. You must obtain this channel through an IGETC call, or you can use the channel 16(decimal) or higher if you have done an ICDFN call

**dblk** is the four-word Radix-50 descriptor of the file to be operated on

**prot** 1 = protect the file  
0 = remove protection from the file

Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return
= 1	Channel is in use
= 2	File not found or not a file-structured device. To identify which condition returned the error code, issue an IDSTAT to determine if a device is file structured.
= 3	Invalid operation.
= 4	Invalid <i>prot</i> value.

Error message *TRAP \$MSARG* will display if any required argument is missing.

Example:

This example protects the file SY:RT11FB.SYS against deletion:

```
      Program FFPROT !demo FPROT  
C  
C      protect SY:RT11FB.SYS  
C  
      Parameter SUCCS = '001'o, FATAL = '010'o  
      Integer*2 DBLK(4)  
      Data DBLK /3rSY , 3rRT1, 3r1FB, 3rSYS/  
C  
      If (IFPROT (IGETC (), DBLK, 1) .ne. 0) Then  
          Call Print ('?FFPROT-F-FPROT failed')  
          Call Exit (FATAL)  
      Else  
          Call Print ('!FFPROT-I-Protected: SY:RT11FB.SYS')  
          Call Exit (SUCCS)  
      End If  
      End
```

---

## FREER/IFREER

### Mapping

FREER/IFREER detaches from a specified global region that you have attached to using the IGETR/MGETR subroutine. FREER can also eliminate that global region when you specify the type argument. FREER does not eliminate a global region that is attached to another job, but does detach the calling job from that global region.

Form:

```
CALL FREER (work[,<type>])  
i = IFREER (work[,<type>])
```

where:

**work** is a 7-word work area block. Work area specified in FREER must be the same as the IGETR work area. The first five words of the work area block contain information from the region definition block (RDB):

- A unique region identification (R.GID)
- The size of the region (R.GSIZ)
- The region status word (R.GSTS)
- The region name in two RAD50 words (R.NAME and R.NAME+2)  
The last two words in the work block area are reserved by RT-11.

**<type>** is 'e' for *eliminate*. If you do not specify the *type* argument, you detach but do not eliminate the global region.

Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return.
= -10	Memory too fragmented to return at .ELRG (-.ELRG)
= -11	Global region not found (-.ELRG)
= -18	Any .ELRG error except memory fragment (-10) and region not found (-11)
= -19	First character of <type> is invalid; not 'e'
= -20	Required argument <i>work</i> is missing

FREER can be called from MACRO-11 programs if the standard FORTRAN calling convention is followed. All register contents are destroyed across the call. FREER calls IGETC and IFREEC, which are FORTRAN-dependent routines. To use FREER in a MACRO-only program, use the IGETC and IFREEC substitutes shown in the example.

Example:

See GETR/MGETR.

---

# GCMAP/IGCMAP

## Full Mapping

GCMAP/IGCMAP returns the previous CMAP status.

Form:

```
CALL GCMAP (iold [,ierr])
ierr = IGCMAP (iold)
```

where:

**ierr**      Error return  
**iold**      Previous CMAP status

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return.
= -257	Required argument missing.

Example:

```
Subroutine FGCMAP           !Display mapping status
C
C     Display the mapping status for this job
C
C     Include 'SRC:CMPDF'       !get bit definition for GCMAP
Parameter CNFG3 = '466'o !third configuration word in fixed area
Parameter CF3SI = '100000'o !Monitor supports extended mapping
Parameter CF3HI = '040000'o !Hardware       "       "       "
C
If (IAND (ISPY (CNFG3), IOR (CF3SI, CF3HI)) .eq.
1     IOR (CF3SI, CF3HI)) Then
   Call GCMAP (ISTAT) !get status
   If (IAND (ISTAT, CMUID - CMUXX) .eq. CMUID - CMUXX)
1       Type *, 'Separated I and D in User space'
   If (IAND (ISTAT, CMJAS - CMXXS) .eq. CMJAS - CMXXS) Then
      Type *, 'Supy space enabled'
      If (IAND (ISTAT, CMSID - CMSXX) .eq. CMSID - CMSXX)
1          Type *, 'Separated I and D in Supy space'
      If (IAND (ISTAT, CMPAR) .eq. 0) Then
          Type *, 'All User and Supy Data PARS locked'
      Else
          If (IAND (ISTAT, CMPR0) .eq. CMPR0)
1            Type *, 'PAR 0 unlocked'
          If (IAND (ISTAT, CMPR1) .eq. CMPR1)
1            Type *, 'PAR 1 unlocked'
          If (IAND (ISTAT, CMPR2) .eq. CMPR2)
1            Type *, 'PAR 2 unlocked'
          If (IAND (ISTAT, CMPR3) .eq. CMPR3)
1            Type *, 'PAR 3 unlocked'
          If (IAND (ISTAT, CMPR4) .eq. CMPR4)
1            Type *, 'PAR 4 unlocked'
          If (IAND (ISTAT, CMPR5) .eq. CMPR5)
1            Type *, 'PAR 5 unlocked'
```

```

        If (IAND (ISTAT, CMPR6) .eq. CMPR6)
1          Type *, 'PAR 6 unlocked'
        If (IAND (ISTAT, CMPR7) .eq. CMPR7)
1          Type *, 'PAR 7 unlocked'
        End If
    Else
        Type *, 'Supy space disabled'
    End If
Else
    Type *, 'Monitor / hardware do not support extended mapping'
End If
Return
End
```

---

# GETR/IGETR

## Mapping

GETR/IGETR attaches to a specified global region. GETR can initialize a global region by reading a portion of a file into the global region or by calling a specified subroutine.

IGETR does not fetch handlers. Any handler required by I/O in GETR must be loaded or fetched by the program.

Form:

```
CALL GETR (arguments)
i = GETR (arguments)
(work,char,name,addr [,csize],[,offset[,msize]]
[,chan[,blk]][,file[,blk]] [,sbrtn,-1])
```

where:

- work** is a 7-word work area block. The first five words of the work area block contain information from the region definition block (RDB):
- A unique region identification (R.GID)
  - The size of the region (R.GSIZ)
  - The region status word (R.GSTS)
  - The region name in two RAD50 words (R.NAME and R.NAME+2)
  - The last two words in the work block area are reserved by RT-11.
  - The work area specified in GETR must also be the work argument specified in FREER.
- char** is a character constant specifying the type of ownership of the global region. Only the first letter of the character constant need be specified and that letter must be enclosed in single quotes ('). Specify one of the following:
- 'private'*—Program solely owns global region
  - 'shared'*—Global region available to other programs
  - 'age'*—Enables automatic global elimination
- name** is the 2-word name of the global region in six RAD50 characters
- addr** is a variable specifying the global region's base address. The base address must begin on a PAR boundary (4K-word multiples beginning at 000000)

- csize** is the size of the global region you want to create, expressed in words. If you specify *csize* as zero or omit it, the actual global region size is used. Specifying zero for *csize* is invalid unless the global region already exists
- offset** is the offset from the beginning of the global region, expressed in units. A unit is 64(decimal) bytes. The offset is the number of units you skip before mapping begins. If you specify *offset* as zero or omit it, you begin mapping at the beginning of the global region
- msize** is the number of words you wanted mapped to the global region. If you specify *msize* as zero or omit it, you map the whole global region
- chan** is a channel opened on a file from which to read initialization data. When specifying *chan*, the argument value must be from 0 through 255(decimal), and the *blk* argument cannot be -1
- file** is a pointer to a 4-word data block. The last three words contain a device and file specification for a file containing initialization data to open and read. If the device specification is valid, the first word contains a value greater than 255(decimal)  
The value in the *blk* argument must be -1.
- sbrtn** is the name of a subroutine that initializes the global region. The *addr* and *msize* arguments are passed to that subroutine  
The value in the *blk* argument must be -1.
- blk** is the number of the first block to use in the file that initializes the global region. Specify a zero value in this argument to load from the beginning of the file  
The value must be -1 if *blk* is coupled with the *sbrtn* argument.

The *work*, *name*, *addr*, *csize*, *offset*, *msize*, *chan*, *file*, and *blk* arguments are INTEGER\*2 values. The *sbrtn* argument is EXTERNAL type.

IGETR can be called from MACRO-11 programs, if the standard FORTRAN calling convention is followed. All register contents are destroyed across the call. GETR calls IGETC and IFREEC, which are FORTRAN-dependent routines. To use IGETR in a MACRO-only program, use the following IGETC and IFREEC substitutes:

Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return (success).
= -1	Invalid <i>addr</i> alignment (detected by IGETR).
= -2	No window definition block for .CRAW.
= -3	Any .CRAW error except no window definition block (-2).
= -4	End-of-file on .READW.

## GETR/IGETR

= -5	I/O error on .READW.
= -6	Channel closed when .READW attempted; channel not available from IGETR.
= -7	No region control block for .CRRG.
= -8	Insufficient memory for .CRRG.
= -9	Reserved.
= -10	Memory too fragmented to return at .ELRG.
= -11	Global region not found (and no nonzero size specified).
= -12	No global region control block for .CRRG.
= -13	Reserved.
= -14	Reserved.
= -15	.LOOKUP found channel already open.
= -16	.LOOKUP could not find requested file.
= -17	.LOOKUP found device in use and not shareable.
= -18	Any .ELRG error except memory too fragmented (-10).
= -19	First character of char argument invalid (not 'p', 's', or 'a').
= -20	Required argument missing: <i>work, char, name, or addr</i> .

IGETR returns the following errors if the .SERR programmed request is in effect:

<b>Value</b>	<b>Meaning</b>
i = -129	Called USR from completion routine.
= -130	No device handler; this operation needs one.
= -131	Error doing directory I/O.
= -132	.FETCH error. An I/O error occurred while the handler was being used or an attempt was made to load the handler over USR or RMON.
= -133	Error reading an overlay.
= -134	No more room for files in the directory.
= -135	Reserved.
= -136	Invalid channel number. Number is greater than number of channels that exist.
= -137	Invalid EMT, an invalid function code has been decoded.
= -138	Reserved.
= -139	Reserved.
= -140	Invalid directory.

= -141      Unloaded XM handler.  
= -142      Reserved.  
through -146

---

## GFDAT/IGFDAT

GFDAT/IGFDAT returns the file creation date from a file's directory entry (E.DATE word). GFDAT is not supported for the distributed special directory handlers LP, LS, MM, MS, MT, MU, and SP.

Form:

```
CALL GFDAT (chan,dblk,idate)
i = IGFDAT (chan,dblk,idate)
```

<b>chan</b>	is a BYTE or INTEGER*2 channel number
<b>dblk</b>	is a 4-element INTEGER*2 array containing a 4-word device and file specification in Radix-50; the file specification for which you want to return the creation date
<b>idate</b>	on return, contains the requested INTEGER*2 creation date of the specified file

Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return
= -1	Channel was open
= -2	File not found, or not a file-structured device. To determine what condition returned the error code, issue a .DSTAT request to determine if a device is file structured
= -3	Invalid operation (internal error)
= -4	Invalid offset (internal error)
= -257	Required argument missing

Example:

See IDCOMP.

---

## GFINF/IGFINF

GFINF/IGFINF returns the word contents of the directory entry offset you specify from a file's directory entry. GFINF is not supported for the distributed special directory handlers LP, LS, MM, MS, MT, MU, and SP.

Form:

```
CALL GFINF (chan,dblk,offset,ival)
i = IGFINF (chan,dblk,offset,ival)
```

where:

- chan** is a BYTE or INTEGER\*2 channel number
- dblk** is a 4-element INTEGER\*2 array containing a 4-word device and file specification in Radix-50; the file specification for which you want to return directory entry information
- offset** is the octal byte offset for the directory entry word you want. The offset must be even. For example, specifying offset 12 returns the contents of E.USED in *ival*
- ival** on return, contains the requested INTEGER\*2 directory entry word

Function Result:

Value	Meaning
i = 0	Normal return
= -1	Channel was open
= -2	File not found, or not a file-structured device. (If it is necessary to determine what condition returned the error code, issue a .DSTAT request to determine if a device is file structured.)
= -3	Invalid operation (internal error)
= -4	Invalid offset
= -257	Required argument missing

Example:

```
Program FGFINF !demo GFINF
C
C Display the file "time",using the contents of offset 10(10)
C of the directory entry. This is treated as units of seconds
C after midnight / 3.
C
Parameter FATAL = '010'o
Integer*2 CHAN !Channel number
Integer*2 FILSPC(39) !DBLK(s)
Integer*2 DEFTYP(4) !default extensions
Data DEFTYP /4*0/ !none
Integer*2 DBLK(4) !DBLK
Integer*2 ERROR !error/success value
```

## GFINF/IGFINF

```
Integer*2 TIME           !time word value
Integer*2 HOUR           !hour part
Integer*2 MINUTE         !minute part
Integer*2 SECOND         !second part
Equivalence (FILSPC(16), DBLK(1)) !use 1st input file only

C
CHAN = IGETC ()
1000 Continue
    Call PRINT (' ') !clean up display
    ERROR = ICSI (FILSPC, DEFTYP, , ,0) !get filename
    If (ERROR .ne. 0) Go To 2000 !command error
    ERROR = IFETCH (DBLK) !fetch handler
    If (ERROR .ne. 0) Go To 2100 !fetch error
    ERROR = IGFINF (CHAN, DBLK, 10, TIME) !get "time" word
    If (ERROR .eq. -2) Then
        Type *, 'File not found '
        Go To 1000 !try again
    End If
    If (Error .ne. 0) Go To 2200 !gfinf error
    HOUR = TIME / (60 * (60 / 3)) !expressed in 3 sec units
    TIME = MOD (TIME, (60 * (60 / 3))) !dump hours part
    MINUTE = TIME / (60 / 3)
    TIME = MOD (TIME, (60 / 3)) !dump minutes part
    SECOND = TIME * 3 !back to real seconds
    Type 1, HOUR, MINUTE, SECOND
1 Format (' ', I3.2, ':', I2.2, ':', I2.2)
    Go To 1000
2000 Type *, 'CSI error'
    Go To 3000
2100 Type *, 'Fetch error'
    Go To 3000
2200 Type *, 'Gfinf error'
3000 Call Exit (FATAL)
    End
```

---

## GFSTA/IGFSTA

GFSTA/IGFSTA returns the word contents of the directory entry status word (E.STAT) from a file's directory entry. GFSTA is not supported for the distributed special directory handlers LP, LS, MM, MS, MT, MU, and SP.

Form:

```
CALL GFSTA (chan,dblk,istat)
i = IGFSTA (chan,dblk,istat)
```

where:

**chan** is a BYTE or INTEGER\*2 channel number

**dblk** is a 4-element INTEGER\*2 array containing a 4-word device and file specification in Radix-50; the file specification for which you want to return directory entry status word

**istat** on return, contains the requested INTEGER\*2 directory entry status word

Errors:

Value	Meaning
i = 0	Normal return
= -1	Channel was open
= -2	File not found, or not a file-structured device. (If it is necessary to determine what condition returned the error code, issue a .DSTAT request to determine if a device is file structured.)
= -3	Invalid operation (internal error)
= -4	Invalid offset (internal error)
= -257	Required argument missing

Example:

(See also GFDAT example.)

```
Program FGFSTA
C
C This program displays the directory
C entry status word contents for the selected file.
C Entries with "?" appended are values that are not expected.
C
Parameter FATAL = '010'o
Integer*2 CHAN !Channel to use
Integer*2 FILSPC(39) !DBLK(s)
Integer*2 DEFTYP(4) !default extensions
Data DEFTYP /4*0/ !no defaults
Integer*2 DBLK(4) !DBLK
Integer*2 ERROR !error/success value
Integer*2 STATUS !status word value
Integer*2 BIT !sliding bit mask
```

## GFSTA/IGFSTA

```
Character*7 BITNAM(0:15)!names for status word bits
Data BITNAM(0) //'000001?'/, BITNAM(1) //'000002?'/
Data BITNAM(2) //'000004?'/, BITNAM(3) //'000010?'/

2300 Call Print ('?FGFSTA-F-GFSTA failed')
3000 Call Exit (FATAL)
End
```

---

## GICLOS/GIOPEN/GIREAD/GIWRT (GIDIS)

GIDIS consists of four FORTRAN system subroutines that can be used on the Professional Series only, instead of using the .SPFUN programmed requests:

GICLOS  
GIOPEN  
GIREAD  
GIWRT

Each GIDIS subroutine can return error information in a 2-word status array. Relevant error codes are listed with each subroutine. See GIDIS error codes description and sample GIDIS program.

### GICLOS

The GICLOS subroutine ends the GIDIS connection to the Professional interface (PI) handler. The output device treats a GICLOS subroutine as an END-PICTURE instruction. Control is returned to the calling program once all data specified by the GIWRT subroutine has been sent to the output device.

Form:

**GICLOS (status,lun)**

where:

- status** is a 2-word integer array used to return a code indicating the results of the requested operation
- lun** is the unit number assigned by GIOPEN to terminate. If no GIOPEN has been sent for the specified value, *status* is set to (-5,-1)

Errors:

See GIDIS error codes.

Example:

See sample GIDIS program.

### GIOPEN

The GIOPEN subroutine initiates contact with the Professional interface (PI) handler and assigns a logical unit number (LUN) for this GIDIS operation. GIOPEN does not affect the current GIDIS state; all attributes currently selected remain in force.

To initialize the Professional video screen, execute the INITIALIZE -1 (complete initialization) instruction followed by the NEW\_PICTURE instruction.

Form:

**GIOPEN (status,lun[,message][,msglen][,devtype][,driver])**

## GICLOS/GIOPEN/GIREAD/GIWRIT (GIDIS)

where:

- status** is a 2-word integer array to return a code indicating the results of the requested operation
- lun** is the unit number to associate with this GIOPEN; an integer number from 0 through 15  
If *lun* is already connected to a GIDIS operation, *status* is set to (-5,-4)
- message** is a word containing a 0
- msglen** is the number of words in the message; normally a 1. If *msglen* is less than 0 or greater than 128(decimal) words, *status* is set to (-5,-3)
- devtype** is 6. Integer values 0 through 5, 7, and 8 are reserved
- driver** is 0

Errors:

See GIDIS error codes.

Example:

See sample GIDIS program.

### GIREAD

The GIREAD subroutine returns a report from GIDIS requested by a report handling instruction sent by GIWRIT. GIREAD waits until GIDIS returns a report, then places the report in the buffer. If the report is longer than the buffer, the excess is lost. If the report is shorter than the buffer, the trailing words of the buffer are left unchanged. The first byte of the report contains the number of data words in the report.

Form:

**GIREAD (status,lun,buffer,buflen)**

where:

- status** is a 2-word integer array used to return a code indicating the results of the requested operation
- lun** is the unit number assigned by GIOPEN. If no GIOPEN has been issued for the specified value, *status* is set to (-5,-1)
- buffer** is the buffer for the report returned by GIDIS
- buflen** is the number of words in the report buffer

Errors:

See GIDIS error codes.

Example:

See sample GIDIS program.

### GIWRIT

The GIWRIT subroutine sends the buffer of GIDIS command data to the Professional interface (PI) handler. You can pass a maximum of 2048(decimal) words to PI in one

## GICLOS/GIOPEN/GIREAD/GIWRIT (GIDIS)

GIWRIT system subroutine. The data in the buffer need not start or end on a command boundary.

Form:

**GIWRIT (status,lun,message,msglen)**

where:

- status** is a 2-word integer array used to return a code indicating the results of the requested operation
- lun** is the unit number assigned by GIOPEN. If no GIOPEN has been executed for the specified value, status is set to (-5,-1)
- message** is the command data to send
- msglen** is the number of words in the message.  
The *msglen* parameter accepts a value equal to or greater than -1. Specify the -1 value for *msglen* to reset GIDIS. If less than 0 or greater than 2048(decimal) words, status is set to (-5,-3)

Errors:

See GIDIS error codes.

Example:

See sample GIDIS program.

### GIDIS Error Codes

GIDIS subroutines can return the following error codes and subcodes in the 2-word status array. The error code specifies the class of error and is returned in the first word of the status array. The subcode specifies the actual error and is returned in the second word of the status array.

Directive error code (-1) can return the following subcode:

- 1 No handler. The output device handler is not loaded.

Interface error code (-5) can return the following subcodes:

- 1 Channel not open. The logical unit number (LUN) for that GIDIS is not assigned.
- 2 DEVTYPE is out of range or invalid. The output device specified in a GIOPEN is invalid.
- 3 MSGLEN out of range. The message length in a GIOPEN or GIWRIT is out of range.
- 4 Channel in use. The logical unit number (LUN) specified for that GIDIS is already in use.

## GICLOS/GIOPEN/GIREAD/GIWRT (GIDIS)

RT-11 specific error code (-7) can return the following subcodes during a GIDIS operation:

- 1 Required argument missing. A required argument in a GIDIS subroutine is not specified.
- 2 Handler not loaded. The output device handler is not loaded.
- 3 File not found. The indicated file was not found on the device.
- 4 File open on nonshareable or non-file-structured device.
- 5 An attempt was made to read or write past the end-of-file (EOF) mark.
- 6 Hard error. The GIDIS operation experienced a hard error on the output device.

Errors that occur if .SERR is in effect are listed under the .SERR request in the *RT-11 System Macro Library Manual*.

## GICLOS/GIOPEN/GIREAD/GIWRT (GIDIS)

### Sample GIDIS Program

The following FORTRAN program fragment uses the GIDIS subroutines to request the current cursor position:

```

      Program FGIDCA !demo GIDIS interface routines
C
C      Declare storage
C
      Integer*2 BUFLen, LUN, MSGLEN, OCLen, OPCODE
      Integer*2 BUFFER(3), MESSAG(1), STATUS(2)
C
C      user program here
C
      LUN = 5          !assign logical unit number
      OPCODE = 55*256 !request current position
      OCLen = 0       !opcode length is 0
C
C      Put OPCODE and OCLen into MESSAG buffer
C
      MESSAG(1) = OPCODE + OCLen
      MSGLEN = 1     !length of message
C
C      Send to GIDIS
C
      Call GIWRT (STATUS, LUN, MESSAG, MSGLEN)
      If (STATUS(1) .le. 0) Go To 999 ! error
C
      BUFLen = 3     !length of report
C
C      Get report from GIDIS
C
      Call GIREAD (STATUS, LUN, BUFFER, BUFLen)
      If (STATUS(1) .le. 0) Go To 999 ! error
C
C      Contents of buffer after successful return:
C
      BUFFER(1) = 258 ((1*256) + 2)
      1 = report header
      2 = number of data elements in buffer
C
      BUFFER(2) = Current 'X' position
      BUFFER(3) = Current 'Y' position
C
C      more user program
C
999  Continue          !diagnose errors here
      End
```

---

## GMCX/IGMCX

### Mapping

GMCX/IGMCX (get mapping context) returns the mapping status of an extended memory window. Status is returned in the window definition block.

Form:

```
CALL GMCX (iwdb [,ierr])
i = GMCX (iwdb)
```

where:

<b>ierr</b>	Error return
<b>iwdb</b>	Address of Window Definition Block

Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return.
= -5	Invalid window identifier specified.
= -257	Required argument missing.

Example:  
See CRAW.

---

## GTDIR/IGTDIR

GTDIR/IGTDIR (get directory) sets up parameters for a wildcard directory search operation on an RT-11 file-structured volume or logical disk file. Subsequent calls to the IGTENT function retrieve the directory entries that meet the criteria specified in GTDIR. GTDIR performs no searches itself and should be followed by calls to the IGTENT function.

GTDIR works outside of the USR. If you call GTDIR in a multijob monitor environment, you may want to explicitly lock the USR by calling the .LOCK and .UNLOCK routines. Locking the USR prevents alteration of the directory being searched.

Along with the required parameters, GTDIR supports numerous optional parameters that determine the criteria used for the directory search. Both required and optional parameter information are stored in the work area and buffer (after error checking is performed), and IGTENT then uses that information for the directory search.

If any optional parameter is specified, then any prior parameter not included in the function call must be marked with a comma pair ( , ) to show the position of that parameter.

Form:

```
CALL GTDIR (arguments)
i = IGTDIR (arguments)
      (wksize,wkarea,chan,buffer[,header][,dblk][,string]
      [,stvalu][,stmask][,datrel][,datewd][,resrv1]
      [,resrv2][,stofst])
```

where:

- wksize** is a 1-word INTEGER\*2 variable containing the value 64
- wkarea** is a 64-word INTEGER\*2 work area array
- chan** is a 1-word INTEGER\*2 variable. The meaning of *chan* is determined by the value specified for *chan* and the contents of the *dblk* parameter:
- If the first word of *dblk* is specified as nonzero and *chan* is specified as 0 through 255, then *chan* is an RT-11 channel, and *dblk* is a device or file on which to perform the operation.
  - If the first word of *dblk* is specified as zero and *chan* is specified as 0 through 255, then *chan* is an RT-11 channel which has been previously opened by a lookup operation. The IGTDIR function is then directed to the device already opened on the specified channel.

## GTDIR/IGTDIR

- If *dblk* is not specified or is specified as zero and *chan* is specified as a value greater than 255, then *chan* is the address of an externally supplied MACRO-11 read routine. Such an external read routine could be written to provide RT-11 directory segments to IGTDIR in an unconventional manner. The entry environment of the external read routine is:

R1 = <buffer address>

R2 = <word count>

R3 = <block number>

**buffer** is a 512-word INTEGER\*2 array used by GTDIR and IGTENT to contain directory segments

**header** is a 5-word INTEGER\*2 array that, on return, contains the directory segment header

**dblk** is a 4-word INTEGER\*2 array that can be defined in one of the three ways, depending on the value of the first word:

- Word one contains a Radix-50 device specification for the device containing the directory to be searched. Words two, three, and four contain zero.
- Word one contains a Radix-50 device and file specification for a logical disk (.DSK) containing the directory to be searched.
- Word one contains the value 0, specifying a special mode operation. Specifying a special mode operation indicates that a channel is already open on the device you want to search. Therefore, an internal lookup operation is not performed; a device is already open on *chan*.
- Word two must contain the starting block number for the device directory.
- Word three of the array controls which entries are returned by IGTENT:

- If the third word in the array contains the value 0, IGTENT returns only those entries that match the specified GTDIR criteria.
- If the third word in the array contains the value 1, IGTENT returns all entries, governed only by the setting of the status characteristics bits in E.STAT. In this mode, entries returned that do not match the wildcard string are indicated by IGTENT returning the function result -20.

- Word four should contain the value zero and is reserved for Digital.

If *dbl* is not specified, see *chan*.

- string** is a string of up to eight ASCII RT-11 file specifications, separated by commas (.). Device specifications are not allowed. Each file specification can contain trailing blanks in either or both the name and extension fields. Each file name and extension must be separated by a period (.). Each file specification can contain general replacement wildcards (\*) or single-character wildcards (%) in either or both the file name and extension. If either or both the file name or extension is left blank, it is treated as a general replacement wildcard.
- stvalu** is an INTEGER\*2 value specifying bit values for the directory entry status (E.STAT) characteristics that apply to the directory search. The default is E.PERM (002000); only permanent files are returned.
- stmask** is an INTEGER\*2 variable that contains the bit mask of the directory entry status (E.STAT) bits that are tested against the value specified in *stvalu*. By default, *stmask* checks the values for the E.PERM, E.TENT, and E.MPTY bits in E.STAT.

## GTDIR/IGTDIR

**datrel** is a 2-byte character string that specifies a code to be used in a date relationship directory search. The relationship is between an RT-11 date word you supply for *datewd* and directory entry dates. The default for *datrel* is 'EQ' if *datewd* is specified, or 'AL' if *datewd* is not specified. The following are valid codes:

<b>Value</b>	<b>Meaning</b>
'EQ'	Equal
'NE'	Not equal
'LE'	Less than or equal to
'LT'	Less than
'GE'	Greater than or equal to
'GT'	Greater than
'AL'	All dates

**datewd** is an INTEGER\*2 variable specifying the RT-11 date word to check against directory entry dates.

The default for *datewd* is the current RT-11 system date if *datrel* is specified and all dates if *datrel* is not specified. The format of the RT-11 date word is:

<b>Bits</b>	<b>Contents</b>
0-4	Year minus the base (base specified by bits 14,15)
5-9	Day (1-31)
10-13	Month (1-12)
14,15	Age bits. Age bits extend the directory date by 32(decimal) year increments and have the following meaning:

15	14	Meaning When Set
0	0	Base year 1972
0	1	Base year 2004
1	0	Base year 2036
1	1	Base year 2068

**resrv1** is reserved for Digital  
**resrv2** is reserved for Digital  
**stofst** is a rarely used INTEGER\*2 variable that specifies a starting offset from which to begin the directory search.

The value for *stofst* can be supplied from the IGTENT parameter *entofs* value. The *stofst* parameter lets you begin a directory search at the point where you previously stopped searching the directory.

The *stofst* parameter is especially useful when GTDIR/GTENT have previously performed a directory search through to a particular segment of a device directory. IGTENT can return a value representing the current directory search position in parameter *entofs*. In a subsequent search through the directory, specify the *entofs* value from the previous search in the GTDIR parameter *stofst*, to begin the search in the directory at that offset.

**i** is a returned INTEGER\*2 result of function

#### Errors:

Value	Meaning
i = 0	Success
= -1	Channel in use
= -2	File not found
= -3	Directory already open
= -5	Invalid directory structure
= -7	Error reading directory segment
= -12	Invalid device for operation
= -13	Invalid date relationship code
= -16	Supplied work area is inadequate
= -19	Invalid arguments

#### Example:

```

Program FGTDIR
C
C Display file(s) on SY:
C
Parameter ERRO R= '010'o
Integer*2 WKAREA(64) !area for IGTDIR/IGTENT
Integer*2 ENTRY(7) !single directory entry
Integer*2 BUFFER(512) !directory buffer
Integer*2 DBLK(4) !Device/file to search
Integer*2 BLOCK2
Integer*4 BLOCK !really unsigned 16 bit
Byte NAME(11) !file name
Byte DATSTR(11) !date in ascii

```

## GTDIR/IGTDIR

```
Byte STRING(81)          !filespec(s) w/o device
Byte Prompt(8)           !command prompt
Data Prompt /'F', 'i', 'l', 'e', 's', '?', ' ', ' ', '200'o/
Data DBLK /3rSY , 3*0/   !system device
Data BLOCK /0/
Equivalence (BLOCK2, BLOCK)

C
  ICHAN = IGETC ( )
1000  Continue
      Call RCTRL0          !reset ^O
      Type *, ' '         !blank line
      Call GTLIN (STRING, PROMPT) !get filespec(s)
      IERR = IGTDIR (64, WKAREA, ICHAN, BUFFER, , DBLK, STRING)
      If (IERR .ne. 0) Go To 2000
1100  IERR = IGTENT (WKAREA, ENTRY, , BLOCK2, NAME)
      If (IERR .lt. 0) Go To 1000
      Call DATE4Y (DATSTR, ENTRY(7))
      Type 1, (NAME(I), I = 1, 10), ENTRY(5), DATSTR, BLOCK
1    Format (' ', 10a1, ' ', i6, ' ', 11a1, ' ', i6)
      Go To 1100
2000  Call Print ('?FGTDIR-F-GTDIR failed')
      Call Exit (FATAL)
      End
```

---

## GTDUS/IGTDUS

GTDUS/IGTDUS provides information about a specified MSCP (DU) or TMSCP (MU) class device unit. Issue the IGTDUS function only to MSCP or TMSCP class devices.

Information returned by IGTDUS includes:

- Whether the device unit is offline, available, or online.
- Whether the device media is removable (for example, the RC25).
- Whether the device unit is write-protected.
- Whether the device controller supports bad block replacement (MSCP only).
- The number of physical addressable blocks in the device unit (MSCP only).

The MSCP volume size returned by IGTDUS is determined by which partition, if any, the unit number is mapped to when you issue IGTDUS. If you issue IGTDUS against the RT-11 unit that is partition zero of the device, it returns the entire volume size. If the unit number is mapped to a particular partition, IGTDUS returns the volume size from the base of that partition to the end of the volume. This change in IGTDUS functionality makes the information it returns more usable with, for example, the JWRITE subroutine.

- The media name, such as RC25, RCF25, RA60, RA80, RA81, RD31, RD32, RD51, RD52, RD53, RD54, RX33, RX50, TK50, or TU81.

