PenPoint® Application Writing Guide
Expanded Second Edition

Updated to include Versions 1.0 and 2.0
PenPoint Application Writing Guide, Expanded Second Edition provides a tutorial on writing PenPoint applications, including many coding samples. It also provides information about PenPoint 2.0 Japanese and how it supports internationalized applications. This is the first book you should read as a beginning PenPoint application developer.

PenPoint Architectural Reference, Volume I presents the concepts of the fundamental PenPoint classes. Read this book when you need to understand the fundamental PenPoint subsystems, such as the class manager, application framework, windows and graphics, and so on.

PenPoint Architectural Reference, Volume II presents the concepts of the supplemental PenPoint classes. You should read this book when you need to understand the supplemental PenPoint subsystems, such as the text subsystem, the file system, connectivity, and so on.

PenPoint API Reference, Volume I provides a complete reference to the fundamental PenPoint classes, messages, and data structures.

PenPoint API Reference, Volume II provides a complete reference to the supplemental PenPoint classes, messages, and data structures.

PenPoint User Interface Design Reference describes the elements of the PenPoint Notebook User Interface, sets standards for using those elements, and describes how PenPoint uses the elements. Read this book before designing your application's user interface.

PenPoint Development Tools describes the environment for developing, debugging, and testing PenPoint applications. You need this book when you start to implement and test your first PenPoint application.
Many of the designations used by manufacturers and sellers to distinguish their products are claimed as trademarks. Where those designations appear in this book and Addison-Wesley was aware of a trademark claim, the designations have been printed in initial capital letters.

The authors and publishers have taken care in preparation of this book, but make no expressed or implied warranty of any kind and assume no responsibility for errors or omissions. No liability is assumed for incidental or consequential damages in connection with or arising out of the use of the information or programs contained herein.

GO Corporation does not warrant, guarantee, or make any representations regarding the use or the results of the use of the PenPoint software, other products, or documentation in terms of its correctness, accuracy, reliability, currentness, or otherwise. The entire risk as to the results and performance of the PenPoint software and documentation is assumed by you. The exclusion of implied warranties is not permitted by some states. The above exclusion may not apply to you.

In no event will GO Corporation, its directors, officers, employees, or agents be liable to you for any consequential, incidental, or indirect damages (including damages for loss of business profits, business interruption, loss of business information, cost of procurement of substitute goods or technology, and the like) arising out of the use or inability to use the documentation or defects therein even if GO Corporation has been advised of the possibility of such damages, whether under theory of contract, tort (including negligence), products liability, or otherwise. Because some states do not allow the exclusion or limitation of liability for consequential or incidental damages, the above limitations may not apply to you. GO Corporation’s total liability to you from any cause whatsoever, and regardless of the form of the action (whether in contract, tort [including negligence], product liability or otherwise), will be limited to $50.

The PenPoint documentation is provided with RESTRICTED RIGHTS. Use, duplication, or disclosure by the U.S. Government is subject to restrictions as set forth in FAR 52.227-19 (Commercial Computer Software—Restricted Rights) and DFAR 252.227-7013 (c) (1) (ii) (Rights in Technical Data and Computer Software), as applicable. Manufacturer is GO Corporation, Suite 400, 919 East Hillsdale Boulevard, Foster City, CA 94404, USA.
Preface

The PenPoint Application Writing Guide: Expanded Second Edition is an updated version of the PenPoint Application Writing Guide printed in March 1992. This expanded edition includes new information that reflects GO Corporation's enhancements to the PenPoint™ operating system for PenPoint 2.0 Japanese and the PenPoint Software Development Kit (SDK) 2.0 Japanese.

This book is an up-to-date introduction to the PenPoint SDK 2.0 Japanese operating system and contains errata and additional information for earlier PenPoint SDKs. Unless stated otherwise, discussions of the PenPoint operating system and the PenPoint SDK in this book are valid for PenPoint 1.0, PenPoint 1.01, and PenPoint 2.0 Japanese.

PenPoint 2.0 Japanese is a Japanese product with Japanese system resources (on-line help, menu choices, and so on). Developers who do not read Japanese can run the PenPoint SDK 2.0 Japanese with U.S. English resources, but there are some parts of the system that show Japanese text even with the U.S. English feature enabled.

Intended audience

This book is intended for programmers who want to write applications for the PenPoint operating system. It assumes that you are familiar with the C programming language and related development tools such as MAKE utilities.

Document structure

This book contains several parts:

- **Part 1: PenPoint Application Writing Guide** is an introduction to the PenPoint operating system and the PenPoint SDK. It introduces you to basic PenPoint programming concepts, then illustrates those concepts by examining some of the sample applications included with the PenPoint SDK.

- **Part 2: PenPoint Internationalization Handbook** describes the features PenPoint provides that allow you to write an application that is easy to port from one national locale to another.

- **Part 3: PenPoint Japanese Localization Handbook** shows how to use features of the PenPoint SDK 2.0 Japanese that support Japanese-language application development.

- **Part 4: PenPoint Development Tools Supplement** provides new information about the development tools you use with the PenPoint SDK. This part is an update to PenPoint Development Tools originally published for the PenPoint SDK 1.0.
Preface

♦ Part 5: *PenPoint Architectural Reference Supplement* provides new information about the architecture of the PenPoint operating system and the classes that it provides. This part is an update to *PenPoint Architectural Reference* originally published for the PenPoint SDK 1.0.

♦ Part 6: *PenPoint User Interface Design Reference Supplement* provides new information about user interface design and the user interface classes that PenPoint provides. This part is an update to *PenPoint User Interface Design Reference* originally published for the PenPoint SDK 1.0.

♦ Part 7: *Sample Code* provides descriptions and listings of the sample applications used as examples in this book, and descriptions of the other sample code included with the PenPoint SDK.

Each of these parts was at one time intended to be a separate document, but they have been bound together into a single volume for your convenience. Be aware that you may still find some cross-references that refer to a part of this volume as though it were still a separate book.

Other sources of information

Several parts of this book supplement existing books published for the PenPoint SDK 1.0. These books include *PenPoint Development Tools*, *PenPoint Architectural Reference*, and *PenPoint User Interface Design Reference*.

For information on the classes, messages, macros, functions, and structures that the PenPoint SDK header files define, see the header files themselves. Many of the header files have changed since the *PenPoint API Reference* was published for the PenPoint SDK 1.0.
Part 1 / PenPoint Application Writing Guide
1 / Introduction 5
2 / PenPoint System Overview 7
3 / Application Concepts 23
4 / PenPoint Class Manager 43
5 / Developing an Application 61
6 / A Simple Application (Empty Application) 91
7 / Creating Objects (Hello World: Toolkit) 111
8 / Creating a New Class (Hello World: Custom Window) 123
9 / Saving and Restoring Data (Counter) 133
10 / Handling Input (Tic-Tac-Toe) 145
11 / Refining the Application (Tic-Tac-Toe) 155
12 / Releasing the Application 169

Part 2 / PenPoint Internationalization Handbook
13 / Introduction 175
14 / Overview 177
15 / PenPoint Support for International Software 183
16 / Procedures 209
17 / Porting to PenPoint 2.0 229
18 / Localization Guidelines 235
19 / Additional Resources 237

Part 3 / PenPoint Japanese Localization Handbook
20 / Introduction 243
21 / Japanese Characters 245
22 / Processing Japanese Text 255
23 / Development Environment 273
24 / Procedures 283
25 / Resources 301
26 / Japanese Character Set 303

Part 4 / PenPoint Development Tools Supplement
27 / Introduction 375
28 / Road Map 377
29 / Creating Applications and Services 381
30 / Debugging 395
31 / Tools and Utilities 403
32 / Miscellaneous 415

Part 5 / PenPoint Architectural Reference Supplement
33 / Overview 427
34 / Class Manager 433
35 / Application Framework 435
36 / Windows and Graphics 441
37 / UI Toolkit 445
38 / Input and Handwriting Recognition 451
39 / Text 463
40 / The File System 467
41 / System Services 471
42 / Utility Classes 479
43 / Connectivity 483
44 / Resources 495
45 / Installation API 499
46 / Writing PenPoint Services 503
47 / International Services and Routines 507

### Chapter 1 / Introduction

5 Intended audience
5 Other sources of information

### Chapter 2 / PenPoint System Overview

7 Design considerations
7 User interface
The pen
Notebook metaphor
9 Object-oriented architecture
9 Architecture and functionality
10 Kernel layer
11 System layer
   File system
   Resource manager
   Networking
   Windowing
   Graphics
   Printing
   User Interface Toolkit
   Input and handwriting translation
   Selection Manager and data transfer
16 Component layer
16 Application Framework layer
17 Application layer
17 Software development environment
   Software development kit
   Coding conventions
   Extensibility
18 PenPoint design guidelines
   Conserve memory
   Think small
   Use a modular design
   Your application must recover
   Take advantage of object-oriented programming
   Consider sharing code and data
   Use document orientation
   Design for file format compatibility
   Exploit the pen
   Use the PenPoint user interface

### Chapter 3 / Application Concepts

24 PenPoint programming is unique
24 How applications work
   Installing and starting applications
   MS-DOS installation
   PenPoint installation
   Installer responsibilities
   Running a PenPoint application
   Life cycle of a document
   Activating a document
   Not all active documents are on-screen
   Application classes and instances
28 PenPoint drives your application
29 Application objects
   A descendant of clsApp
   An instance of clsWin
   An instance of clsObject
31 Understanding the application hierarchy
   The Notebook's own hierarchy
   The Bookshelf
   The Notebook
   Page-level applications
   Sections
   Floating accessories
   Embedded applications
   Application data
38 Activating and terminating documents
   Turning a page and msgAppClose
   Restoring inactive documents
   Page-turning instead of closing
   Saving state (no quit)
40 Documents, not files and applications
   No new, no save as . . .
   Stationery
41 Shutting down and terminating applications
   Conserving memory
   Avoiding duplication
   Hot mode
   Components

### Chapter 4 / PenPoint Class Manager

43 Objects instead of functions and data
44 Messages instead of function calls
45 Classes instead of code sharing
   Handling messages
47 Sending a message
   Message arguments
   ObjectCallO parameters
   Returned values
   How objects know how to respond
49 Creating an object
   Classes and instances
   An alternative explanation
   The _NEW structure
   Identifying _NEW structure elements
   Code to create an object
   Identifying the new object: UIDs
55 Creating a class
   New class message arguments
   Method tables
   Self
   Possible responses to messages
Chapter 5 / Developing an Application

61 Designing your application
   Designing the user interface
   Designing classes
   Designing messages
   Designing message handlers
   Designing program units

63 Designing for internationalization and localization
   Porting from PenPoint 1.0 to PenPoint 2.0 Japanese
   Preparing for internationalization

66 Development strategy
   Application entry point
   Application instance data
   Creating stateful objects
   Displaying on screen
   Creating component classes

67 Development cycles
   Compiling and linking
   Installing the application
   Debugging

69 A developer's checklist
   Checklist of required interactions
   Checklist of nonessential items

71 GO's coding conventions
   Typedefs
   Variables
   Functions
   Defines (macros and constants)
   Class manager constants
   Exported names

74 PenPoint file structure
   File header comment
   Include directives
   Defines, types, globals
   Function prototypes
   Message headers
   Indentation
   Comments
   Some coding suggestions

77 PenPoint types and macros
   Data types
   Basic constants
   Legibility
   Compiler isolation
   Data conversion and checking
   Bit manipulation
   Tags
   Return values
   Return status debugging function
   Error-handling macros

84 Debugging assistance
   Printing debugging strings
   Assertions

87 The tutorial programs
   Empty Application
   Hello World (Toolkit)
   Hello World (Custom Window)
   Counter Application
   Tic-Tac-Toe
   Template Application
   Other code available

Chapter 6 / A Simple Application (Empty Application)

91 Files used
   Not the simplest

92 Compiling and linking the code
   Compiling method tables

92 Installing and running Empty Application

92 Interesting things you can do with Empty Application

94 Code run-through
   PenPoint source code file organization
   Empty Application's source code
   Libraries and header files
   Class UID
   Class creation
   Documents, accessories and stationery

101 Where does the application class come from?
   Installation and activation

104 Handling a message
   Method table
   msgDestroy

105 Message handler
   Parameters
   Parameters in EmptyAppDestroy()
   Status return value
   Message handlers are private

108 Using debugger stream output

108 The debugger stream
   Seeing debug output

Chapter 7 / Creating Objects (Hello World: Toolkit)

111 HelloTK
   Compiling and installing the application
   Interesting things you can do with HelloTK

112 Code run-through for HELLOTK1.C
   Highlights of HELLOTK1
   Sending messages
   Creating toolkit components
   Where the window goes
   Why msgAppInit?
Why did the window appear?
Possible enhancements

119 Highlights of the second HelloTK
Only one client window per frame
Layout
Possible enhancements

Chapter 8 / Creating a New Class (Hello World: Custom Window)

123 Hello World (Custom Window)
Compiling the code
Highlights of clsHelloWorld
Highlights of clsHelloWin

125 Graphics overview
System drawing context
Coordinates in drawing context
When to paint

127 When to create things
Instance data
Is it msgNew or msgInit?
Window initialization

129 Using instance data
No filing yet

130 Drawing in a window

131 Possible enhancements

131 Debugging Hello World (Custom Window)

Chapter 9 / Saving and Restoring Data (Counter)

133 Saving state

133 Counter application
Compiling and installing the application
Counter Application highlights
Counter class highlights
Instance data
Getting and setting values

138 Object filing
Handling msgSave
Handling msgRestore

140 Counter Application's instance data
Memory-mapped file
Opening and closing the file
Filing the counter object

143 Menu support
Buttons

Chapter 10 / Handling Input (Tic-Tac-Toe)

145 Tic-Tac-Toe objects
Application components
Separate stateful data objects

146 Tic-Tac-Toe structure

147 Tic-Tac-Toe window
Coordinate system
Advanced repainting strategy

148 View and data interaction
Data object design
Instance data by value vs. by reference
Saving a data object
Handling failures during msgInit and msgRestore

150 The selection and keyboard input
How selection works

151 More on view and data interaction

152 Handwriting and gestures
Input event handling
Gesture handling
Keyboard handling

Chapter 11 / Refining the Application (Tic-Tac-Toe)

155 Debugging
Tracing
DebugfO statements and debug flags
Dumping objects
Symbol names

159 Installation features

159 Stationery
Creating stationery
How Tic-Tac-Toe handles stationery

160 Help notebook
Creating help documents

161 Quick Help
Creating Quick Help resources

164 Standard message facility
Using StdMsg() facilities
Substituting text and defining buttons
StdMsg() and resource files or lists
StdMsg() customization function

166 Bitmaps (icons)
Creating icons

Chapter 12 / Releasing the Application

169 Registering your classes

169 Documenting the application
Writing manuals
Screen shots
Gesture font

170 On-disk structure

170 Sharing your classes
Chapter 1 / Introduction

The PenPoint™ operating system is an object-oriented, multitasking operating system that is optimized for pen-based computing. Writing applications for the PenPoint operating system will present you with some new challenges. However, PenPoint contains many features that make application development far easier than development in many other environments.

One feature that makes application development easier is the PenPoint Application Framework, which eliminates the need to write "boilerplate" code. In other operating systems, programmers must write code to perform housekeeping functions, such as application installation, input and output file handling, and so on. These are provided automatically by the PenPoint Application Framework.

PenPoint also provides most of the on-screen objects used by the PenPoint Notebook User Interface (NUI). By using these objects, your application can conform to the PenPoint NUI, without a great amount of work on your part.

In this manual, you will learn about the PenPoint operating system, the PenPoint development environment, and, of course, how to write applications for the PenPoint operating system. The PenPoint Software Development Kit (SDK) contains several sample applications that you can compile and run. These sample applications are used throughout this manual to demonstrate concepts and programming techniques.

**Intended audience**

This manual is intended for programmers who want to write applications for the PenPoint operating system. It assumes that you are familiar with the C programming language and related development tools, such as make utilities.

You should also be aware of the information in the companion volume, *PenPoint Development Tools*. Pay particular attention to Chapter 2, Roadmap to SDK Documentation, which describes the organization of the PenPoint SDK documentation and recommends a path through the manuals.

**Other sources of information**

For conceptual information about the various classes in PenPoint, see the *PenPoint Architectural Reference*.

For information on running PenPoint on a PC, see the *Running PenPoint on a PC* document that comes with the PenPoint SDK.
To learn how to use the PenPoint development tools and utilities, such as the PenPoint source-level debugger, see *PenPoint Development Tools*.

For reference information on the classes, messages, macros, functions, and structures defined by PenPoint, see the *PenPoint API Reference*. The information in the *PenPoint API Reference* is derived directly from the PenPoint header files (in PENPOINT\SDK\INC).
Chapter 2 / PenPoint System Overview

When GO Corporation undertook to build a mobile, pen-based computer system, we quickly recognized that existing standard operating systems were not adequate for the task. Those systems, designed for the very different needs of keyboard-based desktop computers, would require such extensive rewriting to support this new market that they would no longer run the installed base of applications that made them standard in the first place. We therefore determined that a new, general-purpose operating system would be needed, designed specifically for the unique requirements of pen-based computing. The result is the PenPoint™ operating system. This document is a brief introduction and overview of its design goals, architecture, and functionality.

Design considerations
After extensive research and analysis, GO identified the following key requirements for pen-based system software:

- A direct, natural, intuitive, and flexible graphical user interface.
- Strong support for handwriting recognition and gesture based commands.
- A richer organizational metaphor than the traditional file-system model.
- A high degree of memory conservation through extensive sharing of code, data, and resources.
- Priority-based, preemptive multitasking.
- Detachable networking and deferred data transfer.
- Hardware independence (ability to move to new processors quickly).

The PenPoint operating system was developed to satisfy these requirements.

User interface
PenPoint’s most distinctive feature is its innovative user interface. The user interface is the cornerstone on which the entire system is built; all other design considerations follow from it. The user interface, in turn, is based on two main organizing principles:

- The use of a pen as the primary input device.
- The use of a notebook metaphor that is natural and easy to use.

The consequences of these two basic design features permeate the entire system.
The pen

The pen naturally combines three distinct system control functions: pointing, data input, and command invocation. Like a mouse, it can point anywhere on the screen to designate an operand, specify a location, draw a picture, drag an object, or select from a menu. Through sophisticated handwriting recognition software, it can replace the keyboard as a source of text input. Finally, it can do something neither a mouse nor a keyboard can do: issue commands through graphical gestures.

Gestures

Gestures are simple shapes or figures that the user draws directly on the screen to invoke an action or command. For example, a cross out \( \times \) gesture is used to delete, a circle \( \circ \) to edit, and a caret \( \wedge \) to insert. A set of built-in core gestures form the heart of the PenPoint user interface:

- Caret \( \wedge \)
- Circle \( \circ \)
- Flick left \( \leftarrow \)
- Flick up \( \uparrow \)
- Insert space \( \_ \)
- Press \( \downarrow \)
- Tap \( \uparrow \)
- Undo \( \checkmark \)

To exploit the unique properties of the pen, PenPoint provides strong support for gestural command invocation. The same handwriting translation subsystem that recognizes characters for text input also recognizes those shapes that constitute meaningful gestures. The form, location, and context of the gesture then determine the action to be performed and the data objects affected. Because a gesture can be made directly over the target object, it can specify both the operand and the operation in a single act. This gives the pen-based interface a directness and simplicity that cannot be achieved with a mouse.

PenPoint control

The pen has one more notable property as a control device. Because it draws directly on the face of the screen (rather than on a physically separate working surface such as a mouse pad or graphics tablet), it eliminates a major source of difficulty among new computer users—the relationship between movement of the mouse and the movement of the cursor on the screen. With a pen, the user's eye is focused exactly where his or her hand is working. Most PenPoint applications can thus dispense with an on-screen cursor for tracking the pen, though one is available as an optional user preference.

Notebook metaphor

Instead of a traditional file system based on a hierarchy of nested directories and cryptic file names, PenPoint uses a "notebook" metaphor for information storage and retrieval. By using familiar models of working with paper-based documents,
the notebook approach provides a rich variety of natural and intuitive techniques for organizing and accessing information:

- A **bookshelf** upon which multiple user notebooks may reside, as well as system notebooks for help information and stationery, an inbox and outbox, and various tools and accessories. A user can have any number of notebooks open at once; typical use involves one main notebook.

- A **table of contents** offering an overview of all available documents in the notebook, allowing easy manipulation and navigation at the global level. The table of contents can be organized in natural page number order, or sorted by name, size, type, or date.

- **Sections** and **subsections** for hierarchical organization.

- **Page numbers** and notebook **tabs** for direct random access.

- **Page turning** for sequential access.

Because the notebook is a familiar, physical, and stable model, a user can employ spatial memory of layout and juxtaposition to help find and organize their information.

## Object-oriented architecture

To facilitate code sharing and overall memory conservation, PenPoint uses an object-oriented approach to system architecture. All application programming interfaces (APIs) above the kernel layer are implemented using object-oriented programming techniques of subclass inheritance and message passing. This helps to ensure that PenPoint and its APIs have these characteristics:

- They are compact, providing a body of shared code that need not be duplicated by all applications.

- They are consistent, since all applications share the same implementation of common system and user interface functions.

- They are flexible, allowing applications to modify PenPoint’s behavior by subclassing its built-in classes.

The event-driven, object-oriented nature of the system minimizes the need to “reinvent the wheel” with each new application. Programmers can “code by exception,” reusing existing code while altering or adding only the specific behavior and functionality that their own applications require. Because the object-oriented architecture is system-wide, these benefits are not restricted to single applications; in fact, applications can share code with each other just as readily as with the system itself.

## Architecture and functionality

PenPoint’s overall software architecture is organized into five layers:

1. The **kernel**, which provides multitasking process support, memory management, and access to hardware. The kernel works closely with the PenPoint class manager, which makes PenPoint object oriented.
2. The **system layer**, which provides windowing, graphics, and user interface support in addition to common operating system services such as filing and networking.

3. The **component layer**, which consists of general-purpose subsystems offering significant functionality that can be shared among applications.

4. The **Application Framework**, which serves as a “head start” for building applications.

5. The applications themselves.

Each of these layers is discussed in detail below.

### Kernel layer

The kernel is the portion of the PenPoint operating system that interacts directly with the hardware. Besides handling such low-level tasks as process scheduling and synchronization, dynamic memory allocation, and resource management, it also provides these services, which are needed to support the object-oriented software architecture:

- Priority-based, preemptive multitasking.
- Processes and threads (lightweight tasks sharing the same address space).
- Interprocess communication and semaphores.
- Task-based interrupt handling.
- 32-bit flat memory model.
- Protected memory management and code execution.
- Heap memory allocation with transparent relocation and compaction (no fixed-length buffers).
- Object-oriented message passing and subclass inheritance.

All hardware dependencies in the kernel are isolated into a library subset called the machine interface layer (MIL) to facilitate porting to a wide variety of hardware and processor architectures. The kernel runs on both PC and pen-based machines. All of PenPoint’s APIs use full 32-bit addresses.

Other parts of the kernel layer support features that keep PenPoint small and efficient. These parts are defined below.