Form:

```
CALL GTDUS (dev,ichan,ibuf[,iunit][,itype][,iwork][,isize])
i = IGTDUS (dev,ichan,ibuf[,iunit][,itype][,iwork][,isize])
```

where:

**dev** is the Radix-50 device name (MSCP or TMSCP class devices only)

**ichan** is the integer specification for an RT-11 channel to be opened by IGTDUS

**ibuf** is a 7-word buffer containing status information returned by IGTDUS. The information returned by IGTDUS in the status buffer includes:

ibuf(1) is the status information word. The following values can be returned in the status information word:

Value	Meaning
0	The device unit is online
1	The device unit is available

2 The device unit is offline

ibuf(2) is the unit bit flag word. One or more of the following values can be returned in the unit flag word:

Value	Meaning
200	Media is removable (always set for TMSCP devices)
20000	Media is write-protected
100000	MSCP device controller supports bad-block replacement (never set for TMSCP devices)

{ ibuf(3) }  
{ ibuf(4) }

For MSCP, a unit-size word is returned as a 28-bit value (16 bits in ibuf(3) and 12 bits in ibuf(4)), containing the size of the volume minus the base of the current partitions.

For TMSCP, the size words are undefined and each contains the value -1

{ ibuf(5) }  
{ ibuf(6) }  
{ ibuf(7) }

Is the media device name in a fixed format 5-byte alphanumeric ASCII string, typically consisting of two characters followed by a space, two numbers, and a null byte. Sometimes the string contains three characters, such as for the RCF25, but is always terminated with a null byte.

**iunit** is the unit number requested. The meaning of *iunit* is determined by *itype*:

- If the *itype* parameter is 'RT11', *iunit* is optional and is the RT-11 unit number. The valid range is 0 through 77<sub>8</sub>. If the unit number is higher than 27<sub>8</sub>, include the *isize* parameter along with the *iwork* parameter to allocate a sufficient work area. If *iunit* is not specified, the default unit is that specified in the *dev* parameter.
- If the *itype* parameter is 'MSCP', *iunit* is required and is the decimal MSCP physical unit number. The valid range is 0 through 255.

- itype** is the type of unit number requested; a character constant specified as 'RT11' (the default) or 'MSCP':
- |        |  |
|--------|--|
| 'RT11' | Supports TMSCP and MSCP devices.   |
| 'MSCP' | Supports TMSCP and MSCP devices and requires the unit parameter. If MSCP is specified, <i>iunit</i> is required. |
- iwork** is a recommended work area used internally by IGTDUS. If you do not define a work area, IGTDUS takes 80 words from the processor stack area. Allow for that when planning stack allocation to avoid stack overflow.
- If the DU handler does not support extended device units, you can specify a work area of 80 words and you can omit the *isize* parameter. You should specify at least a 160-word work area for *iwork*, and include the *isize* parameter if all the following are true:
- The DU handler has been built to support extended device units
  - The *itype* parameter is specified as *RT-11*
  - The device unit number, *iunit*, is higher than  $27_8$
- isize** specifies the work area size, together with *iwork*, when the DU handler has been built to support extended device units, the *itype* parameter is *RT-11*, and the device unit number is higher than  $27_{\text{octal}}$ . The value supplied for *isize* should be the same as that used to declare *iwork*.

Use the IGTDUS function to determine the unit size before issuing the JREAD and JWRITE functions to MSCP devices or anytime you need status information concerning an MSCP or TMSCP device.

IGTDUS implicitly enables .SERR error condition handling while performing the channel lookup operation for the specified MSCP or TMSCP device. Any errors reported during the lookup operation are returned by IGTDUS. After the lookup operation completes, IGTDUS returns error condition handling to any that was previously enabled. Error condition handling by ISERR or IHERR other than during the IGTDUS lookup operation must be explicitly enabled in the program.

Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return
= 1	Logic error. Retry the operation. If the error persists, submit an SPR to Digital.

## GTDUS/IGTDUS

- = 2 Logic error. Retry the operation. If the error persists, submit an SPR to Digital.
- = 3 Logic error. Retry the operation. If the error persists, submit an SPR to Digital.
- = 4 Attempt to read or write past end-of-file or invalid function value
- = 5 Hard error occurred on channel
- = 6 Channel is not open
- = 7 Work area is inadequate; specify at least 160 words for *isize* and *iwork* parameters
- 8-12 Reserved
- = 13 Handler is not loaded
- = 14 Handler is not installed
- = 15 Channel is already in use
- = 16 Logic error (.LOOKUP code 1)
- = 17 Channel already open on a nonshareable device
- = 18 Device does not support MSCP or TMSCP. Inappropriate device for IGTDUS function
- = 19 First character of type argument is not an 'M' or 'R'
- = 20 Logic error (.LOOKUP code 5)
- = 21 Invalid unit
- = 22 Reserved
- = 23 Required argument missing: *dev*, *ichan*, or *ibuf* arguments

Other error codes can be returned by IGTDUS since the ISERR function is in effect. See ISERR in this chapter.

Example:

```
Program FGTDUS !demo GTDUS
C
C Display the (T)MSCP status for the devices listed in
C the DEV array if they are on the system.
C
Integer*2 DEV(9) !devices to check
Integer*2 IBUF(7) !status info returned
Integer*2 IWORK(160) !work area
Character*8 STATUS(0:2) !status strings
Character*3 ANAME !device name in ascii
Byte DTYPE(5) !device type
Equivalence (DTYPE, IBUF(5))
Data DEV /3rDU0, 3rDU1, 3rDU2, 3rDU3,
1 3rDU4, 3rDU5, 3rDU6, 3rDU7, 3rMU0/
Data STATUS /'ONLINE', 'AVAILBL', 'OFFLINE'/
```

```

C
  ICHAN = IGETC ()
  DO 1000, I = 1, 9          !try each device
    Call R50ASC (3, DEV(I), ANAME) !get ascii name
    IERR = IFETCH (DEV(I)) !get handler
    If (IERR .eq. 0) Then
      IERR = IGTDUS (DEV(I), ICHAN, IBUF, , , IWORK, 160)
      If (IERR .eq. 0) Then
        Type 2, ANAME, STATUS(IBUF(1)), DTYPE, (IBUF(J), J=2,4)
        Format (' ', 1a3, ': Status=', 1a8, ', Type=" ', 5a1,
1          '" , IBUF(2--4)=' , 3(o6, ' '))
        Else
          Type *, '?FGTDUS-W-GTDUS failed for ', ANAME, ' with', IERR
        End If
      Else
        Type *, '?FGTDUS-W-Fetch failed for ', ANAME
        End If
1000    Continue
  End

```

---

## GTIM

The GTIM subroutine returns the current time of day. The time is returned in two words and is given in terms of clock ticks past midnight. If the system does not have a line clock, a value of 0 is returned. If an RT-11 monitor TIME command has not been entered, the value returned is the time elapsed since the system was bootstrapped, rather than the time of day.

Form:

**CALL GTIM (itime)**

where:

**itime** is the two-word area to receive the time of day

The high-order time is returned in the first word, the low-order time in the second word. The CVTTIM routine can be used to convert the time into hours, minutes, seconds, and ticks. CVTTIM performs the conversion based on the monitor configuration word for 50- or 60-Hz clocks. Under all monitors, except for SB, the time-of-day is automatically reset after 24:00; under the SB monitor it is not.

Errors:

Error message *TRAP \$MSARG* will display if *itime* argument is missing.

Example:

See CVTTIM.

---

## GTJB/IGTJB

GTJB/IGTJB returns information about a job in the system.

Form:

```
CALL GTJB (addr[,jobblk[,ierr]])  
ierr = IGTJB (addr[,jobblk])
```

where:

<b>addr</b>	is the address of an eight-word or twelve-word block into which the parameters are passed.
<b>jobblk</b>	is a pointer to a three-word ASCII logical job name for which data is being requested: 0–16: Job number for which information is desired -1 or 'ME': Information is passed about issuing job -3: Address of 3-word ASCII job name for which data is desired
<b>ierr</b>	is an error return if the job is not running

The values returned are:

<b>Word 1</b>	Job Number = priority level *2 (background job is 0; system jobs are 2, 4, 6, 8, 10, 12; and foreground job is 14 in system job monitors; background job is 0 and foreground job is 2 in non-system job monitors; job number is 0 in all but SB monitor)
<b>Word 2</b>	High-memory limit
<b>Word 3</b>	Low-memory limit
<b>Word 4</b>	Start of channel area
<b>Word 5</b>	Pointer to impure area
<b>Word 6</b>	Low byte: unit number of job's console terminal (used only with multiterminal option; 0 when multiterminal feature is not used)
<b>Word 7</b>	Virtual high limit for a job created with the linker /V option (mapped monitors; 0 in unmapped monitors and where the Linker /V option is not used.)
<b>Word 8-9</b>	Reserved for future use
<b>Word 10-12</b>	ASCII logical job name (system job monitors only)

If one argument is used with the call, only the first eight words will be returned. For example,

Form:

```
INTEGER IJPARM(8)  
CALL GTJB (IJPARM)  
ierr = IGTJB (IJPARM)
```

## GTJB/IGTJB

At least a comma must follow the argument to pass the information into a 12-word block. For example,

Form:

```
INTEGER IJPARM(12)
CALL GTJB (IJPARM ,)
I = IGTJB (IJPARM ,)
```

Errors:

Value	Meaning
-------	---------

i = 0	Normal return.
=-1	No such job is currently running.

Error message *TRAP \$MSARG* will display if *addr* argument is missing.

Example:

```
          Program FGTJB    !Demo GTJB routine
C
C          Get information about this job
C
          Parameter SUCCS = '001'o
          Parameter FATAL = '010'o
          Integer*2 REPLY(12)
C
          REPLY(10) = '*N'           !assume no job name
          REPLY(11) = 'ON'
          REPLY(12) = 'E*'
          If (IGTJB (REPLY, -1) .ne. 0) Go To 1000
          Type *, 'Job Number =', REPLY(1)
          Type 100, REPLY(4)
100       Format (' ', 'Addr I/O control blocks =', o8)
          Type 110, REPLY(5)
110       Format (' ', 'Addr impure area =', o8)
          Type 120, REPLY(10), REPLY(11), REPLY(12)
120       Format (' ', 'Job name = ', 3a2)
          Call Exit (SUCCS)
1000      Continue
          Type *, '?FGTJB-F-Request failed'
          Call Exit (FATAL)
          End
```

---

## GTLIN/IGTLIN

GTLIN/IGTLIN can transfer a line of input to your program from the terminal or from an active indirect file.

You can force GTLIN to accept input only from the terminal, even if the program is running under the control of an indirect file.

This subroutine requires the USR. The maximum size of the input line is 80 characters. See the .GTLIN programmed request for setting bits in the job status word (JSW) to pass lowercase letters and establish a nonterminating condition.

Form:

```
CALL GTLIN (result[,prompt][,term]
            [,plain])
i = IGTLIN (result[,prompt][,term]
           [,plain])
```

where:

- result** is the array receiving the string. This LOGICAL\*1 array contains a maximum of 80 characters plus 0 as the end indicator and therefore must be dimensioned to at least 81 elements
- prompt** is a BYTE array containing an optional prompt string to be printed before the input line is received. The string format is the same as that used by the PRINT subroutine. If this argument is not present, no prompt is printed
- term** is a string constant specified when you want to take input only from the console terminal, even if the program is running under the control of an indirect command file. Use the 'term' argument when direct response from the program user is required. You need specify only the first character ('t'); case is unimportant
- plain** is a string constant specified when you want to take unaltered input and pass that input to the array specified by the GTLIN result argument. You must specify the 'plain' argument to prevent the operating system from reversing the arguments in the command line. The *plain* argument is helpful when a program requires command input that is not a file specification, such as a SETUP command. You need specify only the first character ('p'); case is unimportant

GTLIN with the *plain* argument, checks the word in location 510 in the chain area for a byte count higher than 1.

- If location 510 does not contain a byte count higher than 1, GTLIN functions as though the 'plain' argument was not specified.
- If location 510 contains a word count higher than 1, GTLIN copies the ASCIZ string, beginning at location 512, into the result argument as specified in the GTLIN call. GTLIN then clears location 510.

## GTLIN/IGTLIN

- GTLIN then takes the input (converted by KMON) from the KMON buffer, thereby purging the buffer. Then GTLIN places the input from the KMON buffer into the chain area, beginning at location 512.

At the completion of the GTLIN call:

- The program has the unaltered input.
- Location 510 is clear.
- The KMON buffer is clear.

### Notes

To avoid possible problems, Digital recommends that the GTLIN subroutine with the *plain* argument not be used in a program that uses the .CSIGEN and .CSISPC requests or the GTLIN subroutine without the *plain* argument.

GTLIN can be called from MACRO-11 programs if the standard FORTRAN calling convention is followed. All register contents are destroyed across the call. GTLIN has no dependencies on FORTRAN code or routines.

Errors:

Value	Meaning
-------	---------

i = 0	Success.
= -1	Line too long.

Error message *TRAP \$MSARG* will display if *result* argument is missing.

Example:

```
C
C      Get input without file (CCL) processing
C
      Byte INPUT(81)
      Byte PROMPT(6)
      Data PROMPT /'N', 'a', 'm', 'e', '?', "200/
      Call GTLIN (INPUT, PROMPT, 'P')
```

---

## HERR/IHERR

HERR/IHERR turns off ISERR (*error interception*) and allows the monitor to abort a job and generate an error message under fatal error conditions. IHERR itself returns no error codes.

Form:

```
CALL HERR ( )
i = IHERR ( )
```

where:

i is a returned INTEGER\*2 result of the function, a flag indicating the previous IHERR/ISERR setting:

Value	Meaning
i = 0	IHERR was in effect
i = 1	ISERR was in effect

Errors:

None.

Example:

```
Program FHERR !demo HERR and SERR
C
C Demonstrate how to save, modify and restore the
C HERR/SERR status in a subroutine
C
Parameter SUCCS = '001'o, FATAL = '010'o
Integer*2 DBLK(4) !unknown device/file
Integer*2 CHAN !channel to use
Integer*2 OLD1 !mainline SERR/HERR setting
Data DBLK /3rZZZ, 3*3rYYY/ !non existant device
C
CHAN = IGETC ( )
OLD1 = IHERR ( ) !get old setting
OLD1 = IHERR ( ) !confirm it
Call TEST (CHAN, DBLK) !call routine that uses SERR
If (OLD1 .ne. IHERR ( )) Then
  Type *, '?FHERR-F-S/HERR status not saved'
  Call Exit (FATAL)
Else
  Type *, '!FHERR-I-Success'
End If
OLD1 = ISERR ( ) !get old setting
OLD1 = ISERR ( ) !confirm it
Call TEST (CHAN, DBLK) !call routine that uses SERR
If (OLD1 .ne. IHERR ( )) Then
  Type *, '?FHERR-F-S/HERR status not saved'
  Call Exit (FATAL)
Else
  Type *, '!FHERR-I-Success'
  Call Exit (SUCCS)
End If
```

## HERR/IHERR

```
End
Subroutine TEST (CHAN, DBLK)
Integer*2 DBLK(4)      !unknown device/file
Integer*2 CHAN        !channel to use
Integer*2 ERROR       !error code
Integer*2 OLDERR      !previous SERR/HERR setting
C
OLDERR = ISERR ()     !set SERR, save old setting
ERROR = LOOKUP (CHAN , DBLK) !open that WILL fail
Type *, 'LOOKUP returned', ERROR
If (OLDERR .eq. 0) CALL HERR !restore setting
RETURN
END
```

---

## IADDR

The IADDR function returns the 16-bit absolute memory address of its argument as the integer function value.

Form:

**i - IADDR (arg)**

where:

**arg** is the variable or constant whose memory address is to be obtained.  
The value obtained by passing an expression as *arg* is unpredictable.

Errors:

Error message *TRAP \$MSARG* will display if *arg* is missing.

Example:

```

      Program FADDR ! demo IADDR function
C
C      This is example code of an actual use of IADDR.
C      Mapping requests often need addresses on PAR boundaries
C      and this code demonstrates how you can create such an address
C      dynamically.
C
      Implicit Integer*2 (A-Z)
      Parameter SUCCS = '001'o
      Parameter FATAL = '010'o
      Integer*2 AREA(0:1)      !must disable subscript checking
C
      AREA0 = IADDR (AREA(0)) !find addr of AREA(1)
      PAR1 = ('20000'o - AREA0) / 2 !find element of AREA
C
      ! that is base of PAR1
      AREAN = IADDR (AREA(PAR1)) !verify it
      Type 100, AREA0, PAR1, AREAN
100  Format (' ', 'Base address of AREA() is ', o8 /
      1      ' ', 'Address of AREA(', i5, ') is ' o8)
      If (AREAN .ne. '20000'o) Go To 1000
      Type *, '!FADDR-I-Success'
      Call Exit (SUCCS)
C
1000  Continue
      Type *, '?FADDR-F-Failed'
      Call Exit (FATAL)
      End
```

---

## IDATE

The IDATE function returns three INTEGER\*2 values representing the current (system) *month*, *day*, and *year* or an optional RT-11 date word you provide. IDATE was previously located in the distributed FORTRAN subroutine libraries, FORLIB and F77OTS.

Form:

**i = IDATE (mon,day,year[,opdate])**

where:

- mon** is an INTEGER\*2 variable that, on return, contains an integer representation of the month. January is represented as 1. December is represented as 12. Returned as zero if the system date has not been set
- day** is an INTEGER\*2 variable that, on return, contains the integer day of the month
- year** is an INTEGER\*2 variable that, on return, contains the positive difference between 1900 and the current year
- opdate** is an optional RT-11 date word to be converted. Specifying a 0 value for *opdate* returns the current system date. Note that the value you enter for *opdate* is not validated. The format of the date word is:

Bits	Contents
0-4	Year minus the base (base specified by bits 14,15)
5-9	Day (1-31)
10-13	Month (1-12)
14,15	Age bits. Age bits extend the directory date by 32(decimal) year increments and have the following meaning:

15	14	Meaning When Set
0	0	Base year 1972
0	1	Base year 2004
1	0	Base year 2036
1	1	Base year 2068

## IDATE

*i* is one of the following values returned (only when IDATE is called in the form *i = IDATE*:)

<b>Value</b>	<b>Meaning</b>
<i>i</i> = 0	Success

Error message *TRAP \$MSARG* will display if *month*, *day* or *year* argument is missing.

Example:  
See DATE.

---

## IDCOMP

The IDCOMP function compares two RT-11 date words and returns an integer value that reflects the relationship between those dates.

Form:

**i = IDCOMP (date1[,date2])**

where:

**date1** is the first RT-11 date word; that word is compared against *date2*. The format of the RT-11 date word is:

<b>Bits</b>	<b>Contents</b>
0-4	Year minus the base (base specified by bits 14,15)
5-9	Day (1-31)
10-13	Month (1-12)
14,15	Age bits. Age bits extend the directory date by 32(decimal) year increments and have the following meaning:

15	14	<b>Meaning When Set</b>
0	0	Base year 1972
0	1	Base year 2004
1	0	Base year 2036
1	1	Base year 2068

**date2** is the optional second RT-11 date word (default is current system date)

Function Result:

<b>Value</b>	<b>Meaning</b>
i = 0	The dates are the same
< 0	A negative value indicates <i>date1</i> is before <i>date2</i>
> 0	A positive value indicates <i>date1</i> is after <i>date2</i>

Errors:

<b>Value</b>	<b>Meaning</b>
i = -257	Invalid or missing argument.

## Example:

```

      Program FDCOMP !demo IDCOMP and GFDAT
C
C      Compare the creation DATES of an OBJ and associated SAV
C
      Parameter SUCCS = '001'o, FATAL = '010'o
      Integer*2 DBLKO(4), DBLKS(4), CHAN, ODATE, SDATE
      Data DBLKO /3rOBJ, 3rFDC, 3rOMP, 3rOBJ/
      Data DBLKS /3rSRC, 3rFDC, 3rOMP, 3rFOR/
C
      CHAN = IGETC ()
      IERR = IGFDAT (CHAN, DBLKO, ODATE)
      If (IERR .ne. 0) Go To 300
      IERR = IGFDAT (CHAN, DBLKS, SDATE)
      If (IERR .ne. 0) Go To 300
      If (IDCOMP (ODATE, SDATE)) 110, 120, 130
110   Call Print ('!FDCOMP-I-SAV is newer than OBJ')
      Go To 200
120   Call Print ('!FDCOMP-I-SAV and OBJ have the same date')
      Go To 200
130   Call Print ('!FDCOMP-I-SAV is OLDER than OBJ')
200   Call Exit (SUCCS)
300   Call Print ('?FDCOMP-F-GFDAT returned an error')
      Call Exit (FATAL)
      End

```

---

## IFWILD

The IFWILD function tests a file specification string (file name and extension only) for a match against up to eight wildcard file specifications (file name and extension only). IFWILD returns the result of the test (success or no success) and, if the test is successful, which of the file directory entries produced the match.

Form:

**i = IFWILD (tststr,matstr[,explct])**

where:

- tststr** is a character string test file specification; that file name and extension for which you are seeking a match. The test file specification can contain trailing blanks in either or both the name and extension fields, so long as their length does not exceed 6 and 3 characters respectively. The file name and extension must be separated by a period (.), and the file specification is terminated with a NULL character.
- matstr** is a character string of up to eight file specifications separated by commas (,) and terminated by a NULL. Device specifications are invalid. Each file specification can contain trailing blanks, general replacement wildcards (\*), or single-character wildcards (%) in either or both the file name and extension. If the extension is left blank, it is treated as a general replacement wildcard, unless the optional parameter *explct* is specified as 'E'. Each file name and extension must be separated by a period (.), each file specification must be separated by a comma (,), and the complete string must be terminated by a NULL
- explct** is either 'E' or 'I'. Specify 'E' to indicate explicit wildcarding; functionally equivalent to the command SET WILD EXPLICIT. Specify 'I' to indicate implicit wildcarding; functionally equivalent to the command SET WILD IMPLICIT (the default). If *explct* is omitted, current monitor setting of SET WILD is used.
- i** is the INTEGER\*2 function result.

Errors:

<b>Value</b>	<b>Meaning</b>
i = -2	Invalid arguments or missing arguments
= -1	No match
= >0	A match occurred and can be interpreted according to the following bitmap:

<b>Bits</b>	<b>Contents</b>
15	Clear indicates a match
10-14	Reserved
9	Successful exact match for file name ( <i>nam</i> ). The test file specification ( <i>tststr</i> ) name exactly matched at least one of the matching file specification ( <i>matstr</i> ) names. A wildcard match for file name does not set this bit.
8	Successful exact match for file extension ( <i>ext</i> ). The test file specification ( <i>tststr</i> ) extension exactly matched one of the matching file specification ( <i>matstr</i> ) extensions. A wildcard match for file extension does not set this bit.
0-7	Each bit corresponds to a match string file specification. For example, bit 0 corresponds to the first file specification in the match string, and bit 7 corresponds to the eighth. A successful test string match of the test string file name and extension with the corresponding match string file specification sets the corresponding bit. More than one file specification can match, therefore, more than one bit can be set. Each match can be an exact match or a wildcard match. Check bits 8 and 9 to determine if match is exact for file name and/or extension

## IFWILD

### Example:

```
Program FIFWIL !demo IFWILD
C
C Try to match the wildcard file formats:
C T*.DAT and T*.INP
C Rejecting all command lines that do not match
C
Byte FILSPC(81)
Character*15 MATCH
Data MATCH /'T*.DAT,T*.INP'/
Character*14 PROMPT
Byte P(14)
Equivalence (PROMPT, P)
Data PROMPT /'input file? '/
C
Call SCOPY (MATCH, MATCH, 14) !null terminate the string
P(14) = '200'o !and no CRLF on prompt
100 Continue
Call GTLIN (FILSPC, PROMPT)
If (IFWILD (FILSPC, MATCH) .gt. 0) Then
Type 1, '!FIFWIL-I-Valid file was: ', (FILSPC(I), I=1,14)
1 Format (' ', a27, 14a1)
Call Exit
Else
Type *, '!FIFWIL-I-Invalid file name, try again'
Go To 100
End If
End
```

---

## IGTENT

The IGTENT function returns the next directory entry that matches the criteria specified in the IGTDIR function. If there are no remaining matching entries, IGTENT returns an error code.

Form:

**i = IGTENT (wkarea,entry[,entofs][,filblk][,ascnam])**

where:

- wkarea** is the 64-word work area array specified in the IGTDIR function *wkarea* parameter
- entry** is an INTEGER\*2 array, the length and contents of which are determined by the IGTDIR *header* parameter.
- If *header* is not specified in IGTDIR, *entry* is a 7-word INTEGER\*2 array that, on return, contains the 7-word directory entry matching the criteria specified in IGTDIR.
  - If *header* is specified in IGTDIR, *entry* contains the entire directory entry (including any optional extra words) matching the criteria specified in IGTDIR. The fourth word in the directory header returned in the IGTDIR *header* parameter specifies the number of extra bytes in directory entries.
- entofs** is an INTEGER\*2 variable that, on return, contains a value representing the position of the next directory entry (see the IGTDIR function *stofst* parameter.)
- filblk** is an INTEGER\*2 variable that, on return, contains the starting block number for the directory entry that matches the criteria specified in IGTDIR.
- ascnam** is an 11-byte array that, on return, contains a fixed-format ASCII string file specification of the directory entry matching the criteria specified in IGTDIR. The directory entry is padded in the name and extension fields with blanks up to 6 and 3 characters respectively and is terminated with a NULL.

Function Result:

<b>Value</b>	<b>Meaning</b>
i = -7	Error reading directory segment
= -9	No directory open
= -10	End of directory encountered

## IGTENT

- = -19 Invalid arguments
- = -20 Returned file entry does not match (special mode operation)
- = >0 A match occurred and can be interpreted according to the following bit fields:

Bits	Contents
15	Clear indicates a match
10-14	Reserved
9	Successful exact match for exact file name (nam). The test file name exactly matched that of at least one of the matching file specifications. A wildcard match for file name does not set this bit
8	Successful exact match for file extension (ext). The test file extension exactly matched that of at least one of the matching file specifications. A wildcard match for file extension does not set this bit
0-7	Each bit corresponds to a match string file specification. For example, bit 0 corresponds to the first file specification in the match string and bit 7 corresponds to the eighth. A successful test string match of the test string file name and extension with the corresponding match string file specification sets the corresponding bit. More than one file specification can match, therefore more than one bit can be set. Each match can be an exact match or a wildcard match. Check bits 8 and 9 to determine if match is exact for file name and/or extension

Example:  
See example for GTDIR/IGTDIR.

---

## IJCVT

The IJCVT function converts an INTEGER\*4 value to INTEGER\*2 format. If you do not specify *ires*, the result returned is the INTEGER\*2 value of *jsrc*. If you specify *ires*, the result is stored there.

Form:

**i = IJCVT (jsrc[,ires])**

where:

**jsrc** specifies the INTEGER\*4 variable or array element whose value is to be converted

**ires** specifies the INTEGER\*2 entity to receive the conversion result

Function Result (if *ires* is specified):

Value	Meaning
i = 0	Normal return; the result is 0.
= 1	Normal return; the result is positive.
= -1	Normal return; the result is negative.
= -2	An overflow occurred during conversion.

Errors:

Unpredictable results will occur if the *jsrc* argument is omitted.

Example:

```
Program FIJCVT !Demo IJCVT
C Demonstrate the boundary conditions for IJCVT
C
Integer*4 JVAL           !Long to convert from
Integer*2 IVAL           !short to convert into
Integer*2 IERR           !error/result codes
Character*8 RESULT(-2:1) !strings describing results
Data RESULT /'Overflow', 'Negative', 'Zero', 'Positive'/
C
JVAL = 0
IERR = IJCVT (JVAL, IVAL)
Type *, JVAL, IVAL, ' ', RESULT(IERR)
JVAL = -32768
IERR = IJCVT (JVAL, IVAL)
Type *, JVAL, IVAL, ' ', RESULT(IERR)
JVAL = +32767
IERR = IJCVT (JVAL, IVAL)
Type *, JVAL, IVAL, ' ', RESULT(IERR)
JVAL = -32769
IERR = IJCVT (JVAL, IVAL)
Type *, JVAL, IVAL, ' ', RESULT(IERR)
JVAL = +32768
IERR = IJCVT (JVAL, IVAL)
Type *, JVAL, IVAL, ' ', RESULT(IERR)
End
```

---

# INDEX

INDEX searches a source string for the occurrence of a pattern string and returns the character position of the first occurrence of the pattern within the source.

Form:

```
CALL INDEX (a,patrn[,i],m)
i = INDEX (a,patrn[,i],m)
```

or

```
m = INDEX (a,patrn[,i])
```

where:

- a** is the array containing the source string to be searched; it must be terminated by a null byte
- patrn** is the string being sought; it must be terminated by a null byte
- i** is the integer starting character position of the search in *a*. If *i* is omitted, *a* is searched beginning at the first character position
- m** is an integer variable to store the result of the search; *m* is set to the starting character position of pattern in *a*, if found; otherwise, *m* is 0

Errors:

Unpredictable results will occur if required arguments are omitted.

Example:

The following example searches the array STRING for the first occurrence of strings EFG and XYZ and searches the string ABCABCABC for the occurrence of string ABC after position 5.

```
Program FINDEX !demo INDEX
C
C Show several forms of INDEX (as function and
C subroutine) and w/o optional arguments
C
C Byte STRING(10)
C
Call SCOPY ('ABCDEFGHI', STRING) !init for test
Call INDEX (STRING, 'EFG', , M) !expect 5
Call INDEX (STRING, 'XYZ', , N) !expect 0
Type *, 'M=', M, ' N=', N, ' INDEX =', !display results
1 INDEX ('ABCABCABC', 'ABC', 5) !expect 7
END
```

---

# INSERT

The INSERT subroutine replaces a portion of one string with another string.

Form:

**CALL INSERT (in,out,i[,m])**

where:

- in** is the array containing the string being inserted. The string must be terminated with a null if the number of characters is less than the value of *m* (below), or if *m* is not specified
- out** is the array containing the string being modified. The string must be terminated with a null
- i** is the integer specifying the character position in *out* at which the insertion begins
- m** is the integer maximum number of characters to be inserted

If the maximum number of characters (*m*) is not specified, all characters to the right of the specified character position (*i*) in the string being modified are replaced by the string being inserted. The insert string (*in*) and the string being modified (*out*) can be in the same array only if the maximum number of characters (*m*) is specified and is less than or equal to the difference between the position of the insert (*i*) and the maximum string length of the array.

**Errors:**

Unpredictable results will occur if required arguments are omitted.

**Example:**

```
          Program FINSER
C
C          Show various options with INSERT
C
C          Byte S1(11), S2(11), S3(11)
C
          Call SCOPY ('ABCDEFGH IJ', S1)    !init test string
          Call SCOPY (S1, S2)              !and another one
          Call SCOPY (S1, S3)              !and another one
          Call INSERT ('123', S1, 6)        !S1 = ABCDE123
          Call INSERT ('123', S2, 6, 2)    !S2 = ABCDE12HIJ
          Call INSERT ('123', S3, 6, 4)    !S3 = ABCDE123IJ
          Call PRINT (S1)
          Call PRINT (S2)
          Call PRINT (S3)
          End
```

---

## IPEEK

The IPEEK function returns the contents of the word located at a specified 16-bit address in the current job's address space. The subroutine can examine device registers if the registers are located in the current job's address space.

Form:

**i = IPEEK (iaddr)**

where:

**iaddr** is the integer specification of the 16-bit address in the current job's address space to be examined. If this argument is not an even value, a trap results (except on an LSI-11 or a PDP-11/23)

Function Result:

The function result (i) is set to the value of the word examined.

Errors:

Error message *TRAP \$MSARG* will display if argument *iaddr* is missing.