**Loader**  Unlike a traditional, disk-based operating system, PenPoint's loader does not require multiple copies of system and application code to be present in the machine at the same time. Instead, it maintains a single instance of all code and resources, which are shared among all clients. When installing a new application, the loader reads in only those components that are not already present in memory.
Power Conservation  When running on battery-powered hardware, the kernel reduces power consumption by shutting down the CPU whenever there are no tasks awaiting processor time. Subsequent events such as pen activity or clock-chip alarms generate interrupts that reactivate the CPU. The kernel also monitors the main battery and will refuse to run if power is too low, ensuring reliable protection of user data.

Class Manager  PenPoint’s Class Manager works closely with the kernel to support object-oriented programming techniques such as single-inheritance subclassing and message passing. The Class Manager also provides important protection and multitasking services not found in C++ or other object-oriented languages. These services safeguard the operating system against possible corruption arising from the use of object-oriented techniques. For example, instance data for system-defined classes is protected so that the data cannot be altered by any subclasses. Applications thus derive the benefits of subclassing without jeopardizing the integrity of the system.

System layer

PenPoint’s system layer provides a broader range of support services than a traditional operating system. In addition to the usual system facilities such as filing and networking, it also provides such high-level services as windowing, graphics, printing, and user interface support. This helps keep application code compact and consistent while facilitating application development for the machine.

File system

PenPoint’s file system is designed for compatibility with other existing file systems, particularly MS-DOS, and includes full support for reading and writing MS-DOS-formatted disks. It provides many of the standard features of traditional file systems, including hierarchical directories, file handles, paths, and current working directories, as well as such extended features as 32-character file names, memory-mapped files, object-oriented APIs, and general, client-specified attributes for files and directories.

The PenPoint file system is a strict superset of the MS-DOS file system; all PenPoint-specific information is stored as an MS-DOS file within each MS-DOS directory. This approach is used when mapping to other file systems as well. Additional, installable volume types are also supported.

Resource manager

PenPoint’s Resource Manager and the resource files that it controls allow applications to separate data from code in a clean, structured way. The Resource Manager can store and retrieve both standard PenPoint objects and application-defined data, in either a specific file or a list of files. Resources can be created directly by the application or by compiling a separate, text-based resource definition file.
Networking

PenPoint provides native support for smooth connectivity to other computers and networks. Multiple, “autoconfiguring” network protocol stacks can be installed on the fly. AppleTalk™ protocol is built in, enabling connection to other networks through a variety of AppleTalk-compatible gateways. With the appropriate TOPS software, users can configure their systems to connect directly to desktop computers.

Through the use of these networking facilities, remote services such as printers are as easily accessible to PenPoint applications as if they were directly connected. Remote file systems on desktop computers and network file servers are also transparently available via a remote-file-system volume. A user can browse PC and file-server directories, for instance, using PenPoint’s Connections notebook. Several remote volumes can be installed at once: for example, a PenPoint system can hook directly to a Macintosh and a DOS computer at the same time.

A typical user, while on an airplane, might mark up a fax, fill out an expense report to be electronically mailed to the payables department, draft a business letter to be printed, edit an existing document, and export it to a PC’s hard disk. Upon connection to the physical devices, conventional operating systems would require that user to run each application, load each document and dispense with it. PenPoint’s Inbox and Outbox services allow the user to defer and batch data transfer operations for completion at a later time. Upon returning to the office and establishing the physical connection, the documents are automatically faxed, printed, and mailed. These services are extensible and can support a wide variety of transfer operations, including electronic mail, print jobs, fax transmissions, and file transfers.

Windowing

The window system supports nested hierarchies of windows with multiple coordinate systems, clipping, and protection. Windows are integrated with PenPoint’s input system, so that incoming pen events are automatically directed to the correct process and window. Windows use little memory and can therefore be used freely by applications to construct their user interface.

Usually windows appear on screen, but they can also be created on other, off-screen image devices, such as printers.

The window system maintains a global, screen-wide display plane called the acetate plane, which is where ink from the pen is normally “dribbled” by the pen-tracking software as the user writes on the screen. The acetate plane greatly improves the system’s visual responsiveness, both in displaying and in erasing pen marks on the screen.
Graphics

PenPoint's built-in graphics facility, the ImagePoint™ imaging model, unifies text with other graphics primitives in a single, PostScript-like imaging model. ImagePoint™ graphics can be arbitrarily scaled, rotated, and translated, and can be used for both screen display and printing. ImagePoint's graphics capabilities include these elements:

- Polylines
- Rectangles
- Rounded rectangles
- Polygons
- Sampled images
- Text
- Bezier curves
- Ellipses
- Arcs
- Sectors
- Chords

A picture segment facility allows ImagePoint messages to be stored and played back on demand, facilitating a variety of drawing and imaging applications. For improved performance, the imaging system dynamically creates machine code when appropriate for low-level graphics operations such as direct pixel transfer. The ImagePoint API also supports the use of color, (specified in conventional RGB values) allowing PenPoint to run on grey-scale and color screens.

To conserve memory, ImagePoint uses outline fonts to render text at any point size. (Bitmap fonts are automatically substituted at low resolutions for improved visual clarity.) Fonts are heavily compressed and some character styles are synthesized to minimize memory requirements. If a requested font is not present, ImagePoint will find the closest available match. Text characters can be scaled and rotated in the same way as other graphical entities.

Printing

The ImagePoint imaging model is used for printing as well as screen display, allowing applications to use the same image-rendering code for both purposes, rebinding it to either a screen window or a printer as the occasion demands. PenPoint handles all printer configuration, and automatically controls margins, headers, and footers, relieving the application of these details. (As in most other areas of PenPoint, applications can override the default behavior.)

One key benefit of this approach is that documents to be faxed are rendered specifically for a 200-DPI output device. The resulting output will be of sufficiently high quality that mobile users may not require a portable printer at all, opting instead to use a nearby plain paper fax machine.

PenPoint supports Epson-compatible dot-matrix printers and HP Laserjet-compatible laser printers. When the printer does not have a requested font, the ImagePoint imaging model will render and download one from its own set of outline fonts, ensuring good WYSIWYG correspondence and shielding the user from the complexities of font management.
User Interface Toolkit

PenPoint's User Interface Toolkit offers a wide variety of on-screen controls:

- Menu bars
- Pulldown menus
- Section tabs
- Window frames
- Title bars
- Scroll bars
- Option sheets
- Dialog boxes
- Progress bar
- Modal alerts
- Trackers

- Nonmodal alerts
- Pushbuttons
- Exclusive choice buttons
- Nonexclusive choice buttons
- Pop-up choice lists
- List boxes
- Editable text fields
- Handwriting pads
- Grabbers
- Busy clock

A major innovation in PenPoint's User Interface Toolkit is automatic layout. Instead of specifying the exact position and size of controls, the application need only supply a set of constraints on their relative positions, and the Toolkit will dynamically calculate their exact horizontal and vertical coordinates. This makes it easy for programmers or users to resize elements of the user interface, change their fonts or other visual characteristics, or switch between portrait and landscape screen orientations, while preserving the correct proportions and positional relationships.

Input and Handwriting Translation

PenPoint's input subsystem translates input events received by the hardware into messages directed to application objects. The low-level pen events include:

- In proximity
- Tip down
- Move down
- Window enter

- Out of proximity
- Tip up
- Move up
- Window exit

These low-level events can be grouped into higher-level aggregates called scribbles, which are then translated by the handwriting translation (HWX) subsystem into either text characters or command gestures. These characters or gestures in turn are dispatched to the appropriate objects via a rich input distribution model that includes filtering, grabbing, inserting, and routing of input up and down the window hierarchy.

The portion of the GOWrite handwriting translation engine that matches and recognizes character shapes is replaceable, allowing PenPoint to improve its HWX techniques as better algorithms become available. There are two parts to the handwriting translation engine: the first part matches shapes, the second part uses context to improve the translation.
The current HWX engine recognizes hand-printed characters and has the following characteristics:

- Operates in real time (shape matcher operates at 60 characters per second on 33 MHz 80486).
- Runs in a background process.
- Handles mixed upper- and lowercase letters, numerals, and punctuation.
- Tolerates characters that overlap or touch.
- Recognizes characters independently of stroke order, direction, and time order.
- Uses context to distinguish nonunique character forms such as the letter “O” and the numeral “0”.
- Tolerates inconsistency by same user (that is, the user may shape the same character in different ways at different times).
- Accepts optional context-sensitive aids (such as word lists, dictionaries, and character templates) provided by an application. Applications are given great control over this process; they may issue constraints that merely influence the result or force a match against a predefined list.

Although PenPoint is designed primarily for pen-based input, it is not limited to the pen. For high-volume data entry, PenPoint accepts input from a keyboard. As an alternative, PenPoint also provides a software “virtual keyboard.” Users can display the keyboard on the screen and input text by tapping on the keys with the pen.

**Selection Manager and data transfer**

The Selection Manager subsystem maintains a system-wide selection, which is the target for all editing operations. The Selection Manager also implements a single-level stack for temporarily saving the current selection. Editing is based on a move-and-copy model, rather than a “clipboard” (cut-and-paste) model. The source and destination applications negotiate data transfers from one application to another. The destination application requests a list of available data formats from the source application. PenPoint supports a variety of standard transfer formats, including Rich Text Format (RTF), structured graphics, and Tagged Image File Format (TIFF); applications can extend this list to include other formats as well.

PenPoint’s object-oriented architecture also makes possible the PenPoint EDA™ or embedded document architecture. This is a unique form of “live” data transfer in which the transferred data carries with it an instance of its own source application. Through object-oriented message passing, this embedded application instance can then be used to display, edit, or otherwise manipulate the data from within the destination application. Although more conventional forms of “hot links” and Dynamic Data Exchange (DDE) linking are still possible in PenPoint, such live application embedding obviates the need for most of them.
**Component layer**

Above and beyond the traditional kernel and system facilities, PenPoint adds a rich, powerful, and extensible component layer. Components are general-purpose code units with application-level functionality that can be shared and reused as building blocks by multiple client applications. They speed the development of applications, reduce memory consumption, and provide for more consistent user interfaces and tighter integration across diverse applications.

PenPoint includes several components, such as a multifont, WYSIWYG text editor and a scribble editing window that can be embedded within any application that needs them. You can include these components in your application without paying any license fee to GO.

Third-party developers may market components to other developers. Applications may also provide their own general-purpose components to be installed and shared in the PenPoint runtime environment.

**Application Framework layer**

The Application Framework is a set of protocols rigorously defining the structure and common behavior of a PenPoint application. Through the Application Framework, applications inherit a wide variety of standard behavior, including installation and configuration, creation of new documents, application stationery (template documents), on-line help, document properties, spell checking, search and replace, import/export file dialogs, and printing. New code is required only for added functionality or to modify or override specific aspects of the default behavior. Use of the Application Framework thus yields significant savings in programming time and code space.

An application developer creates the application code and any resources needed by the application. When a user installs an application, the PenPoint Application Framework takes care of:

- Copying the application code and all other auxiliary files to the system.
- Creating new documents.
- Creating and terminating tasks.
- Storing and retrieving user data in the file system.
- Creating and destroying a main window for the application.

Active documents save their internal state in the file system, but this is invisible to the user: there is no need to save or load the application's state explicitly from one session to the next.
**Application layer**

Using the “live” recursive embedding available through EDA, PenPoint’s notebook metaphor and user interface are implemented as a set of bundled system applications. Although the user simply perceives these collectively as “the Notebook,” they are in fact distinct applications, providing a cleanly delineated and modular architecture.

The key bundled applications include Bookshelf, Notebook, and Section applications that together constitute the core notebook metaphor. In addition:

- The Table of Contents (TOC) application provides a user interface for specialized organization and retrieval at the front of the notebook.
- A bundled text editor provides end users with intuitive, pen-based Rich Text editing.
- A standard Send user interface and an Address List allow for the addressing of all electronic mail, fax, and file transfers.
- A file browser allows the user to point to files and directories and use standard gesture commands to manipulate them.

Multiple instances of the Notebook can be created; in fact, the Create, Help, Configuration, In box, and Out box applications are all instances of the notebook application. Developers benefit from this code sharing; users benefit from decreased memory requirements as well as greater consistency in the user interface. The Help notebook, for example, consists of help documents ordered by section (application), and therefore looks just like the standard table of contents. Users already know how to navigate through this notebook and can even create hyperlink references to important sections. Developers can simply write ASCII text to provide online documentation. Documents in the Help notebook can be any type of PenPoint application documents. Developers can also leverage existing application code to build very powerful help systems that can demonstrate real functionality.

**Software development environment**

With the exception of some hardware-dependent code, PenPoint and the applications it supports are written in ANSI C, using current versions of leading PC-based development tools. Developers already acquainted with object-oriented concepts, and with the graphical user interfaces and multitasking found in operating systems like OS/2 and Macintosh System 7, will find the development environment familiar.

**Software development kit**

The PenPoint SDK provides developers with the documentation and tools to develop applications. The kit includes a source-level symbolic debugger, as well as an outline font editor for creating scalable and rotatable application-specific glyphs. Because PenPoint runs on DOS 386 machines, the full application edit-compile-debug cycle can be accomplished solely on a PC, or on a combination of a PC and a pen computer running PenPoint. In the former configuration, you use a pen-driven digitizer tablet to simulate pen input. In the latter configuration, the PC serves as
a debugging monitor, as well as a convenient repository of the development system libraries, header files, on-line documentation, and source code.

**Coding conventions**

All PenPoint code is written in accordance with modern software engineering standards, including:

- Consistent naming conventions for modules, functions, and variables.
- Carefully designed modularity.
- Proper commenting and formatting of source code.

Almost all of the C code is structured using object-oriented programming techniques. Classes are defined and objects are created and sent messages by making calls into a library of C routines called the Class Manager. These techniques are in the mainstream of currently evolving industry practices, but the details are unique to GO and are well documented in the SDK materials.

**Extensibility**

PenPoint is extensible in a variety of ways, allowing for the addition of new networking protocols, imaging models, font models, and file-system volumes. PenPoint can run on computer architectures ranging from solid-state, pocket pen computers to powerful disk-based workstations with pen-tablet screens.

The operating system is a working whole, with most modules integrated and tested as part of the full system since early 1988. Because of techniques such as hardware memory protection, object-oriented programming, rigorous modularization, and extensive sharing of code, PenPoint is a highly reliable operating system.

**PenPoint design guidelines**

To this point, this chapter has presented concepts that relate to the PenPoint operating system as a whole. The remainder of the chapter describes important points that application developers will have to keep in mind while designing and coding PenPoint applications.

**Conserve memory**

Do not squander memory. Your application should use little memory when active. It must be able to further reduce its memory usage when off-screen. An application that is packed with functionality but consumes a lot of memory is less likely to be successful than one that meets key needs and requires very little memory.

**Think small**

Most PC programs stand alone as large monolithic programs that attempt to do everything. In the cooperative, multitasking PenPoint environment with its Embedded Document Architecture, it makes more sense to provide programs that present a facet of functionality or that orchestrate other applications and compo-
nents. Use existing classes and components where possible rather than writing your own from scratch.

**Use a modular design**

Consider writing your application as a set of separable components. A component is a separately loadable module (a dynamic link library or DLL) that provides software functionality. A component has a well-defined programmatic interface so that other software can reuse it or replace it. With modular design, your application becomes an organizing structure that ties together other components in a useful way. For example, an outliner application might use a drawing component, a charting component, and a table entry component; you could license these components to or from other developers. GO is working to develop a market for third-party components, and offers several components itself, including Text View™ and the TableServer™.

**Your application must recover**

Users may go for weeks or months without backing up their PenPoint computer's file system. If your application goes wrong, the PenPoint operating system will try to halt your application rather than the entire computer, but it is your responsibility to ensure that a new invocation of your application will be able to recover cleanly using whatever information it finds in the file system. This precept sometimes conflicts with avoiding data duplication, because the memory file system is more bullet-proof than the address space of a running application. For this reason, filed state will usually survive a process crash.

Moreover, most users will not have the PenPoint computer boot disks on hand. That means you cannot rely on the user being able to press the reset switch in a jam. PenPoint uses hardware and software protection techniques to secure against applications unintentionally corrupting the kernel and/or file system, but it is not foolproof.

**Take advantage of object-oriented programming**

You don't get to vote on using object-oriented techniques. You must write a class for your application that inherits from clsApp. The windows your application displays on the screen must be instances of clsWin (or instances of a class that inherits from clsWin). Of course, there are tremendous payoffs from PenPoint’s object-oriented approach in program size reduction, code sharing, application consistency, programmer productivity, and elimination of boilerplate code (those large chunks of setup or housekeeping code that appear unchanged in every application).

**Consider sharing code and data**

Think about what other parts of PenPoint need to access your classes, what tasks need to run the code in them, and who maintains their data. If your application has a client-server architecture, with a separate back-end or a core engine, you'll need to have the big picture in mind when choosing local or global memory, dynamic or
well-known objects, process or subtask execution, protecting shared data with
semaphores and queued access, and so on.

PenPoint is a rich operating system that makes its kernel features available to applica-
tions. A straightforward application may not need to concern itself with any of
the kernel features. It just interacts with PenPoint subsystems, which make careful
use of the kernel. For example, none of the sample programs use any advanced
kernel features.

**Use document orientation**

In the PenPoint operating system, the user sees documents, not separate programs
and program files. Every document on a page is the conjunction of data and a pro-
cess running an application. This leads to a document-centered approach to appli-
cation design in place of a program-oriented approach. By comparison, on a
Macintosh or IBM PC-compatible computer, the user tends to start a program and
work on a succession of files. Under PenPoint, the user turns to a new document
(or taps in a floating document) and the system unobtrusively turns control over to
the right program for that document.

There are many ramifications of this orientation: applications have no Open . . .
or Save As . . . commands; the PenPoint operating system, not the user, saves data
and quits programs; you deliver application templates and defaults to the user as
stationery.

**Design for file format compatibility**

The PenPoint application environment differs from that of other operating systems
in that PenPoint saves your application data, along with information about objects
in the document. Because of this filing method, your data formats within PenPoint
will differ from their PC equivalents.

Most PenPoint users, however, will need to read and write application data in for-
mats that are understood by other non-PenPoint applications. Either your applica-
tion should be able to read and write data in other formats, or you should create an
import or export filter for your PenPoint files. PenPoint provides import and export
filters for some common file formats. Because the import-export mechanism is class
based, you or other application developers can create import-export filters for other
file formats.

**Exploit the pen**

Graphical user interfaces built around a mouse or other pointing devices lead to
flexible program architectures that respond to the user's actions instead of requiring
the user to perform certain steps. The pen-oriented notebook interface of PenPoint
is even more free-form. Just as with a mouse, the user can point to and manipulate
(click, drag, stretch) entities on-screen, but in the PenPoint operating system the
user can also make gestures and handwrite characters "on" the visual entities.
Taking advantage of the pen is a challenge and a tremendous opportunity.
Use the PenPoint user interface

The Notebook User Interface (NUI) differs from other graphical user interfaces. If you are porting a DOS or Macintosh-based program to PenPoint, rather than create new user interface classes, try to create a user interface that takes advantage of the PenPoint UI Toolkit.

The *PenPoint User Interface Design Reference* describes the PenPoint user interface, its rationale, and how and when to use its components. You should not deviate from the PenPoint interface. Remember that a consistent user interface allows users to learn your application quickly; an inconsistent user interface will count against your application in product reviews (and acceptance in the marketplace).

The PenPoint UI Toolkit contains classes that create almost every on-screen object in the PenPoint NUI. If you use these classes, it is hard to deviate from the standard. Additionally, it is easier to follow the conventions by using these classes than to subclass and change their default behavior.
Chapter 3 / Application Concepts

This chapter gives you the big picture of application development for the PenPoint™ operating system. It introduces the design issues you need to consider when writing an application for a mobile, pen-based computer, how applications work under PenPoint, and how you use the PenPoint classes.

This chapter also presents concepts in general terms to provide the fundamental understanding that puts the balance of this manual in context. You needn't have read any of the other documentation before reading this chapter. However, if you have the SDK software, you might want to read the “Getting Started” document in the Open Me First packet for detailed instruction on how to compile and run the tutorial programs.

If you want a basic look at how the PenPoint operating system works, without a focus on writing applications, read Chapter 2, PenPoint System Overview. If you need an introduction to object-oriented programming, read these industry publications:

However you do it, make sure you come to understand the basics of object-oriented programming, because in PenPoint every application must be class-based.

This chapter points out some of the aspects of the PenPoint operating system that may have an notable effect on your approach to application design.

As you know, application development takes place at two levels:

- At the architectural level, where you design your application.
- At the implementation level, where you write and test program statements.

At the architectural level, this chapter assumes that you have basic familiarity with object-oriented programming. In developing a PenPoint application you'll be designing different kinds of objects and the interactions between them and PenPoint. The section “How Applications Work” introduces the PenPoint Application Framework, which influences and supports the structure of all PenPoint applications.
At the programming statement level, this chapter assumes that you are well-versed in C programming. You'll be writing C code that makes heavy use of the PenPoint Class Manager. Chapter 4, PenPoint Class Manager introduces the Class Manager and shows you what lines of code in PenPoint look like.

With some understanding of the Application Framework and the Class Manager, you'll have the tools necessary to understand both the architecture and implementation of simple PenPoint programs and applications. Later chapters in this manual describe the SDK sample programs in PENPOINT\SDK\SAMPLE (the installation procedure for the SDK creates the PENPOINT directory on your hard disk).

**PenPoint programming is unique**

Just as a PenPoint computer is used in work environments that differ from other computers, PenPoint applications execute in an environment that differs from conventional PC application environments. There are eight key differences found in PenPoint application environments:

- Stylus-based user interaction.
- Object-oriented programming.
- Disk storage unnecessary.
- Multitasking.
- Cooperating, simultaneously active, embeddable applications.
- Graphics-intensive user interface.
- Notebook metaphor.
- Document orientation instead of application and file orientation.

Dealing with these aspects of PenPoint requires you to observe a number of guidelines, described in the following sections. The benefit is that the software architecture of PenPoint eliminates much of the work for you.

The Class Manager supports the pervasive use of classes and objects throughout PenPoint; not only in the user interface area, but also in areas such as the file system and the imaging model. These classes provide you with ready-made components that you can use as is or customize in your applications. These objects already conserve memory, exploit the pen interface, cooperate with other processes, and so on. In particular, nearly all of the work your application needs to do to work within the PenPoint Notebook is already implemented by pre-existing classes that comprise the PenPoint Application Framework.

**How applications work**

In the PenPoint operating system, the environment in which your application runs and how it starts up are unlike any other operating system.

MS-DOS accepts a command line, executes a single program at a time, and does little while that program is running. The PenPoint Application Framework takes an active role in running your application. The Application Framework is responsible
for activating, saving, restoring, and terminating your application. Additionally, the Application Framework plays a part in installing and deinstalling your application. Because all PenPoint applications use the Application Framework, all applications behave consistently. Additionally, the Application Framework handles the housekeeping functions that Macintosh or MS-DOS programs must perform from boilerplate code. Meanwhile, the PenPoint Application Framework presents the PenPoint user with multiple small, concurrent documents as part of a consistent, rich notebook metaphor.

It's difficult to cleanly define the PenPoint Application Framework, because it is both external to your application and something your application is itself a part of. But here's an attempt:

PenPoint Application Framework  Both the protocol for supporting multiple, embeddable, concurrent applications in PenPoint, and the support code that implements most of an application's default response to the protocol.

To help you understand how an application fits into the PenPoint computing environment, this section walks through some important stages in the life of an application. By the end of this section you should understand a little about the PenPoint Application Framework, some of the classes of objects in PenPoint, and why classes are so important. The next section explains class-based programming in PenPoint.

With an understanding of the PenPoint Application Framework and the Class Manager under your belt, you'll be able to work through the tutorials on PenPoint programming that begin in Chapter 6. The tutorial summarizes other PenPoint subsystems: windows, User Interface (UI) Toolkit, filesystem, and handwriting translation. The tutorial incorporates these subsystems into a set of increasingly functional sample programs.

Installing and starting applications

After acquiring an application, the user must install the application in the PenPoint computer. Usually an application distribution disk contains the code and data that implement the application's classes, and any other classes required by the application.

We'll first look at how a user installs and starts a program on a traditional PC operating system (MS-DOS). Then we'll compare these operations with installing and running an application on PenPoint.

MS-DOS installation

In MS-DOS, the user usually installs a program by copying the program from distribution disk to a hard disk. Once on the hard disk, the program does nothing until the user types a command to start the program.

Some MS-DOS programs require the user to copy the files from distribution disks to the hard disk; others provide their own installation programs that copy the files to
the hard disk and alter system configuration parameters for their program. Installation varies tremendously from program to program.

When the user types the startup command for a program, MS-DOS loads the program into memory from the hard disk and transfers control to the program. Once the program is running, it controls most of the operations of the CPU until the user leaves the program.

**PenPoint installation**

In PenPoint, the user installs a program by opening the Connections or Settings notebook on the Bookshelf and turning to the installable software sheet (or by inserting a disk that contains quick installer information).

From the installable software sheet, the user can choose various categories of installable items, including applications, services, dictionaries, and so on. When the user turns to a page for an installable item, the Installer shows all the available applications that can be installed from the currently open volumes. The user selects an item and taps the Installed? checkbox next to the item. The Installer copies the program to an area of memory set aside for programs (the loader database) and copies other files required by the program (such as help files, application resource files, and stationery files) to the file system.

From this point, running PenPoint applications differs significantly from the MS-DOS model. Once a program is in the loader database, PenPoint can transfer control directly to it; there is no intermediate step of loading the program into memory, because it is there already.

PenPoint transfers control to your program under two conditions: the user is installing your program, or the user is opening a document that requires your program (we will cover this case in the next section).

**Installer responsibilities**

During installation, the Installer calls a standard entry point (called main()) in your program in such a way that you can tell that your program is being installed. At this time, most programs create their application class and any other classes that they need. Some programs initialize files or common data structures such as dictionaries or stationery.

If your application requires code for other classes (such as a special character-entry class) and resources (such as a special font), the Installer ensures that these classes and resources are present in the computer. If they are not present, the Installer copies and installs them also. In turn, these classes may require additional classes and resources, and so on.

The Installer keeps track of all installed applications. When the Installer initializes your application, the application specifies whether it should go in the Tools Accessory palette or in the Stationery notebook, or both (or neither). Depending how your application initializes itself, the user will now see the application in the Accessories window, or in the Stationery notebook and Create pop-up menu.
Running a PenPoint application

When running an MS-DOS program, the user has to find a file that contains data understood by the program. When the user decides to stop using the program, he or she must save the data to a file and then exit. If the user chooses a file that the program doesn’t understand, the program might display garbled information, at best, and at worst the program might crash.

PenPoint takes a fundamentally different approach: the user creates a document from a list of available applications and, at some later time, tells PenPoint to activate the document. The user doesn’t have to activate the document immediately after creating it and, in fact, can create many, many documents without activating any of them.

Life cycle of a document

The standard components of an application include its application code, application object, resource file, instance directory, process, and main window. The full life cycle of a document created by an application includes the following operations:

- Document creation (create file)
- Activation (create process)
- Opening (open on screen)
- Closing (remove from screen)
- Termination (terminate process)
- Destruction (delete file)

Active documents save their internal state in the file system, but this is invisible to the user: there is no need to save or load the application’s state explicitly from one session to the next.

Activating a document

When the user activates the document, PenPoint finds out from the document what application it requires and creates a process that “runs” the application (see “Application classes and instances” on the following page for more details). When the user deactivates the document, PenPoint saves all of the document’s information and then destroys the application process.

Not all active documents are on-screen

It’s only when the user activates a particular document that the document has a running application process. When the user activates a document, the PenPoint Application Framework creates an application process and calls the standard `main()`
entry point in your code in such a way that your application can tell that it is
starting an application process (and not being installed).

However, just because a document is running, doesn't mean that it must be on­
screen; conversely, if a document is not on-screen, its process might still be running.

The most common example of this is when the user makes a selection in a docu­
ment and then turns to another document (perhaps to find a target for a move or
copy). The document that owns the selection must remain active until it is told to
release the selection.

A second example is when the user chooses accelerated access speed (sometimes
called hot mode) from the Access document option sheet, the application processes
will continue running, even when the user has turned to another page.

For a third example, you might want to create a stock-watcher-type program that
runs in the background most of the time. This type of program will also be active,
but not on-screen.

**Application classes and instances**

A PenPoint computer contains only one copy of your application code in memory,
but a user can simultaneously activate several documents that use your application.
PenPoint can do this because your application code is a PenPoint class and an active
document is an instance of your application class.

When the user installs your application, your application creates your application
class. When the user activates a document that uses your application, the Applica­
tion Framework creates an instance of your application class.

Accept this as fact for now. We will spend pages and pages in this and other man­
uals explaining how this works.

**PenPoint drives your application**

Because of all the states that an application can be in, an application can't take con­
trol and start drawing on the screen and processing input when its `main()` function
is called. In addition, your application can't find out on its own if it is on-screen or
should terminate. Instead it **must** be directed what to do by the PenPoint Applica­
tion Framework. The Application Framework sends messages to documents (and
hence to your application code) to initialize data, display on screen, save their state,
read their state, shut down, and so on. This is why applications must be imple­
mented as classes.

For example, when a document needs to be started up to do some work, the Pen­
Point Application Framework sends `msgAppActivate` (read this as “message app
activate”) to the document. When the user turns to a document's page, the Pen­
Point Application Framework sends it `msgAppOpen`.

A typical MS-DOS program written in C has a `main()` routine that displays a wel­
come message, parses its command line, creates a user interface, initializes struc­
tures, and then waits for user input. By contrast, a PenPoint application's `main()`
routine usually creates the application object and then immediately goes into a loop waiting for messages to the application object to arrive. Because all applications enter this loop, there is a routine, AppMain(), which enters the loop for you.

**Application objects**

Most PenPoint applications perform three minimum actions:

- Respond to user and system events (including PenPoint Application Framework messages).
- Create one or more windows for user input and to display output.
- Create one or more objects to maintain their data.

There are object classes already written in PenPoint for each of these actions: clsApp, clsWin, and clsObject, respectively. These classes do the right kinds of things for applications themselves, for windows, and for data. They provide a skeleton of correct behavior, although obviously GO's code doesn't create the user interface and data classes needed to implement behavior specific to your application. To get the behavior you want, you often need to create descendant classes that inherit from existing classes.

**A descendant of clsApp**

Lots of the behavior that is common to all applications is already implemented for you.

The PenPoint Application Framework's interactions are sophisticated and complex. You'll learn more about them in the following sections. Applications need to behave in a standard way to work well in the framework. To simplify life for the application developer, your application class inherits most of this standard behavior from the class clsApp. clsApp handles all the common machinery of application operation, so that many applications do not need to do anything in response to messages like msgAppActivate and msgAppOpen. Applications rely on clsApp to create their main window, display the main window, save state, terminate the application instance, and so on.

You must write a descendant class of clsApp and create it during installation. In the example shown here, the descendant is clsTttApp. At the appropriate time, the PenPoint Application Framework sends this class a message to create an instance of the class (Tic-Tac-Toe application instance in the figure). However, you must decide when to create your application's other objects (windows and filing objects).

**An instance of clsWin**

The PenPoint Application Framework creates a frame for your application by default. This is a window with many decorations: a title bar, a shadow if the window is floating, optional resize corners, close box, menu bar, tab bar, command bar, etc. These decorations surround space for a client window. It is up to you to create the client window. You can also create windows to go into your frame's menu bar, tab bar, and command bar, and you can create floating windows, additional...
frames, and so on. Most applications create one or more windows to draw in and allow user input.

All window classes inherit from clsWin. This class does not paint anything useful in its window, so you must either create your own window class that draws what you want or you must use some of the many window descendant classes in PenPoint.

**Some window classes**

The Tic-Tac-Toe application, for example, creates several kinds of windows based on existing classes in PenPoint (see Figure 3-1):

- A scrolling client window (an instance of clsScrollWin), which lets the user scroll its contents.
- An option sheet for its options (clsOption).
- An option card for the option sheet (clsOptionTable).
Understanding the application hierarchy

- Various user interface component windows (clsButton, clsLabel, clsIntegerField) for the option card.
- Menus.
- A Tic-Tac-Toe view (clsTttView) to display the grid and Xs and Os.

Like clsTttApp, you have to write the code for clsTttView and create the class at installation. Your application must create the various windows at the appropriate times, such as when it receives msgAppInit or msgAppOpen.

**Using clsView**

Many applications will use clsView, a specialized descendant of clsWin, for their custom windows. clsView associates its window with the data object it is displaying; the data object sends the view a message when its data changes. In the case of Tic-Tac-Toe, clsTttView inherits from clsView, so the Tic-Tac-Toe window is a view.

In Tic-Tac-Toe, a clsTttView instance observes the data object (an instance of clsTttData). More than one view can be associated with the same data; in theory two views of the Tic-Tac-Toe board could show their state in different ways. When the data changes, all the views are notified and can redraw themselves.

**An instance of clsObject**

Instead of managing all of the data involved with an application itself, a PenPoint application typically creates separate objects that maintain and file different parts of the data. These objects respond to messages like “Save yourself” and “Restore yourself from a file.”

clsObject is actually the ancestor of all classes in PenPoint, including clsWin and clsApp. There is no class specifically for objects that must be filed. Filing is such a general operation that all objects in the PenPoint operating system are given the opportunity to respond to msgSave and msgRestore messages. PenPoint supplies various descendant classes, which help in storing structured data, such as a list class (clsList), a picture segment (clsPicSeg), a block of styled text (clsText), and so on.

In Figure 3-1, the data for the Tic-Tac-Toe application (the values of the nine squares) is maintained by a separate object, Tic-Tac-Toe square values, an instance of the specialized class clsTttData.

**Understanding the application hierarchy**

You may have wondered how PenPoint keeps track of all the sections, documents, and embedded documents in a notebook if application objects are not immediately up and running when they are created. The answer is that each document and section in a notebook is represented in an application hierarchy in the PenPoint file system. The Notebook table of contents displays a portion of this application hierarchy.
The reason it is called an application hierarchy is that the directory structure is the same as the hierarchy of documents in PenPoint (including embedded documents, accessories, and other floating documents not on a page in the Notebook). Each notebook has a directory in the file system. Within the notebook, each document or section has a directory. Within each section, each document or section has a directory. Within each document, all embedded documents have a directory, and so on (see Figure 3-3).

As an example, when the user creates a document in a section of the Notebook, the PenPoint Application Framework creates a new application directory in that section's directory. When the application is told to save its state by the PenPoint Application Framework, the PenPoint Application Framework gives it a file to save to in that application directory.

All PC operating systems have a file system, and in most you can store application data in a similar hierarchy of directories and subdirectories. Some may even provide a folder or section metaphor for their file system. But they do not directly weave applications into this file system. The Notebook's TOC (tap on its Contents tab to move to it) shows the organization of documents in the Notebook, and this is the organization of part of PenPoint's file system.

In PenPoint, the application hierarchy exists in the PENPOINT\SYS\BOOKSHELF directory on the selected volume. You can inspect the application hierarchy yourself. Modify your ENVIRON.INI file so that the DebugSet parameter specifies /DB800. Run PenPoint and go to the Connections notebook. Using the directory view, browse through the disk volume. In the PENPOINT directory, you should see directories called NOTEBOOK, SECTION, and so on. Compare this with the Notebook TOC. The Browser shows exactly what the file system looks like, while the Notebook TOC interprets this part of the file system as the application hierarchy.

If your selected volume is your hard drive, you can also inspect this hierarchy from DOS. However, to keep path names short, all of the PenPoint directory names below PENPOINT use two letter names. For example, the SYS directory is SS in DOS, the Bookshelf directory is BF, the Notebook is NK, and so on.

**The Notebook's own hierarchy**

The PenPoint classes and application hierarchy probably seem obscure and confusing at this point. So let's look at how the Notebook itself is written using this metaphor. Each component of the Notebook is itself a document, with its own main window, a parent window, and a directory in the file system's application hierarchy.

The important concept to grasp is that there is a correspondence among:

- The PenPoint applications.
- The functionality of the parts of the notebook metaphor.
- The visual presentation of parts of the Notebook.
- The PenPoint file system layout.
Some of these relationships are:

- **Running documents** are instances of application classes.
- **Functionality of notebooks, sections, and pages** is delivered by application classes.
- **Visual components of a notebook** are these applications' windows.
- **Sections and pages in a notebook** are these applications' directories.
- **Section name and page number location in a notebook** combine to form a location in the file system.

This figure shows how a typical mix of applications in a running PenPoint system uses different kinds of classes.

**Application Framework and Notebook hierarchy**

The following figures are explained in more detail in Part 2: Application Framework of the PenPoint Architectural Reference.
The Notebook hierarchy as mirrored by the file system

Figure 3-3 and Figure 3-4 indicate how the same visual components exist in the file system, and as processes and objects.

You can use the Connections notebook to explore the relationship between documents and the file system yourself. To view the running PenPoint file system in the Connections notebook, you need to set the B debug flag to hexadecimal 800 in order to view the contents of the boot file system. The easiest way to do this is to modify the DebugFlag line in ENVIRON.INI.

The Bookshelf

The highest level of the application hierarchy is the Bookshelf. This is an application, but there is only one instance of it—you can't create additional bookshelves. The Bookshelf application manages bookshelves and floating applications. Its parent window is the entire screen of the PenPoint computer. It draws the white background.

The Notebook

Below the Bookshelf's directory lies the directory of the main Notebook (and other documents on the bookshelf). The Notebook application presents the familiar visual metaphor of a notebook with pages and tabs. All applications that "live" on a page have subdirectories in the Notebook. There are usually several notebooks on a PenPoint computer: the main Notebook, the Stationery notebook, and the Help notebook. Even the In box and Out box are implemented as notebooks.
Notebook hierarchy and application processes

CHAPTER 3 / APPLICATION CONCEPTS
Understanding the application hierarchy

FIGURE 3-4

Notebook hierarchy and application processes

NB Process
- NB Application Class

Notebook Contents
- Section Application Class
- Samples
- Package Design Letter
- MiniText Application Class
- Suggestion
- MiniNote Application Class
The Notebook document stores the section tab size, the current page shown in the Notebook, the page numbering scheme, and so on in its directory.

When the user taps to turn a page in the Notebook, the Notebook traverses the application hierarchy to the next document directory and sends a PenPoint Application Framework message to that document’s application to start it up.

The Notebook’s window covers most of the screen except for the Bookshelf at the bottom.

**Page-level applications**

The subdirectories in the Notebook’s directory relate directly to the documents and sections in the Notebook. The name of the subdirectory is the name of the document or section. Each of these subdirectories contains the filed state of an instance of a section or document.

This table lists some of the items in the Notebook (shown in Figure 3-3), the directory in which each of the items are stored, and the class from which each item is instantiated.

<table>

</tbody>
</table>

Most applications have a menu bar. The PenPoint Application Framework supplies a set of standard application menus (SAMS), to which applications add their own menu items. The PenPoint Application Framework provides support for the menus (Document, Edit, and Options) and many of the items on the menus.

Applications draw in the window that the Notebook provides for them. A page-level application’s window is the Notebook area; except for the tabs area.

**Sections**

Sections are similar to other applications: they are instances of an application class (clsSectApp), they appear on a Notebook page, they can have tabs. A section application displays a table of contents showing the documents that are in that section: these are simply the application subdirectories in the section’s own directory.

One difference between a section and other applications is that a section has a special attribute in its directory entry. When the Notebook is traversing the application hierarchy (to display its table of contents, or turn to the next page), if it comes across a section it descends into the section. This enables the Notebook to number pages correctly.

Section data stored in the section’s directory entry includes the state of its table of contents view (expanded or compressed). The Notebook Contents page is an instance of clsSectApp, just like other sections.
Floating accessories

Most PenPoint applications are part of the Notebook. But some applications, such as the calculator, the disk viewer, and the snapshot tool, don’t “live” on a page in the Notebook. These accessories “float” on the Bookshelf when active, appearing over pages in the Notebook. Their parent window is the Bookshelf, not the Notebook page area. They aren’t part of the Notebook’s table of contents and you can’t turn the page to them. However, a floating application is still part of the same underlying model: it has a directory (it’s just not a subdirectory of the Notebook), it is sent messages, and so on.

Embedded applications

It is possible to embed documents in other documents that permit it. For example, an on-line “electronic newspaper” document might embed an instance of a crossword puzzle application in itself; the crossword puzzle class might allow the user to embed an instance of a text application in a crossword puzzle document to let the user jot down notes and guesses. The design of PenPoint makes it easy to write applications that can embed, and can be embedded in, other applications.

When the user creates a new document in the Notebook, PenPoint actually embeds the application in the Notebook application. This document embedded in the Notebook is called a page-level application.

Only page-level applications appear in the Notebook’s Table of Contents; applications that are embedded in page-level applications do not. It doesn’t make sense for a user to turn the page to an application embedded in the current page.

Application embedding is very straightforward. When the user moves or copies an application, the Bookshelf application sends a msgAppCreateChild message to the destination application. If the application permits embedding, the PenPoint Application Framework handles this message by creating a directory for the embedded application within the destination application’s directory.

When an application is embedded in another, the embedded application is inserted into two hierarchies: the file system hierarchy and the window system hierarchy. In the file system, the application directory for an embedded application is a subdirectory of the application directory of the application in which it is embedded. In the window system, the parent application supplies a window into which the embedded application can insert its main window.

Thus, in our example, the newspaper application uses an application directory for the newspaper document. Within that directory is an application directory for the crossword document. Within the crossword application directory is a directory for the text editor document. The newspaper document window contains a window that is the main window for the crossword document. The crossword document window contains a window that is the main window for the text editor.
Application data

A document stores data in its directory so that when its running process is terminated, its state lives on in the file system. The Application Framework can later create a new process for the document and direct the document's application to restore the document from this file state.

Some information is of interest to this instance only, such as the visible part of the file, the user's current selection, and so on. This would probably be saved by the application itself, that is to say, when the application receives msgSave it writes this information out.

The application can also tell the Application Framework to send msgSave to other objects to get them to save their data (your application can't send msgSave directly to another object). For example, the image in a sketching program might be implemented as a separate object; when the application is told to save, it tells the Application Framework to save the image object.

By default clsApp saves the information about the document, including its comments, frame window position, mode, and so on, so you only need to save those things created by your application class.

Activating and terminating documents

In the section “Application classes and instances” on page 28, we described how an instance of the application is created. The previous section should help clarify the relationship between the file system and an instance of your application. The location of a document in the file system hierarchy has a one-to-one correspondence with its location in the Notebook, on a page, within a section, and so on. See the figure to get a sense of the relationship.

The main determinant of how and when documents blossom from being directories and data in the file system to being live running processes and objects is the user's action of turning the page.

When the user turns to a page, the documents on that page become visible; if they aren't already running, the Application Framework activates them.

Turning a page and msgAppClose

When the user turns to another page, the document on the original page no longer needs to appear on screen, so the PenPoint Application Framework sends msgAppClose to the application instance, indicating that it can close down its user interface.

When it receives msgAppClose, the application might still have some processing to do or it might be talking to another application. The application can finish its work before acting in response to msgAppClose.

To respond to msgAppClose, the application should save (to the file system) any data about on-screen objects that the user moved or changed. The application
should then destroy and remove all windows that it created, thereby reducing memory usage.

An application instance may receive `msgAppTerminate` after `msgAppClose` (if it isn't in "hot mode"). When it receives `msgAppTerminate`, the application must save all data that will be required to restore the document to the screen exactly as it was before, because `msgAppTerminate` kills the document's process.

**Restoring inactive documents**

When the user turns back to the saved document, the Application Framework looks at that document's directory. If the process for the document was terminated, the Application Framework starts a new process, creates a new instance of the application class, and recreates the document based on information in the directory. As part of this re-creation, the Application Framework sends the document `msgRestore`, which tells it to read its state back in from the file system.

The Application Framework then sends `msgAppOpen` to the application, telling it to prepare to draw on the screen. The Application Framework also sends `msgRestore` and `msgAppOpen` to any embedded applications in that document.

Finally, the Application Framework inserts the application's windows into the screen, and the windows receive messages telling them to paint.

From this point the user can interact with the document. When the user makes a gesture within the document, the document's application controls the resulting action.

**Page-turning instead of closing**

As described in "Turning a page and msgAppClose," most PenPoint applications don't need a Close menu item. Most documents are active until the user turns the page; others may be active even when off-screen (for instance, if they have the selection or are involved in a copy operation). The user doesn't know what a running application is: when the user turns to a page, everything on it appears exactly as it was when the page was last "open," and every window responds to the pen. The fact that some of the applications may have been running all the time while others were terminated and restarted should be inconsequential to the user.

**Saving state (no quit)**

In an MS-DOS or Macintosh program, the user explicitly quits the application, and thus doesn't expect the application to reappear in exactly the same state.

Because of PenPoint's notebook and paper paradigm, you must preserve all the visual state of your application so that when it is restarted it appears the same. This has strong implications for the kinds of information your application needs to save when an application receives `msgSave`. 
**Documents, not files and applications**

It's important to understand that the application instance and the file it is editing are conjoined.

The user should rarely, if ever, see “files.” Instead, she or he sees only documents. (The exception to this is when importing data from and exporting data to other computers.) Ordinarily, for every document in the application hierarchy there is an application.

A user can deinstall an application without deleting the application's documents in the file system. If the user tries to turn to one of these documents, there is no code to activate them. Instead, these orphan applications are handled by a “mask” application that tells the user that the application has been deinstalled and prompts the user to reinstall the application.

**No new, no save as . . .**

On a PC, the user usually starts an application, and then chooses what file to open with that application. But in the PenPoint operating system, the user can start an application by:

- Turning to the page that contains a document.
- Floating a document.
- Creating a new embedded document.

The document open on a page, and any floating or embedded documents on that page, are all applications with open files. You do not open a file from within an application. Instead, you turn to (or float or embed) another document and PenPoint starts up the correct application for that document.

Thus, it does not make sense to try to open another document from the current application, or to save the current document as another document.

The only time that an application needs to actually open a file from disk is when it is importing or exporting data that will be used by a file-oriented program on a file-oriented operating system.

**Stationery**

Users often want new instances of an application to start off from a particular state. Instead of opening a template from within the application, Penpoint supports application-specific stationery. The default piece of stationery is an application instance started from scratch. The user can create additional stationery documents, which are just filed documents kept in a separate notebook.