Example:

```
Program FPEEK
C
C Use (I)PEEK(B) and (I)POKE(B) to work with
C the SYSCOM area
C
Parameter JSW = '44'o !Job Status Word
Parameter TTLC = '040000'o !lower case bit in JSW
Parameter ERRBY = '52'o !Emt eRRor BYte
Parameter USRRB = '53'o !USer program eRRor Byte
Parameter SUCCS = '001'o !success bit
Integer*2 UNKFIL(4) !DBLK for non-existant file
Data UNKFIL /3rSY , 3rXXX, 3rXXX, 3rZZZ/
Integer*2 OLDJSW !original JSW
Byte OLDERR !original ERRBY
Byte BUFFER(81) !character buffer
Byte PROMPT(6) !input prompt
Data PROMPT /'t', 'e', 's', 't', ':', '200'o/
C
OLDJSW = IPEEK (JSW) !get original JSW
Type 1, OLDJSW !display JSW
1 Format (' ', 'JSW=', o7)
OLDERR = IPEEK (ERRBY) !get old error byte
Type 2, OLDERR
2 Format (' ', 'ERRBY=', o3)
Call Print ('000'o) !clean up screen
Call POKE (JSW, IAND (OLDJSW, NOT (TTLC))) !clear TTLC
Call RCTRL0
Call GTLIN (BUFFER, PROMPT) !get a line (in uppercase)
Call Print (BUFFER) !display it
Call POKE (JSW, IOR (OLDJSW, TTLC)) !set TTLC
Call RCTRL0
Call GTLIN (BUFFER, PROMPT) !get a line (in lowercase)
```

```
Call Print (BUFFER)      !display it
Call POKE (JSW, OLDJSW) !restore it to the original state
ICHAN = IGETC ()
IERR = LOOKUP (ICHAN, UNKFIL) !look for non-existent file
Type 2, IPEEK (ERRBY) !get error code from SYSCOM
Call POKEB (USRRB, IOR (IPEEK (USRRB), SUCCS))
C                               !set success code
C                               !(Call EXIT (SUCCS) is easier
Type 3, IPEEK (USRRB) !display it
3  Format (' ', 'USRRB=', o3)
End
```

---

## IPEEKb

IPEEKb returns the contents of the byte located at a specified 16-bit address in the current job's address space. Since this subroutine operates in a byte mode, the address supplied can be odd or even. The subroutine can examine device registers if the registers are located in the current job's address space. The return is zero extended; that is, the high byte is 0.

Form:

**i = IPEEKb (iaddr)**

where:

**iaddr** is the integer specification of the 16-bit address in the current job's address space to be examined. Unlike the IPEEK subroutine, the IPEEKb subroutine allows odd addresses

Function Result:

The function result (i) is set to the value of the byte examined.

Errors:

Error message *TRAP \$MSARG* will display if argument *iaddr* is missing.

Example:

See IPEEK.

---

## IRAD50

The IRAD50 function converts a specified number of ASCII characters to Radix-50 and returns the number of characters converted. Conversion stops on the first non-Radix-50 character encountered in the input, or when the specified number of ASCII characters have been converted.

Form:

**n = IRAD50 (icnt,input,output)**

where:

**n** is the integer number of input characters actually converted  
**icnt** is the number of ASCII characters to be converted  
**input** is the area from which input characters are taken  
**output** is the area in which Radix-50 words are stored

Three characters of text are packed into each word of output. The number of output words modified is computed by the expression (in integer words):

**(icnt+2)/3**

Thus, if a count of 4 is specified, two words of output are written even if only a one-character input string is given as an argument.

Function Result:

The integer number of input characters actually converted (n) is returned as the function result.

Errors:

Unpredictable results will occur if any required argument is omitted.

Example:

```
Real*8 FSPEC  
Call IRAD50 (12, 'SY SWAP SYS', FSPEC)
```

---

## ISPY

The ISPY function returns the integer value of the word at a specified offset from the RT-11 resident monitor. This subroutine uses the .GVAL programmed request to return fixed monitor offsets. (See *RT-11 System Macro Library Manual* for information on fixed offset references.)

Form:

**i = ISPY (ioff[,ierr])**

where:

**ioff** is the offset (from the base of RMON) to be examined.

**ierr** is the optional error return.

Function Result:

The function result (i) is set to the value of the word examined.

Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Success
= -1	Offset <i>ioff</i> is out of range. (Not contained within RMON)
= -2	Trap 4: Odd or nonexistent address.

Error message *TRAP \$MSARG* will display if argument *ioff* is missing.

Example:

See PUT.

---

## ISWILD

The ISWILD function checks for matching, either using or not using wildcards, between two ASCII strings. Valid wildcards are the asterisk (\*) and percent sign (%).

By default, the strings are terminated by a NULL. Optionally, other terminators can be specified. By default, the string character comparisons are case-insensitive for alphabetic characters. Optionally, the comparison can be made case sensitive.

Form:

**i = ISWILD (tststr,matstr[,term][,case][,explct])**

where:

- tststr** is the test string; the string you submit to check against a match string. The test string can contain any ASCII characters and is terminated with a NULL character or a character specified in the *term* parameter
- matstr** is the match string; the string against which you compare the test string. The match string can contain any ASCII character except an embedded NULL. An asterisk wildcard (\*) indicates a match-all sequence of unknown length, while a percent sign wildcard (%) indicates a match-all sequence of exactly one character
- term** is an optional ASCII string containing other terminators made valid for this comparison, such as a period (.), comma (,), blank, or tab. NULL is always recognized as a valid string terminator.
- case** determines case sensitivity requirements. The default is no sensitivity; all alphabetic characters are forced to uppercase before comparison. Specify 'C' to choose case sensitivity (7-bit ASCII only)
- explct** is either 'E' or 'I'. Specify 'E' to indicate explicit wildcarding; functionally similar to the command SET WILD EXPLICIT. Specify 'I' to indicate implicit wildcarding; functionally similar to the command SET WILD IMPLICIT. Implicit wildcarding is the default.
- i** contains the result of the comparison.

Errors:

<b>Value</b>	<b>Meaning</b>
<b>i = 0</b>	Exact match
<b>= 1</b>	Wildcard match
<b>=-1</b>	No match
<b>=-2</b>	Invalid arguments

## ISWILD

Example:

```

      Program FISWIL
C
C      Search the specified file for lines containing strings
C      matching the specified wildcard search argument(*).
C
      Byte FILNAM(16), MATCH(80), TEST(80)
      Byte PFILE(7)
      Data PFILE /'F', 'i', 'l', 'e', '?', ' ', '200'o/
      Byte PSTRIN(8)
      Data PSTRIN /'S', 't', 'r', 'i', 'n', 'g', ' ', '200'o/
C
      Call GtLin (FILNAM, PFILE)
      Open (Unit=2, Name=FILNAM, Type='OLD', Err=990)
      Call GtLin (MATCH, PSTRIN)
C
      LINE = 0
100   Continue
          LINE = LINE + 1
          Read (2, 1101, End=999) NCH, TEST
          TEST(NCH+1) = 0           !terminate string
          If (ISWILD (TEST, MATCH) .lt. 0) Go To 100
          Write (5, 1105) LINE, (TEST(K), K=1,MIN (72,NCH))
          Go To 100
C
990   Write (5, 1991) FILNAM
999   Call Exit
C
1101  Format (q, 80a1)
1105  Format (' ', I4, ':', 72a1)
1991  Format (' ', '?FISWIL-F-File not found - ', 16a1)
      End
```

---

# ITLOCK

## Multijob

The ITLOCK function is used in a multijob system to attempt to gain ownership of the USR. It is similar to LOCK in that, if successful, the user job returns with the USR in memory. However, if a job attempts to LOCK the USR while the other job is using it, the requesting job is suspended until the USR is free. With ITLOCK, if the USR is not available, control returns immediately and the lock failure is indicated.

Form:

**i = ITLOCK()**

For further information on gaining ownership of the USR, see the .TLOCK programmed request.

Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return.
= 1	USR is already in use.

Example:  
See LOCK.

---

## ITTINR

The ITTINR function transfers a character from the console terminal to the user program. If no characters are available, system action is determined by the setting of bit 6 of the Job Status Word.

Form:

`i = ITTINR()`

If the function result (i) is less than 0 when execution of the ITTINR function is complete, it indicates that no character was available. ITTINR does not return a result of less than zero unless bit 6 of the Job Status Word was on when the request was issued.

There are two modes of doing console terminal input, and they are governed by bit 12 of the Job Status Word (JSW). The JSW is at octal location 44. If bit 12 is 0, normal I/O is performed under the following conditions:

- The monitor echoes all characters typed.
- CTRL/U and RUBOUT perform line deletion and character deletion, respectively.
- A carriage return, line feed, CTRL/Z or CTRL/C must be struck before characters on the current line are available to the program. When one of these is typed, characters on the line typed are passed one by one to the user program.

If the console is in special mode (bit 12 set to 1), the following conditions apply:

- The monitor does not echo characters typed except for CTRL/C and CTRL/O.
- CTRL/U and RUBOUT do not perform special functions.
- Characters are immediately available to the program.

In special mode, the user program must echo the characters desired. However, CTRL/C and CTRL/O are acted on by the monitor in the usual way.

Bit 12 in the JSW must be set by the user program if special console mode is desired. Bit 14 in the JSW must be set if lowercase characters are desired. These bits are cleared when control returns to RT-11.

Regardless of the setting of bit 12, when a carriage return is entered, both carriage return and line feed characters are passed to the program; if bit 12 is 0, these characters will be echoed.

Lowercase conversion is determined by the setting of bit 14. If bit 14 is 0, lowercase characters are converted to uppercase before being echoed (if bit 12 is 0) and passed to a program; if bit 14 is 1, lowercase characters are echoed (if bit 12 is 0) and passed as received. Bit 14 is cleared when the program terminates.

### Notes

To set and/or clear bits in the JSW, do an IPEEK and then an IPOKE (See IPOKE example.) In special terminal mode (JSW bit 12 set), normal FORTRAN formatted I/O from the console is undefined.

If the single-line editor has been enabled with the SET SL ON and SET SL TTYIN commands, input from an ITTINR request can be edited by the single-line editor if JSW bits 4 and 12 are 0. However, if either bit 4 or bit 12 is set, SL will not edit ITTINR input. If SL is editing input, the state of bit 6 (inhibit TT wait) is ignored and an ITTINR request will not return until an edited line is available.

In multijob monitors, CTRL/F and CTRL/B (and CTRL/X in monitors with the system job feature) are not affected by the setting of bit 12. The monitor always acts on these characters if the SET TT FB command is in effect.

Also under the multijob monitor, if a terminal input request is made and no character is available, job execution is normally suspended until a character is ready. If a program requires execution to continue and ITTINR to return a result of less than zero, it must turn on bit 6 of the JSW before the ITTINR. Bit 6 is cleared when a program terminates. The results of ITTINR must be stored in an INTEGER type variable for the purposes of error checking. Once it is known that the call did not have an error return, the result can be moved into a LOGICAL\*1 variable or array element. Direct placement into a LOGICAL\*1 variable will lead to incorrect results, because the negative flag (bit 15 set) is lost in conversion to a LOGICAL\*1 variable.

Function Results:

<b>Value</b>	<b>Meaning</b>
i = >0	Character read.
i = <0	No character available.

Example:

See example in Section 1.5.2.

---

## ITTOUR

The ITTOUR function transfers a character from the user program to the console terminal if there is room for the character in the monitor buffer. If it is not currently possible to output a character, an error flag is returned.

Form:

**i = ITTOUR (char)**

where:

**char** is the character to be output, right-justified in the integer (can be LOGICAL\*1 entity if desired)

If the function result (*i*) is 1 when execution of the ITTOUR function is complete, it indicates that there is no room in the buffer and that no character was output. ITTOUR normally does not return a result of 1. Instead, the job is blocked until room is available in the output buffer. If a job requires execution to continue and a result of 1 to be returned, it must turn on bit 6 of the JSW before issuing the request.

### Notes

If a foreground job has characters in the TT output buffer, they are not output under the following conditions:

- If a background job is doing output to the console TT, the foreground job cannot output characters from its buffer until the background job outputs a line feed character. This can be troublesome if the console device is a graphics terminal and the background job is doing graphic output without sending any line feeds.
- If no background job is running (that is, KMON is in control of background), the foreground job cannot output its characters until the user types a carriage return or a line feed. In the former case, KMON gets control again and locks out foreground output as soon as the foreground output buffer is empty.

Note that the use of PRINT eliminates these problems.

Function Results:

<b>Value</b>	<b>Meaning</b>
i = 0	Character was output.
= 1	Ring buffer is full.

Errors:

Unpredictable results will occur if required arguments are omitted.

Example:

See example in Section 1.5.2.

---

## IWEEKD

The IWEEKD function, supplied with a month, day, and year returns an integer value representing the day of the week for that month, day, and year.

Form:

**i = IWEEKD (month,iday,iyear)**

where:

**month** is the number of the month between 1 and 12 (no default)  
**iday** is the number of the day between 1 and 31 (no default)  
**iyear** is the number of the year between 72 (representing 1972) and 199 (representing 2099), or 1972 through 2099. No default

Function result:

<b>Value</b>	<b>Meaning</b>
i = -1	Invalid argument
= 1	Sunday
= 2	Monday
= 3	Tuesday
= 4	Wednesday
= 5	Thursday
= 6	Friday
= 7	Saturday

Example:  
See DATE.

---

# JADD

JADD computes the sum of two INTEGER\*4 values.

Form:

```
CALL JADD (jopr1,jopr2,jres)
i = JADD (jopr1,jopr2,jres)
```

where:

**jopr1** is an INTEGER\*4 variable  
**jopr2** is an INTEGER\*4 variable  
**jres** is an INTEGER\*4 variable that receives the sum of *jopr1* and *jopr2*.

Function Results:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return; the result is zero.
= 1	Normal return; the result is positive.
= -1	Normal return; the result is negative.

Errors:

<b>Value</b>	<b>Meaning</b>
i = -2	An overflow occurred while computing the result.

Unpredictable results will occur if any argument is omitted.

Example:

```
      Program FJADD !FORTRAN IV
C      using JJCVT and TIMASC to display results
C
      Integer*4 HOUR1      !value of 1 hour
      Integer*4 HOUR12    !value of 12 hours
      Integer*4 JA, JB, JC !variables
      Logical*1 ASCII(9)  !variables
      Data ASCII(9) /0/   !terminate string with null
C
C      init "constants"
C
      Call JTIME (1, 0, 0, 0, HOUR1)
      Call JTIME (12, 0, 0, 0, HOUR12)
C
C      convert from RT-11 time format to I*4 format
      Call JJCVT (HOUR1)
      Call JJCVT (HOUR12)
      Call JMOV (HOUR1, JA) !JA = 1hr
      Call JMOV (HOUR12, JB) !JB = 12hr
      Call JADD (JA, JB, JC) !JC = JA + JB
      Call JJCVT (JC) !back to time format
      Call TIMASC (JC, ASCII) !display results
      Call PRINT (ASCII) !...
      End
```

---

# JAFIX

JAFIX converts a REAL\*4 value to INTEGER\*4.

Form:

```
CALL JAFIX (asrc,jres)
i = JAFIX (asrc,jres)
```

where:

**asrc** is a REAL\*4 variable, constant, or expression to be converted to INTEGER\*4

**jres** is an INTEGER\*4 variable that is to contain the result of the conversion

Function Results:

Value	Meaning
i = 0	Normal return; the result is zero.
= 1	Normal return; the result is positive.
= -1	Normal return; the result is negative.

Errors:

Value	Meaning
i = -2	An overflow occurred while computing the result.

Unpredictable results will occur if any argument is omitted.

Example:

```
Program FJAFIX !FORTRAN IV
C      using JJCVT and TIMASC to display results
      Real*4 RTRY          !test value
      Real*4 RPTRY        !previous test value
      Real*4 RNEW         !reconverted value
      Integer*4 JTRY      !integer equivalent
      Integer*4 JA, JB, JC !variables
      Logical*1 ASCII(9) !variables
      Data ASCII(9) /0/   !terminate string with null
      RTRY = 1.          !start at the beginning
      RPTRY = RTRY       !remember last value
100    Continue
        IERR = JAFIX (RTRY, JTRY) ! convert to I*4
        If (IERR .eq. -2) Type *, '?FJAFIX-W-Overflow', RTRY
        RNEW = AJFLT (JTRY) !convert back
        If (RNEW .ne. RTRY) Go To 200 !lost some bits
        RPTRY = RTRY
        RTRY = RTRY * 2.
        Go To 100
200    Continue
      Type *, RTRY, RNEW
      End
```

---

## JCMP

The JCMP function compares two INTEGER\*4 values and returns an INTEGER\*2 value that reflects the signed comparison result.

Form:

**i = JCMP (jopr1,jopr2)**

where:

**jopr1** is the INTEGER\*4 variable or array element that is the first operand in the comparison

**jopr2** is the INTEGER\*4 variable or array element that is the second operand in the comparison

Function Results:

<b>Value</b>	<b>Meaning</b>
i = 0	If <i>jobpr1</i> is equal to <i>jopr2</i>
= 1	If <i>jopr1</i> is greater than <i>jopr2</i> .
= -1	If <i>jopr1</i> is less than <i>jopr2</i> .

Errors:

Error message *TRAP \$MSARG* will display if any argument is missing.

Example:

```
      Program FJCMP      !FORTRAN IV
C
C      Demonstrate J series Integer*4 routines
C      using JJCVT and TIMASC to display results
C
      Integer*4 HOUR1      !value of 1 hour
      Integer*4 HOUR12    !value of 12 hours
      Integer*4 SECON1    !value of 1 second
      Integer*4 JA, JB, JC !variables
      Logical*1 ASCII(9)  !variables
      Data ASCII(9) /0/    !terminate string with null
C
C      init "constants"
C
      Call JTIME (1, 0, 0, 0, HOUR1)
      Call JTIME (12, 0, 0, 0, HOUR12)
      Call JTIME (0, 0, 1, 0, SECON1)
C
C      convert from RT-11 time format to I*4 format
C
      Call JJCVT (HOUR1)
      Call JJCVT (HOUR12)
      Call JJCVT (SECON1)
C
      Call JMOV (HOUR12, JA) !JA = 12hr
      Call JMOV (SECON1, JB) !JB = 1sec
      Call JADD (JA, JB, JC) !JC = JA + JB
```

```

If (JCMP (HOUR12, JC) .ge. 0)
1 Stop '12:00:00 ge 12:00:01'
Call JJCVT (JC)          !back to time format
Call TIMASC (JC, ASCII) !display results
Call PRINT (ASCII)      !...

C

Call JSUB (JA, JB, JC)  !JC = JA - JB
If (JCMP (HOUR12, JC) .le. 0)
1 Stop '12:00:00 le 11:59:59'
Call JJCVT (JC)          !back to time format
Call TIMASC (JC, ASCII) !display results
Call PRINT (ASCII)      !...
End
```

---

## JDFIX

The JDFIX function converts a REAL\*8 (DOUBLE PRECISION) value to INTEGER\*4.

Form:

**i = JDFIX (dsrc,jres)**

where:

**dsrc** is a REAL\*8 variable, constant, or expression to be converted to INTEGER\*4

**jres** is an INTEGER\*4 variable to contain the conversion result

Function Results:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return; the result is zero.
= 1	Normal return; the result is positive.
= -1	Normal return; the result is negative.

Errors:

<b>Value</b>	<b>Meaning</b>
i = -2	An overflow occurred while computing the result.

Unpredictable results will occur if any argument is omitted.

Example:

```
Program FJDFIX !FORTRAN IV
C      using JJCVT and TIMASC to display results
      Real*8 RTRY          !test value
      Real*8 RPTRY        !previous test value
      Real*8 RNEW         !reconverted value
      Integer*4 JTRY      !integer equivalent
      Integer*4 JA, JB, JC !variables
      Logical*1 ASCII(9) !variables
      Data ASCII(9) /0/  !terminate string with null
      RTRY = 1.          !start at the beginning
      RPTRY = RTRY      !remember last value
100    Continue
        IERR = JDFIX (RTRY, JTRY) ! convert to I*4
        If (IERR .eq. -2) Type *, '?FJDFIX-W-Overflow', RTRY
        RNEW = AJFLT (JTRY) !convert back
        If (RNEW .ne. RTRY) Go To 200 !lost some bits
        RPTRY = RTRY
        RTRY = RTRY * 2.
        Go To 100
200    Continue
      Type *, RTRY, RNEW
      End
```

---

## JDIV

JDIV computes the quotient of two INTEGER\*4 values.

Form:

```
CALL JDIV (jopr1,jopr2,jres[,jrem])  
i = JDIV (jopr1,jopr2,jres[,jrem])
```

where:

**jopr1** is an INTEGER\*4 variable that is the dividend of the operation  
**jopr2** is an INTEGER\*4 variable that is the divisor of *jopr1*  
**jres** is an INTEGER\*4 variable that receives the quotient of the operation;  
that is,  $jres=jopr1/jopr2$ .  
**jrem** is an INTEGER\*4 variable that receives the remainder of the  
operation. The sign is the same as that for *jopr1*

Function Results:

Value	Meaning
i = 0	Normal return; the quotient is 0.
= 1	Normal return; the quotient is positive.
= -1	Normal return; the quotient is negative.

Errors:

Value	Meaning
i = -3	An attempt was made to divide by 0.

Unpredictable results will occur if any required argument is omitted.

Example:

```
      Program FJDIV    !FORTRAN IV  
C  
C      Demonstrate J series Integer*4 routines  
C      using JJCVT and TIMASC to display results  
C  
      Integer*4 JA, JB          !variable  
      Integer*4 JHOUR, JMIN, JSEC  !more vars  
      Integer*4 J60            !constant  
      Logical*1 ASCII(8)  
C  
C      init "constants"  
C  
      Call JTIME (23, 59, 59, 59, JA)  
      Call JICVT (60, J60)  
C  
C      convert from RT-11 time format to I*4 format  
C  
      Call JMOV (JA, JB)          !save time format version  
      Call JJCVT (JA)            !make I*4 format version  
C
```

## JDIV

```
C      split out ticks
C
C      Call TIMASC (JB, ASCII)          !convert w/SYSLIB
C
C      convert w/JDIV
C
C      Call JDIV (JA, J60, JA)          !dump ticks
C      Call JDIV (JA, J60, JA, JSEC)    !get seconds
C      Call JDIV (JA, J60, JHOUR, JMIN) !get minutes and hours
C
C      Type 100, JHOUR, JMIN, JSEC, ASCII
100    Format (' ', i2, ':', i2, ':', i2, ' ', 8a1)
      End
```

---

# JICVT

JICVT converts a specified INTEGER\*2 value to INTEGER\*4.

Form:

```
CALL JICVT (isrc[,jres])  
i = JICVT (isrc[,jres])
```

where:

**isrc** is the INTEGER\*2 quantity to be converted

**jres** is the INTEGER\*4 variable or array element to receive the result

Function Results:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return; the result is 0.
= 1	Normal return; the result is positive.
= -1	Normal return; the result is negative.

Errors:

Unpredictable results will occur if any argument is omitted.

Example:

```
      Program FJICVT  !FORTRAN IV  
C  
C      Demonstrate J series Integer*4 routines  
C  
      Integer*4 JA, JB           !variables  
      Integer*2 IA(2), IB(2)     !overlay vars  
      Equivalence (JA, IA(1)), (JB, IB(1))  
      Data IA /12345, 23456/     !junk patterns  
      Data IB /31234, 11111/  
C  
      Call JICVT (+32000, JA)  
      Call JICVT (-2, JB)  
C  
      Type 100, IA, IB  
100  Format (' ', 2o7, ' ', 2o7)  
      End
```

---

## JJCVT

The JJCVT subroutine interchanges words of an INTEGER\*4 value to form an internal format time (or vice versa) whenever the INTEGER\*4 variable is to be used as an argument in a timer-support function such as ITWAIT. When a two-word internal format time is specified to a function such as ITWAIT, it must have the high-order time as the first word and the low-order time as the second word.

Form:

```
CALL JJCVT (jsrc)
```

where:

**jsrc** is the INTEGER\*4 variable whose contents are to be interchanged

Errors:

Error message *TRAP \$MSARG* will display if any argument is missing.

Example:

See JDIV.

---

## JMOV

JMOV assigns the value of an INTEGER\*4 variable to another INTEGER\*4 variable and returns the sign of the value moved.

Form:

```
CALL JMOV (jsrc,jdest)
i = JMOV (jsrc,jdest)
```

where:

**jsrc** is the INTEGER\*4 variable whose contents are to be moved  
**jdest** is the INTEGER\*4 variable that is the target of the assignment

Function Result:

The value of the function is an INTEGER\*2 value that represents the sign of the result as follows:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return; the result is 0.
= 1	Normal return; the result is positive.
= -1	Normal return; the result is negative.

Errors:

Unpredictable results will occur if any argument is omitted.

Example:

See JCMP.

---

# JMUL

JMUL computes the product of two INTEGER\*4 values.

Form:

```
CALL JMUL (jopr1,jopr2,jres)
i = JMUL (jopr1,jopr2,jres)
```

where:

**jopr1** is an INTEGER\*4 variable that is the multiplicand  
**jopr2** is an INTEGER\*4 variable that is the multiplier  
**jres** is an INTEGER\*4 variable that receives the product of the operation

Function Results:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return; the product is 0.
= 1	Normal return; the product is positive.
= -1	Normal return; the product is negative.

Errors:

<b>Value</b>	<b>Meaning</b>
i = -2	An overflow occurred while computing the result.

Unpredictable results will occur if any argument is omitted.

Example:

```
      Program FJMUL      !FORTRAN IV
C
C      Demonstrate J series Integer*4 routines
C      using JICVT and TIMASC to display results
C
      Integer*4 JA, JB, JC           !variable
      Integer*4 JHOUR, JMIN, JSEC, JTICK !more vars
      Integer*4 J60, J3600          !constant
      Logical*1 ASCII1(8), ASCII2(8)
C
C      init "constants"
C
      Call JTIME (23, 59, 59, 59, JA)
      Call JICVT (59, JTICK)
      Call JICVT (59, JSEC)
      Call JICVT (59, JMIN)
      Call JICVT (23, JHOUR)
      Call JICVT (60, J60)
      Call JICVT (3600, J3600)
C
C      convert w/JMUL
C
      Call JMOV (JTICK, JB)           !put ticks in accum
      Call JMUL (JSEC, J60, JC)       !calc sec value
```

## JMUL

```
Call JADD (JC, JB, JB)           !add in
Call JMUL (JMIN, J3600, JC)      !calc min value
Call JADD (JC, JB, JB)           !add in
Call JMUL (JHOUR, J3600, JC)     !calc hour value
Call JMUL (JC, J60, JC)          !...
Call JADD (JC, JB, JB)           !add in
Call JJCVT (JB)                  !convert to time format

C

Call TIMASC (JA, ASCII1)
Call TIMASC (JB, ASCII2)
Type 100, ASCII1, ASCII2
100 Format (' ', 8a1, ' ', 8a1)
End
```

---

## JREAD/JREADC/JREADF/JREADW

JREAD/JREADC/JREADF/JREADW use non-file-structured access to transfer into memory a specified number of words from an MSCP device. They are therefore especially useful because they use a 32-bit starting block number and can read from any block on any DU device.

Use the IQSET function to allocate the extra queue element required with JREAD, JREADC, JREADF functions. JREADW doesn't require an extra queue element since it is synchronous.

### JREAD

The JREAD function transfers into memory a specified number of words from an MSCP device associated with the indicated channel. The channel must be opened to the MSCP device in a non-file-structured manner. The monitor returns control to the user program immediately after the JREAD function is initiated. No special action is taken when the transfer is completed.

Form:

```
CALL JREAD (wcnt,buff,jblock,chan[,area][,BMODE=strg])  
i = JREAD (wcnt,buff,jblock,chan[,area][,BMODE=strg])
```

where:

<b>wcnt</b>	is the integer number of words to be transferred
<b>buff</b>	is an array to be used as the buffer; that array must contain at least <i>wcnt</i> words
<b>jblock</b>	is a 2-word (32-bit) starting block number of the MSCP device to be read. The first word contains the low order bits. The second word contains the high order bits.

For all currently supported Digital MSCP devices, the high four bits of the second word must be zero. (In FORTRAN-77, *jblock* can be expressed as an INTEGER\*4 variable, and can be manipulated as such.) The first block of the MSCP device is physical block 0. The first block of each MSCP device partition is logical block 0. The *jblock* argument is offset from physical or logical block number 0.

The *jblock* argument refers to a physical block when the MSCP disk has not been partitioned, or to a logical block when the MSCP disk has been partitioned. When an MSCP disk has been partitioned, the block you address with the *jblock* argument depends on which partition is assigned to the RT-11 unit (DU0 through DU7 or D10 through D77).

## JREAD/JREADC/JREADF/JREADW

The *jblock* argument must be updated (incremented) when necessary. For example, if the program is reading two sequential blocks at a time, *jblock* should be incremented by two for each read

**chan** is the integer specification for the RT-11 channel to be used  
**area** is accepted and ignored  
**BMODE=strg** Specify one of the following: 'UI'/'UD'/'SI'/'SD'/'CD'/'CI'. Value is used to specify the mapping mode for the *buff* argument.

Issue an IWAIT function when the user program needs to access the data read on the specified channel. IWAIT makes sure that the JREAD operation has been completed. IWAIT indicates if a hard error occurs during the transfer.

Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return.
= -2	Hardware error occurred on channel on last completed operation.
= -3	Specified channel is not open.
= -4	Invalid request (attempted file access), channel is opened to a file.
= -5	Channel not open as a non-file-structured device.
= -6	Address translation not available in monitor.
= -19	Invalid BMODE value.
= -257	Required argument missing.

Example:

See JREADW. See also RCVD.

### JREADC

The JREADC function transfers into memory a specified number of words from an MSCP device associated with the indicated channel. The channel must be opened to the MSCP device in a non-file-structured manner. The monitor returns control to the user program immediately after the JREADC function is initiated. When the operation is complete, the monitor enters the specified assembly language routine (*crtn*) as an asynchronous completion routine.

Form:

```
CALL JREADC (wcnt, buff, jblock, chan, [, area], crtn [, BMODE=strg] [, CMODE=strg])  
i = JREADC (wcnt, buff, jblock, chan, [, area], crtn [, BMODE=strg] [, CMODE=strg])
```

## JREAD/JREADC/JREADF/JREADW

where:

<b>wcnt</b>	is the integer number of words to be transferred
<b>buff</b>	is an array to be used as the buffer; that array must contain at least <i>wcnt</i> words
<b>jblock</b>	is a 2-word (32-bit) starting block number of the MSCP device to be read. The first word contains the low order bits. The second word contains the high order bits. For all currently supported Digital MSCP devices, the high four bits of the second word must be zero. (In FORTRAN-77, <i>jblock</i> can be expressed as an INTEGER*4 variable, and can be manipulated as such.) The first block of the MSCP device is physical block 0. The first block of each MSCP device partition is logical block 0. The <i>jblock</i> argument is offset from physical or logical block number 0. The <i>jblock</i> argument refers to a physical block when the MSCP disk has not been partitioned, or to a logical block when the MSCP disk has been partitioned. When an MSCP disk has been partitioned, the block you address with the <i>jblock</i> argument depends on which partition is assigned to the RT-11 unit (DU0 through DU7 or D10 through D77). The <i>jblock</i> argument must be updated (incremented) when necessary. For example, if the program is reading two sequential blocks at a time, <i>jblock</i> should be incremented by two for each read
<b>chan</b>	is the integer specification for the RT-11 channel to be used
<b>area</b>	is accepted and ignored
<b>crtn</b>	is an assembly language routine to be activated when the transfer is complete. That routine must be specified in the EXTERNAL statement in the FORTRAN routine that issues the JREADC function
<b>BMODE=strg</b>	Specify one of the following: 'UI'/'UD'/'SI'/'SD'/'CD'/'CI'. Value is used to specify the mapping mode for the BUFF statement.
<b>CMODE=strg</b>	Specifying <i>strg</i> as string "S" specifies Supervisor address.

Errors:

<b>Value</b>	<b>Meaning</b>
<b>i = 0</b>	Normal return.
<b>= -2</b>	Hardware error occurred on channel on last completed operation.
<b>= -3</b>	Specified channel is not open.
<b>= -4</b>	Invalid request (attempted file access), channel is opened to a file.

## JREAD/JREADC/JREADF/JREADW

- = -5 Channel not open as a non-file-structured device.
- = -6 Address translation not available in monitor.
- = -19 Invalid BMODE or CMODE value.
- = -257 Required argument missing.

Example:

See JREADW. See also RCVDC.

### JREADF

JREADF transfers into memory a specified number of words from an MSCP device associated with the indicated channel. The channel must be opened to the MSCP device in a non-file-structured manner. The monitor returns control to the user program immediately after JREADF is initiated. When the operation is complete, the monitor enters the specified FORTRAN subprogram (*frtn*) as an asynchronous completion routine.

Form:

```
CALL READF (wcnt,buff,jblock,chan,[,area],lblk,frtn)
i = JREADF (wcnt,buff,jblock,chan,[,area],lblk,frtn)
```

where:

- wcnt** is the integer number of words to be transferred
- buff** is an array to be used as the buffer; that array must contain at least *wcnt* words
- jblock** is a 2-word (32-bit) starting block number of the MSCP device to be read. The first word contains the low order bits. The second word contains the high order bits.