In the case of Tic-Tac-Toe, each document shows a view of its own board. There is no new command, because the user can always create a new document. There is no save command either—the Tic-Tac-Toe state is saved on every page turn. There's no open command, because the user can either turn to another Tic-Tac-Toe's page to "read it in," or can start from a desired template by accessing documents in the Stationery menu or auxiliary notebook.
Shutting down and terminating applications

If a document is in the application hierarchy, it always exists as a directory in the file system, whether it has a running process or not, and whether it is visible or not. When the user deletes a document (page-level or embedded), PenPoint deletes its directory from the file system.

The user can also elect to use the installer to deinstall or deactivate an application. This might be necessary when the user needs more room on the computer for a different application, or when the user isn't using an application any more. Deinstallation removes all application code from the loader database, which prevents the user from running it. However, the documents still exist in the application hierarchy, and can spring back to life if and when the user re-installs the application. Deactivation also removes the application code, but PenPoint remembers where the application came from, so that it can prompt the user to insert the appropriate disk if the user chooses to reactivate the application.

Conserving memory

When a document is active, it is obviously consuming memory, but when it is not active, it can still consume memory (if the computer is using a RAM-based file system). The document's saved state is in the application hierarchy, which can be in the RAM file system; the RAM file system shares RAM with running processes. This emphasizes how important it is to conserve memory.

You should also try to conserve memory when an instance is running but not open (for example, if it has the selection but is off-screen). This is an opportunity to destroy UI controls and other objects which are only needed when your application is on-screen.

Avoiding duplication

Documents receive messages from the Application Framework telling them to save their state to their directory. When a document starts up, its corresponding application often reads all of this state back into memory. This means that there are two copies of the document's state; the one in its address space and the saved copy in the file system. This can be quite wasteful of space. There are several approaches to eliminating this redundancy:

- Don't read state back into memory. Read information in from the file system when needed. This works well for database-type objects. Because the application hierarchy is in memory, file I/O is faster than you might think, but this is still slow. It does prevent the user from reverting to the filed state of the document, since the filed state is always being updated. Your application would have to disable Revert, or make its own backup copy of filed state.

- Use memory-mapped files to map filed state into the application's address space. This works well for large data files, but it does interfere with Revert.
Read state back into memory, then delete the information from the file system. This means that if the application instance crashes, there is nothing in the file system to recover.

Refuse to save state to the file system. This implies that the application process can't be terminated. This also means that the application state can't be recovered.

**Hot mode**

The last alternative above is supported by the PenPoint Application Framework. An application class or the user (by choosing Accelerated for Access Speed in the application's option sheet) can tell the PenPoint Application Framework that an application instance should not be terminated. This is called hot mode. It means that the document will appear much faster when the user turns to it, because its process never went away. Ordinarily the Application Framework must start a new process, create a new application object, tell it to restore its state, then put it on-screen.

**Components**

As we have seen, you can embed applications within other applications. This is the basis for the Application Framework's hierarchy. Applications require a good deal of overhead: each has its own directory, has code in the loader database, and runs as its own process (in addition to the directories and processes used by that application's documents).

You can reduce the size of an application by using components. Components are separate DLLs that provide a well-defined API to their clients. Most components can be used as part of an applications, but they don't require much overhead.

Components don't run as a separate process, and don't have a separate directory. Some components, such as Reference buttons, manifest themselves as visible objects and let the user embed, move, and copy them. Others, such as text views, are visible but can be added to applications only programmatically. Still others, such as the Address Book, do not even have a UI; that is, they do not display on-screen (the address book provides information that other applications then format and display).
Chapter 4 / PenPoint Class Manager

The previous chapter introduced some of the concepts in the PenPoint™ Application Framework. This section quickly covers the PenPoint operating system's object-oriented Class Manager. The Application Framework largely determines the overall structure of your applications; sending messages to objects using the Class Manager makes up 80% of the line-by-line structure of your code. With an understanding of the Application Framework and the Class Manager, you can start the tutorial.

There are three elements to the PenPoint operating system's object-oriented software environment: objects, messages, and classes.

Perhaps the simplest way to introduce the concepts of objects, classes, and messages is by looking at an example. The example discussed in the next three sections outlines what must happen to set the title of an icon. A user sets an icon’s title by making the check ✓ gesture over it. When its option sheet appears, the user enters a new icon title, makes sure the layout style is one that includes the title, and taps Apply.

If you feel that you understand the concepts of object-oriented, message-passing, class-based systems, you can skip this introduction and go directly to the section titled “Sending a Message.”

**Objects instead of functions and data**

In a non-object-oriented system, the icon and its title would be stored in a data structure. Any piece of code that gets or sets information pertaining to the icon must know the exact organization of that data structure. To modify the icon title, the program would locate the data structure that represented the icon; for example, it might change the icon’s title string by changing a pTitleString pointer. This program will break if the internal structure changes or if the string is later implemented by storing a compact resource identifier.

In an object-oriented system, anything in the system can be an object. In our example, the icon is represented by an object. The object knows about both the data for an icon and the functions that manipulate it. The object hides, or encapsulates, the details of its data structures and implementation from clients. One of the messages understood by the object might be “Set Your Title String,” which tells the object to change its title.

Because the object contains the code for the functions that manipulate it, the object locates its own internal data structures that represent the title, and changes the title.
This encapsulation reduces the risk of clients depending, either deliberately or accidentally, on implementation details of a subsystem. If the internal structure changes, only the object's code that manipulates the structures must change. Any client that sends the “Set Your Title String” message can still send that message and will still get the same effect.

Some object-oriented systems, including PenPoint, use software and hardware protection facilities to prevent clients from accessing or altering the internal structures of objects, whether accidentally or maliciously.

Ideally, in object-oriented operating systems, the objects presented to clients should model concrete ideas in the application. For example, if your application's user interface requires a button, it should create an object for that button; if your application has a counter, it should create an object to maintain that counter value.

**Messages instead of function calls**

Modular software systems are sometimes object-oriented without being message-passing. That is to say, they have objects that hide data structures from clients (such as “window”), and you pass these software objects as arguments to functions which act on them. Using the example of setting an icon's string, in such systems you might pass the iconWindow object to a routine called WindowSetString().

But this approach requires that clients know which function to call, or that the function handle many different kinds of objects. The implementation of icon strings might change so that icons need to be handled specially by a new IconSetString() function. Again, all clients would have to change their function calls.

Message-passing systems flip this control structure so that the object hides the routines it uses. A client simply sends a message to the object, and the object figures out what to do. This is known as data encapsulation. In the example we're using, clients send the message msgLabelSetString to the icon; the only argument for the message is a pointer to the new title string.

Because icons (or other objects) respond to messages, it doesn't restrict the implementation of icons: if, in the future, icons handle titles differently than other labels, they can still respond to msgLabelSetString correctly.

“The object figures out what to do” sounds like black magic, but it is actually not very complicated. You call a C routine to send a message to an object. Inside the Class Manager code, the Class Manager looks up that message in a table (created by the developer of the icon class) that specifies what function to call for different messages. If the message is in the table, the Class Manager then calls the icon's internal function which actually implements the message.

One benefit of using messages instead of function calls is that many different objects can respond to the same message. All objects that come from a common ancestor will usually respond to the messages defined by that ancestor. For instance, you can send msgLabelSetString to almost any object. (In some systems, this is called “operator overloading.”)
You can send any message to any object. Depending on whether it knows how to respond to the message, the object chooses what to do:

- If the object understands the message and can handle it, the object processes the message.
- If the object doesn’t understand the message, it gives the message to its ancestor, to see if its ancestor knows how to handle the message (more on ancestors later in this section).
- If the object understands the message, but doesn’t want to handle it, the object can ignore the message (by returning a nonerror completion status), reject the message (by returning an error completion status), or give the message to its ancestor.

### Classes instead of code sharing

Icons and several other similar objects have titles. Thus, each of those objects that has a modifiable title must handle the “set string” message in some way or other.

In other programming methodologies, programmers take advantage of functional overlap by copying function code, trying to make data structures conform so the same routine can be used, or calling general routines from object-specific routines. However, whether you copy code or link with general routines, the resulting executable file contains a static copy of the shared code. The best you can hope for is shared code implemented by the system, which is rare.

In a class-based system, an object is an **instance** of a specific class. The class defines the data structures that are used by its instances, but doesn’t necessarily describe the data in the structures (it is the data stored in these structures that differentiates each instance). The class also contains the functions that manipulate the object’s data.

Each instance of a class contains the data for the specific thing being described (such as an icon). Each instance also knows to which class it belongs. Thus, there can be many instances of a class (and data for each instance), but the code for that class exists in only one place in the entire system.

If an existing class does almost, but not quite, everything you want, you can create a new class that **inherits** its behavior from the existing class. The new class is said to be a **subclass** or **descendant** of its **ancestor** class. The subclass contains unique functionality that was not previously available in its ancestor.

The subclass should not reproduce anything that was defined by its ancestor. The subclass only defines the additional data structures required to describe the new thing and the functions required to handle messages for the new thing.

Of course, subclassing does not stop at one generation. The icon window class, for example, has eight ancestors between it and `clsObject`, which is the fundamental class for all classes in PenPoint.

Take a look at the PenPoint Class Hierarchy in the class hierarchy poster. Find the relationship between `clsIcon` and `clsLabel` (they’re near the lower right edge).
Handling messages

An object can send a message to its ancestor class either when it doesn’t recognize the message or when it chooses to allow its ancestor class to handle the message. Because the icon window class inherits from the window class, the icon window automatically responds to all the messages that a window responds to (such as msgWinDelta to move it or msgWinSetVisible to hide it) in addition to all the messages specific to an icon window (such as msgIconSetPictureSize). A class can override or change some of its ancestors’ messages; for example, the icon window responds to msgWinRepaint by letting its ancestor label paint the string, then it draws its picture.

Message handling by a class and its ancestors

By making it very easy to inherit behavior from existing classes, class-based systems encourage programmers to extend existing classes instead of having to write their own software subsystems from scratch. If you create a new kind of window, say an icon with a contrast knob, you can make it a descendant of another class, and it will inherit all the behavior of that class, or as much behavior as you choose.

You may find it easier to understand class-based programming by viewing code instead of reading abstract explanations. The next few pages give some simple examples of using messages and classes, and even the very simplest program in the tutorial is fully class-based (in fact, for an application to run under PenPoint, it must be class-based).
Sending a message

In PenPoint, you usually send a message to an object using the `ObjectCall()` function (or `ObjectSend()` if the object is owned by another process). The differences between `ObjectCall()` and `ObjectSend()` are detailed in Part 1: Class Manager, of the *PenPoint Architectural Reference*.

Here’s a real-life example of sending a message. PenPoint provides a utility class, `clsList`, which maintains a list object. The messages that `clsList` responds to are documented in Part 9: Utility Classes, of the *PenPoint Architectural Reference* and in the `clsList` header file (PENPOINT\SDK\INC\LIST.H). This is the definition of `msgListAddItemAt` from LIST.H:

```c
/* msgListAddItemAt takes P_LIST_ENTRY, returns STATUS
   Adds an item to a list by position.
   *********************************************************************************/
#define msgListAddItemAt MakeMsg(clsList, 10)
```

Don’t worry about the details of the definition right now; this just tells us that `msgListAddItemAt` is defined by `clsList`, that the message uses a `P_LIST_ENTRY` structure to convey its arguments, and that the message returns a value of type `STATUS` when it completes.

We want to send `msgListAddItemAt` to a list object, telling it to add the value ‘G’ to itself at position three in the list.

**Sending `msgListAddItemAt` to a list**

![Message arguments](image)

Message arguments

Now, in order for a list object to respond appropriately to `msgListAddItem`, it’s going to need some additional information. In this case the additional information is the item to add to the list (G), and where to add it (third position). Most messages need certain information for objects to respond correctly to them. The information, called message arguments, you pass to the recipient along with the message.

In this case, the header file informs us that `msgListAddItemAt` takes a `P_LIST_ENTRY`. In PenPoint’s C dialect, this means “a pointer to a LIST_ENTRY” structure. Here’s the structure:

```c
typedef struct LIST_ENTRY {
    U16    position;
    LIST_ITEM  item;
} LIST_ENTRY, *P_LIST_ENTRY;
```

U16 is an unsigned 16-bit number, `P_UNKNOWN` means a 32-bit pointer to an unknown. (Chapter 5, Developing an Application, describes the rest of PenPoint’s ubiquitous `typedefs` and `#defines`.)
When you can deliver the message and its arguments to a list object, you're set.
Here's the C code to do it:

```c
LIST list;        // the object
LIST_ENTRY add;  // structure for message arguments
STATUS s;        // most functions return a STATUS value
// Add an item to the list:
// 1. Assemble the message arguments;
add.position = 3;
add.item = (LIST_ITEM) 'G';
// 2. Now send the message and message arguments to the object.
if ((s = ObjectCall(msgListAddItemAt, list, &add)) != stsOK) {
    Dbg(Debugf(U_L("add item failed: status is: 0x%lx", s)));}
```

**ObjectCall() parameters**

The code fragment above assumes that the list object (list) has already been created; object creation is covered later in this chapter. As you can see, ObjectCall() takes three parameters:

- The message (msgListAddItem). Messages are just 32-bit constants defined by a class in its header file. You can send an object a message defined by any of the classes from which it inherits. (Some objects even respond to messages defined by classes that are not their ancestors.)
- The object (list). Objects are referenced by UIDs, unique 32-bit ID numbers. UIDs are discussed in more detail later.
- The arguments for the message (add). Not all messages take arguments (msgFrameClose, for example, takes none), but others do (msgIconSetPictureSize, for example, takes a width and height). The PenPoint Architectural Reference manual and the header files (in this case, PENPOINT\SDK\INCL\LIST.H) document each message's arguments.

ObjectCall() has one 32-bit parameter for all the message's arguments; if a message takes more arguments than can fit in 32 bits, you must assemble the arguments in a structure and pass ObjectCall() a pointer to the structure. In this case, msgListAddItem takes a P_LIST_ENTRY, a pointer to a LIST_ENTRY structure. (The PenPoint convention is that a type that begins with P_ is a pointer to a type.) Hence the address of the add structure (&add) is passed to ObjectCall().

**Returned values**

The result of sending a message is returned as a status value (type STATUS). stsOK ("status OK") is zero. All status values that represent error conditions are less than zero. Note that STATUS is a 32-bit quantity, hence the %lX in the Debugf() statement to print out a long hexadecimal.

Some messages are designed to return errors that you should test for. For example, the status returned by sending msgIsA to an object is stsOK if the object inherits from the specified class, and stsBadAncestor if the object does not.

Some objects respond to messages by returning a positive value (which is not a status value, but an actual number). Others return more complex information by
filling in fields of the message argument structure supplied by the caller (or buffers indicated by pointers in the message argument structure) and passing back the structure.

How objects know how to respond

The list object responds to \texttt{msgListAddItem} because it is an instance of \texttt{clsList}. But what does that mean?

The list object has several attributes. Among them are the class that created the object and the instance data for that object. As described above, when you define a class, you must also create a table of the messages handled by your class.

The Class Manager finds out which class created the object and looks for the method table for that class. The method table tells the Class Manager that the class has a function entry point for that message, so the Class Manager calls that function entry point, passing in the message and the message argument structure.

Although the object receives the message, its class has the code to handle the message.

If the class decides to give the message to its ancestor, it passes the message and the message arguments to the ancestor (but the instance data is still the instance data for the object that received the message).

How messages to instances are processed by classes

Creating an object

Where did the list object in the example above come from?

The short answer is that a client asked \texttt{clsList} to create an instance of itself by sending \texttt{msgNew} to \texttt{clsList}. In many ways this is no different than when we sent \texttt{msgListAddItem} to the list object in the previous example.

Classes and instances

The longer answer involves understanding the relationship among classes and instances. In the section “Sending a Message,” we discussed the fact that you send messages to objects and those objects respond to the messages. We also discussed how a class describes the data structures and the code used by its instances.

A class responds to \texttt{msgNew} by manufacturing an instance of itself. What is an instance? It is merely an identifier and the data structures that represent an object.
Thus, the class asks the Class Manager to allocate the data structure and assign an identifier to the structure.

How can a class respond to a message? This is a fundamental concept and one that is hard to understand at first: a class is an object, just like any other PenPoint object. And just like any other PenPoint object, an object is an instance of a class. In the case of classes, all classes are instances of clsClass.

You can think of classes as objects that know how to create instances.

When a client sends a message to a class, the class behaves like any other object and allows the class that created it (clsClass) to handle the message. clsClass contains the code that creates new objects.

Thus, in answer to our original question about how did the list object come into being: a client sent msgNew to the object named clsList. clsList is an instance of clsClass, so the code in clsClass created a new object that is an instance of clsList.

**An alternative explanation**

At an implementation level, here's what actually happens.

The PenPoint Class Manager maintains a database of data structures; each data structure represents an object. The PenPoint Class Manager locates these objects by 32-bit values, called UIDs (unique identifiers); UIDs are explained later in this chapter in “Identifying the new object: UIDs” on page 54. The data structure for each object contains some consistent information (defined by clsObject) that indicates the class to which the object belongs and other attributes for the object. Other information in the data structure varies from object to object, depending on which class created the object.

When a client sends a message to an object, the Class Manager uses the UID to locate the object. The Class Manager then uses the object's data structure to find the class that created the object. The Class Manager finds the class and uses the class's method table to find the entry point for the function that handles the message.

To create an object, the process works the same way. A client sends msgNew to a class object. The Class Manager locates the object, finds the class that created the object (clsClass), and calls the function in clsClass that creates new objects.

**The _NEW structure**

For many classes, the _NEW structure is identical to the structure that contains the object's metrics.

You send msgNew to nearly every class to create a new instance of that class. In the case of msgNew, the message argument value is always a pointer to a structure that defines characteristics for the new object. This structure is commonly called the class's _NEW structure because the name of the structure is a variation of the class name, followed by _NEW. For clsList, the _NEW structure is LIST_NEW.
CHAPTER 4 / PENPOINT CLASS MANAGER
Creating an object

The _NEW structure is mainly used to initialize the new instance. For example, when creating a new window you can give it a size and specify its visibility.

The _NEW structure differs depending on the class to which you send it. You can find the specific _NEW structure to use when creating an instance of a class by looking in the *PenPoint API Reference* manual or in the class's header file. For clsList, messages and message arguments are defined in PENPOINT\SDK\INC\LIST.H. The _NEW structure is LIST_NEW. This excerpt comes from the LIST.H file:

```c
typedef struct LIST_NEW_ONLY {
    LIST_STYLE style;
    LIST_FILE_MODE fileMode;
    U32 reserved[4]; // Reserved
} LIST_NEW_ONLY, *P_LIST_NEW_ONLY;

#define listNewFields
    objectNewFields \ LIST_NEW_ONLY list;

typedef struct LIST_NEW {
    listNewFields
} LIST_NEW, *P_LIST_NEW;
```

**Reading the _NEW structure definition**

To read the _NEW structure definition, you need to perform the work that the compiler does in its preprocessor phase, expanding the macro definitions. The _NEW structures in the *PenPoint API Reference* have all been expanded for your convenience.

Start by looking for the definition for the _NEW structure (typedef struct LIST_NEW) at the end of the example. The structure is represented by a #define name (in this case listNewFields).

Here's where it gets tricky; start thinking about inheritance. The #define name (listNewFields) has two parts:

- The #define name for the objectNewFields structure of the class's immediate ancestor (in this case, objectNewFields, which defines the arguments required by clsObject).
- A _NEW_ONLY structure for the class being defined (LIST_NEW_ONLY). The LIST_NEW_ONLY structure contains the actual msgNew arguments required for clsList.

Each subclass of a class adds its own _NEW_ONLY structure to the ...NewFields #define used by its immediate ancestor. This is how the _NEW structure for a class contains the arguments required by that class, by its ancestor class, by that class's ancestor, by that class's ancestor, and so on.

In this case, however, there is only one ancestor, clsObject. objectNewFields is defined in PENPOINT\SDK\INC\CLSMGR.H:

```c
#define objectNewFields OBJECT_NEW_ONLY object;
```
OBJECT_NEW_ONLY is defined in the same file. It has many fields:

```c
typedef struct OBJECT_NEW {
    U32 newStructVersion; // Out: [msgNewDefaults] Validate msgNew
        // In:[msgNew] Valid version
    OBJ_KEY key; // In:[msgNew] Lock for the object
    OBJECT uid; // In:[msgNew] Well-known uid
    OBJ_CAPABILITY cap; // Out: [msgNew] Dynamic or Well-known uid
    CLASS objClass; // In:[msgNew] Initial capabilities
        // Out: [msgNewDefaults] Set to self
    OS_HEAP_ID heap; // In:[msgNew] Class of instance
        // In:[msg*] Used by toolkit components
    U32 spare1; // Unreserved storage. If capCall then
        // OSProcessSharedHeap else OSProcessHeap
    U32 spare2; // Unused (reserved)
} OBJECT_NEW_ONLY, OBJECT_NEW, *P_OBJECT_NEW_ONLY, *P_OBJECT_NEW;
```

Most elements in an argument structure are passed *In* to messages—you’re specifying what you want the message to do. *Out* indicates that an element is set during message processing and passed back to you. *In:Out* means that you pass in an element and the message processing sets the field and passes it back to you.

**A _NEW_ONLY for each class**

Why such a complicated set of types? Thanks to class inheritance, when you create an instance of a class, you are also creating an instance of that class’s immediate ancestor class, and that ancestor’s ancestor class, and so on up the inheritance hierarchy to the root Object class. Each ancestor class typically allows the client to initialize some of its instance data. Many classes allow you to supply the msgNew arguments of their ancestor(s) along with their own arguments.

This is true for clsList: it inherits from clsObject (as do all objects) and part of its msgNew argument structure is the OBJECT_NEW argument structure for clsObject. clsList has three msgNew arguments of its own: how it should file the entries in the list, a list style, and a reserved U32.

These large message argument structures are intimidating, but the good news is that by sending msgNewDefaults, you get classes to do the work of filling in appropriate default values. You then only need to change a few fields to get the new object to do what you want.

**Identifying _NEW structure elements**

As a class adds a _NEW_ONLY structure to a _NEW structure, it also gives a name to the _NEW_ONLY structure. From the clsList example, we can expand the LIST_NEW definition as:

```c
typedef struct LIST_NEW {
    objectNewFields
        LIST_NEW_ONLY list;
} LIST_NEW, *P_LIST_NEW;
```
The name list identifies the LIST_NEWONLY structure within the LIST_NEW structure with the name list. We can carry on the expansion to apply the definition of objectNewFields:

```c
typedef struct LIST_NEW {
  OBJECT_NEWONLY object;
  LIST_NEWONLY list;
} LIST_NEW, *P_LIST_NEW;
```

You can see now, when you create an identifier of type LIST_NEW, you can specify the _NEWONLY structures by specifying their names. For example, if your code contains:

```c
LIST_NEW myList;
```

You can refer to the LIST_NEWONLY structure by myList.list, and the OBJECT_-NEWONLY structure by myList.object.

**Code to create an object**

This example code creates the list object to which we sent a message in the first code fragment. Later code will show how the list class is itself created.