For all currently supported Digital MSCP devices, the high four bits of the second word must be zero. (In FORTRAN-77, *jblock* can be expressed as an INTEGER\*4 variable, and can be manipulated as such.) The first block of the MSCP device is physical block 0. The first block of each MSCP device partition is logical block 0. The *jblock* argument is offset from physical or logical block number 0.

## JREAD/JREADC/JREADF/JREADW

The *jblock* argument refers to a physical block when the MSCP disk has not been partitioned, or to a logical block when the MSCP disk has been partitioned. When an MSCP disk has been partitioned, the block you address with the *jblock* argument depends on which partition is assigned to the RT-11 unit (DU0 through DU7 or D10 through D77).

The *jblock* argument must be updated (incremented) when necessary. For example, if the program is reading two sequential blocks at a time, *jblock* should be incremented by two for each read

<b>chan</b>	is the integer specification for the RT-11 channel to be used
<b>area</b>	is accepted and ignored
<b>lblk</b>	is a 4-word area to be set aside for link information; that area must not be modified by the FORTRAN program or swapped over by the USR. That area can be reused by other FORTRAN completion functions when <i>frtn</i> has returned
<b>frtn</b>	is a FORTRAN routine activated on completion of the transfer. This name must be specified in an EXTERNAL statement in the routine that issues the JREADF call

### Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return.
= -2	Hardware error occurred on channel on last completed operation.
= -3	Specified channel is not open.
= -4	Invalid request (attempted file access), channel is opened to a file.
= -5	Channel not open as a non-file-structured device.
= -6	Address translation not available in monitor.
= -257	Required argument missing.

### Example:

See JREADW. See also RCVDF.

### JREADW

JREADW transfers into memory a specified number of words from an MSCP device associated with the indicated channel. The channel must be opened to the MSCP device in a non-file-structured manner. The monitor returns control to the user program when the transfer is complete or when an error is detected.

## JREAD/JREADC/JREADF/JREADW

Form:

```
CALL JREADW(wcnt, buff, jblock, chan[, area][, BMODE=strg])  
i = JREADW(wcnt, buff, jblock, chan[, area][, BMODE=strg])
```

where:

<b>wcnt</b>	is the integer number of words to be transferred
<b>buff</b>	is an array to be used as the buffer; that array must contain at least <i>wcnt</i> words
<b>jblock</b>	is a 2-word (32-bit) starting block number of the MSCP device to be read. The first word contains the low order bits. The second word contains the high order bits. For all currently supported Digital MSCP devices, the high 4 bits of the second word must be zero. (In FORTRAN-77, <i>jblock</i> can be expressed as an INTEGER*4 variable and can be manipulated as such.) The first block of the MSCP device is physical block 0. The first block of each MSCP device partition is logical block 0. The <i>jblock</i> argument is offset from physical or logical block number 0. The <i>jblock</i> argument refers to a physical block when the MSCP disk has not been partitioned or to a logical block when the MSCP disk has been partitioned. When an MSCP disk has been partitioned, the block you address with the <i>jblock</i> argument depends on which partition is assigned to the RT-11 unit (DU0 through DU7 or D10 through D77). Do not specify a block number higher than the physical size of the device (the physical size of an MSCP device is returned by the IGTDUS function). The <i>jblock</i> argument must be updated (incremented) when necessary. For example, if the program is writing two sequential blocks at a time, <i>jblock</i> should be incremented by two for each write
<b>chan</b>	is the integer specification for the RT-11 channel to be used
<b>area</b>	is accepted and ignored
<b>BMODE=strg</b>	Specify one of the following: 'UI'/'UD'/'SI'/'SD'/'CD'/'CI'. Value is used to specify the mapping mode for the <i>buff</i> argument.

Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return.
= -2	Hardware error occurred on channel on last completed operation.
= -3	Specified channel is not open.
= -4	Invalid request (attempted file access), channel is opened to a file.

## JREAD/JREADC/JREADF/JREADW

- = -5 Channel not open as a non-file-structured device.
- = -6 Address translation not available in monitor.
- = -19 Invalid BMODE value.
- = -257 Required argument missing.

### Example:

```
Program FJREAD
C
C Read the first block following the last user block
C
C NOTE: writing in this area would be a disaster!!!!
C
Parameter SUCCS = '001'o, FATAL = '010'o
Integer*2 DBLK(4) !device name
Data DBLK /3rSY , 0, 0, 0/ !no file name
Integer*2 REPLY(7) !info from IGTUDS
Integer*4 BLK !block number
Equivalence (BLK, REPLY(3)) !overlay in reply area
Parameter WRKSIZ = 80 !size of work area for IGTUDS
Integer*2 WORK(WRKSIZ) !work area for IGTUDS
Parameter WCNT = 256 !I/O word count
Integer*2 BUFFER(WCNT) !I/O buffer
C
ICHAN = IGETC() !get a channel
IERR = IGTUDS (DBLK, ICHAN, REPLY, , , WORK, WRKSIZ)
If (IERR .ne. 0) Go To 1000 !failed
Call LOOKUP (ICHAN, DBLK) !open up system device
IERR = JREADW (WCNT, BUFFER, BLK, ICHAN)
If (IERR .ne. 0) Go To 1100 !failed
Type 100, BLK
100 Format ( ' ', 'Block number = ', i12)
Do 500 I = 0, 255/8
Type 101, I*16, (BUFFER(J), J=I, I+7)
101 Format ( ' ', o3.3, 8o8.6)
500 Continue
Close (Unit=5)
Call EXIT (SUCCS)
C
1000 Type *, '?FJREAD-F-IGTDUS failed, code = ', IERR
Call EXIT (FATAL)
1100 Type *, '?FJREAD-F-JREAD failed, code = ', IERR
Call EXIT (FATAL)
End
```

---

## JSUB

JSUB computes the difference between two INTEGER\*4 values.

Form:

```
CALL JSUB (jopr1,jopr2,jres)
i = JSUB (jopr1,jopr2,jres)
```

where:

**jopr1** is an INTEGER\*4 variable that is the minuend of the operation.  
**jopr2** is an INTEGER\*4 variable that is the subtrahend of the operation.  
**jres** is an INTEGER\*4 variable that is to receive the difference between *jopr1* and *jopr2*; that is,  $jres=jopr1-jopr2$ .

Function Results:

Value	Meaning
i = 0	Normal return; the result is 0.
= 1	Normal return; the result is positive.
= -1	Normal return; the result is negative.

Errors:

Value	Meaning
i = -2	An overflow occurred while computing the result.

Unpredictable results will occur if any argument is omitted.

Example:

```
      Program FJSUB !FORTRAN IV
C
C      using JJCVT and TIMASC to display results
C
      Integer*4 HOUR1      !value of 1 hour
      Integer*4 HOUR12    !value of 12 hours
      Integer*4 JA, JB, JC !variables
      Logical*1 ASCII(9)  !variables
      Data ASCII(9) /0/   !terminate string with null
C
C      init "constants"
C
      Call JTIME (1, 0, 0, 0, HOUR1)
      Call JTIME (12, 0, 0, 0, HOUR12)
C
C      convert from RT-11 time format to I*4 format
C
      Call JJCVT (HOUR1)
      Call JJCVT (HOUR12)
      Call JMOV (HOUR1, JA) !JA = 1hr
      Call JMOV (HOUR12, JB) !JB = 12hr
      Call JSUB (JB, JA, JC) !JC = JB + JA
```

## JSUB

```
Call JJCVT (JC)           !back to time format
Call TIMASC (JC, ASCII) !display results
Call PRINT (ASCII)      !...
End
```

---

## JTIME

The **JTIME** subroutine converts the time specified to the internal two-word format time.

Form:

**CALL JTIME (hrs,min,sec,tick,time)**

where:

<b>hrs</b>	is the integer number of hours
<b>min</b>	is the integer number of minutes
<b>sec</b>	is the integer number of seconds
<b>tick</b>	is the integer number of ticks (1/60 of a second for 60-Hz clocks; 1/50 of a second for 50-Hz clocks)
<b>time</b>	is the two-word area to receive the internal format time: time(1) is the high-order time; time(2) is the low-order time.

Errors:

Unpredictable results will occur if any argument is omitted.

Example:

See **JMUL**.

---

## JWRITE/JWRITC/JWRITF/JWRITW

JWRITE/JWRITC/JWRITF/JWRITW, issued as functions or subroutines, use non-file-structured access to transfer a specified number of words from memory to an MSCP (DU) device. They use a 32-bit starting block number and can, therefore, write to any block on any DU device. JWRITE, JWRITC, and JWRITW have optional arguments that specify mapping for the *buff* argument.

When you don't know the physical size of an MSCP device, use IGTDUS to determine the size of that device, then specify a starting block that is lower than the device size returned by IGTDUS.

### CAUTION

If you inadvertently specify a block number higher than the device size returned by IGTDUS, you corrupt formatting and bad-block replacement information contained on the device, making it unusable. You must reformat the device, removing all information contained on it.

Use the IQSET function to allocate the extra queue element required with JWRITE, JWRITC, JWRITF functions. JWRITW does not require an extra queue element, since it is synchronous.

**JWRITE**

The JWRITE function transfers a specified number of words from memory to an MSCP device associated with the indicated channel. The channel must be opened to the MSCP device in a non-file-structured manner. The monitor returns control to the user program immediately after queuing the request. No special action is taken upon completion of the operation.

Form:

```
CALL JWRITE (wcnt, buff, jblock, chan[, area][, BMODE=strg])
i = JWRITE (wcnt, buff, jblock, chan[, area][, BMODE=strg])
```

where:

- wcnt** is the integer number of words to be transferred
- buff** is an array to be used as the output buffer
- jblock** is a 2-word (32-bit) starting block number of the MSCP device to be written. The first word contains the low order bits. The second word contains the high order bits. For all currently supported Digital MSCP devices, the high 4 bits of the second word must be zero. (In FORTRAN-77, *jblock* can be expressed as an INTEGER\*4 variable and can be manipulated as such.) The first block of the MSCP device is physical block 0. The first block of each MSCP device partition is logical block 0. The *jblock* argument is offset from physical or logical block number 0. The *jblock* argument refers to a physical block when the channel is opened on the first partition or to a logical block when the channel is opened on any other partition. When an MSCP disk has been partitioned, the block you address with the *jblock* argument depends on which partition is assigned to the RT-11 unit (DU0 through DU7 or D10 through D77). Do not specify a block number higher than the physical size of the device (the physical size of an MSCP device is returned by the IGT DUS function). The *jblock* argument must be updated (incremented) when necessary. For example, if the program is writing two sequential blocks at a time, *jblock* should be incremented by two for each write
- chan** is the integer specification for the RT-11 channel to be used. Obtain this channel through an IGETC call or use channel 16(decimal) or higher, if you have obtained extra channels with an ICDFN call
- area** is accepted and ignored
- BMODE=strg** Specify *strg* with one of the following: 'UI'/'UD'/'SI'/'SD'/'CD'/'CI'. Value specifies the mapping mode of the *buff* argument.

## JWRITE/JWRITC/JWRITF/JWRITW

Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return
= -2	Hardware error occurred on channel on last completed operation
= -3	Channel is not open
= -4	Invalid request (attempted file access), channel is opened to a file
= -5	Channel not open as non-file-structured device.
= -6	Address translation not available in monitor.
= -19	Invalid BMODE argument.
= -257	Required argument missing.

Example:

See JREADW. See also SDAT.

**JWRITC**

JWRITC transfers a specified number of words from memory to an MSCP device associated with the indicated channel. The channel must be opened to the MSCP device in a non-file-structured manner. The monitor queues the request and returns control to the user program. When the transfer is complete, the monitor enters the specified assembly language routine (*crtn*) as an asynchronous completion routine.

Form:

```
CALL JWRITC (wcnt,buff,jblock,chan,[,area],crtn[,BMODE=strg][,CMODE=strg])
i = JWRITC (wcnt,buff,jblock,chan,[,area],crtn[,BMODE=strg][,CMODE=strg])
```

where:

<b>wcnt</b>	is the integer number of words to be transferred
<b>buff</b>	is an array to be used as the output buffer
<b>jblock</b>	is a 2-word (32-bit) starting block number of the MSCP device to be written. The first word contains the low order bits. The second word contains the high order bits. For all currently supported Digital MSCP devices, the high 4 bits of the second word must be zero. (In FORTRAN-77, <i>jblock</i> can be expressed as an INTEGER*4 variable and can be manipulated as such.) The first block of the MSCP device is physical block 0. The first block of each MSCP device partition is logical block 0. The <i>jblock</i> argument is offset from physical or logical block number 0. The <i>jblock</i> argument refers to a physical block when the channel is opened on the first partition or to a logical block when the channel is opened on any other partition. When an MSCP disk has been partitioned, the block you address with the <i>jblock</i> argument depends on which partition is assigned to the RT-11 unit (DU0 through DU7 or D10 through D77). Do not specify a block number higher than the physical size of the device (the physical size of an MSCP device is returned by the IGTDUS function). The <i>jblock</i> argument must be updated (incremented) when necessary. For example, if the program is writing two sequential blocks at a time, <i>jblock</i> should be incremented by two for each write.
<b>chan</b>	is the integer specification for the RT-11 channel to be used. Obtain this channel through an IGETC call or use channel 16(decimal) or higher, if you have obtained extra channels with an ICDFN call
<b>area</b>	is accepted and ignored
<b>BMODE=strg</b>	Specify <i>strg</i> with one of the following: 'UI'/'UD'/'SI'/'SD'/'CD'/'CI'. This value specifies the mapping mode of the <i>buff</i> argument.

## JWRITE/JWRITC/JWRITF/JWRITW

**CMODE=strg** Specifying *strg* as string "S" specifies a Supervisor address.  
**crtn** is an assembly language routine to be activated when the transfer is complete. That routine must be specified in the EXTERNAL statement in the FORTRAN routine that issues the JWRITC function.

### Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return
= -2	Hardware error occurred on channel on last completed operation
= -3	Channel is not open
= -4	Invalid request (attempted file access), channel is opened to a file
= -5	Channel not open as non-file-structured device.
= -6	Address translation not available in monitor.
= -19	Invalid BMODE or CMODE argument.
= -257	Required argument missing.

### Example:

See JREADW. See also SDATC.

**JWRITF**

JWRITF transfers a specified number of words from memory to an MSCP device associated with the indicated channel. The channel must be opened to the MSCP device in a non-file-structured manner. The monitor returns control to the user program immediately after queuing the request. When the transfer is complete, the monitor enters the specified FORTRAN subprogram (crtn) as an asynchronous completion routine.

Form:

```
CALL JWRITF (wcnt,buff,jblock,chan,[,area],lblk,frtn)
i = JWRITF (wcnt,buff,jblock,chan,[,area],lblk,frtn)
```

where:

- wcnt** is the integer number of words to be transferred
- buff** is an array to be used as the output buffer
- jblock** is a 2-word (32-bit) starting block number of the MSCP device to be written. The first word contains the low order bits. The second word contains the high order bits. For all currently supported Digital MSCP devices, the high 4 bits of the second word must be zero. (In FORTRAN-77, *jblock* can be expressed as an INTEGER\*4 variable and can be manipulated as such.) The first block of the MSCP device is physical block 0. The first block of each MSCP device partition is logical block 0. The *jblock* argument is offset from physical or logical block number 0. The *jblock* argument refers to a physical block when the channel is opened on the first partition or to a logical block when the channel is opened on any other partition. When an MSCP disk has been partitioned, the block you address with the *jblock* argument depends on which partition is assigned to the RT-11 unit (DU0 through DU7 or D10 through D77). Do not specify a block number higher than the physical size of the device (the physical size of an MSCP device is returned by the IGTDUS function). The *jblock* argument must be updated (incremented) when necessary. For example, if the program is writing two sequential blocks at a time, *jblock* should be incremented by two for each write
- chan** is the integer specification for the RT-11 channel to be used. Obtain this channel through an IGETC call or use channel 16(decimal) or higher, if you have obtained extra channels with an ICDFN call
- area** is accepted and ignored
- lblk** is a 4-word area to be set aside for link information; this area must not be modified by the FORTRAN program or swapped over by the USR. This area can be reused by other FORTRAN completion functions when crtn has returned

## JWRITE/JWRITC/JWRITF/JWRITW

**frtn** is a FORTRAN routine to be activated on completion of the transfer. This name must be specified in an EXTERNAL statement in the routine that issues the JWRITF call

### Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return
= -2	Hardware error occurred on channel on last completed operation
= -3	Channel is not open
= -4	Invalid request (attempted file access), channel is opened to a file
= -5	Channel not open as non-file-structured device.
= -6	Address translation not available in monitor.
= -257	Required argument missing.

### Example:

See JREADW. See also SDATF.

**JWRITW**

JWRITW transfers a specified number of words from memory to an MSCP device associated with the indicated channel. The channel must be opened to the MSCP device in a non-file-structured manner. The monitor returns control to the user program when the transfer is complete.

Form:

```
CALL JWRITW (wcnt, buff, jblock, chan[, area][, BMODE=strg])
i = JWRITW (wcnt, buff, jblock, chan[, area][, BMODE=strg])
```

where:

- wcnt** is the integer number of words to be transferred
- buff** is an array to be used as the output buffer
- jblock** is a 2-word (32-bit) starting block number of the MSCP device to be written. The first word contains the low order bits. The second word contains the high order bits. For all currently supported Digital MSCP devices, the high 4 bits of the second word must be zero. (In FORTRAN-77, *jblock* can be expressed as an INTEGER\*4 variable and can be manipulated as such.) The first block of the MSCP device is physical block 0. The first block of each MSCP device partition is logical block 0. The *jblock* argument is offset from physical or logical block number 0. The *jblock* argument refers to a physical block when the channel is opened on the first partition or to a logical block when the channel is opened on any other partition. When an MSCP disk has been partitioned, the block you address with the *jblock* argument depends on which partition is assigned to the RT-11 unit (DU0 through DU7 or D10 through D77). Do not specify a block number higher than the physical size of the device (the physical size of an MSCP device is returned by the IGTDUS function). The *jblock* argument must be updated (incremented) when necessary. For example, if the program is writing two sequential blocks at a time, *jblock* should be incremented by two for each write
- chan** is the integer specification for the RT-11 channel to be used. Obtain this channel through an IGETC call or use channel 16(decimal) or higher, if you have obtained extra channels with an ICDFN call
- area** is accepted and ignored
- BMODE=strg** Specify *strg* with one of the following: 'UI'/'UD'/'SI'/'SD'/'CD'/'CI'. This value specifies the mapping mode of the *buff* argument.

Errors:

## JWRITE/JWRITC/JWRITF/JWRITW

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return
-2	Hardware error occurred on channel on last completed operation
-3	Channel is not open
-4	Invalid request (attempted file access), channel is opened to a file
-5	Channel not open as non-file-structured device.
-6	Address translation not available in monitor.
-19	Invalid BMODE argument.
-257	Required argument missing.

Example:

See JREADW. See also SDATW.

---

## KPEEK

The KPEEK function returns the contents of the word located at a specified 16-bit address. The function can examine any location in Kernel memory. For description of PS, see KPOKE.

Form:

**i = KPEEK (iaddr[,ierr])**

where:

**iaddr** is the integer specification of the 16-bit (Kernel-mapped) address to be examined. As a special case, if the value -2 is specified for *iaddr*, KPEEK returns the PS associated with the calling program, rather than the monitor. However, condition codes are undefined.

**ierr** is a returned error condition.

Function result:

<b>Value</b>	<b>Meaning</b>
i = n	Value (n) of the location in Kernel mapping.

Errors:

<b>Value</b>	<b>Meaning</b>
ierr = 0	Normal return
= -2	Odd or nonexistent address

Error message *TRAP \$MSARG* will display if argument *iaddr* is missing.

Example:

```
Program FKPEEK
C
C Demo program to show using KPEEK and KPOKE accessing the PS
C
C WARNING: invoking KPEEK uses an EMT which is executed at PR0!
C
Integer*2 PS, PR7      !Proc status register, priority 7 mask
Data PS /"177776/, PR7 /"000340/
Integer*2 OLDPS, NEWPS !copies of PS
Integer*2 SHARED       !location shared with a
Common /STATUS/ SHARED ! completion routine
Integer*2 OLDSHR       !local copy of old value
C
OLDPS = KPOKE (PS, PR7, 'BIS') !Set PS to PR7 (BIS)
NEWPS = KPEEK (PS)           !get modified PS
OLDSHR = SHARED              !get current value
SHARED = SHARED + 3         !change shared location, protected
C                             ! with PR7 from interference
CALL KPOKE (PS, OLDSHR, 'MOV') !Put old PS back
Type 100, OLDPS, NEWPS, KPEEK (PS) !display PSs
100 Format (' ', 3o10)
End
```

---

# KPOKE

KPOKE, either as a function or as a subroutine, stores a specified 16-bit integer value into a 16-bit (Kernel mapped) address. The subroutine can store values at any location in Kernel memory.

Form:

```
CALL KPOKE (iaddr,ivalue[,type][,ierr])  
i = KPOKE (iaddr,ivalue[,type][,ierr])
```

where:

**iaddr** is the integer specification of the 16-bit address to be modified. As a special case, if the value -2 is specified for *iaddr*, KPEEK returns the PS associated with the calling program, rather than the monitor. However, condition codes are undefined.

**ivalue** is the integer value to be stored in the address specified by the *iaddr* argument.

**type** is the operation to be used to modify the address to the value specified by the *ivalue* argument:

- MOV = Replace with a MOV operation (default).
- BIC = Change with a BIC operation.
- BIS = Change with a BIS operation.

**ierr** is a returned error condition.

Function result:

<b>Value</b>	<b>Meaning</b>
i = n	Value (n) of the location in Kernel mapping.

Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return
= -2	Odd or nonexistent address (has meaning only if <i>ierr</i> is specified).

Error message *TRAP \$MSARG* will display if any required argument is missing or if *type* argument is incorrect.

## Altering the Processor Status Word

The KPOKE request can successfully alter priority bits in the processor status (PS) word:

- A KPOKE function returns the contents of the PS with undefined condition codes.
- A KPOKE can modify all bits in the PS except the 000020 (trace trap) and 140000 (current mode) bits. However, modifying the 000400 (instruction suspension)

or 004000 (register set) bits can cause unexpected results and, although not prohibited, is not recommended.

Modifying the priority bits is supported. However, changing processor priority with KPOKE automatically lowers processor priority to zero (PR0) during the time KPOKE is executing. Therefore, a period of lowest processor priority exists between the time the processor is running at a given priority and the time the processor priority change takes effect.

Setting the carry bit is not recommended as it causes KPOKE to return an error.

- The priority bits of the modified PS are preserved at the completion of KPOKE.

Example:

See KPEEK.

---

## LEN

The LEN function returns the number of characters currently in the string contained in a specified array. This number is computed as the number of characters preceding the first null byte encountered. If the specified array contains only a null string, a value of 0 is returned.

Form:

**i = LEN (a)**

where:

**a** specifies the array containing the string, which must be terminated by a null byte

Errors:

Unpredictable results will occur if argument *a* is omitted.

Example:

See SDAT.

---

## LOCK/UNLOCK

The LOCK subroutine, in a multijob environment, keeps the USR in memory for a series of operations involving various RT-11 file management functions. The UNLOCK subroutine releases the User Service Routine (USR) from memory, if it was placed there by the LOCK routine.

### LOCK

If all the conditions that cause swapping are satisfied, a portion of the user program is written out to the disk file SWAP.SYS and the USR is loaded. Otherwise, the USR in memory is used, and no swapping occurs. The USR is not released until an UNLOCK is given. (Note that in a multijob system, calling the CSI can also perform an implicit UNLOCK.) To save time in swapping, a program that makes multiple USR requests can LOCK the USR in memory, make all the requests, and then UNLOCK USR.

Form:

**CALL LOCK**

In a multijob environment, LOCK inhibits another job from using USR. USR should be locked only for as long as necessary.

### Notes

If any job does a LOCK, it can cause the USR to be unavailable for other jobs for a considerable period of time. The USR is not reentrant and only one job has use of the USR at a time, which should be considered for systems requiring concurrent foreground and background jobs. This is particularly true when magtape and/or cassette are active.

File operations by the USR require a sequential search of the tape for magtape and cassette. This could lock out the foreground job for a long time while the background job does a tape operation. The programmer should keep this in mind when designing such systems. The multijob monitors supply the ITLOCK routine, which permits the job to check for the availability of the USR.

After a LOCK has been executed, the UNLOCK routine must be executed to release the USR from memory. The LOCK/UNLOCK routines are complementary and must be matched. That is, if three LOCKs are issued, at least three UNLOCKs must be done, otherwise the USR is not released. More UNLOCKs than LOCKs can occur without error; the extra UNLOCKs are ignored.

The LOCK call must not come from within the area into which the USR will be swapped. If this should occur, the return from the USR request would not be to the user program, but to the USR itself, since the LOCK function causes part of the user program to be saved on disk and replaced in memory by the USR. Furthermore, subroutines, variables, and arrays in the area where the USR is swapping should not be referenced while the USR is locked in memory.

## LOCK/UNLOCK

Once a LOCK has been performed, it is not advisable for the program to destroy the area the USR is in, even though no further use of the USR is required. This causes unpredictable results when an UNLOCK is done.

LOCK cannot be called from a completion or interrupt routine.

If a SET USR NOSWAP command has been issued, LOCK and UNLOCK do not cause the USR to swap. However, LOCK still inhibits the other job from using the USR, and UNLOCK allows the other job access to the USR.

The USR cannot accept argument lists, such as device file name specifications, located in the area into which it has been locked.

Errors:

None.

Example:

```
          Program FLOCK
C
C          Demo ITLOCK, LOCK, & UNLOCK
C
          If (ITLOCK () .eq. 0) Go To 100 !USR available
C
          do stuff not requiring the USR
C
100       Continue
          Call LOCK                      !USR now required
C
          do stuff requiring the USR
C
          Call UNLOCK
          End
```

**UNLOCK**

The UNLOCK subroutine releases the User Service Routine (USR) from memory if it was placed there by the LOCK routine. If the LOCK required a swap, the UNLOCK loads the user program back into memory. If the USR does not require swapping, the UNLOCK involves no I/O. The USR is always resident in mapped monitors.

Form:

**CALL UNLOCK**

**Notes**

- You should give at least as many UNLOCK calls as LOCK calls. Otherwise, the USR remains locked in memory. Extra UNLOCK calls are ignored.
- When running in a multijob system, use the LOCK/UNLOCK pairs only when absolutely necessary. If one job locks the USR, the other job cannot use the USR until it is unlocked.
- In a multijob system, calling the CSI (ICSI) with input coming from the console terminal performs a temporary implicit UNLOCK.

For further information on releasing the USR from memory, see the .LOCK /.UNLOCK programmed requests.

Errors:

None.

Example:

See LOCK.

---

## LOOKUP

The LOOKUP function associates a specified channel with a device and/or file for the purpose of performing I/O operations. The channel used is then busy until one of the following functions is executed:

**CLOSEC/ICLOSE**  
**CLOSZ**  
**ISAVES**  
**PURGE**

Form:

**CALL LOOKUP (chan,dblk[,seqnum,])**  
**i = LOOKUP (chan,dblk[,seqnum,])**  
**CALL LOOKUP (chan,jobdes)**  
**i = LOOKUP (chan,jobdes)**

where:

- chan** is the integer specification for the RT-11 channel to be associated with the file. You must obtain this channel through an IGETC call, or you can use channel 16(decimal) or higher if you have done an ICDFN call
- dblk** is the four-word area specifying the Radix-50 file descriptor. Note that unpredictable results occur if the USR swaps over this four-word area
- seqnum** is a file number.  
For magtape, it describes a file sequence number. The action taken depends on whether the file name is given or null. The sequence number can have the following values:

- 1** Suppress rewind and search for the specified file name from the current tape position. If a file name is given, a file-structured lookup is performed (do not rewind). If the file name is null, a non-file-structured lookup is done (tape is not moved). You must specify a -1 and no other negative number.
- 0** Rewind to the beginning of the tape and do a non-file-structured lookup.
- n** Where *n* is any positive number. Position the tape at file sequence number *n* and check that the file names match. If the file names do not match, an error is generated. If the file name is null, a file-structured lookup is done on the file designated by *seqnum*.

**jobdes** is an argument that allows communication between jobs in a system job environment. It is a pointer to a four-word job descriptor of the job to which messages will be sent or received. The syntax is:

```
jobdes: .RAD50 /MQ/
        .ASCII /logical-job-name/
```

where the logical-job-name is six characters long (right-padded with nulls). If the logical-job-name is zero, the channel will be opened only for .READ/C/W requests, and such requests will accept messages from any jobs.

### Non-File-Structured Lookup

The handler for the selected device must be in memory for a LOOKUP. If the first word of the file name in *dbl* is 0 and the device is a file-structured device, absolute block 0 of the device is designated as the beginning of the file. This technique, called a non-file-structured lookup, allows I/O to any physical block on the device. If a file name is specified for a device that is not file structured (such as NL:FILE.TYP), the name is ignored.

Since a non-file-structured lookup allows I/O to any physical block on the device, in this mode, you could possibly overwrite the RT-11 device directory, destroying all information on the device. Position the LOOKUP arguments so that the USR does not swap over them.

### Function Result:

Value	Meaning
i = >0	Successful file-structured lookup on a random-access storage volume. Value is length in blocks of file just opened. Note: Value can be of sufficient size to create a negative value.
= 0	Successful non-file-structured lookup on both random-access and non-file-structured volumes, or a successful file-structured lookup on magtape.

### Errors:

Value	Meaning
i = -1	Channel specified is already open.
= -2	File specified was not found on the device.
= -3	Device in use.
= -6	Invalid argument error with a non-file-structured volume.
= -7	Invalid unit number.

Error message *TRAP \$MSARG* will display if any argument is missing.

## LOOKUP

Example:

See also CHCPY.

```
      Program FLOOKU
C
C      demo JOB LOOKUP
C
      Integer*2 JBLK(4)      !jobblk
      Logical*1 JNAM(6)      !name part
      Equivalence (JBLK(2), JNAM(1))
      Data JBLK(1) /3rMQ /
      Data JNAM /'S', 'P', 'O', 'O', 'L', "000/
C
C      open a message channel to SPOOL
C
      ICHAN = IGETC ()
      If (LOOKUP (ICHAN, JBLK) .lt. 0)
      1 Call PRINT ('?FLOOKU-F-SPOOL is not running')
      End
```

---

# MAP

## Mapping

The MAP (MAP window) function maps a previously defined address window into a dynamic region of extended memory or into the static region in the lower 28 KW.

Form:

```
ierr= MAP (iwdb)
CALL MAP (iwdb [,ierr])
```

where:

<b>ierr</b>	Error return
<b>iwdb</b>	Address of Window Descriptor Block

Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Function completed successfully.
= -3	Invalid region identifier specified.
= -4	Invalid region identifier specified.
= -5	Specified region not mapped because of one of the following: <ul style="list-style-type: none"><li>• Offset is beyond the end of the region.</li><li>• Window is larger than the region.</li><li>• Window would extend beyond the bounds of the region.</li></ul>
= -16	Mode/space not available.
= -257	Required argument missing.

Example:  
See CRAW.

---

# MRKT

## Timer (SYSGEN Option)

MRKT schedules an assembly language completion routine to be entered after a specified time interval has elapsed. An optional parameter, *CMODE*, can be used to specify a Supervisor address.

Form:

```
CALL MRKT (id,crtn,time[,CMODE=strg])  
i = MRKT (id,crtn,time[,CMODE=strg])
```

where:

- |             |   |
|-------------|---|
| <b>id</b>   | is an integer identification number to be passed to the routine being scheduled   |
| <b>crtn</b> | is the name of the assembly language routine to be entered when the time interval elapses. This name must be specified in an EXTERNAL statement in the FORTRAN routine that issues the MRKT call                        |
| <b>time</b> | is the two-word internal format time interval; when this interval elapses, the routine is entered. If considered as a two-element INTEGER*2 array:<br>time(1) is the high-order time.<br>time(2) is the low-order time. |

**CMODE=strg** Specifying *strg* as string "S" sets on low bit of *crtn* address to indicate an S-I address.

## Notes

- MRKT requires a queue element, which should be considered when the IQSET function is executed.
- If the system is busy, the time interval that elapses before the completion routine is run can be greater than that requested.

For further information on scheduling completion routines, see the .MRKT programmed routine discussion in the *RT-11 System Macro Library Manual*.

Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return.
= 1	No queue element was available; unable to schedule request.
= -19	Invalid CMODE value.

Error message *TRAP \$MSARG* will display if any argument is missing.

## Example:

```

Program FMRKT ! Demo MRKT and CMKT
C
C Run two timers at 5 and 50 ticks each, shutdown
C first timer after 5 times and wait for second.
C
Integer*2 COUNT
Integer*4 TIME, TIME2, RTIME
Common /TIMING/ COUNT, TIME
External FAMRKT !macro completion routine
C
Call IQSET (10) !get some queue elements
COUNT = 1 !init count
TIME = 5 !init at 5 ticks
Call JJCVT (TIME) !and convert from int to time
TIME2 = 50 !init at 50 ticks
Call JJCVT (TIME2) !and convert from int to time
Call MRKT (12345, FAMRKT, TIME) !timer 1
Call MRKT (02222, FAMRKT, TIME2)!timer 2
100 Continue
Call SUSPND !wait for completion
If (COUNT .eq. 5) Then
    Call CMKT (12345, RTIME) !on 5th, shutdown timer 1
    Go To 200
Else
    Go To 100
End If
C
200 Continue
Call PRINT ('!FMRKT-I-Normal Termination')
End

.TITLE FAMRKT macro completion routine for FMRKT
.MCALL .RSUM .PRINT .MRKT

FAMRKT::
.PRINT #HERE ;indicate entered
INC COUNT ;indicate entered
.RSUM ;resume suspended mainline
.MRKT #AREA,#TIME,#FAMRKT ;reissue the request
RETURN

AREA: .BLKW 3
HERE: .ASCIZ "... in FAMRKT"

.PSECT TIMING,RW,D,GBL,REL,OVR ;Common /TIMING/ ...
COUNT: .BLKW 1
TIME: .BLKW 2
.END

```

---

# MSDS

## Full Mapping

The MSDS subroutine controls the linkage of Supervisor and User data space.

Form:

```
CALL MSDS (ival [,iold] [,ierr])
ierr = MSDS (ival [,iold])
```

where:

<b>ierr</b>	Error return
<b>ival</b>	New value for CMAP status
<b>iold</b>	Previous CMAP status

Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Success.
i = -257	Required argument missing.

Example:

See CMAP.

---

# MTATCH

## Multiterminal Option

The MTATCH subroutine attaches a terminal for exclusive use by the requesting job. This operation must be performed before any job can use a terminal with multiterminal programmed requests. An optional argument, *amode*, lets you specify an S-D address.

Form:

```
CALL MTATCH (unit[,addr][,jobnum][,AMODE=strg])
i = MTATCH (unit[,addr][,jobnum][,AMODE=strg])
```

where:

<b>unit</b>	is the unit number of the terminal
<b>addr</b>	is the optional address of an asynchronous terminal status word. Omit this argument. For example: <pre>I = MTATCH (unit,,jobnum)</pre>
<b>jobnum</b>	is the job number associated with the terminal if the terminal is not available
<b>AMODE=strg</b>	Specify <i>amode</i> as the string "S" to set on the low bit of the address of <i>iflag</i> to indicate an S-D address.

Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return.
= 3	Nonexistent unit number.
= 5	Unit attached by another job (job number returned in <i>jobnum</i> .)
= 6	In XM monitor, the optional status word address is not in a valid user virtual address space.
= 7	Unit attached by handler (name returned in <i>jobnum</i> .)
=-19	Invalid AMODE value.

Error message *TRAP \$MSARG* will display if any argument is missing.

Example:

Refer to the *RT-11 System Macro Library Manual* for an example.

---

# MTDTCH

## Multiterminal Option

The MTDTCH subroutine is the complement of the MTATCH subroutine. Its function is to detach a terminal from a particular job and make it available for other jobs.

Form:

```
CALL MTDTCH(unit)
i = MTDTCH(unit)
```

where:

**unit** is the unit number of the terminal to be detached

Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return.
= 2	Invalid unit number; terminal is not attached.
= 3	Nonexistent unit number.

Error message *TRAP \$MSARG* will display if any argument is missing.

Example:

Refer to the *RT-11 System Macro Library Manual* for an example.

---

# MTGET

## Multiterminal Option

The MTGET subroutine furnishes the user with information about a specific terminal in a multiterminal system. You do not need to do an MTATCH before using MTGET.

Form:

```
CALL MTGET (unit,addr[,jobnum])  
i = MTGET (unit,addr[,jobnum])
```

where:

**unit** is the unit number of the line and terminal whose status is desired  
**addr** is the four-word area to receive the status information.  
**jobnum** is the job number associated with the terminal if the terminal is not available

Status information including bit definitions for the terminal configuration words and the terminal state byte are described in detail under the .MTGET programmed request.

Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return.
= 3	Nonexistent unit number.
= 5	Unit attached by another job (job number returned in <i>jobnum</i> .)
= 6	In XM monitor, the optional status word address is not in a valid user virtual address space.
= 7	Unit attached by handler (name returned in <i>jobnum</i> .)

Error message *TRAP \$MSARG* will display if any argument is missing.

Example:

Refer to the *RT-11 System Macro Library Manual* for an example.

---

# MTIN

## Multiterminal Option

MTIN transfers characters from a specified terminal to the user program. This subroutine is a multiterminal form of ITTINR. If no characters are available, an error flag is set to indicate an error upon return from the subroutine. If no character count argument is specified, one character is transferred.

Form:

```
CALL MTIN (unit,char[,chrcnt][,ocnt])
i = MTIN (unit,char[,chrcnt][,ocnt])
```

where:

- unit** is the unit number of the terminal
- char** is the variable to contain the characters read in from the terminal indicated by the unit number
- chrcnt** is an optional argument that indicates the number of characters to be read
- ocnt** is an optional argument that indicates the number of characters actually transferred

When a request for a multiple-character transfer is requested, if the optional fourth argument (ocnt) is specified and bit 6 of the M.TSTS word is set, the variable specified as the argument will have a value equal to the actual number of characters transferred upon return from the subroutine.

Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return.
= 1	No input available.
= 2	Unit not attached.
= 3	Nonexistent unit number.
= 6	In XM monitor, the optional status word address is not in a valid user virtual address space.

Error message *TRAP \$MSARG* will display if any argument is missing.

Example:

Refer to the *RT-11 System Macro Library Manual* for an example.

---

# MTOUT

## Multiterminal Option

The MTOUT subroutine transfers characters to a specified terminal. This subroutine is a multiterminal form of ITTOUR. If no room is available in the output ring buffer, an error flag is set to indicate an error upon return from the subroutine. If no character count argument is specified, one character is transferred.

Form:

```
CALL MTOUT (unit,char[,chrcnt][,ocnt])
i = MTOUT (unit,char[,chrcnt][,ocnt])
```

where:

- unit** is the unit number of the terminal
- char** is the variable or array containing the characters to be output, right-justified in the integer (can be LOGICAL\*1 if desired)
- chrcnt** is an optional argument that indicates the number of characters to be output
- ocnt** is an optional argument that indicates the number of characters actually transferred

When a request for a multiple-character transfer is requested, if the optional fourth argument *ocnt* is specified and bit 6 of the M.TSTS word is set, the *ocnt* will have a value equal to the actual number of characters transferred upon return from the subroutine.

Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return.
= 1	No room in output ring buffer.
= 2	Unit not attached.
= 3	Nonexistent unit number.
= 6	In the XM monitor, the address of the user buffer is outside the valid program limits.

Error message *TRAP \$MSARG* will display if any argument is missing.

Example:

Refer to the *RT-11 System Macro Library Manual* for an example.

---

# MTPRNT

## Multiterminal Option

The MTPRNT subroutine allows output to be printed at any terminal in a multiterminal environment. This subroutine has the same effect as the PRINT subroutine. See PRINT.

Form:

```
CALL MTPRNT (unit,string)
i = MTPRNT (unit,string)
```

where:

**unit** is the unit number associated with the terminal

**string** is the character string to be printed. Note that all quoted literals used in FORTRAN subroutine calls are in ASCIZ format, which ends in null (0) for a RETURN instruction or a 200<sub>8</sub> to suppress RETURN instruction

Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return.
= 2	Unit not attached.
= 3	Nonexistent unit number.
= 6	In the XM monitor, the address of the character string is outside the valid program limits.

Error message *TRAP \$MSARG* will display if any argument is missing.

Example:

Refer to the *RT-11 System Macro Library Manual* for an example.

---

# MTRCTO

## Multiterminal Option

The MTRCTO subroutine resets the CTRL/O command typed at the specified terminal in a multiterminal environment. This subroutine has the same effect as the .MTRCTO programmed request.

Form:

```
CALL MTRCTO(unit)
i = MTRCTO(unit)
```

where:

**unit** is the unit number associated with the terminal

Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return.
= 2	Unit not attached.
= 3	Nonexistent unit number.

Error message *TRAP \$MSARG* will display if any argument is missing.

Example:

Refer to the *RT-11 System Macro Library Manual* for an example.

---

# MTSET

## Multiterminal Option

The MTSET subroutine sets terminal and line characteristics. The set conditions remain in effect until the system is booted or the terminal and line characteristics are reset. See the .MTSET programmed request for more details.

Form:

```
CALL MTSET (unit,addr)
i = MTSET (unit,addr)
```

where:

**unit** is the unit number of the line and terminal whose characteristics are to be changed

**addr** is a four-word area to pass the status information. The area is a four-element INTEGER\*2 array

Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return.
= 2	Unit not attached.
= 3	Nonexistent unit number.
= 6	In the XM monitor, the address of the status block is outside the valid program limits.

Error message *TRAP \$MSARG* will display if any argument is missing.

Example:

Refer to the *RT-11 System Macro Library Manual* for an example.

---

# MTSTAT

## Multiterminal Option

The MTSTAT subroutine returns multiterminal system status in an eight-word status block.

Form:

```
CALL MTSTAT (addr)
i = MTSTAT (addr)
```

where:

**addr** is the address of an eight-word array where multiterminal status information is returned. The status block contains the following information:

<b>addr(1)</b>	Offset from the base of the resident monitor to the first Terminal Control Block (TCB).
<b>addr(2)</b>	Offset from the base of the resident monitor to the terminal control block of the console terminal for the program.
<b>addr(3)</b>	The value (0-16 decimal) of the highest logical unit number (LUN) built into the system.
<b>addr(4)</b>	The size of the terminal control block in bytes.
<b>addr(5)-(8)</b>	Reserved.

Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return.
= 6	In the XM monitor, the address of the status block is not in valid user address space.

Example:

Refer to the *RT-11 System Macro Library Manual* for an example.

---

# MWAIT

## **Multijob**

The MWAIT subroutine suspends main program execution of the current job until all messages sent to or from the other job have been transmitted or received. It provides a means for ensuring that a required message has been processed. MWAIT is used primarily in conjunction with the IRCVD and ISDAT calls, where no action is taken when a message transmission is completed. This subroutine requires a queue element, which should be considered when the IQSET function is executed.

Form:

**CALL MWAIT**

Errors:

None.

Example:

See SDAT.

---

## POKE/IPOKE

IPOKE stores a specified 16-bit integer value into a 16-bit address in the current job's address space. The subroutine can store values in device registers if the register is in the current job's address space.

Form:

```
CALL POKE (iaddr,ivalue)
i = IPOKE (iaddr,ivalue)
```

where:

**iaddr** is the integer specification of the 16-bit address in the current job's address space to be modified. If this argument is not an even value, a trap results (except on an LSI-11 or a PDP-11/23)

**ivalue** is the integer value to be stored in the address specified by the iaddr argument

Errors:

None.

Example:

To set bit 12 in the JSW without zeroing any other bits in the JSW, refer to example under PEEK.

---

## POKEB/IPOKEB

POKEB/IPOKEB stores a specified 8-bit integer value into a 16-bit address in the current job's address space. Since this subroutine operates in a byte mode, the address supplied can be odd or even. The subroutine can store values in device registers if the register location is in the current job's address space.

Form:

```
CALL POKEB(iaddr,ivalue)
i = IPOKEB(iaddr,ivalue)
```

where:

**iaddr** is the integer specification of the 16-bit address in the current job's address space to be modified. Unlike the IPOKE subroutine, the IPOKEB subroutine allows odd addresses

**ivalue** is the integer value to be stored in the address specified by the iaddr argument. Only the low byte of ivalue is actually stored

Errors:

None.

Example:

See PEEK.

---

# PRINT

Refer to WRITE, MWRITC, MWRITW.

The PRINT subroutine prints output from a specified string to the terminal. This routine can be used to print messages from completion routines without using the FORTRAN formatted I/O system. Control returns to the user program after all characters have been placed in the output buffer.

Form:

**CALL PRINT (string)**

where:

**string** is the string to be printed. Note that all quoted literals used in FORTRAN subroutine calls are in ASCIZ format, as are all strings produced by the SYSLIB string-handling package (The CONCAT routine can be used to append an octal 200 to an ASCIZ string; see example.)

The string to be printed can be terminated with either a null (0) byte or a 200(octal) byte. If the null (ASCIZ) format is used, the output is automatically followed by a carriage return/line feed pair (octal 15 and 12). If a 200 byte terminates the string, no carriage return/line feed pair is generated.

In the FB monitor, a change in the job that is controlling terminal output is indicated by a B> or F>. Any text following the message has been printed by the job indicated (foreground or background) until another B> or F> is printed. In a system job monitor the job name is printed; for example, SPOOL>. When PRINT is used by the foreground job, the message appears immediately, regardless of the state of the background job. Thus, for urgent messages, PRINT should be used rather than ITTOUR.

Errors:

If an argument is missing, a random portion of memory is printed, as if it were text.

Example:

```
Program FPRINT
C
C This shows calls to PRINT with normal CRLF and with
C it suppressed.
C
C Byte PROMPT (80)
C
C Call PRINT ('This is a normal line of output')
C Call CONCAT ('Name? ', '200'o, PROMPT)
C Call PRINT (PROMPT) !and one w/o CRLF
C Call Print ('Frank Johnson') !"answer" prompt
End
```

---

## PROTE/IPROTE

PROTE/IPROTE lets a job obtain exclusive control of a two-word vector in the region 0 to 474. If PROTE returns successfully:

- Specified locations are not currently in use by another job or the monitor.
- Calling job can place an interrupt address and priority in the protected 2-word vector and begin the device associated with those vectors.

Form:

```
CALL PROTE (addr)
i = IPROTE (addr)
```

where:

**addr** is the address of the 2-word vector pair to be protected

Errors:

Value	Meaning
i = 0	Normal return
= -1	Protect failure; location already in use.
= -2	<i>Addr</i> is greater than 474 or not a multiple of 4.
= -257	Required argument <i>addr</i> missing.

Example:

```

      Program FPROTE
C
C      Try to protect all the vectors, see which are
C      already protected.
C      Then unprotect all of them.
C
      Parameter MAXVEC = '474'o
      Integer*2 VEC          !vector to try
C
      Do 100, VEC = 0, MAXVEC, 4
          If (IPROTE (VEC) .ne. 0) Type 1, VEC
1          Format (' ', o3, ' was protected')
          Call UNPRO (VEC) !just unprotect everything (we can)
100      Continue
      End
```

---

## PURGE

The PURGE subroutine deactivates a channel. Any tentative file currently associated with the channel is not made permanent. This subroutine prevents entered (IENTER or .ENTER) files from becoming permanent directory entries.

Form:

**CALL PURGE(chan)**

where:

**chan** is the integer specification for the RT-11 channel to be deactivated

Errors:

Error message *TRAP \$MSARG* will display if any argument is missing.

Example:

Refer to the example under ENTER/IENTER.

---

## PUT/IPUT

PUT replaces the value of a monitor fixed offset. PUT uses the monitor .PVAL programmed request.

Form:

```
CALL PUT (ioff,value[,operation][,ierr])
ierr = IPUT (ioff,value[,operation])
```

where:

<b>ioff</b>	is the offset (from the base of RMON) to be modified
<b>value</b>	Specifies an integer replacement value to replace current contents of offset location or specifies a BIC/BIS mask, if <i>operation</i> is specified.
<b>operation</b>	If specified, one of the following: <ul style="list-style-type: none"><li>• MOV = Replace with a MOV operation (default).</li><li>• BIC = Change with a BIC operation.</li><li>• BIS = Change with a BIS operation.</li></ul>
<b>ierr</b>	the word that will get the error status of the request.

Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Success, except for trap message.
= -1	Offset out of range.
= -2	Trap 4 (odd address/non-existent memory.) location.

Error message *TRAP \$MSARG* will display if any argument is missing.

Example:

```
Program FPUT
C Change the default max file size to 10 and try
C a ENTER to verify the effect, then put it back.
Parameter MAXBL = '314'o !fixed offset for max block
Integer*2 OLDMAX          !old value
Integer*2 DBLK(4)
Data DBLK /3rDK , 3rTES, 3rT , 3rTMP/
OLDMAX = ISPY (MAXBL)    !get old value
Type 1, OLDMAX
1 Format (' ', 'MAXBL=', o7)
Call PUT (MAXBL, 10)     !set it to 10
IERR = IENTER (IGETC (), DBLK, 0) !ask for default space
Type 2, IERR
2 Format (' ', 'Created file size', o7)
Type 1, IPUT (MAXBL, OLDMAX) !put it back
Type 1, ISPY (MAXBL)      !verify
End
```

---

## R50ASC

The R50ASC subroutine converts a specified number of Radix-50 characters to ASCII.

Form:

**CALL R50ASC (icnt,input,output)**

where:

- icnt** is the integer number of ASCII characters to be produced
- input** is the area from which words of Radix-50 values to be converted are taken. Note that  $(icnt+2)/3$  words are read for conversion
- output** is the area into which the ASCII characters are stored

Errors:

Error message *TRAP \$MSARG* will display if any argument is missing.

If an input word contains illegal Radix-50 codes—that is, if the input word is greater (unsigned) than 174777(octal)—the routine outputs question marks for the value.

Example:

See CSI.

---

## RAD50

The RAD50 function provides a method of encoding RT-11 file descriptors in Radix-50 notation. The RAD50 function converts six ASCII characters from the specified area, returning a REAL\*4 result that is the two-word Radix-50 value.

Form:

**a = RAD50 (input)**

where:

**input** is the area from which the ASCII input characters are taken

The RAD50 call:

**A = RAD50 (LINE)**

is exactly equivalent to the IRAD50 call:

**CALL IRAD50 (6,LINE,A)**

Function Results:

The two-word Radix-50 value is returned as the function result.

Errors:

Unpredictable results will occur if any required argument is omitted.

Example:

```
Real*8 FSPEC  
Call IRAD50 (12, 'SY SWAP SYS', FSPEC)
```

---

## RAN/RANDU

RT-11 adds the RAN function and RANDU subroutine, uniform pseudo-random number generators to SYSLIB. These are the same default routines as those previously supplied with FORTRAN-77. RAN and RANDU were previously located in the FORTRAN IV and FORTRAN-77 object time system libraries. RAN and RANDU are different from the routines previously supplied with FORTRAN IV.

RAN and RANDU generate a floating-point number that is evenly distributed in the range between 0.0 inclusive and 1.0 exclusive (1.0 is never generated).

When you provide a 32-bit seed number, that number is automatically updated according to the following:

$$\text{SEED} = 69069 * \text{SEED} + 1 \pmod{2^{32}}$$

The value of SEED is a 32-bit number. The high-order 24 bits of SEED are converted to floating point and returned as the result *f*.

Form:

```
f = RAN (jseed)
f = RAN (iseed1,iseed2)
CALL RANDU(iseed1,iseed2,f)
```

where:

**f** is a 32-bit floating-point variable  
**jseed** is an INTEGER\*4 seed number  
**iseed1** is the low-order INTEGER\*2 seed variable  
**iseed2** is the high-order INTEGER\*2 seed variable

RAN and RANDU are multiplicative-congruential, general-random-number generators. They are fast, but prone to nonrandom sequences if you construct and analyze triples of generated numbers.

There are no restrictions on the seed. The seed should be initialized to different values on separate runs to obtain different random sequences.

Errors:

Unpredictable results will occur if any required argument is omitted.

Example:

This example illustrates a simple way to get a uniform random integer selector. Multiply the value returned by the RAN function by the number of cases—in this example, five.

```
GO TO (1,2,3,4,5), (1 + IFIX(5.*RAN(JSEED)))
```

The explicit IFIX is necessary before adding 1 to avoid possible rounding during the normalization after the addition of floating-point numbers.

---

## RCHAIN

The RCHAIN subroutine allows a program to determine whether it has been chained to and to access variables passed across a chain. If RCHAIN is used, it must be used in the first executable FORTRAN statement in a program.

Form:

**CALL RCHAIN (flag,var,wcnt)**

where:

- flag** is an integer variable that RCHAIN will set to -1 (true) if the program has been chained to; otherwise, it is 0 (false)
- var** is the first variable in a sequence of variables with increasing memory addresses to receive the information passed across the chain (See CHAIN).
- wcnt** is the number of words to be moved from the chain parameter area to the area specified by var. RCHAIN moves *wcnt* words into the area beginning at *var*.

Errors:

Error message *TRAP \$MSARG* will display if any argument is missing.

Example:

See also CHAIN.

```
      Program FRCHAI  ! test RCHAIN routine
C
C      Receive .CHAIN and expect 100,200,301 as input
C
      Logical*2 FLAG
      Parameter SUCCS = '001'o, ERROR = '004'o, FATAL = '010'o
      Common /RCHAIN/ L, M, N
C
      Call RCHAIN (FLAG, L, 3)
      If (.not. FLAG) Go To 1000      !not chained to
      If (L .ne. 100) Go To 2000     !wrong value
      If (M .ne. 200) Go To 2000     !wrong value
      If (N .ne. 301) Go To 2000     !wrong value
      Type *, ' !FRCHAI-I-Successful chain entry'
      Call EXIT (SUCCS)
C
1000  Type *, ' ?FRCHAI-F-Not chained to'
      Call EXIT (FATAL)
C
2000  Type *, ' ?FRCHAI-E-Wrong value'
      Call EXIT (ERROR)
      End
```

---

## RCTRLO

The RCTRLO subroutine resets the effect of any console terminal CTRL/O command that was typed. After an RCTRLO call, any output directed to the console terminal prints until another CTRL/O is typed. It should also be issued after the program changes any JSW bits, to synchronize internal monitor data structures.

Form:

**CALL RCTRLO**

Errors:

None.

Example:

See PEEK.

---

## \*RCVD/\*RCVDC/\*RCVDF/\*RCVDW

### Multijob

Four forms of \*RCVD can be used in conjunction with the ISDAT (send data) functions to allow a general data/message transfer system. All forms of \*RCVD, issued either as a function or subroutine, issue RT-11 receive-data programmed requests. These functions require a queue element which should be a consideration when the IQSET function is executed.

Specify mapping for MRCVD, MRCVDC and MRCVDW by optional parameters *BMODE* and *CMODE*.

### RCVD/IRCVD/MRCVD

RCVD/IRCVD/MRCVD requests data and continues execution. The operation is queued and the issuing job continues execution. When the job has to receive the transmitted message, an MWAIT should be executed. This causes the job to be suspended until all pending messages have been received.

Form:

```
CALL RCVD (buff,wcnt)
i = IRCVD (buff,wcnt)
CALL MRCVD (buff,wcnt[,BMODE=strg])
i = MRCVD (buff,wcnt[,BMODE=strg])
```

where:

**buff** is the array to be used to buffer the data received. The array must be one word larger than the message to be received because the first word contains the integer number of words actually transmitted when IRCVD is complete.

**wcnt** is the maximum integer number of words that can be received

**BMODE=strg** Specify *strg* with one of the following: 'UI'/'UD'/'SI'/'SD'/'CD'/'CI'. Value specifies the mapping mode of the *buff* argument.

Errors:

Value	Meaning
i = 0	Normal return.
= 1	No other job exists in the system. A job exists as long as it is loaded, whether or not it is active.
= -19	Invalid BMODE value.

Error message *TRAP \$MSARG* will display if *buff* or *wcnt* argument is missing.

**Example:**

```
Program FRCVD !demo RCVD (use with FSDATx)
C
C Try to get a message from the other job, when
C you get it, display it and exit.
C
Parameter SUCCS = '001'o, FATAL = '010'o
Parameter RVCNT = 0, RCVMSG = 1, WCNT = 42
Integer*2 CTRLZ
Data CTRLZ /'032'o/
Integer*2 BUFFER(RVCNT:WCNT)
C
100 Continue
      IERR = IRCVD (BUFFER, WCNT) !try for a message
      If (IERR .eq. 1) Go To 100 !wait for the job
      If (IERR .ne. 0) Go To 200 !unknown error
      Call MWAIT !wait for a message
      If (BUFFER(RCVMSG) .eq. CTRLZ) Go To 300 !"EOF"
      Call PRINT (BUFFER(RCVMSG)) !display message (skip count)
      Go To 100 !get another
C
200 Call PRINT ('?FRCVD-F-Unknown error code from IRCVD')
      Call EXIT (FATAL)
C
300 Call PRINT ('!FRCVD-I-Normal termination')
      Call EXIT (SUCCS) !and done
End
```

**RCVDC/IRCVDC/MRCVDC**

RCVDC/IRCVDC/MRCVDC requests data and enters an assembly language completion routine when the message is received. RCVDC/IRCVDC/MRCVDC is queued, and program execution stays with the issuing job. When the other job sends a message, the completion routine specified is queued and run according to standard scheduling of completion routines.

Form:

```
CALL RCVDC (buff,wcnt,crtn)
i = IRCVDC (buff,wcnt,crtn)
CALL MRCVDC (buff,wcnt,crtn[,BMODE=strg][,CMODE=strg])
i = MRCVDC (buff,wcnt,crtn[,BMODE=strg][,CMODE=strg])
```

where:

**buff** is the array to be used to buffer the data received. The array must be one word larger than the message to be received because the first word contains the integer number of words actually transmitted when IRCVDC is complete

**wcnt** is the maximum integer number of words to be received

## \*RCVD/\*RCVDC/\*RCVDF/\*RCVDW

**crtn** is the assembly language completion routine to be entered. This name must be specified in a FORTRAN EXTERNAL statement in the routine that issues the IRCVDC call

**BMODE=strg** Specify *strg* with one of the following: 'UI'/'UD'/'SI'/'SD'/'CD'/'CI'. This value specifies the mapping mode of the *buff* argument.

**CMODE=strg** Specify *strg* as string 'S' to specify a Supervisor address.

### Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return.
= 1	No other job exists in the system. A job exists as long as it is loaded, whether or not it is active.
=-19	Invalid BMODE or CMODE value.

Error message *TRAP \$MSARG* will display if *buff*, *wcnt*, or *crtn* argument is missing.

### Example:

See SFDAT examples.

**RCVDF/IRCVDF**

RCVDF/IRCVDF requests data and enters a FORTRAN completion subroutine when the message is received. The RCVDF/IRCVDF is queued, and program execution continues with the issuing job. When the other job sends a message, the FORTRAN completion routine specified is entered.

Form:

**CALL RCVDF (buff,wcnt,area,frtn)**  
**i = IRCVDF (buff,wcnt,area,frtn)**

where:

- buff** is the array to be used to buffer the data received. The array must be one word larger than the message to be received because the first word contains the integer number of words actually transmitted when IRCVDF is complete
- wcnt** is the maximum integer number of words to be received
- area** is a four-word area to be set aside for linkage information. This area must not be modified by the FORTRAN program and the USR must not swap over it. This area can be reclaimed by other FORTRAN completion routines when crtn has been entered
- frtn** is the FORTRAN completion routine to be entered. This name must be specified in an EXTERNAL statement in the FORTRAN routine that issues the RCVDF call

Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return.
= 1	No other job exists in the system. A job exists as long as it is loaded, whether or not it is active.

Error message *TRAP \$MSARG* will display if *buff*, *wcnt*, *area* or *frtn* argument is missing.

Example:

See also SDAT\*.

```

Program FRCVDF !demo RCVDF (use with FSDATx)
C
C Try to get a message from the other job, when
C you get it, display it and exit.
C
Parameter SUCCS = '001'o, FATAL = '010'o
Parameter RCVCNT = 0, RCVMSG = 1, WCNT = 42
Integer*2 BUFFER(RCVCNT:WCNT)
Common /DATA/ BUFFER
Integer*2 LINKAG(4) !area for linkage
External FRCVDG !completion routine
C
100 Continue

```

## \*RCVD/\*RCVDC/\*RCVDF/\*RCVDW

```
        IERR = IRCVDF (BUFFER, WCNT, LINKAG, FRCVDG) !try for a message
        If (IERR .eq. 1) Go To 100 !wait for the job
        If (IERR .ne. 0) Go To 200 !unknown error
C
C      other processing not requiring message could be done here
C
        Call SUSPND !wait for completion routine to
C      ! resume us
        Call PRINT ('!FRCVDF-I-Termination successfully completed')
        Call EXIT (SUCCS) !and done
C
200    Call PRINT ('?FRCVDF-F-Unknown error code from IRCVDF')
        Call EXIT (FATAL)
        End

Subroutine FRCVDG !completion routine for FRCVDF
Parameter FATAL = '010'o
Parameter RCVCNT = 0, RCVMSG = 1, WCNT = 42
Integer*2 CTRLZ
Data CTRLZ /'032'o/
Integer*2 BUFFER(RCVCNT:WCNT)
Common /DATA/ BUFFER
Integer*2 LINKAG(4) !area for linkage
External FRCVDH !fakeout the recursion detection
C
        If (BUFFER(RCVMSG) .eq. CTRLZ) Go To 100 !"EOF"
        Call PRINT (BUFFER(RCVMSG)) !print the data
        IERR = IRCVDF (BUFFER, WCNT, LINKAG, FRCVDH) !try for next message
        If (IERR .ne. 0) Go To 200 !unknown error
        Return
C
100    Call RESUME !restart mainline so it can exit
        Return
C
200    Call PRINT ('?FRCVDG-F-Unknown error code from IRCVDF')
        Call EXIT (FATAL) !can't really exit cleanly from
C      !completion, but dying is ok anyway
        End

        .TITLE FRCVDH -- Just call FRCVDG
FRCVDH::CALLR FRCVDG ;slip around recursion detection
;in the compiler
        .END
```

**RCVDW/IRCVDW/MRCVDW**

RCVDW/IRCVDW/MRCVDW requests data and waits until it is available. This function queues a message request and suspends the job issuing the request until the other job sends a message. When execution of the issuing job resumes, the message has been received, and the first word of the buffer indicates the number of words transmitted.

Form:

```
CALL RCVDW (buff,wcnt)
i = IRCVDW (buff,wcnt)
CALL MRCVDW (buff,wcnt[,BMODE=strg])
i = MRCVDW (buff,wcnt[,BMODE=strg])
```

where:

**buff** is the array to be used to buffer the data received. The array must be one word larger than the message to be received because the first word contains the integer number of words actually transmitted when IRCVDW is complete

**wcnt** is the maximum integer number of words to be received

**BMODE=strg** Specify *strg* with one of the following: 'UI'/'UD'/'SI'/'SD'/'CD'/'CI'. This value specifies the mapping mode of the *buff* argument.

Errors:

Value	Meaning
i = 0	Normal return.
= 1	No other job exists in the system. A job exists as long as it is loaded, whether or not it is active.
=-19	Invalid BMODE value.

Error message *TRAP \$MSARG* will display if *buff* or *wcnt* argument is missing.

Example:

See also SDAT\*.

```

Program FRCVDW !demo RCVDW (use with FSDATx)
C
C Try to get a message from the other job, when
C you get it, display it and exit.
C
Parameter SUCCS = '001'o, FATAL = '010'o
Parameter RCVCNT = 0, RCVMSG = 1, WCNT = 42
Integer*2 CTRLZ
Data CTRLZ /'032'o/
Integer*2 BUFFER(RCVCNT:WCNT)
C
100 Continue
IERR = IRCVDW (BUFFER, WCNT) !try for a message
If (IERR .eq. 1) Go To 100 !wait for the job
If (IERR .ne. 0) Go To 200 !unknown error
If (BUFFER(RCVMSG) .eq. CTRLZ) Go To 300 !"EOF"
```

**\*RCVD/\*RCVDC/\*RCVDF/\*RCVDW**

```
                Call PRINT (BUFFER(RCVMSG)) !display message (skip count)
                Go To 100
C
200            Call PRINT ('?FRCVDW-F-Unknown error code from IRCVDW')
                Call EXIT (FATAL)
C
300            Call PRINT ('!FRCVDW-I-Success')
                Call EXIT (SUCCS)                !and done
                End
```

---

## \*READ/\*READC/\*READF/\*READW

### Multijob

Four forms of \*READ, issued as a function or as a subroutine, transfer a specified number of words from a file into memory. These functions require a queue element, which should be considered when the IQSET function is executed.