The preceding discussion mentioned that the client sends msgNew to a class to create an instance of the class. The function parameters used in ObjectCall() for msgNew are the same as before (the object to which you send the message, the message, and the message argument value).

As we have seen, the _NEW structure can get quite large (because most subclasses add their own data fields to the _NEW structure). Many classes have default values for fields in the _NEW structure, yet clients must be able to override these defaults, if they want.

To initialize the _NEW structure to its defaults, clients must send msgNewDefaults to a class before sending msgNew. msgNewDefaults tells a class to initialize the defaults in the _NEW structure for that class. After msgNewDefaults returns, the client can modify any fields in the _NEW structure and then can call msgNew.

```c
LIST list;  // Object we are creating.
LIST_NEW new;  // Structure for msgNew arguments sent to clsList.
STATUS s;
// Initialize _NEW structure (in new).
ObjCallRet(msgNewDefaults, clsList, &new, s);
// Modify defaults as necessary.
new.list.fileMode = listFileItemsAsData;
// Now create the object by sending msgNew to the class.
ObjCallWarn(msgNew, clsList, &new, s);
// The UID of the new object is passed back in the _NEW structure.
list = new.object.uid;
```

Because almost every message returns a status value (to say nothing of most function calls), your code tends to become littered with status checking. Hence PENPOINTSDKINCCLSMGR.H defines several macros to check for bad status values. This fragment uses one of those macros, ObjCallWarn(). ObjCallWarn() does a standard ObjectCall() with its first three parameters, and assigns the return value to its fourth. If the returned value is less than stsOK, ObjCallWarn() prints a Status values less than stsOK indicate errors.
warning to the debugging output device (when compiled with the DEBUG flag).
There are many other macros of a similar nature; they are documented in Part 1:
Class Manager of the PenPoint Architectural Reference.

**Identifying the new object: UIDs**

When you send `msgNew` to a class, the message needs to give you an identifier for
the new object (so your code can use it). As mentioned previously, messages often
pass back values in the structure that contains the message arguments. In this case,
`clsObject` passes back the UID of the newly created object in its `OBJECT_NEW`
structure (in `object.uid`).

In our code example, the UID for the new object was passed back in `new.object.uid.`
The sample copied the value to the object named list, and henceforth uses list when
referring to the new list object.

You refer to objects using UIDs. A UID is a 32-bit number used by the Class Man­
ger to indicate a specific PenPoint object. An object’s UID is not a C pointer; it con­
sists of information used by the Class Manager to find an object and information
about the object’s class and other things. The symbol list in this example is the UID
of our list object; `clsList` is the UID of the list class.

PenPoint defines many classes that clients can use to create instances for their own
use (such as the list class, the window class, and so on). All of these built-in classes
are depicted in the class hierarchy poster.

When a client sends `msgNew` to a class to create a new object, the class is identified
by a unique value. If an application knows this value and the class is loaded in
PenPoint, the application can create an instance of the class. This value is called a
global well-known UID.

The global well-known UIDs of all the public PenPoint classes, including `clsList`,
are defined in `PENPOINT\SDK\INC\UID.H`. Because all PenPoint programs include
this header file when they are compiled, all programs know about these classes.

`clsList` is defined with this line in `UID.H`:

```c
#define clsList MakeWKN(10, 1, wknGlobal)
```

`MakeWKN()` (pronounced “make well-known”) is a macro that returns a 32-bit
constant. Here the parameters to `MakeWKN()` mean “create a well-known UID in
global memory for version 1 of administered ID 10.” No other well-known UID
uses the number 10.

Eventually, when you finalize your application, you will need to define your own
well-known UIDs. Contact GO Customer Services at 1-415-358-2040 (or by
Internet electronic mail at gocustomer@go.com) for information on how to get a
unique administered value.

Until that time, you can use some spare UIDs, defined in `PENPOINT\SDK\INC\UID.H`, for this purpose. These UIDs have the values `wknGDTa` through
`wknGDTg`.

There are other types of UIDs: local well-known UIDs and local private UIDs. There
are no global, private UIDs.
Creating a class

You have seen how to send a message to an object and how to send `msgNew` to a class to create a new object. You use the same procedure to create any object and send it messages, so you can send messages to any instance of any class in PenPoint.

The last step is to create your own classes for your application. At the very least, you must create a class for your own application; frequently, you will also create special window classes and data objects that draw and store what you want.

Creating a class is similar to creating an instance, because in both cases you send `msgNew` to a class. When you create a class, you send `msgNew` to `clsClass`. This is the class of classes. Remember that a class is just an object that knows how to create instances of itself; in this case, `clsClass` knows how to create objects which themselves can create objects.

In short, to create a class, you send `msgNew` to `clsClass`, and it creates your new class object. A routine much like this in the PenPoint source files creates `clsList`; it is executed when the user boots PenPoint (when the `SYSUTIL.DLL` is loaded).

```c
/****************************************************************************
ClsListInit
Install clsList
****************************************************************************/
STATUS ClsListInit (void)
{
    CLASS_NEW   new;
    STATUS      s;
    ObjCallWarn(msgNewDefaults, clsClass, &new, s);
    new.object.uid   = clsList;
    new.class.pMsg   = (P_MSG) ListMethodTable;
    new.class.ancestor = clsObject;
    new.class.size   = SizeOf(P_UNKNOWN);
    new.class.newArgsSize = SizeOf(LIST_NEW);
    ObjCallRet(msgNew, clsClass, &new, s);
    return stsOK;
} // ClsListInit
```

New class message arguments

The important thing, as always, is the group of message arguments. Here the message is `msgNew`, just as when we created the list object; because we are sending it to a different class, the message arguments are different. When sent to `clsClass`, `msgNew` takes a pointer to a `CLASS_NEW` structure. Like `LIST_NEW`, `CLASS_NEW` includes the arguments to `OBJECT_NEW` as part of its message arguments. Briefly, the `CLASS_NEW` message arguments are:

- The same `OBJECT_NEW` arguments used by other objects—a lock, capabilities, a heap to use (and a UID field in which the Class Manager returns the UID of the object).
- The method table (`new.class.pMsg`) which is where you tell the class which functions handle which messages. You must write the method table. This is the core of a class, and is discussed in great detail in the next section.
• The ancestor of this class (new.class.ancestor). The Class Manager has to know what the class's ancestor is so that your class can inherit behavior from it; that is, let the ancestor class handle some messages. In this case, clsList is an immediate descendant of clsObject.

• The size of the data needed by instances of the class (new.class.size). The Class Manager needs the information to know how much room to allocate in memory when it creates a new instance of this class.

• The size of the structure that contains information used to create a a new instance of the class (new.class.newArgsSize).

For a list, the instance data is just a pointer to the heap where it stores the list information, hence the size is SizeOf(P UNKNOWN). For other objects, the instance data may include a lot of things, such as window height and width, title, current font, etc. Note that an object has instance data for each of the classes it is an instance of—not just its immediate class, but that class's ancestor, and that ancestor's ancestor, and so on.

The instance data size must be a constant! If, say, a title string is associated with each instance of your class, then you need either to have a (small) fixed-size title or to keep the string separate and have a pointer to it in the instance data.

Method tables

Nearly all classes respond to messages differently than their ancestors do—otherwise, why create a new class? As a class implementer, you have to write methods to do whatever it is you want to accomplish in response to a particular message.

In PenPoint, a method is a C function, called a message handler. The terms message handler and method are used interchangeably.

When a client sends a message to an instance of your class, you want the Class Manager to call the message handler that is appropriate for that message. You tell the Class Manager what to do with each message through a method table.

A method table is simply a mapping that says "for message msgSomeMsg, call my message handler MyFunction()." You specify the table as a C array in a file that is separate from your code (you must compile it with the method table compiler, described below). A method table file has the extension .TBL. Each class has its own method table; however, a single method table file can have method tables for several classes. At the end of the file is a class info table that maps a class to the method table for that class. There must be an entry in the class info table for each method table in the file. The file looks something like this:

```c
MSG_INFO clsYourClassMethods[] = {
    msgNewDefaults, "myClassNewDefaults", objCallAncestorBefore, msgSomeMsg, "MyFunction", flags, 0,
};
CLASS_INFO classInfo[] = {
    "clsYourClass", clsYourClassMethods, 0,
};
```

P UNKNOWN is the typedef used in PenPoint for a pointer to an unknown type.

Important! Instance data size must be a constant.

Some classes exist just to define a set of messages; the implementation of those messages is up to its descendants.
The quotation marks around the messages and classes are required. You can tell
the Class Manager to call your ancestor class with the same message before or
after calling your function by setting flags in the third field in the method table
(the third field in the CLASS_INFO table is not currently used and should always
contain 0).

**Identifying a class's message table**

To convert the method table file into a form the Class Manager can use, you com­
pile the table file with the C compiler, then run the resulting object through the
Method Table compiler (PENPOINT\SDK\UTIL\CLSMGR\MT.EXE). This turns it into
a .OBJ file that you link into your application.

The most important argument you have to pass to msgNew when creating a class is
a pointer to this method table (new.class.pMsg in the code fragment above). When
you create the class, you set new.class.pMsg to clsYourClass.

When an object is sent a message, the Class Manager looks in its class's method
table to see if there is a method for that message. If not, the Class Manager looks in
the class's ancestor's method table, and so on. If the Class Manager finds a method
for the message, it transfers execution to the function named in the method table.

When the Class Manager calls the function named in the method table, it passes
the function several parameters:

- The message sent (msg).
- The UID of the object that originally received the message (self).
- The message arguments (pArgs). The Class Manager assumes that the message
  arguments are a pointer to a separate message arguments structure).
- The internal context the Class Manager uses to keep track of classes (ctx).
- A pointer to the instance data of the instance.

**Self**

Self is the UID of the object that received the message.

As we discussed before, when an object receives a message, the class manager first
sees if the object's class can handle the message, then it passes the message to its
ancestor, which passes the message to its ancestor, and so on. However, the data
that each of those classes work on is the data in the object that first received the
message (which is identified by self). This is fundamental to understanding object­
oriented programming in PenPoint: calling ancestor makes more methods available
to the data in an object, it doesn't add any new data.

A second fundamental concept is that an ancestor may need to make a change
to the data in the object. However, rather than making the change immediately
by calling a function, the ancestor sends a message to self to make the change.
Be careful not to get pulled into the semantic pit here; self means the object
that received the original message, not the ancestor class handling the message.
(Remember that the ancestors only make more functions available; not more data.)
Because the message is sent to self, self's class can inspect the message and choose whether it wants to override the message or allow its ancestor to handle it. Each ancestor inspects the message and can either override the message or pass it to its ancestor. This continues until the ancestor that sent the original message receives the message itself and, having given all of its descendants the opportunity to override the message, now handles the message itself (or even passes the message to its ancestor!).

**Possible responses to messages**

Here are some of the flavors of responses you can make to a message in a message handler:

- Do something before and/or after passing it to the ancestor class. This might include modifying the message arguments, sending self some other message, calling some routine, and so on. This means that the class will respond to the message differently than its ancestor.

- Do something with the message, but don't pass the message to the ancestor class. This is appropriate if the message is one you defined, because it will be unknown to any ancestor classes. If the message is one defined by an ancestor, this response means that you're blocking inheritance, which is occasionally appropriate.

- Do nothing, but return some status value. This blocks inheritance, and means that it's up to descendant classes to implement the message. This is not as rare as it sounds; many classes send out advisory messages informing their instances or other objects that something has happened. For example, clsWindow sends self the message msgWinSized if a window changes size. This is useful for descendant classes that need to know about size changes, but clsWin itself doesn't care.

What messages does your message handler have to respond to? It usually ought to respond to all the messages specific to your class which you define—no other ancestor class will. Ordinarily an instance of each class has its own data, so most classes intercept msgNew to execute a special initialization routine; if there are defaults for an instance's data, the class will also respond to msgNewDefaults. Most classes should also respond to msgFree to clean up when an instance is destroyed.

Here is clsList's method table.

```c
#include <list.h>     // where the messages are defined
MSG_INFO ListMethods [] =
{
    /* clsObject methods */
    msgNewDefaults, "ListNewDefaults", 0,
    msgInit, "ListInit", 0,
    msgFree, "ListMFree", 0,
    msgSave, "ListSave", 0,
    msgRestore, "ListRestore", 0,
```
Note that clsList responds to most intercepted messages by calling an appropriate function (ListInit(), ListMFree(), and so on). The functions that implement the various list messages are not printed here; indeed, external code should never call routines internal to a class. One of the goals of object-oriented programming is to hide the implementation of a class from clients using the class.
Chapter 5 / Developing an Application

Thus far, we have described the PenPoint™ operating system and PenPoint applications from a conceptual point of view. By now you should understand how PenPoint differs from most other operating systems and what the PenPoint Application Framework and Class Manager do for you.

With this chapter we start to address what you, as a PenPoint application developer, have to do when writing PenPoint applications.

• The first section describes many of the things that you have to think about when designing an application.

• The second section describes some of the things that you have to consider when designing an application for an international market.

• The third section describes the functions and data structures that you will create when you write an application.

• The fourth section describes the cycle of compiling and linking that you will follow when developing an application.

• The fifth section provides a checklist of things that you must do to ensure that your application is complete.

• The sixth and following sections describe the coding standards and naming conventions used by GO. Included in these sections is a discussion of some of the debugging assistance provided by PenPoint.

• The last section describes the tutorial programs provided with the SDK.

Designing your application

When you design a PenPoint application, there are several separate elements that you need to design:

• The user interface

• The classes

• The messages

• The message handlers

• The program units

This section points out some of the questions you must ask yourself when designing an application. This section does not attempt to answer any of the questions; many answers require a good deal of explanation, and many decisions involve your own needs.
Just read this section and keep these questions in mind as you read the rest of the manual.

**Designing the user interface**

The most obvious part of a PenPoint application is the user interface. Almost as soon as you determine what your application will do, you should begin to consider your user interface.

Your user application should be consistent with the PenPoint user interface, which is described in detail in the *PenPoint User Interface Design Reference*.

**Designing classes**

PenPoint provides a rich set of classes that can do much of the work for your application. Your task is to decide which of these classes will serve you best. The *PenPoint Architectural Reference* describes the PenPoint classes and what they can provide for you.

If the classes provided by PenPoint don't do exactly what you need, you should look for the class that comes closest to your needs, then create your own class that inherits behavior from that class.

**Designing messages**

After determining that you need to create your own class, you need to decide what messages you need. Usually you add new messages to those already defined by your class's ancestors.

However, the real trick to subclassing comes when you decide how to handle the messages provided by your class's ancestors. If you do not specify how your class will handle your ancestors' messages, the PenPoint class manager sends the messages to your immediate ancestor, automatically. If you decide to handle an ancestor message, you then need to decide when your ancestors handle the message, if at all. Do you:

- Call the ancestor before you handle the message?
- Call the ancestor after you handle the message?
- Handle the message without passing it to your ancestor at all (thereby overriding ancestor behavior)?

**Designing message handlers**

After determining the messages that you will handle, you then need to design the methods that will do the work for each of the messages. In considering the methods and the information they need, you will probably start to get an idea of the instance data that your class needs to maintain.
Designing program units

When you understand the classes that you require, you should consider how to organize your classes and their methods into program units. The common approach used in our sample code is to place the source for each class into a separate file.

You should consider whether a class will be used by a number of different applications or used by a single application. If the class can be used by more than one application (such as a calculator engine), you should compile and link it into a separate DLL (dynamic link library). Each application tells the installer which DLLs it needs at install time. The installer then determines whether the DLL is present or not. If not, it installs the DLL.

Designing for internationalization and localization

PenPoint 2.0 Japanese contains support for applications that are written for more than one language or region. The process of generalizing an application so that it is suitable for use in more than one country is called internationalization. Modifying an application so that it is usable in a specific language or region is called localization.

PenPoint 1.0 already includes many features that will be used to support internationalization. For example, PenPoint 1.0 uses PenPoint resource files to store its text strings. When localizing to a specific language, a different resource file will be created that contains text strings in that language.

There are two aspects to the changes implied by PenPoint 2.0 Japanese. The first is making your application port easily to PenPoint 2.0 Japanese. The second is internationalizing your application.

Porting from PenPoint 1.0 to PenPoint 2.0 Japanese

PenPoint 2.0 Japanese incorporates some major changes that will cause applications compiled for PenPoint 1.0 to be incompatible with PenPoint 2.0 Japanese. The data created by 1.0 applications should still work under PenPoint 2.0 Japanese, and properly written 1.0 applications should be portable to PenPoint 2.0 Japanese with nothing more than a recompilation.

This section describes how to write your PenPoint 1.0 application so that it will be portable to PenPoint 2.0 Japanese. Using these guidelines does not mean that you will have internationalized your application! Internationalization and localization are much larger issues, and are dealt with elsewhere. These instructions are intended only to make it easier for you to port your United States English application to PenPoint 2.0 Japanese.

The biggest change is that PenPoint 1.0 uses the ASCII character set, while PenPoint 2.0 Japanese uses Unicode. ASCII is an 8-bit character set; Unicode is a 16-bit character set. This affects character types, string routines, quoted strings, and other string-related entities.
**Character types**

PenPoint provides three character types: CHAR8, CHAR16, and CHAR. The first two provide 8- and 16-bit characters, respectively. In PenPoint 1.0, the plain CHAR type is 8 bits long; in PenPoint 2.0 Japanese, CHAR is 16 bits long. You need to convert all of your character data to use the CHAR type, except where you know the size you'll need will be the same under PenPoint 1.0 and PenPoint 2.0 Japanese (for example, in the code that saves and restores data).

Any places where you depend on a CHAR having a small value, you should rethink the problem. For example, if you currently translate a character by indexing 256-element array (CHAR array[sizeof(CHAR)]), you probably won't want to use the same strategy when sizeof(CHAR), and therefore the size of your array, is 65,536.

Any places where you depend on sizeof(CHAR) being one byte, you need to change the value.

**String routines**

All of the familiar C string routines (strcmp, strcpy, and so on) still exist in PenPoint 2.0 Japanese, and they still work only on 8-bit characters. The INTL.H header file in PenPoint 1.0 defines a new set of string routines (named Ustrcmp(), Ustrcpy(), and so on) that perform the equivalent functions on 16-bit Unicode characters.

In PenPoint 1.0, the U...() functions are identical to their 8-bit namesakes. In PenPoint 2.0 Japanese, they are 16-bit routines. In other words, the old routines only work on CHAR8 strings, while the U...() routines work on CHAR8 strings in PenPoint 1.0 and on CHAR16 strings in PenPoint 2.0 Japanese. If you use the U...() versions and CHAR strings in your PenPoint 1.0 code, you will not have to change anything for PenPoint 2.0 Japanese, because CHAR is an 8-bit value in PenPoint 1.0 and a 16-bit value in PenPoint 2.0 Japanese.

You should use the U...() versions wherever you use CHAR strings, which should be for every string you display on the screen or debugging output device.

**Character and string constants**

When you use CHAR8, you can use standard C conventions for forming character and string constants. That is:

```c
CHAR8 *s = "string";
CHAR8 c = 'c';
```

When you use the CHAR16 type, you must precede the character or string constant with the letter L, which tells the compiler you are using a 16-bit (long) character, as:

```c
CHAR16 *s = L"string"
CHAR16 c = L'c'
```

When you use the CHAR type, you must precede the character or string constant with the identifier U_L, which means UNICODE, long. In PenPoint 1.0, this tells the compiler to use 8-bit characters; in PenPoint 2.0 Japanese, this tells the compiler to use 16-bit characters.

```c
CHAR *s = U_L"string";
CHAR c = U_L'c';
```
Preparing for internationalization

PenPoint 1.0 does not contain all the messages, functions, and tools that you will need to internationalize your application. However, there are several facilities available in PenPoint 1.0 that you can use to reduce the work needed to internationalize. This section lists these facilities.

Move strings into resource files

You should move as many of your text strings into resource files as possible. When text strings are hard-coded into your application, they are very difficult to translate and do not allow users to change language dynamically. If you move your application's text strings into resource files, they are easy to translate and allow users to change language simply by substituting one resource file for another.

If you use the StdMsg() facility for displaying dialog boxes, error messages, and progress notes, your text strings are already in resource files. The positional parameter facility provided with StdMsg() and the compose text string routines do not depend on the order of replaceable values in the function parameters. These functions are unlike printf(), where the order of the function parameters is directly related to the order of replaceable values in the string. When you use StdMsg() or compose text, the function parameters are always in the same order, but your string can use them in the order dictated by the national language in which you are writing.

Identify and modularize code that varies with locale

When internationalizing an application, moving its text strings to resource files allows users to change the language, but in order to support another language, parts of your application code must be equally replaceable. For example, when sorting characters in another language, you must be prepared to handle different sort sequences.

PenPoint 2.0 Japanese provides a number of services to perform functions that vary by language, such as sorting, number formatting, number scanning, numbers with units, times and dates (input and output), character comparisons, character conversions, spell-checking, and so on.

The PenPoint Services architecture enables you to create functions that users can install and activate whenever they choose. For instance, users can install several different printer drivers, but they only make one driver current at a time. Similarly, users of PenPoint 2.0 Japanese can install several different sort engines and choose one to use with the current language.

You should identify and flag any language-dependent routines, such as text manipulation, in your PenPoint 1.0 application. When you port the code to PenPoint 2.0 Japanese, use services to replace them wherever possible.
Part 13: Writing PenPoint Services in the PenPoint Architectural Reference describes how to create your own services. If you make your language-dependent functions into services in PenPoint 1.0, the change to PenPoint 2.0 Japanese will be much easier.

**New text composition routines**

The file CMPSTEXT.H contains ComposeText() routines for assembling a composite string out of other pieces. Use these routines to create strings in your UI—don't use sprintf()! The ComposeText() routines will also save you effort because you can specify the resource ID of a format string and the code will read it from the res file for you. You can, of course, give the format string directly to the routines.

**Development strategy**

Where do you start writing an application?

The PenPoint Application Framework provides so much boilerplate work for you, it is very easy to create applications through incremental implementation. You start with an empty application, that is, one that allows the Application Framework to provide default handling of most messages. Then, one by one, you add new objects and classes to the application, testing and debugging as you go.

As we shall see in Chapter 6, A Simple Application (Empty Application), the PenPoint SDK includes sources for an empty application called Empty Application. You can copy, compile, install, and run Empty Application.

This section describes the fundamental parts of PenPoint applications. These are the parts that you will probably work on first. They are also the parts you will return to many times to modify.

**Application entry point**

All PenPoint applications must have a function named main(), which is the entry point for an application. When the application is installed, main() creates the application class and can create any other private classes required by all instances of the application.

**Application instance data**

In PenPoint, objects that are instances of the same class share the same code. For example, if there are two insertion pads visible on the screen, they are both running the same copy of the insertion pad class code, but each instance of the insertion pad has different instance data.

As soon as your application has data that can be different for each of its documents, your application needs to maintain instance data.

What do you save in instance data?

The most common use of instance data is to save identifiers for objects created by your application. The PenPoint object-data model suggests that any time you have data, you should use a class to maintain that data.
When your application class has instance data, it must be prepared to respond to 
\texttt{msgInit} by initializing values in the instance data (if needed).

\section*{Creating stateful objects}

Stateful objects contain data that must be preserved when a document is not active.