Specify mapping for MREAD, MREADC and MREADW by optional parameters *BMODE* and *CMODE*.

### READ/IREAD/MREAD

READ/IREAD/MREAD issued either as a function or subroutine, transfers a specified number of words from memory to the device or file specified by channel. Control returns to the user program immediately after the READ/IREAD/MREAD function is initiated. No special action is taken when the transfer is completed.

Form:

```
CALL READ (wcnt,buff,blk,chan)
i = IREAD (wcnt,buff,blk,chan)
CALL MREAD (wcnt,buff,blk,chan[,BMODE=strg])
i = MREAD (wcnt,buff,blk,chan[,BMODE=strg])
```

where:

<b>wcnt</b>	is the relative integer number of words to be transferred
<b>buff</b>	is the array to be used as the buffer; this array must contain at least <i>wcnt</i> words
<b>blk</b>	is the integer block number of the file to be read. The first block of a file is block number 0. The blk argument must be updated when necessary. For example, if the program is reading two blocks at a time, blk should be updated by 2
<b>chan</b>	is the integer specification for the RT-11 channel to be used
<b>BMODE=strg</b>	Specify <i>strg</i> with one of the following: 'UI'/'UD'/'SI'/'SD'/'CD'/'CI.' This value specifies the mapping mode of the <i>buff</i> argument.

Function Return:

**i =** Normal return; *i* equals the number of words requested (0 for non-file-structured read, multiple of 256 for file-structured read). If the read is from a magtape, the number of words requested is returned. For example:

- If *wcnt* is a multiple of 256 and less than that number of words remain in the file, *i* is shortened to the number of words that remain in the file; thus, if *wcnt* is 512 and only 256 words remain, *i*=256.

## \*READ/\*READC/\*READF/\*READW

- If *wcnt* is not a multiple of 256 and more than *wcnt* words remain in the file, *i* is rounded up to the next block; thus, if *wcnt* is 312 and more than 312 words remain, *i* = 512, but only 312 are read.
- If *wcnt* is not a multiple of 256 and less than *wcnt* words remain in the file, *i* equals a multiple of 256 that is the actual number of words being read.

### Errors:

Value	Meaning
<i>i</i> = -1	Attempt to read past end-of-file; no words remain in the file.
= -2	Hardware error occurred on channel.
= -3	Specified channel is not open.
= -19	Invalid BMODE value.

Error message *TRAP \$MSARG* will display if any argument is missing.

### Notes

If an asynchronous operation on a channel (for example, IREAD) results in end-of-file, the following IWAIT will not detect it. IWAIT detects only hard error conditions. A subsequent operation on that channel will detect end-of-file and returns the end-of-file error code. Under these conditions, the subsequent operation is not initiated.

### Example:

```
Program FREAD
C
C Demonstrate IREAD and IWAIT
C Scan SRC: and try to find this source file
C
Parameter SUCCS = '001'o, FATAL = '010'o
Parameter NULL = '000'o, HT = '011'o
Parameter LF = '012'o, CR = '015'o
Integer*2 BUF(256)      !block buffer
Byte CBUF(512)         !char overlay for BUF
Equivalence (CBUF(1), BUF(1))
Integer*2 CHAN         !channel number to use
Integer*2 SRC(2)       !device dblk
Data SRC /3rSRC, 0/    !whole device (no file name)
Integer*2 BLK         !current block number
Integer*2 IERR        !function return value
Byte Search(17)       !our first few chars
Data Search /HT, 'P', 'r', 'o', 'g', 'r', 'a', 'm',
1 ' ', 'F', 'R', 'E', 'A', 'D', CR, LF, NULL/
C
CHAN = IGETC()        !allocate a channel
BLK = 0               !begin at the beginning
Call LOOKUP (CHAN, SRC) !open the device
```

**\*READ/\*READC/\*READF/\*READW**

```
100 Continue
      IERR = IREAD (256, BUF, BLK, CHAN)
      If (IERR .ne. 256) Go To 200 !failure
C
C      The program could do something not dependent on
C      the I/O here
C
      IERR = IWAIT (CHAN) !wait for the data
      If (IERR .ne. 0) Go To 300 !failure
      Call SCOPY (CBUF, CBUF, 16) !truncate the string
      If (ISCOMP (CBUF, SEARCH) .eq. 0)
1      Type 101, BLK !Eureka!
101 Format (' ', '!FREAD-I-Self discovery at block ', i6)
      BLK = BLK + 1 !try next block
      Go To 100
C
200 Continue
      If (IERR .eq. -2) Go To 400 !hard err is expected
      If (IERR .eq. -1) Type 102
102 Format (' ', '?FREAD-F-EOF from IREAD')
      If (IERR .ne. -1) Type 103, IERR
103 Format (' ', '?FREAD-F-Unexpected error from IREAD', i6)
      Call EXIT (FATAL)
300 Continue
      If (IERR .eq. 2) Go To 500 !hard err is expected
      Type 104, IERR
104 Format (' ', '?FREAD-F-Unexpected error from IWAIT', i6)
      Call EXIT (FATAL)
400 Type 105
105 Format (' ', '!FREAD-I-Success (probably)')
      Call EXIT (SUCCS)
500 Type 106
106 Format (' ', '?FREAD-F-Hard error from IREAD')
      Call EXIT (SUCCS)
      End
```

## \*READ/\*READC/\*READF/\*READW

### READC/IREADC/MREADC

READC/IREADC/MREADC, issued either as a function or subroutine, transfers a specified number of words from memory to the device or file specified by channel. Control returns to the user program immediately after the READC/IREADC/MREADC function is initiated. When the operation is complete, the specified assembly language routine (*crtn*) is entered as an asynchronous completion routine.

Form:

```
CALL READC (wcnt,buff,blk,chan,crtn)
i = IREADC (wcnt,buff,blk,chan,crtn)
CALL MREADC (wcnt,buff,blk,chan,crtn[,BMODE=strg][,CMODE=strg])
i = MREADC (wcnt,buff,blk,chan,crtn[,BMODE=strg][,CMODE=strg])
```

where:

<b>wcnt</b>	is the integer number of words to be transferred
<b>buff</b>	is the array to be used as the buffer; this array must contain at least <i>wcnt</i> words
<b>blk</b>	is the integer block number of the file to be read. The user program normally updates <i>blk</i> before it is used again. The first block of a file is block number 0.
<b>chan</b>	is the integer specification for the RT-11 channel to be used
<b>crtn</b>	is the assembly language routine to be activated when the transfer is complete. This name must be specified in an EXTERNAL statement in the FORTRAN routine that issues the IREADC call
<b>BMODE=strg</b>	Specify <i>strg</i> with one of the following: 'UI'/'UD'/'SI'/'SD'/'CD'/'CI'. This value specifies the mapping mode of the <i>buff</i> argument.
<b>CMODE=strg</b>	Specify <i>strg</i> as string 'S' to specify Supervisor address.

Function Return:

**i =** Normal return; *i* equals the number of words requested (0 for non-file-structured read, multiple of 256[decimal] for file-structured read). If the read is from a magtape, the number of words requested is returned. For example:

- If *wcnt* is a multiple of 256 and less than that number of words remain in the file, *i* is shortened to the number of words that remain in the file; thus, if *wcnt* is 512 and only 256 words remain, *i*=256.

- If *wcnt* is not a multiple of 256 and more than *wcnt* words remain in the file, *i* is rounded up to the next block; thus, if *wcnt* is 312 and more than 312 words remain, *i* = 512, but only 312 are read.
- If *wcnt* is not a multiple of 256 and less than *wcnt* words remain in the file, *i* equals a multiple of 256 that is the actual number of words being read.

Errors:

<b>Value</b>	<b>Meaning</b>
<i>i</i> = -1	Attempt to read past end-of-file; no words remain in the file.
= -2	Hardware error occurred on channel.
= -3	Specified channel is not open.
= -19	Invalid BMODE or CMODE value.

Error message *TRAP \$MSARG* will display if any argument is missing.

## \*READ/\*READC/\*READF/\*READW

Example:

See RCVDF for FRCVDM routine.

```
      Program FREADC
C
C      This program demonstrates READC and WRITC
C
      Parameter SUCCS = '001'o, FATAL = '010'o
      Integer*2 DBLKI(4), DBLKO(4)      !file names
      Data DBLKI /3rSRC, 3rFRE, 3rADC, 3rFOR/
      Data DBLKO /3rDK , 3rFRE, 3rADC, 3rTMP/
      Parameter WCNT = 256              !buffer size
      Integer*2 BUFFER (WCNT)          !buffer itself
      Integer*2 ICHAN, OCHAN           !channel numbers
      Integer*2 BLK                     !block number
      External FRCVDM
C
      ICHAN = IGETC()                  !get channel numbers
      OCHAN = IGETC()                  ! ...
      ISIZE = LOOKUP (ICHAN, DBLKI)    !open input file
      If (ISIZE .lt. 0) Go to 1000     !error
      IERR = IENTER (OCHAN , DBLKO, ISIZE) !open output file
      If (IERR .lt. 0) Go To 1100     !error
      Do 500, BLK = 0, ISIZE-1        !copy all the blocks
          IERR = IREADC (WCNT, BUFFER, BLK, ICHAN, FRCVDM)
          If (IERR .ne. WCNT) Go To 1200
C          here you could do something else while waiting for I/O
          Call SUSPND                  !wait for completion routine
          IERR = IWRITC (WCNT, BUFFER, BLK, OCHAN, FRCVDM)
          If (IERR .ne. WCNT) Go To 1300
C          here you could do something else while waiting for I/O
          Call SUSPND                  !wait for completion routine
500      Continue
      Call CLOSEC (ICHAN)
      Call CLOSEC (OCHAN)
      Call EXIT (SUCCS)
C
1000     Type *, '?FREADC-F-LOOKUP failed, code = ', ISIZE
      Call EXIT (FATAL)
1100     Type *, '?FREADC-F-ENTER failed, code = ', IERR
      Call EXIT (FATAL)
1200     Type *, '?FREADC-F-READC failed, code = ', IERR
      Call EXIT (FATAL)
1300     Type *, '?FREADC-F-WRITC failed, code = ', IERR
      Call EXIT (FATAL)
      End
```

**READF/IREADF**

READF/IREADF issued as either as a function or subroutine, transfers a specified number of words from memory to the device or file specified by channel. Control returns to the user program immediately after the IREADF function is initiated. When the operation is complete, the specified FORTRAN subprogram (*frtn*) is entered as an asynchronous completion routine.

Form:

```
CALL READF (wcnt,buff,blk,chan,area,frtn)
i = IREADF (wcnt,buff,blk,chan,area,frtn)
```

where:

<b>wcnt</b>	is the integer number of words to be transferred
<b>buff</b>	is the array to be used as the buffer; this array must contain at least <i>wcnt</i> words
<b>blk</b>	is the integer block number of the file to be used. The user program normally updates <i>blk</i> before it is used again. The first block of a file is block number 0
<b>chan</b>	is the integer specification for the RT-11 channel to be used
<b>area</b>	is a four-word area to be set aside for link information; this area must not be modified by the FORTRAN program or swapped over by the USR. This area can be reclaimed by other FORTRAN completion functions when <i>frtn</i> has been activated
<b>frtn</b>	is the FORTRAN routine to be activated on completion of the transfer. This name must be specified in an EXTERNAL statement in the routine that issues the READF call. See description of completion routines.

Function Return:

**i =** Normal return; *i* equals the number of words requested (0 for non-file-structured read, multiple of 256[decimal] for file-structured read). If the read is from a magtape, the number of words requested is returned. For example:

- If *wcnt* is a multiple of 256 and less than that number of words remain in the file, *i* is shortened to the number of words that remain in the file; thus, if *wcnt* is 512 and only 256 words remain, *i*=256.

## \*READ/\*READC/\*READF/\*READW

- If *wcnt* is not a multiple of 256 and more than *wcnt* words remain in the file, *i* is rounded up to the next block; thus, if *wcnt* is 312 and more than 312 words remain, *i* = 512, but only 312 are read.
- If *wcnt* is not a multiple of 256 and less than *wcnt* words remain in the file, *i* equals a multiple of 256 that is the actual number of words being read.

Errors:

Value	Meaning
<i>i</i> = -1	Attempt to read past end-of-file; no words remain in the file.
= -2	Hardware error occurred on channel.
= -3	Specified channel is not open.

Error message *TRAP \$MSARG* will display if any argument is missing.

Example:

```
Program FREADF

          End
```

**READW/IREADW/MREADW**

READW/IREADW/MREADW issued either as a function or subroutine, transfers a specified number of words from memory to the device or file specified by channel. Control returns to the user program when the transfer is complete or when an error is detected.

Form:

```
CALL READW (wcnt,buff,blk,chan)
i = IREADW (wcnt,buff,blk,chan)
CALL MREADW (wcnt,buff,blk,chan[,BMODE=strg])
i = MREADW (wcnt,buff,blk,chan[,BMODE=strg])
```

where:

<b>wcnt</b>	is the integer number of words to be transferred
<b>buff</b>	is the array to be used as the buffer; this array must contain at least <i>wcnt</i> words
<b>blk</b>	is the integer block number of the file to be read. The user program normally updates <i>blk</i> before it is used again
<b>chan</b>	is the integer specification for the RT-11 channel to be used
<b>BMODE=strg</b>	Specify <i>strg</i> with one of the following: 'UI'/'UD'/'SI'/'SD'/'CD'/'CI'. This value specifies the mapping mode of the <i>buff</i> argument.

Function Return:

- i =** Normal return; *i* equals the number of words requested (0 for non-file-structured read, multiple of 256[decimal] for file-structured read). If the read is from a magtape, the number of words requested is returned. For example:
- If *wcnt* is a multiple of 256 and less than that number of words remain in the file, *i* is shortened to the number of words that remain in the file; thus, if *wcnt* is 512 and only 256 words remain, *i*=256.
  - If *wcnt* is not a multiple of 256 and more than *wcnt* words remain in the file, *i* is rounded up to the next block; thus, if *wcnt* is 312 and more than 312 words remain, *i* = 512, but only 312 are read.
  - If *wcnt* is not a multiple of 256 and less than *wcnt* words remain in the file, *i* equals a multiple of 256 that is the actual number of words being read.

## \*READ/\*READC/\*READF/\*READW

Errors:

Value	Meaning
i = -1	Attempt to read past end-of-file; no words remain in the file.
= -2	Hardware error occurred on channel.
= -3	Specified channel is not open.
= -19	Invalid BMODE value.

Error message *TRAP \$MSARG* will display if any argument is missing.

Example:

```
Program FREADW
C Demonstrate IREADW
C Scan SRC: and try to find this source file
Parameter SUCCS = '001'o, FATAL = '010'o

105 Format (' ', '!FREADW-I-Success (probably)')
    Call EXIT (SUCCS)
End
```

---

# RENAM/IRENAM

## Multijob

RENAM/IRENAM causes an immediate change of the name of a specified file.

Form:

```
CALL RENAM (chan,dblk)
i = IRENAM (chan,dblk)
```

where:

- chan** is the integer specification for the RT-11 channel to be used for the operation. You must obtain this channel through an IGETC call, or you can use channel 16(decimal) or higher if you have done an ICDFN call. The channel is again available for use once the rename operation is completed
- dblk** is the eight-word area specifying the name of the existing file and the new name to be assigned. If considered as an eight-element INTEGER\*2 array, *dblk* has the form:
- Words 1-4 specify the Radix-50 file descriptor for the old file name
  - Words 5-8 specify the Radix-50 file descriptor for the new file name

## NOTE

IRENAM arguments must be positioned so USR does not swap over them.

If a file already exists with the same name as the new file on the indicated device, it is deleted. IRENAM requires that the handler to be used be resident at the time the IRENAM is issued. If it is not, a monitor error occurs. The device names specified in the file descriptors must be the same.

For more information on renaming files, see the .RENAME programmed request.

Errors:

Value	Meaning
i = 0	Normal return.
= 1	Specified channel is already open.
= 2	Specified file was not found.
= 3	Invalid operation.
= 4	A file by that name already exists and is protected.

Error message *TRAP \$MSARG* will display if *chan* or *dblk* argument is missing.

## RENAM/IRENAM

Example:

```
      Program FRENAM
C
C      Demonstrate renaming a file
C
      Parameter SUCCS = '001'o, FATAL = '010'o
      Integer*2 CHAN          !i/o channel
      Integer*2 IERR          !error code
      Integer*2 DBLK2(8)     !a pair of DBLKS
      Data DBLK2
      1 /3rDK , 3rFAT, 3r      , 3rTMP,
      2 3rDK , 3rPOR, 3rTLY , 3rTMP/
C
      CHAN = IGETC ( )          !get a channel
      IERR = IRENAM (CHAN, DBLK2) !apply euphemism
      If (IERR .ne. 0) Go To 100 !problem
      Call PRINT ('!FRENAM-I-Success')
      Call EXIT (SUCCS)
100  Continue
      Type *, '?FRENAM-F-Unexpected error', IERR
      Call EXIT (FATAL)
      End
```

---

# REOPEN/IREOPEN

## Multijob

REOPEN/IREOPEN identifies a specified channel with a file on which an ISAVES was performed. The ISAVES/IREOPEN combination is useful when a large number of files must be operated on at one time. Necessary files can be opened with LOOKUP and their status preserved with ISAVES. When data is required from a file, an IREOPEN enables the program to read from the file. IREOPEN is not required to reference same channel as the original LOOKUP and ISAVES.

Form:

```
CALL REOPEN (chan,cblk)
i = IREOPEN (chan,cblk)
```

where:

**chan** is the integer specification for the RT-11 channel to be associated with the reopened file; this channel must be initially inactive

**cblk** is the five-word block where the channel status information was stored by a previous ISAVES. This block, considered as a five-element INTEGER\*2 array, has the following format:

- |          |   |
|----------|---|
| cblk (1) | Channel status word.  |
| cblk (2) | Starting block number of the file; zero for non-file-structured devices.  |
| cblk (3) | Length of file (in 256-word blocks).  |
| cblk (4) | Reserved for future use.  |
| cblk (5) | Two information bytes: <ul style="list-style-type: none"><li>• Even byte: I/O count of the number of requests outstanding on this channel.</li><li>• Odd byte: Unit number of the device associated with the channel.</li></ul> |

Errors:

Value	Meaning
i = 0	Normal return.
= 1	Specified channel is already in use.

Error message *TRAP \$MSARG* will display if *chan* or *cblk* argument is missing.

## REOPN/IREOPN

Example:

```
      Program FREOPN
C
C      Demo SAVES and REOPN operations on channels
C
      Parameter WCNT = 256
      Integer*2 DBLK1(4), DBLK2(4)      !file names
      Data DBLK1 /3rSRC, 3rFRE, 3rOPN, 3rFOR/
      Data DBLK2 /3rBIN, 3rFRE, 3rOPN, 3rSAV/
      Integer*2 DBLK3(4)                !TT:
      Data DBLK3 /3rTT , 0, 0, 0/
      Integer*2 CBLK1(5), CBLK2(5)      !channel blocks
      Integer*2 ICHAN, OCHAN            !channel numbers
      Integer*2 BUFFER(WCNT)            !block buffer
      Integer*2 BLK                      !block number
C
      ICHAN = IGETC()                   !get a channel
      IERR = LOOKUP (ICHAN, DBLK1)      !lookup the source file
      CALL SAVES (ICHAN, CBLK1)         !save the src lookup
      IERR = LOOKUP (ICHAN, DBLK2)      !lookup the sav file
      CALL SAVES (ICHAN, CBLK2)         !save the sav lookup
      Type 100, CBLK1(3), CBLK2(3)     !compare sizes
100   Format ( ' ', 'Source = ', i6, ' ' save = ', i6///)
      Call IREOPN (ICHAN, CBLK1)        !now open the src again
      OCHAN = IGETC()                   !get an output channel
      Call LOOKUP (OCHAN, DBLK3)        !open TT:
      Do 200 BLK = 0, CBLK1(3)-1       !reveal ourselves
          Call READW (WCNT, BUFFER, BLK, ICHAN)
          Call WRITW (WCNT, BUFFER, BLK, OCHAN)
200   Continue
      Call CLOSEC (ICHAN)
      Call CLOSEC (OCHAN)
      End
```

---

## REPEAT

The REPEAT subroutine concatenates a specified string with itself to produce the indicated number of copies. REPEAT places the resulting string in a specified array.

Form:

```
CALL REPEAT (in,out,i[,len][,err])
```

where:

- in** is the array containing the string to be repeated; it must be terminated with a null byte
- out** is the array into which the resultant string is placed. This array must be at least one element longer than the value of *len*, if *len* is specified. Because string handling always creates null terminated strings, *out* will be a null terminated string when it returns.
- i** is the integer number of times to repeat the string
- len** is the integer number representing the maximum length of the output string
- err** is the logical error flag set if the output string is truncated to the length specified by *len*

Input and output strings can specify the same array only if the repeat count (*i*) is 1 or 0. When the repeat count is 1, this routine is the equivalent of SCOPY; when the repeat count is 0, *out* is replaced by a null string. The old contents of *out* are lost when this routine is called.

Errors:

Error conditions are indicated by *err*, if specified. If *err* is given and the output string will be longer than *len* characters, then *err* is set to .TRUE.; otherwise, *err* is unchanged.

### NOTE

The argument *err* must be specified as BYTE in FORTRAN 77. It can be any logical type in FORTRAN IV and any integer type in PDP-11 C.

Error message *TRAP \$MSARG* will display if argument *a*, *b*, or *out* is missing.

## REPEAT

### Example:

```
Program SREPEA
C
C   This will build a ruler of length 1 to 99
C
Integer*2 SIZE          !length of ruler
Byte LINE1(100), LINE2(100) !strings for ruler
C
SIZE = 12
Call Ruler (SIZE, LINE1, LINE2)
Call PRINT (LINE1)
Call PRINT (LINE2)
SIZE = 36
Call Ruler (SIZE, LINE1, LINE2)
Call PRINT (LINE1)
Call PRINT (LINE2)
End

Subroutine RULER (SIZE, LINE1, LINE2)
Integer*2 SIZE          !length of ruler
Byte LINE1(*), LINE2(*) !ruler strings
Byte NUM19(11)         !constant
Data NUM19 /'1', '2', '3', '4', '5',
1           '6', '7', '8', '9', '0', '000'o/
C
Call REPEAT ('0', LINE1(1), 9, SIZE)
Do 100 I = 1, SIZE/10
    ICHAR = NUM19(I)      !get single char with null term
    Call REPEAT (ICCHAR, LINE1(I*10), 10, SIZE+1-(I*10))
100    Continue
Call REPEAT (NUM19, LINE2(1), 10, SIZE)
Return
End
```

---

## RESUME

The RESUME subroutine allows a job to resume execution of the main program. A RESUME call is normally issued from an asynchronous FORTRAN routine entered on I/O completion or because of a schedule request (See SUSPND subroutine).

Form:

**CALL RESUME**

Errors:

None.

Example:

See RCVDF.

---

## SAVES/ISAVES

### Multijob

SAVES/ISAVES stores five words of channel status information into a user-specified array. These words contain all the information that RT-11 requires to completely define an RT-11 file. (Special directory devices cannot have their file status saved with this request.) When an ISAVES is finished, the data words are placed in memory and the specified channel is closed, so that it is again available for use. When the saved channel data is required, the IREOPN function is used.

ISAVES can be used only if a file was opened with a LOOKUP call. If IENTER was used, ISAVES returns an error. Note that ISAVES is not valid on magtape or cassette files.

Form:

```
CALL SAVES (chan,cbk)
i = ISAVES (chan,cbk)
```

where:

- chan** is the integer specification for the RT-11 channel whose status is to be saved. You must obtain this channel through an IGETC call, or you can use channel 16 or higher if you have done an ICDFN call
- cbk** is a five-word block in which the channel status information describing the open file is stored (See IREOPN for format of this block)

The ISAVES/IREOPN combination is very useful, but care must be exercised when using it. In particular, the following cases should be avoided.

If an ISAVES is performed on a file and the same file is then deleted before it is reopened, the space occupied by the file becomes available as an empty space which could then be used by another file. If this sequence occurs, there is a change in the contents of the file whose status was supposedly saved.

Although the handler for the required peripheral need not be in memory for execution of an IREOPN, a fatal error is generated if the handler is not in memory when an IREAD or IWRITE is executed.

Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return.
= 1	The specified channel is not currently associated with any file.
= 2	The file was opened with an IENTER call.

Error message *TRAP \$MSARG* will display if any argument is missing.

Example:  
See REOPN.

---

## SCCA/ISCCA/MSCCA

SCCA/ISCCA provides a CTRL/C intercept to:

- Inhibit a CTRL/C abort.
- Indicate that a CTRL/C has been entered.
- Distinguish between single and double CTRL/C command.

Global support provides an ISCCA function variant. An optional parameter, *itype*, provided for both SCCA and ISCCA subroutines lets you set local or global SCCA support. An optional parameter, *AMODE*, lets you specify a Supervisor data space address. See *RT-11 System Macro Library Manual* for .SCCA information on local and global SCCA support.

Form:

```
CALL SCCA [(iflag],[itype])
i = ISCCA [(iflag],[itype])
CALL MSCCA [(iflag],[itype],[AMODE=strg])
i = MSCCA [(iflag],[itype],[AMODE=strg])
```

where:

<b>iflag</b>	is an integer terminal status word that must be tested and cleared to determine if two CTRL/Cs were typed at the console terminal; the <i>iflag</i> must be an INTEGER*2 variable (not LOGICAL*1).
<b>itype</b>	is the mode of SCCA operation. Specify 0 (the default) or 1 to select LOCAL or GLOBAL SCCA support: <b>itype = 0</b> LOCAL (default) mode of SCCA operation <b>itype = 1</b> GLOBAL mode of SCCA operation
<b>i</b>	is the returned address of the previous SCCA terminal status word
<b>AMODE=strg</b>	Specify <i>AMODE</i> string "S" to select a Supervisor-Data address.

### Notes

When a CTRL/C is typed, if SCCA is in effect, it is placed in the input ring buffer. While residing in the buffer, the character can be read by the program. The program must test and clear the *iflag* to determine if two CTRL/C commands were typed consecutively. The *iflag* is set to non-zero when two CTRL/Cs are typed together. It is the responsibility of the program to abort itself, if appropriate, on an input of CTRL/C from the terminal. The SCCA subroutine with no argument disables the CTRL/C intercept. A CTRL/C from indirect command files is not intercepted by SCCA.

## SCCA/ISCCA/MSCCA

Errors:

<b>Value</b>	<b>Meaning</b>
i = -19	Invalid AMODE value.

Error message *TRAP \$MSARG* will display if argument *itype* is missing.

Example:

```
          Program FSCCA
C
C          Demonstrate SCCA preventing job termination by ^C
C
          Type 1
1         Format ( ' ', 'Enter chars, including a ^C or ^C^C and ret' /)
          IFLAG = 0                !init flag word
          Call SCCA (IFLAG)        !protect from ^C
10        If (ITTINR() .ne. '003'o) Go To 10 !look for ^C
          Type 2
2         Format ( ' ', 'A ^C was typed' /)
          If (IFlag .eq. 0) Go To 10 !continue until ^C^C
          Type 3
3         Format ( ' ', 'Actually a double ^C^C' /)
          Call SCCA ( )           !unprotect from ^C
          Type 4
4         Format ( ' ', 'Enter ^C to terminate program' /)
20        Go To 20                !loop, see loop
          End
```

---

# SCHED/ISCHED

## SB Timer (SYSGEN Option)

SCHED/ISCHED schedules a specified FORTRAN subroutine to be run as an asynchronous completion routine at a specified time of day.

Form:

```
CALL SCHED (hrs,min,sec,tick,area,id,frtn)
i = ISCHED (hrs,min,sec,tick,area,id,frtn)
```

where:

**hrs** is the integer number of hours  
**min** is the integer number of minutes  
**sec** is the integer number of seconds  
**tick** is the integer number of ticks (1/60 of a second on 60-Hz clocks; 1/50 of a second on 50-Hz clocks)  
**area** is a four-word area that must be provided for link information; this area must never be modified by the FORTRAN program, and the USR must not swap over it. This area can be reclaimed by other FORTRAN completion functions when crtn has been activated  
**id** is the integer identification to be passed to the routine being scheduled  
**frtn** is the name of the FORTRAN subroutine to be entered at the time of day specified. This name must be specified in an EXTERNAL statement in the FORTRAN routine that issues the ISCHED call. The subroutine has one argument. For example:

```
SUBROUTINE frtn(id)
INTEGER id
```

When the routine is entered, the value of the integer argument is the value specified for *id* in the appropriate ISCHED call

## Notes

- The scheduling request made by ISCHED can be canceled at a later time by an ICMKT function call.
- If the system is busy, the actual time of day that the completion routine is run may be later than the requested time of day.
- A FORTRAN subroutine can periodically reschedule itself by issuing its own ISCHED or ITIMER calls from within the routine.
- ISCHED requires a queue element; this should be considered when the IQSET function is executed.

## SCHED/ISCHED

Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return.
= 1	No queue elements available; unable to schedule request.

Error message *TRAP \$MSARG* will display if any argument is missing.

Example:

```
      Program FSCHED
C
C      This program uses timer support to announce lunch.
C
      Integer*2 LINK1(4)      !linkage area for FTN completion
C
      IERR = IQSET (2)        !add some queue elements
      IERR = ISCHED (12, 0, 0, 0, LINK1, 73, NOON)
C
      Type *, 'Do some work'
      Call SUSPND
      Type *, 'Off to lunch'
      End

      Subroutine NOON (ID)
      Type *, 'Time for LUNCH'
      Call RESUME
      Return
      End
```

---

## SCOMP/ISCOMP

The SCOMP/ISCOMP routine compares two character strings and returns the integer result of the comparison.

Form:

```
CALL SCOMP (a,b,i)
i = ISCOMP (a,b)
```

where:

- a** is the array containing the first string; it must be terminated with a null byte
- b** is the array containing the second string; it must be terminated with a null byte
- i** is the integer variable that receives the result of the comparison

The strings are compared from left to right, one character at a time, using the collating sequence specified by the ASCII codes for each character. If the two strings are not equal, the absolute value of variable *i* (or the result of the function ISCOMP) is the character position of the first inequality found. Strings are terminated by a null (0) character.

If the strings are not the same length, the shorter one is treated as if it were padded on the right with blanks to the length of the other string. A null string argument is equivalent to a string containing only blanks.

Function Results:

- $i < 0$  If *a* is less than *b*.
- $= 0$  If *a* is equal to *b*.
- $> 0$  If *a* is greater than *b*.

Errors:

Unpredictable results will occur if any argument is omitted.

Example:

See SDTTM.

---

## SCOPY

The SCOPY routine copies a character string from one array to another. Copying stops either when a null (0) character is encountered or when a specified number of characters have been moved.

Form:

**CALL SCOPY (in,out[,len][,err])**

where:

- in** is the array containing the string to be copied; it must be terminated with a null byte if *len* is not specified, or if the string is shorter than *len*
- out** is the array to receive the copied string. This array must be at least one element longer than the value of *len*, if *len* is specified. It also must be terminated with a null byte if *len* is specified
- len** is the integer number representing the maximum length of the output string. The effect of *len* is to truncate the output string to a given length, using null termination
- err** is a logical variable that receives the error indication if the output string was truncated to the length specified by *len*

### NOTE

The argument *err* must be specified as LOGICAL\*1 in FORTRAN 77. It can be any logical type in FORTRAN IV and any integer type in PDP-11C.

The input (*in*) and output (*out*) arguments can specify the same array. The string previously contained in the output array is lost when this subroutine is called.

Errors:

Error conditions are indicated by *err*, if specified. If *err* is given and the output string was truncated to the length specified by *len*, then *err* is set to .TRUE.; otherwise, *err* is unchanged.

Unpredictable results will occur if either *in* or *out* argument is omitted.

Example:

See INSERT.

---

## **\*SDAT/\*SDATC/\*SDATF/\*SDATW**

### **Multijob Only**

Four forms of \*SDAT, are used with the IRCVD, IRCVDC, IRCVDF, and IRCVDW calls to allow message transfers under the FB or XM monitor. Note that the buffer containing the message should not be modified or reused until the message has been received by the other job. These functions require a queue element, which should be considered when the IQSET function is executed.

Specify mapping for MSDAT, MSDATC and MSDATW by optional parameters *BMODE* and *CMODE*.