You can do some interesting things with an application that uses only the behavior 
provided by the Application Framework. However, soon after you start developing 
an application, you will want the application to be able to save and restore data 
when the user turns away from and turns back to its documents. To save and restore 
documents, you need to create, save, and restore stateful objects.

Usually an application’s instance data contains some stateful objects and some non­
stateful objects.

If your application class has stateful objects, you must be prepared to handle:

\begin{itemize}
  \item \texttt{msgAppInit} by creating and initializing the stateful objects required by 
        a new document. Your application can create additional stateful objects 
        later.
  \item \texttt{msgSave} by saving all stateful objects to a resource file.
  \item \texttt{msgRestore} by restoring all stateful objects from a resource file.
\end{itemize}

\section*{Displaying on screen}

Most applications need to display themselves on screen. The PenPoint Application 
Framework provides access to the screen by creating a frame object.

When your application receives \texttt{msgAppOpen}, it should create the remaining non­
stateful objects that it needs to display on screen, and then should display itself in 
the frame provided by the application framework.

When your application receives \texttt{msgAppClose}, it should remove itself from the 
frame and destroy all of its nonstateful objects.

\section*{Creating component classes}

If you create new component classes that can be shared by a number of different 
applications (or other components), you usually define the component classes in 
a DLL file.

As an application executable file must have a function named \texttt{main()}, a DLL file 
must have a function named \texttt{DLLMain()}. \texttt{DLLMain()} creates the component 
classes defined in the DLL.

\section*{Development cycles}

The compile, install, test, and debug cycle in PenPoint is similar to the develop­
ment cycle for most other operating systems. This section briefly describes the steps 
involved in the development cycle. Later sections cover these steps in greater detail.
Compiling and linking

There are several types of files used to compile and link PenPoint applications. These files include:
- The make file.
- The application's method table files.
- The application's C source and header files.
- The PenPoint SDK header and library files.

Method table files

You create a method table file to equate the messages handled by your class to a function defined in your source. You create one method table per class, but one method table file can contain several method tables.

You compile the method table and then compile the resulting intermediate object file with the PenPoint method table compiler, MT. This produces:
- A header file that you use when you compile your C source.
- An object file that you use when you link your application.

C source and header files

PenPoint applications are written in the C language; the object-oriented extensions are provided through standard C function calls. The source for each class (application or component) is maintained in a separate file.

Following normal C programming practice, it is advisable to define your symbols, structures, macros, and external declarations in one or more header (.H) files.

PenPoint SDK files

The PenPoint SDK header and library files are in the directories PENPOINT\SDK\INC and PENPOINT\SDK\LIB, respectively.

You should include these directories in your compiler and linker search paths.

Installing the application

One difference between PenPoint and most other operating systems is that once you have compiled an application, you must install the application into PenPoint before you can use it. There is no “run” command in PenPoint, so you must use the Notebook to transfer control to the application.

Additionally, all application code in PenPoint is shared. PenPoint must know where your application code is installed so that all instances of your application use the same code.
There are two ways to install an application into PenPoint:

- Install when you boot PenPoint.
- Install explicitly with the PenPoint application installer.

You can install an application when you boot PenPoint by adding your application’s PenPoint name to your PENPOINT\SDK\BOOT\locale\APP.INI file (where locale is USA for United States English and JPN for Japanese).

You can explicitly install a PenPoint application by running the PenPoint application installer (found in the Connections and Settings notebooks).

You can use the Connections notebook to tell PenPoint to display the installable applications (or any other installable items) whenever a volume becomes available.

**Debugging**

There are a number of tools available to you to aid in debugging. Among them are:

- Using Debug() or DPrintf() statements to send text to the debugger stream. You can use a second monitor or the system log application to view the debugger stream. You can also save the debugger stream in a log file. The Debug() and DPrintf() statements are described later in this Chapter. The system log application is described in *PenPoint Development Tools*.

- Using the PenPoint source debugger (DB) to debug your application. The debugger is described in *PenPoint Development Tools*.

- Handling msgDump. msgDump requests an object to format its instance data and send it to the debugger stream. While developing an application, you can send msgDump to any object whose state is questionable. From the PenPoint source debugger, you can use the od command to send msgDump to an object. It is not a good idea to send msgDump in production code.

**A developer’s checklist**

When your PenPoint application does what you want it to, you can stop and move on to your next project. However, PenPoint applications are far more useable when they can interact with the PenPoint operating system and other applications. There is such a wealth of interaction that it is easy to omit some behavior from your application.

This section presents two checklists. The first checklist details all the interactions that you should include in your PenPoint application, starting at the fundamental Application Framework interactions. The second checklist lists the interactions that you should consider adding to your application to improve its appearance or usability.
Checklist of required interactions

You should use this checklist to ensure that your application is complete. The items in the checklist point to parts of this manual and the PenPoint Architectural Reference where the item is described in detail.

- Handle application class installation (in main() when processCount equals 0).
  - Create the application class.
  - Create any private classes used by the application class.
- Handle application object instantiation (in main() when processCount is greater than 0).
  - Create an instance of your class.
  - Create any private classes required by an instance of your application class.
  - Create any other objects required at the time.
- Create and display windows.
  - Insert yourself into frame on msgAppOpen.
  - Remove yourself from frame on msgAppClose.
- Handle application termination.
  - Respond to msgFree protocol.
- Handle application deactivation or deinstallation (msgAppTerminate).
- Handle msgDump.
- Handle msgSave.
  - Save data.
  - Save objects.
- Handle msgRestore.
  - Restore data.
  - Restore objects.
  - Observe objects.
- Handle input.
- Handle selection protocol.
- Respond to Printing messages.

Checklist of nonessential items

Use this checklist to ensure that you have considered all possible nonessential additions to your application. The items in the checklist point to parts of this manual and the PenPoint Architectural Reference where the item is described in detail.

- Add menus to SAMs.
- Handle Option sheet protocols.
  - Create an option sheet.
  - Create application-specific option cards.
- Allow Application Embedding.
- Respond to move/copy protocol.
- Handle document import and export.
- Handle Undo.
- Respond to traversal protocols.
- Define document icons.
- Create Stationery.
- Create Help notebook files.
- Create Quick Help Resources.

**GO's coding conventions**

At GO, we have developed techniques to make PenPoint code easier to write, understand, debug, and port. Some of our techniques are stylistic conventions, such as how variable and function names should be capitalized. Others fall under the category of extensions to C, including a suite of basic data types that are compiler and architecture independent. This section describes:

- The conventions that GO code follows.
- The global types, macros, constants, and constructions provided in PenPoint.
- PenPoint's global debugging macros and other functions that we have found useful to diagnose program errors.

While we would be delighted for you to follow all of our conventions, we obviously do not expect every developer to do so. Conventions are a matter of taste, and you should follow a style that is comfortable to you. However, we do recommend that you make use of our extensions. They will help make your code easier to debug and port. Also, by describing our style, we hope to make it easier for you to understand our header files and sample code.

**Typedefs**

All typedefs are CAPITALIZED and use the underscore character to separate words.

```c
typedef unsigned short U16;
typedef U16 TBL_ROW_COUNT;
```  
Pointer types have the prefix P_.

```c
typedef unsigned short U16, * P_U16;
typedef TBL_ROW_COUNT *P_TBL_ROW_COUNT;
```  
In structure definitions, the name of the structure type is also the structure tag.

```c
typedef struct LIST_ENTRY {
    U16 position;
    LIST_ITEM item;
} LIST_ENTRY, *P_LIST_ENTRY;
```  
The tag name is used by the PenPoint source-level debugger.
Variables
Variable names are mixed case, always starting with a lowercase letter, with capitalization used to distinguish words. Variable names do not normally include underscore characters.

```c
U16 numButtons;
```

Pointer variable names are prefixed with a lowercase `p`. The letter following the `p` is capitalized.

```c
P_U16 pColorMap;
```

Functions
Functions are mixed case, always starting with a capital letter, with capitalization used to distinguish words. Function names do not normally include underscore characters.

Function names often use a Noun-Verb style. The verb is what the function does, the noun is the target of the function’s action.

```c
TilePopUp(); PenStrokeRetrace();
```

However, the `main()` function is simply `main()`.

Defines (macros and constants)
Defines follow the same capitalization rules as variables and functions. Macros follow the rules for function names (mixed-case, first letter uppercase) and constants follow the rules for variable names (mixed-case, first letter lowercase).

```c
#define OutRange(v, l, h) ((v) < (l) || (v) > (h))
#define maxNameLength 32
#define nameBufLength (maxNameLength+1)
```

Class manager constants
You use several special kinds of constants when writing Class Manager code:

- **Class names**
- **Well-known objects**
- **Messages**
- **Status values**

Class names
Class names start with “cls” followed by the name of the class: `clsList`, `clsScrollBar`, and so on.

Well-known objects
Pre-existing objects in PenPoint to which you can send messages have the prefix “the”: `theRootWindow`, `theSystemPreferences`, and so on.
Messages

Messages follow the standard style for constants, but have special prefix “msg”. This is followed by the name of the class that defines the message (possibly abbreviated) and finally by the action requested by the message: msgListRemoveItem, msgAddrBookChanged, and so on.

The exceptions to this rule are the basic clsObject messages, including msgNew, msgSave, and msgFree, which apply to all classes. These basic messages do not identify their class.

Status values

Like messages, status values follow the standard style for constants. However, all status values start with the prefix sts. This is followed by the name of the class that defines the status value (possibly abbreviated) and finally by a description of the status: stsListEmpty and stsListFull.

For more information on the way unique messages and status values are constructed for a class, please refer to Part 1: Class Manager of the PenPoint Architectural Reference.

Exported names

At GO, we use prefixes to indicate the architectural subsystem or component that defines an exported variable, define, type, or function. Prefixes help lower the possibility of name conflicts across PenPoint. They also help developers find which files contain the relevant source code.

Note that fields within exported structures are not prefixed, and locals within sample code source files are generally not prefixed either.

For example, exported System Service names are all prefaced with OS:

```c
#define osNumPriorities 51
#define osDefaultPriority 0
typedef U16 OS_INTERRUPT_ID; // logical interrupt ID
STATUS EXPORTED OSProgramInstall (  
P_CHAR pCommandLine, // d11 or exe name (and arguments)
P_CHAR pWorkingDir, // working dir of the program
P_OS_PROG_HANDLE pProgHandle, // Out: program handle
P_CHAR pBadName,  // Out: If error, d11/exe that was bad
P_CHAR pBadRef   // Out: If error, reference that was bad
); 
```

The file PENPOINT\SDK\UTIL\TAGS\TAGS lists most of the exported names in PenPoint. You can scan it to see if a particular prefix is used.

The standard global include file PENPOINT\SDK\INC\GO.H does not prefix its identifiers—if something is common across PenPoint, such as the U16 type, it is not prefixed in any way.
PenPoint file structure

At GO, we follow a similar structure for both header files and source code files. The general structure of a header file is shown below:

```cpp
file header comment
#includes
#define
typedefs
global variables
function prototypes
message headers
```

Here is the general format of the source code file for a class implementation:

```cpp
file header comment
#define
typedefs
global variables
internal functions
exported functions
"methods" implementing messages
class initialization function
main() function (for application classes)
```

File header comment

The file header comment contains a brief description of the contents of the file. It also includes the revision number of the header file. If you have a problem using a PenPoint API, the revision level of the software is important information.

Include directives

The include directives all follow the file header and are of the form:

```cpp
#include <incfile.h>
```

Note that the filename for the include file does not contain any directory information. To locate include files, you specify an include path externally (either in the INCLUDE system variable or as a compiler flag).

Multiple inclusion

PenPoint has many subsystems, each linked to other subsystems. Each element tends to have its own header file(s). Consequently, including the header file for one subsystem leads to it including dozens of other subsystems. Often the same header files are included by other header files. This can slow down compiling and may lead to errors if header files are compiled in more than once.

All PenPoint header files guard against being included multiple times by defining a unique string (FILENAME_INCLUDED) and checking to see if this string has been defined:

```cpp
/* ******************************************
filename.h
(C) Copyright 1991, GO Corporation, All Rights Reserved.
Include file format.
*/
```
#ifndef FILENAME_INCLUDED
#define FILENAME_INCLUDED

// defines, types, and so on of header file
#endif // FILENAME_INCLUDED

where FILENAME is the name of the include file itself.

You can speed up compiling by putting the same checks in your files to avoid reading even the first few lines of a header file a second time:

#ifndef LIST_INCLUDED
#include <list.h>
#endif // LIST_INCLUDED

Common header files

In a class implementation, if you include the header file of your immediate ancestor, this will usually include the header files of all your ancestors.

If you include any header file at all, you will not need to include <GO.H>.

Defines, types, globals

This section of a file holds all of the #defines, typedefs, and global and static declarations used only in this file. By grouping these items in one place, you will be able to find them more easily.

Function prototypes

Function prototypes in header files indicate the parameters and format of PenPoint functions. Each is preceded by a comment header:

/***************************************************************************/
Function returns TYPE
   Brief description.
   Comments, remarks.
*/
function declaration;

For example:

/*******************************************************************************/
OSHeapBlockSize returns STATUS
   Passes back the size of the heap block.
   The size of the heap block is the actual size of the block. This may
   be slightly larger than the requested size.
See Also
   OSHeapBlockAlloc
   OSHeapBlockResize
*/
STATUS EXPORTED OSHeapBlockSize (  
P_UNKNOWN pHeapBlock,     // pointer to the heap block
   P_SIZEOF pSize      // Out: size of the heap block
);

The header file descriptions of functions provide a “reminder” facility, not a tutorial.
**Message headers**

Many header files contain message headers, which are where messages are described and where their constants and related data structures are defined. Message headers have the following format:

```c
/************************************************************
************
msgXxxAction takes STRUC_TURE, returns STATUS
   category: message use
   Brief description.
   Comments, remarks.
*/
define msgXxxAction MakeMsg(clsXxx, 1)
typedef struct STRUC_TURE {
   ...
} STRUC_TURE, *P_STRUC_TURE;
```

For example:

```c
/************************************************************
************
msgAddrBookGetMetrics takes P_ADDR_BOOK_METRICS, returns STATUS.
   Passes back the metrics for the address book.
*/
define msgAddrBookGetMetrics MakeMsg(clsAddressBook, 8)
typedef struct ADDR_BOOK_METRICS {
   U16 numEntries;  // Total number of entries
   U16 numServices; // Number of known services
   U16 numGroups;   // Number of groups in the address book
   U32 spare1;
   U32 spare2;
} ADDR_BOOK_METRICS, *P_ADDR_BOOK_METRICS;
```

We relied on the regular format of message descriptions in header files to generate the datasheets for messages in the *PenPoint API Reference*.

**In, out, and in-out**

In a message header, you can assume that all parameters and message arguments are input-only (In) unless otherwise specified (Out or In-Out).

**Indentation**

Most PenPoint header files use four spaces per tab for indentation. Most programmer's editors allow you to adjust tab spacing; setting it to four will make it easier to read GO files.

**Comments**

In general, slash-asterisk C comments (/* and */) indicate the start and end of functional areas, and slash C (//) comments are used for in-line comments within functions.

**Some coding suggestions**

Here are some of the other conventions that GO code follows (more or less):

- Always include the default case in your switch statements to explicitly show that you are aware of what happens when the switch fails.
PenPoint types and macros

In developing PenPoint, we found it useful to establish a “base” environment that goes beyond the structures and macros provided by the C language. This section describes many of these extensions. For a complete list, please look at PENPOINT\SDK\INC\GO.H, where all of our extensions are defined.

Data types

To allow for portability between different C compilers and processors, we define six basic data types that directly indicate their size in bits. Three are signed: S8, S16, and S32. The others are unsigned: U8, U16, and U32. We also define corresponding pointers for each, prefixed with P_, and pointers to pointers, which are prefixed with PP_.

To plan for internationalization efforts, we provide the CHAR data type. CHAR is functionally equivalent to char and is defined to be a U8 in PenPoint 1.0. In PenPoint 2.0 Japanese, which includes support for international character sets, we’ve changed CHAR to U16. Simply stated, you should use CHAR instead of char to ensure an easier transition to PenPoint 2.0 Japanese.
CHAR has two related data types: P_CHAR, which represents a pointer to a character, and PP_CHAR, which is a pointer to a string.

P_UNKNOWN is for uninterpreted pointers, that is, pointers that you do not dereference and about which code makes no assumptions.

P_PROC is for pointers to functions. It assumes the Pascal calling convention.

The SIZEOF type is for the sizes of C structures returned by sizeof.

The status values returned by many functions are of type STATUS. This is a signed 32-bit value, although most subsystems encode status values to indicate the class defining the error to avoid status value conflicts. “Return values” on page 80 describes status values in greater detail.

Basic constants

Use the enumerated type BOOLEAN for logical values true and false. The BOOLEAN type also defines the values True, False, TRUE, and FALSE to preempt any discussion about capitalization rules.

Similarly, null is the preferred spelling for null (0), but NULL is also defined. pNull is a null pointer.

minS8, maxS8, minS16, maxS16, minS32, and maxS32 are the minimum and maximum integer values for the three signed types. maxU8, maxU16, and maxU32 are the maximum values of the three unsigned types. Obviously, the minimum unsigned value is zero.

Names in many PenPoint subsystems can be no longer than 32 characters. This limit is defined as maxNameLength. Since strings are normally null-terminated, we define nameBufLength to be maxNameLength + 1.

Legibility

GO.H defines AND, OR, NOT, and MOD to be the corresponding C logical “punctuation;” this avoids confusion with the double-character bit operators & & and II.

Compiler isolation

GO.H provides macros and other #defines that you can use to ensure compiler independence.

Function qualifiers

GO.H introduces a layer in between the special function qualifier keywords, such as STATIC, by providing uppercase versions of all these keywords.

Using the uppercase versions allow you to easily remove or redefine these keywords in source code if necessary. This allows you, for example, to experiment with changing the calling sequences of your code to check for errors or changes.

It’s important to explicitly specify calling conventions in your function prototypes so that code can compile with a different set of compiler switches from GO’s defaults, yet still observe the protocol requirements.
STATIC, LOCAL, and GLOBAL are compiler #defines that support the appearance (if not the reality) of modular programming.

**Enumerated values**

Some compilers base the size of an enum value on the fields in that enum. This has unfortunate side effects if an enum is saved as instance data; programs compiled under different compilers might read or write different amounts of data, based on the size of the enum as they perceive it.

To guarantee that an enum is a fixed size, use the Enum16() and Enum32() macros. These macros create enums that are 16 and 32 bits long, respectively. The macros expect a single argument—the name of the enum to be defined.

Within an Enum16() or Enum32(), use the bit flags (flag0 through flag31, also defined in GO.H) to define enumerated bits.

Most PenPoint header files indicate when bits in an enum can be ORed to specify several flags. If a PenPoint header file uses the flag0-style bit flags, assume that you can OR these flags.

**Data conversion and checking**

Abs(), Even(), and Odd() are macros that perform comparisons, returning a boolean. Max and Min return the larger and lesser of two numbers, respectively.

OutOfRange() and InRange() check whether a value falls within a specified range. They work with any numeric data type.

Be careful when using the Abs(), Min(), Max(), OutRange(), and InRange() macros because their parameters are evaluated multiple times. If a function call is used as an argument, multiple calls to the function will be made to evaluate the macro.

**Bit manipulation**

GO.H defines each bit as flag0 through flag31, with flag0 being the least-significant (rightmost) bit.

LowU16(), HighU16(), LowU8(), and HighU8() extract words and bytes by casting and logical shifts. MakeU16() and MakeU32() assemble words and 32-bit quantities out of 8-bit and 16-bit quantities.

FlagOn() and FlagOff() check whether a particular flag (bit) is set or reset. FlagSet() and FlagClr() set a particular flag. All four can take a combination of flags ORed together. You can use these bit manipulation macros with U8, U16, or U32 data types.
Tags

There are several types of values passed around or otherwise shared among subsystems and applications in PenPoint:

- Class names
- Messages
- Return values
- Window tags

All of these are 32-bit constants (U32). As you develop code and classes, you will define your own. It is vital that they not conflict, so GO provides a tag mechanism to guarantee unique names for them. GO administers a number space in which every developer can reserve a unique set of numbers. A tag is simply a 32-bit constant associated with an administered number. With each administered number you can define 256 different tags: because the administered numbers are unique, so will be the tags.

You usually use your classes’ administered number to define messages, status values, and window tags, since these are all usually associated with a particular class. See Part 1: Class Manager of the PenPoint Architectural Reference for an explanation of how classes, tags, and administered numbers relate to each other.

Return values

Most PenPoint code returns error and feedback information by returning special values from functions rather than generating exceptions. PenPoint still uses exceptions for certain types of errors: GP fault, divide by 0, and so on. Otherwise, functions that return success or failure must return a status value. Status values are 32-bit tags, defined in GO.H:

```c
typedef S32 STATUS, * P_STATUS;
```

The universal status value defined to mean “all is well” is stsOK. By convention, return values less than stsOK denote errors, while return values greater than stsOK indicate that the function did not fail, but may not have completed in the usual way.

There is a set of GO standard status values that you can use in different situations (described below), but usually each subsystem needs to define its own specific status values. To guarantee uniqueness among status values returned by third-party software, group your status values by class, even if the status does not come from a class-based component. GO administers well-known numbers for classes, as explained above in “Tags.”

Defining status values

GO.H defines a macro, MakeStatus(wkn, sts), to make a 32-bit error status value from a well-known 32-bit identifier and an error number. Usually, the well-known number is the class that defines the error.
To make a status value that does not indicate an error, use `MakeWarning(cls, msg)`, which creates a positive tag.

So, if you want to define status values, all you need is a reserved class. GO can allocate one for you. You can then define up to 256 error status values and 255 success status values, using `MakeStatus()` and `MakeWarning()` with numbers in the range 0–255. If you need more status values, you can request another class UID.

**Pseudoclasses for status values**

Since not everything in the PenPoint API is a message-based interface to an object-oriented class, there are several pseudoclasses defined solely to provide “classes” for status values from some subsystems: `clsGO`, `clsOS`, `clsGoMath`, and so on. You can ask GO for your own pseudoclasses for error codes if necessary.

**Testing returned status values**

To test a STATUS value for the occurrence of an error, just test whether the value is less than `stsOK`. To test for one specific error, compare the value to the full error code from the appropriate header file. There are macros to assist in this, described in “Error-handling macros” on page 82.

There are a small number of system-wide error/status conditions. You can return a generic status value instead of defining your own, so long as you use it consistently with its definition. If you need to convey a slightly different sense, define your own context-specific status value.

Here are the generic status values. Their “class” identifier is the pseudo-class `clsGO`.