### **SDAT/ISDAT/MSDAT**

SDAT/ISDAT/MSDAT transfers a specified number of words from one job to the other. Control returns to the user program immediately after the transfer is queued. When your program needs to wait until the other program has received the data, an IWAIT function should be issued to ensure that the ISDAT operation has been completed. If an error occurred during the transfer, the IWAIT function indicates the error.

Form:

```
CALL SDAT (buff,wcnt)
i = ISDAT (buff,wcnt)
CALL MSDAT (buff,wcnt[,BMODE=strg])
i = MSDAT (buff,wcnt[,BMODE=strg])
```

where:

**buff** is the array containing the data to be transferred  
**wcnt** is the integer number of data words to be transferred  
**BMODE=strg** Specify *strg* with one of the following: 'UI'/'UD'/'SI'/'SD'/'CD'/'CI'. This value specifies the mapping mode for the *buff* argument.

Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return.
= 1	No such job currently exists in the system. A job exists as long as it is loadable, whether or not it is active.
= -19	Invalid BMODE value.

Error message *TRAP \$MSARG* will display if *buff* or *wcnt* argument is missing.

Example:

See also \*RCVD.

## \*SDAT/\*SDATC/\*SDATF/\*SDATW

```
Program FSDAT !demo SDAT (use with FRCVDx)
C
C Try to send a message to the other job
C send a null message for EOF and exit
C
Parameter SUCCS = '001'o, FATAL = '010'o
Parameter WCNT = 42
Integer*2 SNDCNT
Integer*2 BUFFER(WCNT)
Integer*2 CTRLZ
Data CTRLZ /'032'o/ !^Z null string equiv
External LEN !use RT-11 SYSLIB LEN func
C
100 Continue
    Call GTLIN (BUFFER) !get a line
    SNDCNT = LEN (BUFFER) !get byte count (-1)
    If (SNDCNT .eq. 0) Then !is it a null string
        BUFFER(1) = CTRLZ !yes, send ^Z
        SNDCNT = 1 !...
    End If
    SNDCNT = (SNDCNT + 2) / 2 ! get word count
200 Continue
    IERR = ISDAT (BUFFER, SNDCNT) !try sending a message
    If (IERR .eq. 1) Go To 200 !wait for the job
    If (IERR .ne. 0) Go To 300 !unknown error
    Call MWAIT !wait for a message
    If (BUFFER(1) .ne. CTRLZ) Go To 100
    Call PRINT ('!FSDAT-I-Normal termination')
    Call EXIT (SUCCS) !and done
C
300 Call PRINT ('?FSDAT-F-Unknown error code from ISDAT')
    Call EXIT (FATAL)
End
```

**SDATC/ISDATC/MSDATC**

SDATC/ISDATC/MSDATC transfers a specified number of words from one job to another. Control returns to the user program immediately after the transfer is queued. When the other job accepts the message through a receive data request, the specified assembly language routine (*crtn*) is activated as an asynchronous completion routine.

Form:

```
CALL SDATC (buff,wcnt,crtn)
i = ISDATC (buff,wcnt,crtn)
CALL MSDATC (buff,wcnt,crtn[,BMODE=strg][,CMODE=strg])
i = MSDATC (buff,wcnt,crtn[,BMODE=strg][,CMODE=strg])
```

where:

- buff** is the array containing the data to be transferred
- wcnt** is the integer number of data words to be transferred
- crtn** is the name of an assembly language routine to be activated on completion of the transfer. This name must be specified in an EXTERNAL statement in the FORTRAN routine that issues the ISDATC call
- BMODE=strg** Specify *strg* with one of the following: 'UI'/'UD'/'SI'/'SD'/'CD'/'CI'. This value specifies the mapping mode of the *buff* argument.
- CMODE=strg** Specify *strg* as string "S" to specify a Supervisor address.

Errors:

Value	Meaning
i = 0	Normal return.
= 1	No such job currently exists in the system. A job exists as long as it is loadable, whether or not it is active.
= -19	Invalid BMODE or CMODE value.

Error message *TRAP \$MSARG* will display if *buff*, *wcnt* or *crtn* argument is missing.

Example:

```
Program FSDATC !demo SDATC (use with FRCVDx)
C
C Try to send a message to the other job
C after sending a null message, exit
C
Parameter SUCCS = '001'o, FATAL = '010'o
Parameter WCNT = 42
Integer*2 SNDCNT
Integer*2 BUFFER(WCNT)
Integer*2 CTRLZ
Data CTRLZ /'032'o/ !^Z null string equiv
External FRCVDM !completion routine
External LEN !use RT-11 SYSLIB LEN func
C
```

## \*SDAT/\*SDATC/\*SDATF/\*SDATW

```
100      Continue
        Call GTLIN (BUFFER)
        SNDCNT = LEN (BUFFER)          !get byte count (-1)
        If (SNDCNT .eq. 0) Then        !is it a null string
            BUFFER(1) = CTRLZ          !yes, send ^Z
            SNDCNT = 1                 !...
        End If
        SNDCNT = (SNDCNT + 2) / 2      ! get word count
200      Continue
        IERR = ISDATC (BUFFER, SNDCNT, FRCVDM) !try sending a message
        If (IERR .eq. 1) Go To 200 !wait for the job
        If (IERR .ne. 0) Go To 400 !unknown error

C
C      other processing not requiring message could be done here
C
        Call SUSPND                    !wait for completion routine to
C                                       ! resume us
        If (BUFFER(1) .ne. CTRLZ) Go To 100
300      Call PRINT ('!FSDATC-I-Successful normal termination')
        Call EXIT (SUCCS)              !and done
C
400      Call PRINT ('?FSDATC-F-Unknown error code from ISDATC')
        Call EXIT (FATAL)
        End
```

**SDATF/ISDATF**

SDATF/ISDATF transfers a specified number of words from one job to the other. Control returns to the user program immediately after the transfer is queued and execution continues. When the other job accepts the message through a receive data request, the specified FORTRAN subprogram (*frtn*) is activated as an asynchronous completion routine.

Form:

```
CALL SDATF (buff,wcnt,frtn)
i = ISDATF (buff,wcnt,area,frtn)
```

where:

- buff** is the array containing the data to be transferred
- wcnt** is the integer number of data words to be transferred
- area** is a four-word area to be set aside for link information; this area must not be modified by the FORTRAN program and the USR must not swap over it. This area can be reclaimed by other FORTRAN completion functions when *crtm* has been activated
- frtn** is the name of a FORTRAN routine to be activated on completion of the transfer. This name must be specified in an EXTERNAL statement in the FORTRAN routine that issues the ISDATF call

Function Return:

- i =** Normal return; *i* equals the number of words requested (0 for non-file-structured read, multiple of 256[decimal] for file-structured read). If the read is from a magtape, the number of words requested is returned. For example:
  - If *wcnt* is a multiple of 256 and less than that number of words remain in the file, *i* is shortened to the number of words that remain in the file; thus, if *wcnt* is 512 and only 256 words remain, *i*=256.
  - If *wcnt* is not a multiple of 256 and more than *wcnt* words remain in the file, *i* is rounded up to the next block; thus, if *wcnt* is 312 and more than 312 words remain, *i* = 512, but only 312 are read.
  - If *wcnt* is not a multiple of 256 and less than *wcnt* words remain in the file, *i* equals a multiple of 256 that is the actual number of words being read.

Errors:

<b>Value</b>	<b>Meaning</b>
<i>i</i> = 0	Normal return.

## \*SDAT/\*SDATC/\*SDATF/\*SDATW

- = 1 No such job currently exists in the system. A job exists as long as it is loadable, whether or not it is active.

;in the compiler

.END
```

### SDATW/ISDATW/MSDATW

SDATW/ISDATW/MSDATW transfers a specified number of words from one job to the other. Control returns to the user program when the other job has accepted the data through a receive data request.

Form:

```
CALL SDATW (buff,wcnt)
i = ISDATW (buff,wcnt)
CALL MSDATW (buff,wcnt[,BMODE=strg])
i = MSDATW (buff,wcnt[,BMODE=strg])
```

where:

**buff** is the array containing the data to be transferred  
**wcnt** is the integer number of data words to be transferred  
**BMODE=strg** Specify *strg* with one of the following: 'UI'/'UD'/'SI'/'SD'/'CD'/'CI'.  
This value specifies the mapping mode of the *buff* argument.

## \*SDAT/\*SDATC/\*SDATF/\*SDATW

### Function Return:

- i =** Normal return; *i* equals the number of words requested (0 for non-file-structured read, multiple of 256[decimal] for file-structured read). If the read is from a magtape, the number of words requested is returned. For example:
- If *wcnt* is a multiple of 256 and less than that number of words remain in the file, *i* is shortened to the number of words that remain in the file; thus, if *wcnt* is 512 and only 256 words remain, *i*=256.
  - If *wcnt* is not a multiple of 256 and more than *wcnt* words remain in the file, *i* is rounded up to the next block; thus, if *wcnt* is 312 and more than 312 words remain, *i* = 512, but only 312 are read.
  - If *wcnt* is not a multiple of 256 and less than *wcnt* words remain in the file, *i* equals a multiple of 256 that is the actual number of words being read.

### Errors:

Value	Meaning
<b>i = 0</b>	Normal return.
<b>= 1</b>	No such job currently exists in the system. A job exists as long as it is loadable, whether or not it is active.
<b>= -19</b>	Invalid BMODE value.

### Example:

```
Program FSDATW !demo SDATW (use with FRCVDx)
C
C Try to send a message to the other job
C after sending a null message, exit
C
Parameter SUCCS = '001'o, FATAL = '010'o

      End
```

---

## SDTTM/ISDTTM

SDTTM/ISDTTM sets the system date and time. An argument of -1 leaves the corresponding value unchanged.

Form:

```
CALL SDTTM (date,hitime,lotime)
i = ISDTTM (date,hitime,lotime)
```

where:

**date** is the new system date  
**hitime** is the high-order time of day, in ticks past midnight  
**lotime** is the low-order time of day, in ticks past midnight

Errors:

Error message *TRAP \$MSARG* will display if any argument is missing.

Example:

```
Program FSDTTM
C
C Accept date in German and set it
C
Parameter SUCCS = '001'o, FATAL = '010'o
Byte MONATE(4, 12)
Data MONATE !month names
1 /'J', 'A', 'N', 0,
2 'F', 'E', 'B', 0,
3 'M', 'A', 'R', 0,
4 'A', 'P', 'R', 0,
5 'M', 'A', 'I', 0,
6 'J', 'U', 'N', 0,
7 'J', 'U', 'L', 0,
8 'A', 'U', 'G', 0,
9 'S', 'E', 'P', 0,
1 'O', 'K', 'T', 0,
2 'N', 'O', 'V', 0,
3 'D', 'E', 'C', 0/
Byte INPUT(81) !raw input
Byte PROMPT(6) !prompt
Data PROMPT /'D', 'a', 't', 'e', '?', '200'o/
Integer*2 DAY, YEAR !day and year integer values
Byte MONTH(4) !month string value
Data MONTH(4) /0/ !with suffixed null
Character*10 DMMY !DD-MON-YY
```

```

C
  Call GTLIN (INPUT, PROMPT) !ask for date
  If (INPUT(2) .eq. '-') Then
    Call CONCAT ('0', INPUT, DMMY) !D-MON-YY
  Else
    Call SCOPY (INPUT, DMMY) !DD-MMM-YY
  End If
  Read (DMMY, 101, ERR=200) DAY, DUMMY1, (MONTH(I), I=1,3),
  1  DUMMY2, YEAR
101  Format (i2, a1, 3a1, a1, i2)
  If ((DUMMY1 .ne. '-') .or. (DUMMY2 .ne. '-')) Go To 200
  DO 100 IMON = 1, 12
    If (ISCOMP (MONATE(1, IMON), MONTH) .eq. 0) Go To 300
100  Continue
200  Continue
  Type *, '?FSDTTM-F-Invalid input'
  Call EXIT (FATAL)
300  Continue
  If (YEAR .lt. 73) Go To 200
  If (DAY .gt. 31) Go To 200
  Call SDTTM (IMON*1024+DAY*32+YEAR-72, -1, -1)
  Call EXIT (SUCCS)
  End

```

---

## SERR/ISERR

SERR/ISERR performs the following functions:

- Inhibits the monitor from aborting a job
- Causes an error return to the EMT that produced the error.

Those error conditions are listed at the end of this section. ISERR itself returns no error codes.

If SERR is in effect and an error occurs on a channel, the channel must be closed by a CLOSEC or PURGE call. Otherwise, subsequent operations on that channel will fail.

Form:

```
CALL SERR ()  
i = ISERR ()
```

where:

i is a returned INTEGER\*2 result of the function, a flag indicating the previous IHERR/ISERR setting:

<b>Value</b>	<b>Meaning</b>
i = 0	IHERR was in effect
= 1	ISERR was in effect

Errors:

The following list contains error codes that can be returned to other EMT requests if SERR is in effect:

<b>Value</b>	<b>Meaning</b>
i = -129	Called USR from completion routine
= -130	No device handler; this operation needs one
= -131	Error doing directory I/O
= -132	.FETCH error. An I/O error occurred while the handler was being used, or an attempt was made to load the handler over USR or KMON
= -133	Error reading an overlay
= -134	No more room for files in the directory
= -135	Reserved
= -136	Invalid channel number; number is greater than actual number of channels that exist

= -137 Invalid EMT, and invalid function code has been decoded  
= -138 Reserved  
= -139 Reserved  
= -140 Invalid directory  
= -141 Unloaded XM handler  
= -142 Reserved  
through  
= -146

Example:  
See HERR.

---

## SETCMD

The SETCMD routine allows a user program to pass a command line to the keyboard monitor to be executed after the program exits. This routine can be used in a program running in the background. The command lines are passed to the chain information area (500-777 octal) and stored beginning at location 512(octal). No check is made to determine if the string extends into the stack space. For this reason, the command line should be short and the subroutine call should be made in the main program unit near the end of the program just before completion.

The monitor commands REENTER, START, and CLOSE are not allowed if the SETCMD feature is used.

Form:

**CALL SETCMD (string)**

where:

**string** is a keyboard monitor command line ASCIZ format with no embedded carriage returns or line feeds

Errors:

Error message *TRAP \$MSARG* will display if any argument is missing.

Example:

```
Program FSETCM
C
C Issue any command supplied as input
C
Byte INPUT(81), PROMPT(8)

Call SETCMD (INPUT)
End
```

---

## SFDDAT/ISFDDAT

SFDDAT/ISFDDAT allows user programs to modify the creation date of an RT-11 file. The device must have an RT-11 file structure.

Form:

```
CALL SFDDAT (chan,dblk[,idate][,iold])
i = ISFDDAT (chan,dblk[,idate][,iold])
```

where:

**chan** is the integer value of the RT-11 channel to be used for the operation. You must obtain this channel through an IGETC call, or you can use channel 16(decimal) or higher if you have done an ICDFN call

**dblk** is the four word RT-11 file specification, in Radix-50, of the file whose date is being changed

**idate** is the integer date in RT-11 date format

**iold** is the INTEGER\*2 result of the request; the original creation date (E.DATE) of the specified file

Errors:

Value	Meaning
i = 0	Normal return.
= 1	Channel in use.
= 2	File not found.
= 3	Invalid operation for magtape.

Error message *TRAP \$MSARG* will display if any argument is missing.

Example:

This example changes the date of the file DY1:OLD23.DAT to July 4, 1976.

```
Program FSFDDAT
C
C This program sets the file date of 4 July 1976 on the
C file DK:BI100L.TMP.
Parameter SUCCS = '001'o, FATAL = '010'o
Integer*2 DBLK(4) !file name
Data DBLK /3rDK , 3rBI1, 3r00L, 3rTMP/
C
ICHAN = IGETC() !get a channel
IDATE = 7*1024 + 4*32 + (1976-1972) !RT-11 format date
IERR = ISFDDAT (ICHAN, DBLK, IDATE) !set it
If (IERR .ne. 0) Go To 100
Call PRINT ('!FSFDDAT-I-Success')
Call EXIT (SUCCS)
100 Continue
Call PRINT ('?FSFDDAT-F-Revoltng development')
Call EXIT (FATAL)
End
```

---

## SFINF/ISFINF

SFINF/ISFINF function saves and then modifies the contents of the directory entry offset you specify from a file's directory entry. ISFINF is not supported for the distributed special directory handlers LP, LS, MM, MS, MT, MU, and SP.

Form:

```
CALL SFINF (chan,dblk,value,oper,offset,[iold])
i = ISFINF (chan,dblk,value,oper,offset,[iold])
```

where:

- chan** is a BYTE or INTEGER\*2 channel number
- dblk** is a 4-element INTEGER\*2 array containing a 4-word device and file specification in Radix-50; the file specification for which you want to return directory entry information.
- value** is the value to be placed in the specified offset location.  
For RT-11 file structured volume directories, if the offset is 0 (E.STAT) and the operation is a BIC or BIS, E.STAT bits 000400, 001000, and 004000 must be clear. If the offset is E.STAT and the operation is a MOV, only the bottom 4 bits of E.STAT are moved. For special directory volumes, no bit restrictions are enforced
- oper** is the name or octal value indicating the type of operation to be performed:
- | Name/Value | Type  | Meaning                        |
|------------|-------|--------------------------------|
| 'G'        | GET   | Get value, an IGFINF operation |
| 'C'        | CLEAR | Bit clear (BIC) operation      |
| 'S'        | SET   | Bit set (BIS) operation        |
| 'M'        | MOVE  | Word move (MOV) operation      |
| 128-255    | USER  | Reserved for the user          |
- offset** is the octal byte offset for the directory entry word for this operation. The offset must be even, and cannot be 8 (E.LENG). For example, specifying offset 10 saves the current contents of E.USED in *iold* and opens that location for modification.
- iold** is the returned INTEGER\*2 previous value in the modified directory entry word

## Errors:

Value	Meaning
i = 0	Normal return
= -1	Channel was open
= -2	File not found
= -3	Invalid operation argument
= -4	Invalid offset
= -257	Required argument missing

## Example:

```

C      Program FSFINF !demo SFINF
C
C      This program modifies the directory entry at offset 10.,
C      setting it to a value based on the value entered for the
C      /T switch.  The /T switch is used as follows:
C
C      /T:11.          11:00:00
C      /T:11.:22.     11:22:00
C      /T:11.:22.:33. 11:22:33
C
C      The value placed in the entry is the number of seconds
C      past midnight in the switch value divided by 3.
C
C      Parameter FATAL = '010'o
C      Integer*2 CHAN          !Channel number
C      Integer*2 FILSPC(39)    !DBLK(s) area
C      Integer*2 DEFTYP(4)     !default types

3100 Call Exit (FATAL)
          End
```

---

## SFSTA/ISFSTA

SFSTA/ISFSTA saves and then modifies the contents of the directory entry status word (E.STAT) from a file's directory entry. ISFSTA is not supported for the distributed special directory handlers LP, LS, MM, MS, MT, MU, and SP.

Form:

**CALL SFSTA (chan,dblk,value,oper,[iold])**

**i = ISFSTA (chan,dblk,value,oper,[iold])**

where:

**chan** is a BYTE or INTEGER\*2 RT-11 channel number

**dblk** is a 4-element INTEGER\*2 array containing a 4-word device and file specification in Radix-50; the file specification for which you want to return directory entry information

**value** is the value to be placed in the directory entry status word.

- If the operation is a BIC or BIS, E.STAT bits 000400, 001000, and 004000, must be clear.
- If the operation is a MOV, only the bottom 4 bits of E.STAT are moved.

For special directory volumes, no bit restrictions are enforced.

**oper** is the name or octal value indicating the type of operation to be performed:

<b>Name/Value</b>	<b>Type</b>	<b>Meaning</b>
'C'	CLEAR	A bit clear (BIC) operation
'S'	SET	A bit set (BIS) operation
'M'	MOVE	A word move (MOV) operation
128-255	USER	Reserved for the user

**iold** is the returned INTEGER\*2 previous value in the modified directory entry status word

## SFSTA/ISFSTA

Error:

Value	Meaning
i = 0	Normal return
= -1	Channel was open
= -2	File not found
= -3	Invalid operation argument (internal error)
= -4	Internal error.
= -257	Required argument missing

Example:

See also GFSTA.

```
Program FSFSTA
C

          Call EXIT (FATAL)
          End
```

---

# SLEEP/ISLEEP

## Timer Support

SLEEP/ISLEEP suspends the main program execution of a job for a specified amount of time. The specified time is the sum of hours, minutes, seconds, and ticks specified in the ISLEEP call. All completion routines continue to execute.

Form:

```
CALL SLEEP (hrs,min,sec,tick)
i = ISLEEP (hrs,min,sec,tick)
```

where:

<b>hrs</b>	is the integer number of hours
<b>min</b>	is the integer number of minutes
<b>sec</b>	is the integer number of seconds
<b>tick</b>	is the integer number of ticks (1/60 of a second on 60-Hz clocks; 1/50 of a second on 50-Hz clocks)

## Notes

- When you execute IQSET, remember that SLEEP requires an extra queue element.
- If the system is busy, time execution may be suspended longer than specified.

Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return.
= 1	No queue element available.

Unpredictable results will occur if any arguments are omitted.

Example:

See also TIMER for FTIMEA and FTIMEC.

```
Program FSLEEP
C
C demonstrate the SLEEP routine
C
Integer*2 HRS, MIN, SEC, TIC
Integer*2 AREAA(4)
External FTIMEA          !fast timer completion
C
Call IQSET (10)          !allocate extra queue elements
Call TIMER (0, 0, 1, 0, AREAA, 12345, FTIMEA)
CALL ISLEEP (0, 0, 5, 0)!sleep for 5 seconds
Call PRINT ('!FSLEEP-I-Exiting')
End
```

---

## SPCPS/ISPCPS

### SYSGEN Option

SPCPS/ISPCPS lets a program's completion routine change the flow of control of the mainline code. ISPCPS saves the mainline PC and PS and changes the mainline PC to a new value.

If ISPCPS is issued by a program running under a monitor for which .SPCPS support was not generated, no action is taken and no error is returned.

Form:

```
CALL SPCPS (addr)
i = ISPCPS (addr)
```

where:

**addr** is the address of the three-word block in user memory. The first word contains the new mainline PC. The following two words, on return, contain the saved mainline PC and PS

Errors:

<b>Value</b>	<b>Meaning</b>
i= 0	Normal return
= -1	ISPCPS was issued from mainline code rather than from a completion routine
= -2	A previous ISPCPS call is outstanding
= -257	Required argument missing

Example:

```
Program FSPCPS
C
C This program demonstrates SPCPS and its ability to change
C the main-line flow of control in an async completion routine.
C
Parameter SUCCS = '001'o, FATAL = '010'o
External FSPCPC
Integer*2 DBLK(4) !file name
Data DBLK /3rSY , 3rSWA, 3rP , 3rSYS/

Common /SPCPS/ NEWPC, OLDPC, OLDPS !argument block for SPCPS
Type *, '!FSPCPS-I-In completion routine'
Call SPCPS (NEWPC)
Return
End
```

---

## \*SPFN/\*SPFNC/\*SPFNF/\*SPFNW

\*SPFN/\*SPFNC/\*SPFNF/\*SPFNW, issued either as functions or subroutines, are used in conjunction with special functions to various handlers having special device-dependent characteristics. Asterisk prefixes indicate generic SPFN forms can begin with the letter *I* when issued as a function or with the letter *M* when the function or subroutine specifies mapping.

You can specify mapping for MSPFN, MSPFNC, and MSPFNW by adding optional arguments *BMODE* and *CMODE*. For details on programming for specific devices, see the *RT-11 Device Handlers Manual*.

All \*SPFN forms provide a means of doing device-dependent functions, such as rewind and backspace, to those devices. If ISPFN function calls are made to any other devices, the function call is ignored. To use these functions, the handler must be in memory, and a channel must be associated with a device. These functions require a queue element; this should be a consideration when the IQSET function is executed.

### Functions—ISPFN 376, 377

Two ISPFN subroutine calls, 376 and 377, perform a non-file-structured write and read operation, using a 32-bit starting block number. See Table 2-1.

**Table 2-1: Device Support (SF.AWR/SF.ARD)**

Device	Code	Name	Action
DL/DM/DU	376	SF.AWR	Write operation without doing bad block replacement; returns definitive error data.
	377	SF.ARD	Read operation without doing bad block replacement; returns definitive error data.
DW	376	SF.AWR	Write
	377	SF.ARD	Read
DX/DY/DZ	376	SF.AWR	Write absolute sector
	377	SF.ARD	Read absolute sector

### DU Support

The DU handler has support for ISPFN 376 (SF.AWR) and 377 (SF.ARD). For DU, SF.AWR performs a write to the specified sector, and SF.ARD performs a read from the specified sector. Those writes and reads are not absolute; bad-block replacement and block vectoring remain in effect. See *RT-11 Device Handlers Manual* for information.

## \*SPFN/\*SPFNC/\*SPFNF/\*SPFNW

For DU, SF.AWR and SF.ARD can return the following error code (in addition to those returned by DM):

Code	Explanation
140000	A forced error occurred. <ul style="list-style-type: none"><li>• If the device is a disk drive that supports bad block replacement (BBR), the device controller or DU handler discovered bad data on a good (replaced) block. (Bad-block replacement was performed, but no data was recovered.)</li><li>• If the device does not support BBR, this is an unexpected condition. Refer to <i>RT-11 Device Handlers Manual</i> for appropriate action.</li></ul>

### DW Support

For DW, ISPFN 376 (SF.AWR) and 377 (SF.ARD) use logical block numbers rather than physical block numbers in the *blk* argument. Therefore, to address a write or read to physical block zero, specify -1 for the *blk* argument. That is necessary because the physical block number of a DW device is one less than the logical block number.

### MU Support

MU, ISPFN 374 (SF.MWE, write with extended file gap) executes as ISPFN 371 (SF.MWR, write). The TK50 magtape device does not support SF.MWE functionality; however, future release of RT-11 may add support for this functionality for other MU devices. See Table 2-2.

**Table 2-2: Device Support (SF.MWE/SF.MWR)**

Device	Code	Name	Action
DM	374	SF.SIZ	Return unit size. Parameter arguments for SF.SIZ for LD and DM are identical.
MU	371	SF.MWR	After initial non-file-structured .LOOKUP and SF.USR, perform write operations of variable word count blocks.
MU	374	SF.MWE	Write with extended gap.

**SPFN/ISPFN/MSPFN**

SPFN/ISPFN/MSPFN queues the specified operation and immediately returns control to the user program. The IWAIT function can be used to ensure completion of the operation.

Form:

```
CALL SPFN (code,chan[,wcnt,buff,blk])
i = ISPFN (code,chan[,wcnt,buff,blk])
CALL MSPFN (code,chan[,wcnt,buff,blk][,BMODE=strg])
i = MSPFN (code,chan[,wcnt,buff,blk][,BMODE=strg])
```

where:

- |             |  |
|-------------|--|
| <b>code</b> | is the integer numeric code of the function to be performed  |
| <b>chan</b> | is the integer specification for the RT-11 channel to be used for the operation. You must obtain this channel through an IGETC call, or you can use channel 16(decimal) or higher if you have done an ICDFN call   |
| <b>wcnt</b> | is the integer number of data words in the operation. This parameter is optional with some ISPFN calls, depending on the particular function. Default value is 0. In magtape operations, it specifies the number of records to space forward or backward. For a backspace operation ( <i>wcnt=0</i> ), the tape drive backsplaces to a tape mark or to the beginning-of-tape. For a forward space operation ( <i>wcnt=0</i> ), the tape drive forward spaces to a tape mark or the end-of-tape.              |
| <b>buff</b> | is the array to be used as the data buffer. This parameter is optional with some ISPFN calls, depending on the particular function. Default value is 0   |
| <b>blk</b>  | This parameter is optional with some ISPFN calls, depending on the particular function. Default value is 0.<br>When this argument is supplied by magtape, it is the address of a four-word error and status block used for returning the exception conditions. The four words must be initialized to zero. The error and status block must always be mapped when running in the XM monitor, and the USR must not swap over it. To obtain the address of the error block, execute the following instructions: |

## \*SPFN/\*SPFNC/\*SPFNF/\*SPFNW

```
INTEGER*2      ERRADR, ERRBLK(4)
DATA ERRBLK    /0,0,0,0,/
               .
               .
               .
ERRADR = IADDR (ERRBLK) !GET THE ADDRESS OF
                       !THE 4-WORD ERROR BLOCK
ICODE = ISPFN (CODE, ICHAN, WDCT, BUF, ERRADR)
```

**BMODE=strg** Specify *strg* with one of the following: 'UI'/'UD'/'SI'/'SD'/'CD'/'CI'.  
This value specifies the mapping mode for the *buff* argument.

Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return.
= 1	Attempt to read or write past end-of-file.
= 2	Hardware error occurred on channel.
= 3	Channel specified is not open.
= -19	Invalid BMODE value.

Example:

See SPFNW. See also SDAT.

**SPFNC/ISPFNC/MSPFNC**

SPFNC/ISPFNC/MSPFNC queues the specified operation and immediately returns control to the user program. When the operation is complete, the specified assembly language routine (*crtn*) is entered as an asynchronous completion routine.

Form:

```
CALL SPFNC (code,chan,wcnt,buff,blk,crtn)
i = ISPFNC (code,chan,wcnt,buff,blk,crtn)
CALL MSPFNC (code,chan,wcnt,buff,blk,crtn[,BMODE=strg][,CMODE=strg])
i = MSPFNC (code,chan,wcnt,buff,blk,crtn[,BMODE=strg][,CMODE=strg])
```

where:

- code** is the integer numeric code of the function to be performed
- chan** is the integer specification for the RT-11 channel to be used for the operation. You must obtain this channel through an IGETC call, or you can use channel 16(decimal) or higher if you have done an ICDFN call
- wcnt** is the integer number of data words in the operation; the default value for this argument is 0
- buff** is the array to be used as the data buffer; the default value for this argument is 0
- blk** This parameter is optional with some ISPFNC calls, depending on the particular function. Default value is 0.  
When this argument is supplied by magtape, it is the address of a four-word error and status block used for returning the exception conditions. The four words must be initialized to zero. The error and status block must always be mapped when running in the XM monitor, and the USR must not swap over it. To obtain the address of the error block, execute the following instructions:

```
INTEGER*2      ERRADR, ERRBLK(4)
DATA ERRBLK    /0,0,0,0,/
.
.
.
ERRADR = IADDR (ERRBLK) !GET THE ADDRESS OF
                    !THE 4-WORD ERROR BLOCK
ICODE = ISPFNC (CODE, ICHAN, WDCT, BUF, ERRADR)
```

## \*SPFN/\*SPFNC/\*SPFNF/\*SPFNW

**crtn** is the name of an assembly language routine to be activated on completion of the operation. This name must be specified in an **EXTERNAL** statement in the FORTRAN routine that issues the ISPFNC call

**BMODE=strg** Specify *strg* with one of the following: 'UI'/'UD'/'SI'/'SD'/'CD'/'CI'. This value specifies the mapping mode for the *buff* argument.

**CMODE=strg** Specify *strg* as string "S" to specify a Supervisor address.

### Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return.
= 1	Attempt of read or write past end-of-file.
= 2	Hardware error occurred on channel.
= 3	Channel specified is not open.
= -19	Invalid BMODE or CMODE value.

Error message *TRAP \$MSARG* will display if any argument is missing.

### Example:

See SPFNW. See also SDATC.

**SPFNF/ISPFNF**

SPFNF/ISPFNF queues the specified operation and immediately returns control to the user program. When the operation is complete, the specified FORTRAN subprogram (*frtn*) is entered as an asynchronous completion routine.

Form:

```
CALL SPFNF (code,chan,wcnt[,buff][,blk],area,crtn)
i = ISPFNF (code,chan,wcnt[,buff][,blk],area,crtn)
```

where:

- code** is the integer numeric code of the function to be performed
- chan** is the integer specification for the RT-11 channel to be used for the operation. You must obtain this channel through an IGETC call, or you can use channel 16(decimal) or higher if you have done an ICDFN call
- wcnt** is the integer number of data words in the operation; this argument must be 0 if not required
- buff** is the array to be used as the data buffer; this argument must be 0 if not required
- blk** This parameter is optional with some ISPFNF calls, depending on the particular function. Default value is 0.  
When this argument is supplied by magtape, it is the address of a four-word error and status block used for returning the exception conditions. The four words must be initialized to zero.  
The error and status block must always be mapped when running in the XM monitor, and the USR must not swap over it. To obtain the address of the error block, execute the following instructions:

```
INTEGER*2      ERRADR, ERRBLK(4)
DATA ERRBLK    /0,0,0,0,/
               .
               .
               .
               .
ERRADR = IADDR (ERRBLK) !GET THE ADDRESS OF
                   !THE 4-WORD ERROR BLOCK
ICODE = ISPFNF (CODE, ICHAN, WDCT, BUF, ERRADR)
```

## \*SPFN/\*SPFNC/\*SPFNF/\*SPFNW

- area** is a four-word area to be set aside for linkage information; this area must not be modified by the FORTRAN program, and the USR must not swap over it. This area can be reclaimed by other FORTRAN completion functions when *frtn* has been activated
- frtn** is the name of a FORTRAN routine to be activated on completion of the operation. This name must be specified in an EXTERNAL statement in the FORTRAN routine that issues the ISPFNF call.

### Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return.
= 1	Attempt to read or write past end-of-file.
= 2	Hardware error occurred on channel.
= 3	Channel specified is not open.

Error message *TRAP \$MSARG* will display if any argument is missing.

### Example:

```
REAL*4 MTNAME(2),AREA(2)
DATA MTNAME/3RMT0,0./
EXTERNAL DONSUB
.
.
.
I=IGETC( )           !ALLOCATE CHANNEL
CALL IFETCH(MTNAME) !FETCH MT HANDLER
CALL LOOKUP(I,MTNAME) !NON-FILE-STRUCTURED LOOKUP ON MT0
IERR-ISPFNF("373,I,0,0,0,AREA,DONSUB) !REWIND MAGTAPE
.
.
.
END
SUBROUTINE DONSUB
C
C   RUNS WHEN MT0 HAS BEEN REWOUND
C
.
.
.
END
```

**SPFNW/ISPFNW/MSPFNW**

SPFNW/ISPFNW/MSPFNW queues the specified operation and returns control to the user program when the operation is complete.

Form:

```
CALL SPFNW (code,chan[,wcnt,buff,blk])
i = ISPFNW (code,chan[,wcnt,buff,blk])
CALL MSPFNW (code,chan[,wcnt,buff,blk][,BMODE=strg])
i = MSPFNW (code,chan[,wcnt,buff,blk][,BMODE=strg])
```

where:

- code** is the integer numeric code of the function to be performed
- chan** is the integer specification for the RT-11 channel to be used for the operation. You must obtain this channel through an IGETC call, or you can use channel 16(decimal) or higher if you have done an ICDFN call
- wcnt** is the integer number of data words in the operation. This parameter is optional with some ISPFNW calls, depending on the function
- buff** is the array to be used as the data buffer. This parameter is optional with some ISPFNW calls, depending on the function
- blk** This parameter is optional with some ISPFN calls, depending on the particular function. Default value is 0.  
When this argument is supplied by magtape, it is the address of a four-word error and status block used for returning the exception conditions. The four words must be initialized to zero. The error and status block must always be mapped when running in the XM monitor, and the USR must not swap over it. To obtain the address of the error block, execute the following instructions:

```
INTEGER*2      ERRADR, ERRBLK(4)
DATA ERRBLK    /0,0,0,0,/
.
.
.
.
ERRADR = IADDR (ERRBLK) !GET THE ADDRESS OF
                       !THE 4-WORD ERROR BLOCK
ICODE = ISPFN (CODE, ICHAN, WDCT, BUF, ERRADR)
```

## \*SPFN/\*SPFNC/\*SPFNF/\*SPFNW

**BMODE=strg** Specify *strg* with one of the following: 'UI'/'UD'/'SI'/'SD'/'CD'/'CI'. This value specifies the mapping mode for the *buff* argument.

Errors:

Value	Meaning
i = 0	Normal return.
= 1	Attempt to read or write past end-of-file.
= 2	Hardware error occurred on channel.
= 3	Channel specified is not open.
= -19	Invalid BMODE argument.

Error message *TRAP \$MSARG* will display if any argument is missing.

Example:

```
      Program FSPFNW
C
C      Demonstate SPFUN
C
      Parameter VARSZ = '000400'o !variable size bit
      Parameter SFSIZ = '373'o !spfun code for size
      Integer*2 DBLK(4) !device name (no file)
      Data DBLK /3rSY , 0, 0, 0/ !system device
      Integer*2 REPLY(4+1) !DSTATUS reply area
      Integer*4 SIZE !trick for unsigned display
      Equivalence (SIZE, REPLY(4))
C
      ICHAN = IGETC () !Get a channel
      Call DSTAT (DBLK, REPLY) !check on the device
      REPLY(5) = 0 !clear high part of I4 Var
      If (IAND (REPLY(1), VARSZ) .eq. VARSZ) Then
          Call LOOKUP (ICHAN, DBLK) !open (CAN'T fail)
          Call SPFNW (SFSIZ, ICHAN, 1, REPLY(4), 0)
          Type *, 'Volume size (Variable) = ', SIZE
      Else
          Type *, 'Volume size (Constant) = ', SIZE
      End If
      End
```

---

## STRPAD

The STRPAD routine pads a character string with right-most blanks until that string is a specified length. This padding is done in place; the result string is contained in its original array. If the present length of the string is greater than or equal to the specified length, no padding occurs.

Form:

**CALL STRPAD (a,len[,err])**

where:

- a** is the array containing the string to be padded. This array must be one element longer than the value of *len* if *len* is specified. It must be terminated by a null byte
- len** is the integer length of the desired result string
- err** is the logical error flag that is set to `.TRUE.` if the string specified by *a* exceeds the value of *len* in length

Errors:

Error conditions are indicated by *err*, if specified. If *err* is given and the string indicated is longer than *len* characters, *err* is set to `.TRUE.`; otherwise, the value of *err* is unchanged.

### NOTE

The argument *err* must be specified as LOGICAL\*1 in FORTRAN 77. It can be any logical type in FORTRAN IV and any integer type in PDP-11C.

Unpredictable results will occur if any argument is omitted.

Example:

```

      Program FSTRPA
C
C      This program demonstrates the STRPAD function
C
      Byte BUFFER(61)
      Byte BUF1(81)
C
      Do 100 I = 1, 60
          BUFFER(I) = '?'
100      Continue
      BUFFER(61) = '000'o
      Call SCOPY ('test', BUFFER)
      Type 101, (BUFFER(I), I=1,60)
101      Format (' ', '( ', 60a1, ' ')
C
      Call STRPAD (BUFFER, 60)
      Type 101, (BUFFER(I), I=1,60)
      End
```

---

## SUBSTR

The SUBSTR routine copies a substring from a specified position in a character string. If desired, the substring can then be placed in the same array as the string from which it was taken.

Form:

**CALL SUBSTR (in,out,i[,len])**

where:

- in** is the array from which the substring is taken; it is terminated by a null byte
- out** is the array to contain the substring result. This array must be one element longer than *len*, if *len* is specified. It also is terminated by a null byte if *len* is specified
- i** is the integer character position in the input string of the first character of the desired substring
- len** is the integer number of characters representing the maximum length of the substring

Errors:

Unpredictable results will occur if any argument is omitted.

---

## SUSPND

The SUSPND subroutine suspends main program execution of the current job and allows only completion routines for I/O and scheduling requests to run.

Form:

**CALL SUSPND**

The monitor maintains a suspension counter for each job. This count is decremented by SUSPND and incremented by RESUME. A job will actually be suspended only if this counter is negative. When RESUME is issued before a SUSPND, the latter routine will return immediately.

A program must issue an equal number of SUSPND and RESUME calls.

A SUSPND subroutine call from a completion routine decrements the suspension counter but does not suspend the main program. If a completion routine does a SUSPND, the main program continues until it also issues a SUSPND, at which time it is suspended. Two RESUME calls are then required to proceed.

Because SUSPND and RESUME are used to simulate an ITWAIT in the monitor, a RESUME issued from a completion routine and not matched by a previously executed SUSPND can cause the main program execution to continue past a timed wait before the entire time interval has elapsed.

For further information on suspending main program execution of the current job, see the .SPND programmed request.

Errors:

None.

Example:

See MRKT.

---

# \$SYTRP

## Trap Handler

\$SYTRP processes SYSLIB-generated TRAP instructions for programs not linked with FORTRAN libraries. \$SYTRP should not be called by any program that will be linked with FORTRAN libraries F77OTS.OBJ or FORLIB.OBJ.

You include the \$SYTRP trap handler module by writing the following line in the program:

Form:

```
.GLOBL $SYTRP
```

When some SYSLIB routines detect an error condition, they execute a TRAP instruction, using a unique error number symbol, \$MSARG. \$SYTRP evaluates the \$MSARG value, prints an error message, and terminates the execution. If the error condition, and therefore the TRAP instruction, is caused by a routine being called with an invalid argument list (too few parameters), \$SYTRP prints the following error message:

*?SYSLIB-F-Invalid argument*

Any other TRAP instruction produces the following error message:

*?SYSLIB-F-Unknown error*

If no trap handler module is called, execution of a TRAP instruction causes the program to terminate.

The following is the source listing for \$SYTRP:

```
.MCALL .MODULE
.MODULE SYTRP,VERSION=04,COMMENT=^\SYSLIB/$SYTRP\,IDENT=NO,LIB=YES
    .NLIST  BEX
    .SBTTL  Definitions:

```

---

# TIMASC

The TIMASC subroutine converts a two-word internal format time into an ASCII string, **hh:mm:ss**.

where:

- hh** is the two-digit hours indication
- mm** is the two-digit minutes indication
- ss** is the two-digit seconds indication

Form:

**CALL TIMASC (itime, strng)**

where:

- itime** is the two-word internal format time to be converted, where
  - *itime(1)* is the high-order time
  - *itime(2)* is the low-order time
- strng** is the eight-element array to contain the ASCII time

Errors:

Error message *TRAP \$MSARG* will display if any argument is missing.

Example:

See JDIV.

---

## TIME

The `TIME` subroutine returns the current system time of day as an eight-character ASCII string, **hh:mm:ss**

where:

**hh** is the two-digit hours indication  
**mm** is the two-digit minutes indication  
**ss** is the two-digit seconds indication

Form:

**CALL TIME (strng)**

where:

**strng** is the eight-element array to receive the ASCII time

### NOTE

A 24-hour clock is used (for example, 1:00 p.m. is represented at 13:00:00).

Errors:

Unpredictable results will occur if any argument is omitted.

Example:

See `TWAIT`.

---

# TIMER/ITIMER

## SYSGEN Option for SB

TIMER/ITIMER schedules a specified FORTRAN subroutine to be run as an asynchronous completion routine after a specified time interval has elapsed. For SB monitor, you must select timer support during SYSGEN.

Form:

```
CALL TIMER (hrs,min,sec,tick,area,id,scrtn)
i = ITIMER (hrs,min,sec,tick,area,id,scrtn)
```

where:

<b>hrs</b>	is the integer number of hours
<b>min</b>	is the integer number of minutes
<b>sec</b>	is the integer number of seconds
<b>tick</b>	is the integer number of ticks (1/60 of a second on 60-Hz clocks; 1/50 of a second on 50-Hz clocks)
<b>area</b>	is a four-word area that must be provided for link information; this area must never be modified by the FORTRAN program, and the USR must never swap over it. This area can be reclaimed by other FORTRAN completion functions when <i>scrtn</i> has been activated
<b>id</b>	is the identification integer to be passed to the routine being scheduled
<b>scrtn</b>	is the name of the FORTRAN subroutine to be entered when the specified time interval elapses. This name must be specified in an EXTERNAL statement in the FORTRAN routine that references ITIMER. The subroutine has one argument. For example:

```
SUBROUTINE scrtn(id)
INTEGER id
```

When the routine is entered, the value of the integer argument is the value specified for *id* in the appropriate ITIMER call.

## Notes

- This function can be canceled at a later time by an ICMKT function call.
- If the system is busy, the actual time interval after which the completion routine is run can be longer than the time interval requested.
- FORTRAN subroutines can periodically reschedule themselves by issuing ISCHED or ITIMER calls.
- ITIMER requires a queue element, which should be considered when the IQSET function is executed.

For more information on scheduling completion routines, see program routines and .MRKT programmed request.

Errors:

Value	Meaning
i = 0	Normal return.
= 1	No queue elements available; unable to schedule request.

Error message *TRAP \$MSARG* will display if any argument is missing.

Example:

```

      Program FTIMER
C
C      demonstrate the FORTRAN timer completion routine
C
      Integer*2 HRS, MIN, SEC, TIC
      Integer*2 AREAA(4), AREAB(4)
      External FTIMEA          !fast timer completion
      External FTIMEB          !slow timer completion
C
      Call IQSET (10)          !allocate extra queue elements
      Call TIMER (0, 0, 1, 0, AREAA, 12345, FTIMEA)
      Call TIMER (0, 0, 5, 0, AREAB, 23456, FTIMEB)
      Call SUSPND
      Call PRINT ('!FTIMER-I-Exiting')
      End

      Subroutine FTIMEA (ID)
C
C      demonstrate the FORTRAN timer completion routine
C
      Integer*2 HRS, MIN, SEC, TIC
      Integer*2 AREAA(4)
      External FTIMEC          !fast timer completion
C
      Call TIMER (0, 0, 1, 0, AREAA, 12345, FTIMEC)
      Call PRINT ('!FTIMEA-I-Entered')
      End

      Subroutine FTIMEB (ID)
C
C      demonstrate the FORTRAN timer completion routine
C
      Call RESUME
      Call PRINT ('!FTIMEB-I-Entered')
      End

      .TITLE FTIMEC - bypass recursion test in F77
      .GLOBL FTIMEA
      FTIMEC::JMP FTIMEA ;let FTIMEA refer to itself
      .END

```

---

# TRANSL

The TRANSL routine performs character translation on a specified string and requires approximately 64(decimal) words on the R6 stack for its execution. This space should be considered when allocating stack space.

Form:

**CALL TRANSL (in,out,r[,p])**

where:

- in** is the array containing the input string; it is terminated by a null byte
- out** is the array to receive the translated string; it is not terminated by a null byte
- r** is the array containing the replacement string; it is terminated by a null byte
- p** is the array of characters in *in* to be translated; it is terminated by a null byte

The string specified by array *out* is replaced by the string specified by array *in*, modified by the character translation process specified by arrays *r* and *p*. If any character position in *in* contains a character that appears in the string specified by *p*, it is replaced in *out* by the corresponding character from string *r*. If the array *p* is omitted, it is assumed to be the 127 seven-bit ASCII characters arranged in ascending order, beginning with the character whose ASCII code is 001. If strings *r* and *p* are given and differ in length, the longer string is truncated to the length of the shorter. If a character appears more than once in string *p*, only the last occurrence is significant. A character can appear any number of times in string *r*.

Errors:

Unpredictable results will occur if any argument is missing.

Examples:

```
Program FTRAN1
C
C demonstrate translating characters
C The following uppercases all the letters
C and changes all numbers to #.
C
Byte IN(81), OUT(81) !string arguments
Byte FROM(81), TO(81) !translation table
C
Call SCOPY ('qwertyuiopasdfghjklzxcvbnm', FROM)
Call SCOPY ('QWERTYUIOPASDFGHJKLZXCVCBNM', TO)
Call CONCAT (FROM, '0123456789', FROM)
Call CONCAT (TO , '#####', TO)
C
Call SCOPY ('abcABC123', IN)
```

```

Call TRANSL (IN, OUT, TO, FROM)
Call PRINT (IN)
Call PRINT (OUT)
End

```

The following is an example of TRANSL being used to format character data.

```

Program FTRAN2
C
C This shows a way to shuffle a string using TRANSL
C
C Byte STRING(27), RESULT(27), PATT(27)
C
C 000000000111111111122222222
C 12345678901234567890123456
C The horn blows at midnight
C
C Data PATT(27)
C 1 /16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 15,
C 2 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 0/
C
C Call SCOPY ('The Horn Blows at Midnight', STRING)
C
C The following call to TRANSL rearranges the chars of
C the input string to the order specified by the pattern.
C
C Call TRANSL (PATT, RESULT, STRING)
C
C RESULT now contains the string 'at Midnight the Horn Blows'.
C In general, this method can be used to format strings of up
C to 127 chars. The resultant string will be as long as the
C pattern string.
C
C Call PRINT (STRING)
C Call PRINT (RESULT)
C End

```

---

## TRIM

The TRIM routine shortens a specified character string by removing all trailing blanks. A trailing blank is a blank that has no non-blanks to its right. If the specified string contains all blank characters, it is replaced by the null string. If the specified string has no trailing blanks, it is unchanged.

Form:

**CALL TRIM (a)**

where:

**a** is the array containing the string to be trimmed; it is terminated by a null byte on input and output

Errors:

Unpredictable results will occur if the argument is omitted.

Example:

```

          Program FTRIM
C
C      This demonstrates the TRIM function
C
          External LEN          !use the RT-11 LEN function
          Byte INPUT(81)        !input buffer
C
          Accept 100, (INPUT(I), I=1,80)
100      Format (80a1)
          Call SCOPY (INPUT, INPUT, 80)    !punch in a null
          Type *, LEN (INPUT)              !length before trimming
          Call TRIM (INPUT)                !trim trailing blanks
          Type *, LEN (INPUT)              !length after trimming
          End
```

---

# TWAIT/ITWAIT

## **SYSGEN Option for SB**

TWAIT/ITWAIT suspends the main program execution of the current job for a specified time interval. All completion routines continue to execute. For SB monitor, you must select timer support during SYSGEN.

Form:

```
CALL TWAIT (itime)
i = ITWAIT (itime)
```

where:

**itime** is the two-word internal format time interval  
**itime(1)** is the high-order time  
**itime(2)** is the low-order time

## **Notes**

TWAIT requires a queue element, which should be considered when the IQSET function is executed.

If the system is busy, the actual time interval during which execution is suspended may be longer than the time interval specified.

Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return.
= 1	No queue element available.

Unpredictable results will occur if any argument is omitted.

Example:

```
          Program FTWAIT
C
C          Wait 10 seconds
C
          Integer*4 TIMEWD          !time variable
          Byte ASCTIM(9)
C
          Call JTIME (0, 0, 10, 0, TIMEWD) !set for 10 sec
          Call TIME (ASCTIM)          !get current time
          Call PRINT (ASCTIM)         !display it
          Call TWAIT (TIMEWD)         !wait 10 seconds
          Call TIME (ASCTIM)          !get current time
          Call PRINT (ASCTIM)         !display it
          End
```

---

## UNMAP/IUNMAP

### Mapping

UNMAP/IUNMAP is used to eliminate the mapping window. See MAP subroutine. See also .WDBDF in the *RT-11 System Macro Library Manual*.

Form:

```
CALL UNMAP (iwdb [,ierr])  
ierr = IUNMAP (iwdb)
```

where:

<b>ierr</b>	Error return
<b>iwdb</b>	Address of Window Descriptor Block

Errors:

<b>Value</b>	<b>Meaning</b>
ierr = 0	Function completed successfully.
= -4	Invalid window identifier.
= -6	Specified window was not already mapped.
= -16	Mode/space not available.
= -257	Required argument missing.

Example:  
See CRAW.

---

## UNPRO/IUNPRO

UNPRO/IUNPRO cancels any protection for the specified 2-word vector in the 0 to 474 area. UNPRO is the complement of PROTE. If the specified two-word vector is currently not protected, UNPRO is ignored.

Form:

```
CALL UNPRO (addr)
i = IUNPRO (addr)
```

where:

**addr** is the address of the two-word vector pair for which protection is to be canceled.

Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return.
= -2	Addr is greater than 474 or not a multiple of 4.
= -257	Required argument <i>addr</i> missing.

Example:

See PROTE/IPROTE.

---

## UNTIL/IUNTIL

The UNTIL/IUNTIL suspends main program execution of the job until the time-of-day specified. All completion routines continue to run. For SB monitor, you must select timer support during SYSGEN.

Form:

```
CALL UNTIL (hrs,min,sec,tick)
i = IUNTIL (hrs,min,sec,tick)
```

where:

**hrs** is the integer number of hours  
**min** is the integer number of minutes  
**sec** is the integer number of seconds  
**tick** is the integer number of ticks (1/60 of a second on 60-Hz clocks; 1/50 of a second on 50-Hz clocks)

### NOTES

- IUNTIL requires a queue element, which should be considered when the IQSET function is executed.
- If the system is busy, the actual time of day that the program resumes execution may be later than that requested.

Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return.
= 1	No queue element available.

Error message *TRAP \$MSARG* will display if any argument is missing.

Example:

```
Program FUNTIL
C
C This program wait until the next even minute (sec=00)
C
Integer*4 NOW
Integer*2 HOURS, MINUTE, SECOND, TICKS
Byte ASCTIM(9)
Data ASCTIM(9) /0/
C
Call GTIM (NOW) !get current time
Call CVTTIM (NOW, HOURS, MINUTE, SECOND, TICKS) !dissect it
MINUTE = MINUTE + 1
If (MINUTE .eq. 60) Then
    MINUTE = 0
```

## UNTIL/IUNTIL

```
        HOUR = HOUR + 1
        If (HOUR .eq. 24) HOUR = 0
        End If
SECOND = 0
TICKS = 0
Call UNTIL (HOURS, MINUTES, SECOND, TICKS)
Call TIME (ASCTIM)
Call PRINT (ASCTIM)
End
```

---

## VERIFY/IVERIFY

VERIFY/IVERIFY checks that a given string is composed entirely of characters from a second string. If a character does not exist in the string being examined, VERIFY returns the position of the first character in the string being examined that is not in the source string. If all characters exist, VERIFY returns a 0.

Form:

```
CALL VERIFY (a,b,i)
i = IVERIF (a,b)
```

where:

- a** is the array containing the string to be scanned; it is terminated by a null byte
- b** is the array containing the string of characters to be accepted in a; it is terminated by a null byte

Function Result:

Value	Meaning
i = 0	If all characters of <i>a</i> exist in <i>b</i> ; also if <i>a</i> is a null string.
i = n	Where <i>n</i> is the character position of the first character in array <i>a</i> that does not appear in array <i>b</i> ; if <i>b</i> is a null string and <i>a</i> is not, <i>i</i> equals 1.

Errors: Error message *TRAP \$MSARG* will display if any argument is missing.

Example:

```
Program FVERIF
C
C Verify that the entered string contains only "hex"
C characters (0-9, a-f, A-F).
C
Character*81 INPUT      !input buffer
Byte VALID(23)         !valid chars
Data VALID
1 /'0', '1', '2', '3', '4', '5', '6', '7', '8', '9',
2 'a', 'b', 'c', 'd', 'e', 'f',
3 'A', 'B', 'C', 'D', 'E', 'F', '000'o/
C
100 Continue
    Call GTLIN (INPUT) !get a command line
    IERR = IVERIF (INPUT, VALID) !check it
    If (IERR .eq. 0) Then
        Type *, '!FVERIF-I-Valid input'
    Else
        Type *, '?FVERIF-W-Invalid input - ', INPUT(IERR:IERR)
    End If
    Go To 100
End
```

---

## WAIT/IWAIT

WAIT/IWAIT suspends execution of the main program until all input/output operations on the specified channel are complete. This function is used with \*READ, \*WRITE, and \*SPFN calls. Completion routines continue to execute.

Form:

```
CALL WAIT (chan)
i = IWAIT (chan)
```

where:

**chan** is the integer specification for the RT-11 channel to be used. You must obtain this channel through an IGETC call, or you can use channel 16(decimal) or higher if you have done an ICDFN call

For further information on suspending execution of the main program, see the .WAIT programmed request in the *RT-11 System Macro Library Manual*.

Errors:

<b>Value</b>	<b>Meaning</b>
i = 0	Normal return.
= 1	Channel specified is not open.
= 2	Hardware error occurred during the previous I/O operation on this channel.

Error message *TRAP \$MSARG* will display if any argument is missing.

Example:  
See READ.

---

## \*WRITE/\*WRITC/\*WRITF/\*WRITW

\*WRITE/\*WRITC/\*WRITF/\*WRITW, issued either as function or subroutine, transfers a specified number of words from memory to the device or file specified by channel. The \*WRITE functions require queue elements; this should be considered when the IQSET function is executed.

Specify mapping for MWRITE, MWRITC and MWRITW by adding optional parameters *BMODE* and *CMODE*.

### WRITE/IWRITE/MWRITE

WRITE/IWRITE/MWRITE transfers a specified number of words from memory to the specified channel. Control returns to the user program immediately after the request is queued. No special action is taken upon completion of the operation.

Form:

```
CALL WRITE (wcnt, buff, blk, chan)
i = IWRITE (wcnt, buff, blk, chan)
CALL MWRITE (wcnt, buff, blk, chan[, BMODE=strg])
i = MWRITE (wcnt, buff, blk, chan[, BMODE=strg])
```

where:

<b>wcnt</b>	is the integer number of words to be transferred
<b>buff</b>	is the array to be used as the output buffer
<b>blk</b>	is the integer block number of the file to be written. The user program normally updates <i>blk</i> before it is used again.
<b>chan</b>	is the integer specification for the RT-11 channel to be used. You must obtain this channel through an IGETC call, or you can use channel 16(decimal) or higher if you have done an ICDFN call
<b>BMODE=strg</b>	Specify <i>strg</i> with one of the following: 'UI'/'UD'/'SI'/'SD'/'CD'/'CI'. Value specifies the mapping mode for the <i>buff</i> argument.

Errors:

<b>Value</b>	<b>Meaning</b>
i = n	Normal return; n equals the number of words written, rounded to a multiple of 256 (0 for non-file-structured writes). If the word count returned is less than that requested, an implied end-of-file has occurred, although the normal return is indicated.
= -1	Attempt to write past end-of-file; no more space is available in the file.
= -2	Hardware error occurred.
= -3	Channel specified is not open.
= -19	Invalid BMODE or CMODE value.

Error message *TRAP \$MSARG* will display if any argument is missing.

**\*WRITE/\*WRITC/\*WRITF/\*WRITW**

Example:  
See ABTIO.

## \*WRITE/\*WRITC/\*WRITF/\*WRITW

### WRITC/IWRITC/MWRITC

WRITC/IWRITC/MWRITC issued either as function or subroutine, transfers a specified number of words from memory to the device or file specified by channel. The request is queued and control returns to the user program. When the transfer is complete, the specified assembly language routine (*crtn*) is entered as an asynchronous completion routine.

Form:

```
CALL WRITC (wcnt, buff, blk, chan, crtn)
i = IWRITC (wcnt, buff, blk, chan, crtn)
CALL MWRITC (wcnt, buff, blk, chan, crtn[, BMODE=strg][, CMODE=strg])
i = MWRITC (wcnt, buff, blk, chan, crtn[, BMODE=strg][, CMODE=strg])
```

where:

<b>wcnt</b>	is the relative integer number of words to be transferred
<b>buff</b>	is the array to be used as the output buffer
<b>blk</b>	is the relative integer block number of the file to be written. The user program normally updates <i>blk</i> before it is used again (for example, if the program is writing two blocks at a time, <i>blk</i> should be updated by 2)
<b>chan</b>	is the relative integer specification for the RT-11 channel to be used. You must obtain this channel through an IGETC call, or you can use channel 16(decimal) or higher if you have done an ICDFN call
<b>crtn</b>	is the name of the assembly language routine to be activated upon completion of the transfer. This name must be specified in an EXTERNAL statement in the FORTRAN routine that issues the IWRITC call
<b>BMODE=strg</b>	Specify <i>strg</i> with one of the following: 'UI'/'UD'/'SI'/'SD'/'CD'/'CI'. Value specifies the mapping mode for the <i>buff</i> argument.
<b>CMODE=strg</b>	Specifying <i>strg</i> as the string "S" specifies a Supervisor address.

Errors:

Same errors as \*WRITE.

Example:

See READC.

**WRITF/IWRITF**

WRITF/IWRITF issued either as function or subroutine, transfers a specified number of words from memory to the device or file specified by channel. The transfer request is queued and control returns to the user program. When the operation is complete, the specified FORTRAN subprogram (*frtn*) is entered as an asynchronous completion routine.

Form:

```
CALL WRITF (wcnt,buff,blk,chan,area,frtn)
i = IWRITF (wcnt,buff,blk,chan,area,frtn)
```

where:

<b>wcnt</b>	is the integer number of words to be transferred
<b>buff</b>	is the array to be used as the output buffer
<b>blk</b>	is the integer block number of the file to be written. The user program normally updates <i>blk</i> before it is used again
<b>chan</b>	is the integer specification for the RT-11 channel to be used. You must obtain this channel through an IGETC call, or you can use channel 16(decimal) or higher if you have done an ICDFN call
<b>area</b>	is a four-word area to be set aside for link information; this area must not be modified by the FORTRAN program, and the USR must not swap over it. This area can be reclaimed by other FORTRAN completion functions when <i>frtn</i> has been activated
<b>frtn</b>	is the name of the FORTRAN routine to be activated upon completion of the transfer. This name must be specified in an EXTERNAL statement in the FORTRAN routine that issues the IWRITF call.

Errors:

See the errors under \*WRITE.

Example:

See IREADF.

## **\*WRITE/\*WRITC/\*WRITF/\*WRITW**

### **WRITW/IWRITW/MWRITW**

WRITW/IWRITW/MWRITW issued either as function or subroutine, transfers a specified number of words from memory to the device or file specified by channel. Control returns to the user program when the transfer is complete.

Form:

```
CALL WRITW (wcnt,buff,blk,chan)
i = IWRITW (wcnt,buff,blk,chan)
CALL MWRITW (wcnt,buff,blk,chan[,BMODE=strg])
i = MWRITW (wcnt,buff,blk,chan[,BMODE=strg])
```

where:

<b>wcnt</b>	is the integer number of words to be transferred
<b>buff</b>	is the array to be used as the output buffer
<b>blk</b>	is the integer block number of the file to be written. The user program normally updates <i>blk</i> before it is used again
<b>chan</b>	is the integer specification for the RT-11 channel to be used. You must obtain this channel through an IGETC call, or you can use channel 16(decimal) or higher if you have done an ICDFN call
<b>BMODE=strg</b>	Specify <i>strg</i> with one of the following: 'UI'/'UD'/'SI'/'SD'/'CD'/'CI'. Value specifies the mapping mode for the <i>buff</i> argument.

Errors:

See the errors under \*WRITE.

Example:

See REOPEN.

## S

### SAVES/ISAVES

See also REOPN  
description, 2-198

### SCCA/ISCCA

description, 2-199  
example, 2-199

### SCHED/ISCHED

description, 2-201  
example, 2-201

### SCOMP/ISCOMP

See also SDTTM  
description, 2-203

### SCOPY

description, 2-204  
example, 2-204

### SDATC/ISDATC/MSDATC

description, 2-207  
example, 2-207

### SDATF/ISDATF

description, 2-209  
example, 2-209

### SDAT/ISDAT/MSDAT

description, 2-205  
example, 2-205

### SDATW/ISDATW/MSDATW

description, 2-211  
example, 2-211

### SDTTM/ISDTTM

description, 2-214  
example, 2-214

### SERR/ISERR

See also HERR  
description, 2-216

### SETCMD

description, 2-218  
example, 2-218

### SFDAT/ISFDAT

description, 2-219  
example, 2-219

### SFINF/ISFINF

description, 2-220  
example, 2-220

### SFSTA/ISFSTA

description, 2-223  
example, 2-223

### SLEEP/ISLEEP

See also TIMER  
description, 2-226

### SPCPS/ISCPS

description, 2-227  
example, 2-227

### SPFN

Added support, 2-229  
DU support, 2-229  
DW support, 2-229  
MU support, 2-229

### SPFNC/ISPFNC/MSPFNC

description, 2-233

### SPFNF/ISPFNF

See also SDATF  
description, 2-235

### SPFN/ISPFN/MSPFN

description, 2-231

### SPFNW/ISPFNW/MSPFNW

description, 2-237  
example, 2-237

### STRPAD

description, 2-239  
example, 2-239

### Subroutine

register usage, 1-24

### Subroutines

added queue elements, 1-14  
invoking, 1-23

### SUBSTR

description, 2-240  
example, 2-240

### SUSPND

See also MRKT  
description, 2-241

### SYSLIB

applicability of routines, 1-2  
conversion calls, 1-34  
FORTRAN naming conventions, 1-3  
functional organization, 1-2  
list of functions, 1-16  
list of subroutines, 1-16  
services not provided, 1-33  
system conventions, 1-2

### SYSLIB conversion calls

table, 1-34

### System conventions

allocating channels, 1-4  
channel numbers, 1-3  
completion routines, 1-4  
functions, 1-3  
subroutines, 1-3

### \$SYTRP

\$SYTRP (Cont.)