### Generic status values

<table>
<thead>
<tr>
<th>Status value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>stsOK</code></td>
<td>Everything’s fine.</td>
</tr>
<tr>
<td><code>stsBadParam</code></td>
<td>One or more parameters to a function call or message are invalid.</td>
</tr>
<tr>
<td><code>stsNoMatch</code></td>
<td>A lookup function or message was unable to locate the desired item.</td>
</tr>
<tr>
<td><code>stsEndOfData</code></td>
<td>Reached the end of the data.</td>
</tr>
<tr>
<td><code>stsFailed</code></td>
<td>Generic failure.</td>
</tr>
<tr>
<td><code>stsTimeOut</code></td>
<td>A time-out occurred before the requested operation completed.</td>
</tr>
<tr>
<td><code>stsRequestNotSupported</code></td>
<td>The message is not supported.</td>
</tr>
<tr>
<td><code>stsReadOnly</code></td>
<td>The target can’t be modified.</td>
</tr>
<tr>
<td><code>stsIncompatibleVersions</code></td>
<td>The message has a different version than the recipient.</td>
</tr>
<tr>
<td><code>stsNotYetImplemented</code></td>
<td>The message is not yet fully implemented.</td>
</tr>
<tr>
<td><code>stsOutOfMem</code></td>
<td>The system has run out of memory.</td>
</tr>
</tbody>
</table>

**Non-error status values**

<table>
<thead>
<tr>
<th>Status value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>stsRequestDenied</code></td>
<td>The recipient decided not to perform the operation.</td>
</tr>
<tr>
<td><code>stsRequestForward</code></td>
<td>The recipient asks the caller to forward the request to some other object.</td>
</tr>
<tr>
<td><code>stsTruncatedData</code></td>
<td>The request was satisfied, but not all the expected data has been passed back.</td>
</tr>
</tbody>
</table>
The macro StsOK() returns true if the status returned by an expression is greater than or equal to stsOK. If you want to check for any status other than stsOK, use StsFailed(). See "Error-Handling Macros," below.

Return status debugging function

The function StsWarn() evaluates any expression that returns a STATUS. If you do not set the DEBUG preprocessor variable during compilation, StsWarn() is defined to be the expression itself—a no-op. This means that whenever you call a function that returns a status value, you can use StsWarn().

If DEBUG is defined, and the expression evaluates to an error (less than stsOK), then StsWarn() prints the status value returned by the expression together with the file and line number where StsWarn() was called (the special compiler keywords _FILE_ and _LINE_).

Human-readable status values

You can load tables of symbol names in the Class Manager so that if you have set DEBUG, the above functions will print out a string for status return values, instead of a number. For an example of this, see the S_TTT.C file of the Tic-Tac-Toe sample program in Part 7: Sample Code.

Error-handling macros

Every PenPoint function or message returns a STATUS that you should check. The following status macros make function checking much easier by handling typical approaches to handling errors.

Status-checking macros

<table>
<thead>
<tr>
<th>Error handling approach</th>
<th>Macro</th>
</tr>
</thead>
<tbody>
<tr>
<td>Check for an error (no warning)</td>
<td>StsChk()</td>
</tr>
<tr>
<td>Check for an error and warn</td>
<td>StsFailed()</td>
</tr>
<tr>
<td>Return if result is an error</td>
<td>StsRet()</td>
</tr>
<tr>
<td>Jump to an error handler if result is an error</td>
<td>StsJmp()</td>
</tr>
<tr>
<td>Check that the result is not an error</td>
<td>StsOK()</td>
</tr>
</tbody>
</table>

The Class Manager defines similar macros for checking the status values returned when sending a message.

Each status value checker works with any expression that evaluates to a STATUS. Each takes the expression and a variable to assign the status to. All of these macros (except StsChk()) call StsWarn(), so that they print out a warning message if you set the DEBUG preprocessor variable during compilation.

Since often one function calls another which also returns STATUS, using these macros consistently will give a "stack trace" indicating the site of the error and the nested set of functions which produced the error.

The examples below assume that MyFunc() returns STATUS.
**StsChk(se, s)**

Checks for an error.

- **Description** Sets the STATUS s to the result of evaluating se. If s is less than stsOK, returns true, otherwise returns false. Does not print out a warning message.

- **Example**
  ```c
  STATUS s;
  if (StsChk(MyFunc(param1, param2), s)) {
    // MyFunc() failed
  }
  ```

**StsFailed(se, s)**

Checks for an error.

- **Description** Sets the STATUS s to the result of evaluating se. If s is anything other than stsOK, returns true and prints an error if DEBUG is set. If s is stsOK, returns false.

- **Example**
  ```c
  STATUS s;
  if (StsFailed(MyFunc(param1, param2), s)) {
    // MyFunc() returned other than stsOK, so check status
    switch (Cls(s)) {
      ...
    } else {
      // MyFunc() did the expected thing, so continue
    }
  }
  ```

- **Remarks** This is analogous to StsOK(), but it reverses the sense of the test in order to be more consistent with other checking macros.

**StsJmp(se, s, label)**

Jump to label on error.

- **Description** Sets the STATUS s to se. If s is less than stsOK, it prints an error if DEBUG is set and does a goto to label. This is useful when you have a sequence of operations, any of which can fail, each having its own clean-up code.

- **Example**
  ```c
  STATUS s;
  pMem1 = allocate some memory;
  StsJmp(MyFunc(param1, param2), s, Error1);
  pMem2 = allocate some more memory;
  StsJmp(MyFunc(param1, param2), s, Error2);
  ...
  return stsOK;
  Error2:
    // Handle error 2.
    OSHetHeapBlockFree(pMem2);
  Error1:
    // Handle error 1.
    OSHetHeapBlockFree(pMem1);
    return s;
  ```
StsOK(se, s)

Checks that things are OK.

- **Description**  Sets the STATUS s to the result of evaluating se. If s is greater than stsOK, returns true. Otherwise, prints an error if DEBUG is set and returns.

- **Example**
  ```
  STATUS s;
  if (StsOK(MyFunc(param1, param2), s)) {
    // MyFunc() succeeded, continue.
  } else {
    // MyFunc() failed, check status.
    switch (Cls(s)) {
      ...
    }
  }
  ```

- **Remarks**  This is analogous to StsFailed(), but reverses the sense of the test and returns true for any status value that is not an error. In other words, this could return true, but the status might be some other value than stsOK, such as stsNoMatch.

StsRet(se, s)

Returns status on error.

- **Description**  Sets the STATUS s to se. If s is less than stsOK, prints an error if DEBUG is set and returns s. This is useful if one function calls another and should immediately fail if the second function fails.

- **Example**
  ```
  STATUS s;
  ...
  // If MyFunc has problems, return.
  StsRet(MyFunc(param1, param2), s);
  ```

Debugging assistance

GO has developed a set of useful functions and macros to assist in debugging PenPoint applications. They are no substitute for DB, the PenPoint Source-level debugger, or the PenPoint mini-debugger (both these debuggers are documented in *PenPoint Development Tools*). However, they help you trace the operation of a program without using a debugger. They are an elaboration of the time-honored technique of inserting printf() lines in your code.

Printing debugging strings

DPrintf() and Debug() print text to the debugger stream. They take a formatting string and optional parameters to display, in the same manner as as the standard C function printf(). The only difference between DPrintf() and Debug() is that Debug() supplies a trailing newline (if you want a newline at the end of DPrintf() output, end it with \n).

```
Debugf("Entering init method for clsApp");
Debugf("main: process count = %d", processCount);
```
**Debugger stream**

The debugger stream is a pseudo-device to which programs (including PenPoint) can write debugging information. There are several ways to view the debugger stream:

- If you have a single screen, you can see the most recent lines written to the debugger stream when you press Pause.

- If you have a second (monochrome) monitor, serial terminal, or PC running communications software, you can constantly watch the debugger stream on this monitor while you run PenPoint on the main (VGA) monitor.

You can send the debugger stream to a log file, by setting the D debugger flag to the hexadecimal value 8000. Usually you do this in the ENVIRON.INI file, but you can also do it from the PenPoint symbolic debugger, or from the mini-debugger.

```
DebugSet=/DD8000
DebugLog=\boot\tmp\run3.log
```

- You can use the System Log application to view the debugger stream while running a PenPoint application.

None of these destinations are mutually exclusive.

**Assertions**

Often when working on functions called by other functions, you assume that the software is in a certain state. The ASSERT() macro lets you state these assumptions, and if DEBUG is set, it checks to see that they are in fact the case. If they are not satisfied, it will print an error. For example, a square root function might rely on never being called with a negative number:

```c
void MySqRoot(int num) {
    ASSERT(num >= 0, "MySqRoot: input parameter is negative!");
    // Calculate square root...
}
```

The test is only performed if DEBUG is defined.

**Debugging flags**

At different times you want to print different debugging information, or you want your program to work a certain way. DEBUG is the common #define used by PenPoint to include debugging output; if you set DEBUG when compiling, the status-checking macros print out additional information, the ASSERT() macro is enabled, and so on. You can use your own C preprocessor directives to get finer control over program behavior, for example:

```c
OBJECT myDc
#ifdef MYDEBUG1
    // Dump DC state
    ObjectCall(msgDump, myDc, Nil(P_ARGS));
#endif
```

The disadvantage of this technique is that you must recompile your program to enable or disable this code.
Another approach is to check the value of a flag in your code. PenPoint supports 256 global debugging flag sets. Each flag set is a 32-bit value, which means that you can assign at least 32 different meanings to each debugging flag set.

Because there are 256 debug flag sets, they can be indexed by an 8-bit character. Commonly, we refer to a specific debugging flag set by the character that indexes that flag. GO has reserved all the uppercase character debug flags sets (A through Z), and has reserved some of the lowercase characters also. To find which debug flag sets are available, see the file PENPOINT\SDK\INC\DEBUG.H.

You can set the value of a flag set, and retrieve it. The typical way you use debugging flag sets is to set the value of a flag set before running a program, and in the program check to see which bits in the flag set are on. The function DbgFlagGet() returns the state of a flag set ANDed with a mask.

For example, if you were using the flag F in your program and were checking the third bit in it to see whether or not to dump an object, the code above would be:

```c
if (DbgFlagGet('F', 0x0004)) {
    // Dump DC state
    ObjectCall(msgDump, mydc, Nil(P_ARGS));
}
```

You only need to compile your program once, and you can turn on object dumping by changing the F flag set to 0x4 (or 0x8, or 0xF004, and so on). The disadvantage of this is that the flag-testing code is compiled into your program, increasing its size slightly. Often programmers bracket the entire DbgFlagGet() test within a Dbg() macro so that the flag-testing code is only compiled while in the testing version of their program.

### Setting debugging flag sets
There are several ways to set debugging flag sets. Note that there is a single set of these flags shared by all processes.

- In PENPOINT\BOOT\ENVIRON.INI, set the flag to the desired bit pattern with:
  
  ```ini
  DebugSet=/DFnnnn/DFmmmm ...
  ```

  where F and f are letters that identify a particular flag set and nnnn and mmmm are a hexadecimal values. For example, DebugSet=/DFE004.

- By typing fs F nnnn in either the PenPoint source-level debugger or the PenPoint mini debugger.

- By using DbgFlagSet() in a program, for example:

  ```c
  DbgFlagSet('F', 0xE004).
  ```

### Suggestions

#### Isolate debugging messages

In general, always isolate all debugging code using preprocessor directives:

```c
#ifdef DEBUG
    Debugf(U_L("Debugging output string"))
#endif
```
DEBUG is the conventional flag for debugging code, used by much of PenPoint. If you have a short statement that you want to isolate for debugging purposes, you can use the Dbg() macro, which has the effect of using the preprocessor directives shown above:

\[
\text{Dbg(Debugf(U_L("Debugging output string")))}
\]

\textbf{Use the status-checking macros}

Using the status-checking macros StsOK(), StsJump(), and so on, and their counterparts for sending messages may seem cumbersome, but they provide useful debugging information if DEBUG is defined. Also, since most functions and message sends return the error status if they encounter an error, the “stack” of status prints provides a traceback showing where the error first occurred and who called it.

This status error listing shows the result of sending msgDrwCtxSetWindow to objNull:

\[
\begin{align*}
\text{ObjectCall: sts=stsBadObject "tttview.c".0232 task=0x05d8} \\
\text{object=objNull} \\
\text{msg=msgDrwCtxSetWindow, pArgs=26ec0438} \\
\text{StatusWarn: sts=stsBadObject "tttview.c".0330 task=0x05d8} \\
\text{StatusWarn: sts=stsBadObject "tttview.c".0743 task=0x05d8} \\
\text{Page fault in task 05D8 at IB:440CCD52. Error code = 0004.} \\
\text{EAX=00000000 EBX=04000002 ECX=E002E5CF EDX=440CCD05 ESI=41BC8EFO EDI=4401EC38} \\
\text{EIP=440CCD52 EBP=004329EO ESP=004329CC FLG=00010246 CR2=0000000C CR3=00077000} \\
\text{CS=001B DS=002B ES=002B FS=0000 GS=0000 TSS=05D8 TNAME=TIC1}
\end{align*}
\]

\textbf{Use the debuggers}

If your code crashes unexpectedly, you can use the PenPoint mini-debugger to get a stack trace at the assembly-language level (type st at its > prompt). The linker’s .MAP files enable you to translate assembly language addresses to functions and line numbers.

If you suspect that your code is going to crash or behave improperly, run it from the PenPoint source-level debugger. This lets you step through your code, query and set values, and evaluate simple C expressions.

Both debuggers are described in \textit{PenPoint Development Tools}.

\textbf{The tutorial programs}

Now that you’ve read the broad overview of PenPoint and its class-based applications, views, and objects, you are ready to get down to some of the nuts and bolts of writing an application. This section describes the remaining chapters in this book and the sample programs used in those chapters. The programs are:

- Empty Application
- Hello World (toolkit)
- Hello World (custom window)
- Counter Application
- Tic-Tac-Toe
- Template Application
Chapter 6, A Simple Application (Empty Application), explains how to compile and run programs using Empty Application. The chapter is quite long because it teaches the general development cycle:

- How to compile an application.
- How to install an application on a PC or PenPoint computer.
- How to run an application.
- Some interesting things to look for when running any application.
- How to use some of the PenPoint debugging tools.

The Empty Application is used to illustrate these steps, but the comments are applicable to all the other sample applications.

**Empty Application**

The tutorial starts off with an extremely simple application, Empty Application. Chapter 6 explains how to build and run it and how the application works. Empty Application has no view, no data, and no application-specific behavior (apart from printing a debugging message). It only responds to one message from the Application Framework. However, it does create an application class (as all PenPoint applications must), and through inheritance from clsApp, you can create, open, float, zoom, close, rename, file, embed, and destroy Empty Application documents.

**Hello World (Toolkit)**

The next application is the traditional “Hello World” application. This prints Hello World! in its window. Rather than creating a window from scratch, this uses the existing User Interface Toolkit components. One of these is clsLabel, which displays a string. Hello World (toolkit) uses this existing class instead of creating its own. The components in the UI Toolkit are rich in features; for example, labels can scale their text to fit. If you can use a toolkit class, do so.

Hello World (toolkit) is described more fully in Chapter 7, Creating Objects (Hello World: Toolkit).
**Hello World (Custom Window)**

Of course it is possible to draw text and graphics yourself. Hello World (custom window) draws the text Hello World in its window, and draws a stylized exclamation mark beside it. To do this, the application must create a separate window class and create a system drawing context to draw in its window, which is substantially harder than using toolkit components.

Hello World (custom window) is described in Chapter 8.

**Counter Application**

Counter Application displays the value of a counter object in a label. It creates a separate counter class and interacts with it. The application has a menu created from UI Toolkit components that lets the user choose whether to display the counter value in decimal, hexadecimal, or octal.

Both the application and the counter object must file state. The tutorial programs presented before Counter Application are not stateful, that is, they don’t have data that the user can change permanently. Realistic applications must allow users to change things, so they must file their state.

The application object uses a memory-mapped file to keep track of its state. Using a memory-mapped file avoids duplicating data in both the memory file system in program memory. By contrast, the counter object writes its value to a file when it is saved.

The counter application is described in Chapter 9.

**Tic-Tac-Toe**

The rest of the tutorial develops a “real” working application, Tic-Tac-Toe. This application is covered in Chapters 10 and 11.

Tic-Tac-Toe presents a tic-tac-toe board and lets the user write Xs and Os on it. It is not a true computerized game—the user does not play tic-tac-toe against the computer. Instead, it assumes that there are two users who want to play the game against each other.

Although a tic-tac-toe game is not exactly a typical notebook application, Tic-Tac-Toe has many of the characteristics of a full-blown PenPoint application. It has a graphical interface, handwritten input, keyboard input, gesture support, use of the notebook metaphor, selection, data import and export, option cards, undo support, stationery, help text, and so on.
Template Application

As its name implies, Template Application is a template, "cookie cutter" application. As such, it does not exhibit much functionality. However, it does handle many "typical" application messages. This aspect makes Template Application a good starting point for building a real application.

Other code available

Other source code is provided in the SDK in addition to the tutorial code.

All the source to sample programs is on-disk in PENPOINT\SDK\SAMPLE. Some of the other sample programs are described in Appendix A, Sample Code. Excerpts from sample programs also appear and are described in those parts of the PenPoint Architectural Reference that cover related subsystems.
Chapter 6 / A Simple Application (Empty Application)

Applications written for many operating systems have to perform housekeeping functions by implementing their own boilerplate code; that is, code that is essentially the same from one application to the next. In the PenPoint™ operating system, the PenPoint Application Framework performs most of these housekeeping functions. By using the Application Framework, you can create an application that can be installed, that can create multiple instances of itself, that can handle page turns, floats and zooms, and that can display an option sheet, all without writing an additional line of code.

Empty Application is a very simple application. Like all PenPoint applications, Empty Application is a subclass of clsApp, so Empty Application inherits all of the Application Framework behavior. The only additional code in Empty Application is a method that responds to msgDestroy by sending a message to the debug stream (when the program is compiled with the DEBUG preprocessor#define name).

The PenPoint Application Framework is responsible for everything else Empty Application does. Because the Application Framework handles so much of an application's interaction with the system, even such an insubstantial application has substantial functionality.

Files used

The code for Empty Application is in PENPOINT\SDK\SAMPLE\EMPTYAPP. There are three files in the directory:

- EMPTYAPP.C Contains the application class's code and initialization routine.
- METHODS.TBL Contains the list of messages that the application class responds to and the associated message handlers to call.
- MAKEFILE Contains rules that tell the make utility how to build Empty Application.

There is also a text file file called README.TXT that describes Empty Application, but the README.TXT file is not required to compile and link the application.

Not the simplest

The name Empty Application is not quite accurate, because it isn't totally empty. You could create an application with no method table at all; that is, one that responds to no messages at all and relies entirely on methods inherited from clsApp. Empty Application handles one message by printing a string to the debug stream, so it needs a method table.
Compiling and linking the code

The source code for sample applications is in subdirectories of \PENPOINT\SDK\SAMPLE. Each subdirectory contains a “makefile” that tells the make utility how to build the application. All you need to do to compile and link Empty Application is make \PENPOINT\SDK\SAMPLE\EMPTYAPP the current directory and start the make utility, but you need to understand what the files are doing so that you can later modify the makefiles to fit your needs.

These sections describe the actual commands used to compile, link, and stamp EMPTYAPP.

Compiling method tables

You compile method tables into an object file by running them through the PenPoint method table compiler (in \PENPOINT\SDK\UTIL\CLSMGR\MT.EXE).

By convention, method tables have the suffix .TBL. The control files that the make utility uses include a default rule for compiling method tables. MT produces an object file and a header file for the method table. You use these files when you compile and link the application.

Installing and running Empty Application

As described in the “How applications work” on page 24, you must install an application in PenPoint before you can run it. To install Empty Application, you either install it at boot time or use the Settings notebook on a running PenPoint system. The Application Installer is described in Using PenPoint.

To install the application at boot time:

- Add a line that says \BOOT\PENPOINT\APP\Empty Application to \PENPOINT\BOOT\locale\APP.INI (where locale is USA or JPN).
- Boot PenPoint on your PC.
- When the Notebook appears, draw a caret in the TOC to insert an Empty Application document in the Notebook.

When you create an Empty Application document in the Notebook, PenPoint creates a directory for the document in the application hierarchy (that’s why it shows up in the table of contents), but it’s only when you turn to the document’s page that a process for the document is activated. Until then the document isn’t running and doesn’t have a process or a valid clsEmptyApp object.

Interesting things you can do with Empty Application

Although Empty Application doesn’t do any useful work, you can learn a lot about the operation of PenPoint by studying it. PenPoint provides a host of features and support to even the simplest application. You can try the following:
Interesting things you can do with Empty Application

- Create multiple instances (documents) of it. The PenPoint file system appends a number to each document to guarantee a unique application directory name in the application hierarchy. You create documents by performing one of these actions:
  - Choose Empty Application from the Create menu in the Notebook contents page.
  - Choose Empty Application from the pop-up menu that appears when you draw a caret on the contents page.
  - Use the Stationery notebook to create Empty Application documents in the Notebook.
  - Tap and hold on the title bar or name of an Empty Application document in the TOC to make a copy of an existing document. Drag the icon that appears to where you want it to go, such as on the icon bookshelf, or elsewhere in the TOC.
  - Tap the Accessories icon in the bookshelf below the Notebook and tap the Empty Application icon in its window.

- Float a Notebook Empty Application document by turning to the Notebook’s table of contents and double-tapping on its page number (you must first enable floating in the Float & Zoom section of PenPoint Preferences). Compare the difference between an accessory and a floating document—accessories have no page number.

- Zoom a floating Empty Application by flicking upwards on its title bar (you must first enable zooming in the Float & Zoom section of PenPoint Preferences).

- Display the properties of an Empty Application document by drawing a check mark in its title bar. An option sheet for the document appears, with several cards in it for the document’s appearance.

- In the table of contents, press and hold on a Empty Application title until a dashed line appears around it. You can now move the document around. Try moving it to another place in the Notebook.

- Give the Empty Application document a tab in the notebook by writing a “T” in its title bar. You can use the tab to navigate to the Empty Application document quickly.

- Give the Empty Application document a corkboard margin by writing a “C” in its title bar. A thick strip appears at the bottom of its window.

- As you turn the pages, note the sequence of messages sent to each instance of clsEmptyApp by the PenPoint Application Framework.

- Select an Empty Application document in the table of contents, then use the disk viewer to open a directory on your hard disk. Copy the document to the hard disk. Then delete the document by drawing a cross out over it.
Set the G debugger flag to 1000 in PENPOINT\BOOT\ENVIRON.INI (or set the flag with the fs mini-debugger command). This turns on debugging info for reading and writing resources in clsResFile. This is the class that files objects during msgAppSave processing.

Select an Empty Application document in the TOC and move it by pressing and holding on its title. Move it inside another open document. If the other application supports it, the PenPoint Application Framework will embed the Empty Application document inside the other.

**Code run-through**

Enough details of running Empty Application; now let's look at its C code. First we'll look at the layout of PenPoint source files.

**PenPoint source code file organization**

Most source code in PenPoint has a similar structure. Although Empty Application is a very simple application, it has a similar layout to other applications.

Remember that application programs have at least one class (the application class itself), so an application program is composed of at least these two files:

- The **method table** that specifies the messages to which this class responds and the functions that handle those messages.
• The C source code for the class.

The organization of the C source code is described in the sections below.

Method table file

The method table file lists all the messages that the class handles. The PenPoint Class Manager sends any messages not listed in the method table to the class’s ancestor for handling (and possibly to the ancestor’s ancestor). Looking at a class’s method table gives you a good feel for what the class does.

The method table file always has the suffix .TBL. It looks like C code, but you process it with the method table compiler MT before linking it into your program.

A single method table file can have method tables for several different classes. The names of the method tables are usually pretty self-explanatory, typically the name of the class with the word Methods appended. For example, Empty Application’s class is clsEmptyApp, and Empty Application’s method table is clsEmptyAppMethods.

Although the normal practice is to define a method for each message, you can use the wild-card feature of method tables to have one method handle several messages. Method table wild cards match any message within a given set of messages, and call the associated method. Method table wild cards are described in Part 1: Class Manager of the PenPoint Architectural Reference.

Application C code file

By convention, an application source code file is usually organized into the following sections:

• #include directives for the header files required by the application.
• #defines and typedefs.
• Utility routines.
• Message handlers.
• Class initialization routine.
• main() entry point.

The application’s main() routine is at the end of the source file. The operating system calls the application’s main() routine under two circumstances:

• When installing the application (this happens only once).
• When activating individual documents (this happens each time the user turns to or floats a document that uses the application).

The C files for nonapplication classes don’t have main() routines, because only applications actually start C processes. The declaration for the main() routine is:

main (argc, argv, processCount)

The argc and argv parameters are not used in PenPoint. PenPoint uses the processCount parameter to pass in the number of processes running this application.

When processCount is 0, there are no other processes running this application; this
indicates that PenPoint is installing the application. Once an application is installed, the process that has a processCount of 0 stays in memory until the application is deinstalled.

On installation, main() initializes the application class, by calling an initialization routine. This routine precedes main() in the source file. Standard practice is to name this routine using the name of the application class (with an initial capital letter), followed by “Init”. For example, the initialization routine for clsEmptyApp is ClsEmptyAppInit().

When the initialization routine creates the application class, it specifies the method table used by the application class.

In the method table, you establish a relationship between the messages that your class handles and the name of a function in your C code file that handles each message. These functions are called message handlers and are similar to the “methods” of other object-oriented systems. Message handlers should be local static routines that return STATUS. If your class does handle a message, the method table also indicates whether the Class Manager should call your class's ancestor before or after (if at all).

**Message handler parameters**

Because the Class Manager calls your message handlers, you don’t get to choose message handler parameters. The arguments passed to all message handlers are:

- **msg**  The message itself.
- **self**  The object that received the message.
- **pArgs**  The message argument. This 32-bit value can be either a single argument or a pointer to a structure containing a number of arguments.
- **ctx**   A context maintained by the Class Manager.
- **pData**  The instance data of self.

Because the parameters to message handlers are always the same, PENPOINT\SDK\ INC\CLSMGR.H defines several macros to generate standard message handler declarations. The `MsgHandler()` macro generates a message handler declaration based on the name of the function. The `MsgHandlerWithTypes()` macro generates a message handler declaration based on the name of the function and the types to which to cast its arguments.

**Empty Application's source code**

This section presents an overview of Empty Application's method table and C source code.
**Method table**

The method table file, METHODS.TBL, specifies that Empty Application has one message handler; clsEmptyApp handles msgDestroy in a function called EmptyAppDestroy().

```c
MSG_INFO clsEmptyAppMethods[] = {
  #ifdef DEBUG
  msgDestroy, "EmptyAppDestroy", objCallAncestorAfter,
  #endif
  0
};
```

The `#ifdef` and `#endif` statements cause the message handler to be defined only when you specify `/DDEBUG` in the compiler options.

**C source code**

There are three significant parts of EMPTYAPP.C:

- The `main()` routine, which handles application installation and application startup.
- The initialization routine, which is invoked by `main()` at installation time.
- The message handler for `msgDestroy`, which was specified in the method table.

This section presents this code without further comment. Subsequent sections in this chapter examine the code in detail.

The `main()` routine for EMPTYAPP.C is:

```c
/*********************************
main

Main application entry point (as a PROCESS -- the app's MsgProc is where messages show up once an instance is running).
***********************************/
void CDECL main(
  S32 argv,
  CHAR * argv[],
  U32 processCount)
{
  Dbg(Debugf(U_L("main: starting emptyapp.exe[%d]"), processCount));
  if (processCount == 0) {
    // Create application class.
    CclsEmptyAppInit();
    // Invoke app monitor to install this application.
    AppMonitorMain(clsEmptyApp, objNull);
  } else {
    // Create an application instance and dispatch messages.
    AppMain();
  }
  // Suppress compiler's "unused parameter" warnings
  Unused(argc); Unused(argv);
} /* main */
```
The initialization routine invoked by main() on installation is:

```c
STATUS ClsEmptyAppInit (void)
{
    APP_MGR_NEW new;
    STATUS s;
    // // Install the Empty App class as a descendant of clsApp.
    // // ObjCallWarn (msgNewDefaults, clsAppMgr, &new);
    // new.cls.object.uid = clsEmptyApp;
    // new.cls.pMsg = clsEmptyAppTable;
    // new.cls.ancestor = clsApp;
    // // This class has no instance data, so its size is zero.
    // new.cls.size = Nil(SIZEOF);
    // // This class has no msgNew arguments of its own.
    // new.cls.newArgsSize = SizeOf(APP_NEW);
    new.appMgr.flags.accessory = true;
    Ustrcpy(new.appMgr.company, U_L("GO Corporation"));
    Ustrcpy(new.appMgr.defaultDocName, U_L("Empty App Document"));
    ObjCallJump(msgNew, clsAppMgr, &new, s, Error);
    // // Turn on message tracing if flag is set.
    // // if (DbgFlagGet('F', OxlL)) {
    // Debugf(U_L("Turning on message tracing for clsEmptyApp"));
    // (void) ObjCallWarn(msgTrace, clsEmptyApp, (P_ARGS) true);
    // }
    return stsOK;
    Error:
    return s;
}
```

Finally, the message handler for msgDestroy is:

```c
EmptyAppDestroy
{
    if (defined DEBUG)
        Debugf(U_L("EmptyApp: app instance %p about to die!"), self);
    // // The Class Manager will pass the message onto the ancestor
    // // if we return a non-error status value.
    // // return stsOK;
    MsgHandlerParametersNoWarning; // suppress compiler warnings
}
```
Libraries and header files

You interact with most of PenPoint by sending messages to objects. Thus a typical application only uses a few functions and only needs to be linked with APP.LIB and PENPOINT.LIB. However, you need to pick up the definitions of all the messages you send, status values you check, and objects to which you send messages from their respective header files.

Because Empty Application only looks for CLSMGR.H and APP.H messages, it only needs to include a few header files from PENPOINT\SDK\INC:

<table>
<thead>
<tr>
<th>Header file</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>GO.H</td>
<td>Fundamental constants and utility macros in PenPoint.</td>
</tr>
<tr>
<td>OS.H</td>
<td>Operating system constants and macros.</td>
</tr>
<tr>
<td>DEBUG.H</td>
<td>Functions and macros to put debugging statements in your code.</td>
</tr>
<tr>
<td>APP.H</td>
<td>Messages defined by clsApp.</td>
</tr>
</tbody>
</table>
| APPMGR.H      | msgNew arguments of clsAppMgr used when an application class is created.
| CLSMGR.H      | Functions and macros that provide PenPoint’s object-oriented extensions to C. |

Class UID

To write even the simplest application you must create your own application class, so that’s primarily what Empty Application does.

Your application needs to have a well-known UID (unique identifier, the “handle” on a Class Manager object) so the system can start it. All well-known UIDs contain a value that is administered by GO—this keeps them unique. When you finalize your application, you must obtain a unique administered value from GO. Contact GO Customer Services at 1-415-358-2040 (or by Internet electronic mail at gocustomer@go.com) for information on how to get a unique administered value. Until you get an administered value for your application, you can use the pre-defined well-known UIDs that are set aside for testing. These test UIDs, wknGDTa through wknGDTg, are defined in PENPOINT\SDK\INC\UID.H for this purpose. Just define your class to be one of them:

```
#define clsMyClass wknGDTa
```

This is the approach that Empty Application takes. However, most other sample applications use well-known UIDs assigned to them by GO. Because most applications aren’t part of the PenPoint API, these well-known UIDs don’t show up in PENPOINT\SDK\INC\UID.H.

You can use local well-known UIDs instead of global well-known UIDs for classes that your application uses internally. These do not contain an administered value; however, you must ensure that they remain unique within your application.

Be on the lookout for conflicts with other test software when using the well-known testing UIDs (wknGDTa through wknGDTg). If another application happens to use the same well-known testing UID for one of its classes, you will have problems installing your application because it has the same UID as another class.
**Class creation**

The initialization routine ClsEmptyAppInit() creates the clsEmptyApp class. It should look familiar to you from the discussion of classes in Chapter 3, Application Concepts. However, application classes are slightly different from other classes. You create most classes by sending msgNew to clsClass, whereas you create application classes by sending msgNew to clsAppMgr.

```c
STATUS ClsEmptyAppInit (void)
{
    APP_MGR_NEW new;
    STATUS s;
    // Install the Empty App class as a descendant of clsApp.
    // ObjCallWarn (msgNewDefaults, clsAppMgr, &new);
    new.object.uid = clsEmptyApp;
    Ustrcpy(new.appMgr.defaultDocName, U_L("Empty App Document"));
    ObjCallJmp(msgNew, clsAppMgr, &new, s, Error);
}
```

**clsAppMgr explained**

The PenPoint Application Framework needs to know a lot of things about an application before it can set in motion the machinery to create an instance of the application. It needs to know:

- Whether the application supports embedding child applications.
- Whether the application saves its data or runs continuously ("hot mode").
- Whether the application's documents appear as stationery or accessories.
- The icon to use for the application's documents.
- The default name for the application's documents.

Instances of the application class can't provide this information because the PenPoint Application Framework needs this information before it creates an application instance. To solve this cleanly, application classes are not instances of clsClass, but instead are instances of clsAppMgr, the application manager class. When an application is installed, its clsAppMgr instance is initialized, and this instance can supply the needed information.

```c
new.cls.newArgsSize = SizeOf(APP_NEW);
new.appMgr.flags.accessory = true;
Ustrcpy(new.appMgr.company, U_L("GO Corporation"));
Ustrcpy(new.appMgr.defaultDocName, U_L("Empty App Document"));
ObjCallJmp(msgNew, clsAppMgr, &new, s, Error);
```

Application classes should be well known so that other processes can send messages to them. Otherwise, the Notebook would not be able to send messages to your application class to create new documents when the user chooses it from the Create menu. You supply the UID for your application class in the msgNew arguments.

**Tip** It is better to specify the company name, default document name, and other locale-dependent information in the USA.RES or JPN.RES file. This helps when porting your application to other locales.
Where does the application class come from?

The `cls.pMsg` argument to `msgNew` establishes the connection between the new class and its method table. More on this later.

**Documents, accessories and stationery**

We have been referring to all copies of an application as documents. Not all documents in the system live on a page in the Notebook. Tools such as the clock and the personal dictionary float above the Notebook.

If you set `appMgr.flags.accessory` to true, `clsAppMgr` will put your application in the Accessories palette. When the user taps on your application's document icon, `clsApp` will insert the new document on screen as a floating document. If you set `appMgr.flags.stationery` to true, `clsAppMgr` will put a blank instance of your application in the Stationery notebook (whether or not your application has custom stationery). When the user selects and copies the stationery document from the Stationery palette, `clsApp` will insert the new document in the Notebook.

**Where does the application class come from?**

The connection between a process running in PenPoint and an application class is not immediately obvious. You're probably wondering who calls the initialization routine for `clsEmptyApp`, who sends `msgNew` to create a new Empty Application instance, what process corresponds to this application instance, and why the familiar-looking C `main()` routine doesn't do very much.

**Installation and activation**

The connection between an application class and a PenPoint process is an application's `main()` routine. Every executable must have a `main()` routine; it is the routine that PenPoint calls when it creates a new process running your application's executable image.

```c
void CDECL main (S32 argc, CHAR * argv[], U32 processCount)
{
    Dbg(Debugf(U_L("main: starting emptyapp.exe[%d]")), processCount);
}
```

The kernel keeps track of the number of processes running a particular program, and passes this to `main()` as a parameter (`processCount`). For applications, there are two points at which PenPoint does this: **application installation** and **document activation**.
Application installation occurs when the user or APPINI installs the application; that is, when PenPoint loads the application from disk into memory. No application documents are active at this point, but the code is present on the PenPoint computer.

Document activation occurs every time the user starts up a document that uses the application, typically by turning to its page.

When the user creates a document in the Notebook's TOC, PenPoint does not execute the application code, it merely creates a directory for the document in the application hierarchy. Try it: while turned to the TOC, create a new Empty Application document. The Debug() statement in main() does not print out anything until you turn to the document.

In MS-DOS, loading and executing code are part of the same operation; on a PenPoint computer, installing an application, creating documents for that application, and executing application code are three separate operations.

On MS-DOS, quitting an application is an action under the control of the user. In PenPoint, when the user turns away from a document, PenPoint determines whether it should destroy the application process or not. PenPoint does not keep running processes around for every application on every page, so it destroys processes that aren't active (thereby destroying application objects).

PenPoint starts and destroys application processes without the user's knowledge and, ideally, without any effect apparent to the user.

\section*{A simple discussion of main()}

When an application is installed, PenPoint creates a process and calls the application's main() to run in the process. At this time, this is the only copy of the application running on the machine; thus, processCount contains the value 0. During installation, you should create your application class and any other classes you need. You then call AppMonitorMain(), which handles application installation, import, copying stationery and resources, and so on. Empty Application doesn't take explicit advantage of any of these features, but other programs do.

```c
if (processCount == 0) {
  // Create application class.
  ClsEmptyAppInit();
  // Invoke app monitor to install this application.
  AppMonitorMain(clsEmptyApp, objNull);
} else {
  ...
```

The process that PenPoint created at application installation keeps on running until PenPoint deactivates or deinstalls the application. Therefore, all subsequent processes that run the application's code will have processCount values greater than 0.

When a document is activated (typically by the user turning to its page), PenPoint calls main() (processCount is greater than zero). At this point you should call the PenPoint Application Framework routine AppMain(). This creates an instance of
your application class and starts dispatching messages to it (and other objects created by the application) so that the new instance can receive Class Manager messages:

```cpp
if (processCount == 0) {
    ...
} else {
    // Create an application instance and dispatch messages.
    AppMain();
}
// Suppress compiler's "unused parameter" warnings
Unused(argc); Unused(argv);
} /* main */
```

Most applications follow these simple steps and have a `main()` routine similar to the one in `EMPTYAPP.C`.

**A complex explanation of `main()`**

The following paragraphs explain the process interactions taking place around `main()`. Read on if you really want to understand how application start-up works.

Installation occurs when PenPoint reads `PENPOINT\BOOT\APP.INI` (and `SYSAPP.INI`) and when the user installs applications using the Installed Applications page of the Settings notebook. PenPoint or the Settings notebook calls the System Services routine `OSProgramInstall()`, which loads the executable code for your application (`EMPTYAPP.EXE`) into a special area of PenPoint memory called the loader database. `OSProgramInstall()` also creates a new PenPoint process and calls the function `main()` with `processCount` equal to 0. At this point your code should initialize any information that all instances will need, such as its application class and any other nonsystem classes required by your application. The one thing every Empty Application instance needs is `clsEmptyApp` itself, hence when the `main()` routine in `EMPTYAPP.C` is called with `processCount` of 0, it creates `clsEmptyApp`.

**Application installation**

The process that PenPoint creates when `processCount` equals 0 also manages other application functions that are not specific to an individual document. These functions include copying stationery during installation, de-installation, file import, and so on. Rather than saddle your application with all these responsibilities, the PenPoint Application Framework provides a class, `clsAppMonitor`, which provides the correct default behavior for all these functions. When you call `AppMonitorMain()` it creates one of these objects and dispatches messages to it. If your application needs to do more sophisticated installation (shared dictionaries, configuration, and so on), or can support file import, you can subclass `clsAppMonitor` and have a custom application installation manager.

Activation occurs in an indirect fashion when the user chooses Empty Application from the Tools notebook or the Stationery notebook. The Notebook or Bookshelf application sends `msgAppCreateChild` to the current selection. When `clsApp` receives this message, it creates a new slot in the application hierarchy for the new document. But a process and an application object aren't created until needed. The
document may not be activated until the user turns to the document's page, or otherwise needs to interact with it.

**Activating an application**

At or before the point where a live application instance is needed, the PenPoint Application Framework sends the application’s parent `msgAppActivateChild`. While processing this, `clsApp` calls the System Services routine `OSProgramInstantiate()`. `OSProgramInstantiate()` creates a new PenPoint process, and in the context of that process it calls the function `main()` with `processCount` set to a non-zero number.

Finally, there is a running process for an Empty Application document! In theory, you could put any code you want in `main()`, just like an ordinary C program. However, the only way a PenPoint application knows what to do—when to initialize, when it’s about to go on-screen, when to file, and so on—is by messages sent to its application object. So, the first and only thing you need to do in `main()` when `processCount` is non-zero is to create an instance of your application class and then go into a dispatch loop to receive messages. This is what the `AppMain()` call does. `AppMain()` does not return until the user turns away from the document and the application instance can be terminated.

**Handling a message**

`clsEmptyApp` only responds to one message. That doesn't mean that Empty Application documents don't receive messages—if you turned on tracing while running Empty Application, you'll have seen the dozens of messages that an Empty Application application instance receives during a page turn. It means only that `clsEmptyApp` lets its ancestor take care of all messages except one, and it turns out that `clsApp` does an excellent job of handling PenPoint Application Framework messages.

A real application or other class has to intercept some messages, otherwise it has the same behavior as its parent class. In the case of an application class, the application needs to respond to PenPoint Application Framework messages that tell documents when to start up, when to restore themselves from the file system, when they are about to go on-screen, and so on. If the application has standard application menus (SAMs), it will receive messages such as `msgAppPrint`, `msgAppPrintSetup`, and `msgAppAbout`, from the buttons in the menus.

Often, the class responds to these messages by creating, destroying, or filing other objects used by the application. `EMPTYPAGE.C` doesn't do any of this; all it does is print a string when it receives one particular message, `msgDestroy`.

**Method table**

Objects of your classes (especially application instances) receive lots of messages regardless of whether or not you want your class to deal with those messages. Your class's method table tells the Class Manager which messages your class intercepts.
This code sample is from Empty Application's method table file (METHODS.TBL):

```c
#ifndef CLSMGR_INCLUDED
#include <clsmgr.h>
#endif

MSG_INFO clsEmptyAppMethods [] = {
    #ifdef DEBUG
    msgDestroy, "EmptyAppDestroy", objCallAncestorAfter,
    #endif
    0
};

CLASS_INFO classInfo[] = {
    "clsEmptyAppTable", clsEmptyAppMethods, 0,
    0
};
```

This basically says "If an instance of clsEmptyApp receives msgDestroy, call EmptyAppDestroy(), then pass the message to clsEmptyApp's ancestor."

The link between the functions in a method table and a particular class is established by one of the msgNew arguments when you create the class (new.cls.pMsg). This is the name you associate with the class's MSG_INFO array in the CLASS_INFO array; in this example, the pMsg is clsEmptyAppTable. This code sample is from ClsEmptyAppInit() in EMPTYAPP.C:

```c
// Install the Empty App class as a descendant of clsApp.
//
ObjCallWarn (msgNewDefaults, clsAppMgr, &new);
new.object.uid = clsEmptyApp;
new.cls.pMsg = clsEmptyAppTable;
new.cls.ancestor = clsApp;
...```

**msgDestroy**

The names of most messages identify the class that defined them: for example, msgAppOpen is defined by clsApp. Messages defined by the Class Manager itself are the exception to this convention. msgDestroy is defined by the Class Manager in PENPOINT\SDK\INC\CLSMGR.H; this is why Empty Application's METHODS.TBL includes this header file. The Class Manager responds to msgDestroy by destroying the object that received msgDestroy.

**Message handler**

The message handler (also known as a method) is just a C routine you write that does something in response to the message. Empty Application's message handler for msgDestroy is EmptyAppDestroy(), which just prints a string to the debugger stream.

The name you give the message handler must match the name you specified in the method table (EmptyAppDestroy()).
Parameters

The parameters that the Class Manager passes to a message handler are:

- **msg**: The message received by the instance.
- **self**: The UID of the instance that received the message.
- **pArgs**: The message arguments passed along with the message by the sender of the message.
- **ctx**: A context that helps the Class Manager keep track of the class in the instance's hierarchy that is currently processing the message.
- **pData**: A pointer to the **instance data**, information specific to the instance whose format is defined by the class.

Here's the definition from CLSMGR.H:

```c
typedef STATUS (CDECL * P_MSG_HANDLER)(
    MESSAGE msg,
    OBJECT self,
    P_ARGS pArgs,
    CONTEXT ctx,
    P_IDATA pData
);
```

You never call your message handlers, the Class Manager does, and always with the same set of parameters. The PenPoint Method Table Compiler generates a header file containing function prototypes for all the message handlers specified in the message table; you can guard against accidentally leaving out a parameter by including these files in your class implementation C files:

```c
#ifndef APP_INCLUDED
#include <app.h>     // for application messages (and clsmgr.h)
#endif
#ifndef DEBUG_INCLUDED
#include <debug.h>   // for debugging statements.
#endif
#ifndef APPMGR_INCLUDED
#include <appmgr.h>  // for AppMgr startup stuff
#endif
#ifndef INTL_INCLUDED
#include <intl.h>    // for international routines
#endif
#include <methods.h> // method function prototypes generated by MT
#include <string.h>   // for strcpy().
...
```

**MsgHandler()** is a macro that expands into the correct definition of a pointer to a message handler. It saves you typing all these parameters.

```c
MsgHandler(EmptyAppDestroy)
    {
        // Respond to msgDestroy by printing a simple message if in DEBUG mode.
        EmptyAppDestroy();
    }
```
Parameters in EmptyAppDestroy()

It turns out that Empty Application's EmptyAppDestroy() routine doesn't need most of the parameters. The informative string prints out the UID of self (the Empty Application document that received the message) and doesn't use the rest of the parameters.

```c
#ifdef DEBUG
    Debugf(U_L("EmptyApp: app instance %p about to die!"), self);
#endif
```

We aren't interested in the msg, since the Class Manager should only call this function with msgDestroy. clsEmptyApp has no instance data, so we don't need pData. (Remember, we specified that class.size is 0 when we created clsEmptyApp.) Although we don't need these parameters, there is no way to tell the Class Manager not to send them.

The C compiler will warn about unused parameters in functions. Since many message handlers won't use all their parameters, CLSMGR.H defines a fragment of code, MsgHandlerParametersNoWarning, which mentions each parameter. You can stick this in your message handler at any point.

```c
MsgHandlerParametersNoWarning; /* EmptyAppDestroy: // suppress compiler warnings */
```

Status return value

Message handlers are supposed to return a status value. This is important both to indicate to the sender of the message that the message was handled successfully, and to control how the Class Manager passes the message up the class ancestry chain. Empty Application's method table directed the Class Manager to pass msgDestroy to clsEmptyApp's ancestor after calling Empty Application's handler:

```c
msgDestroy, "EmptyAppDestroy", objCallAncestorAfter,
```

If EmptyAppDestroy() were to return an error status value, the Class Manager would not call the ancestor, and the normal result of sending msgDestroy would be pre-empted (the application object would not go away). Sometimes this is what you want, but not in this case, so we return stsOK.

```c
return stsOK;
```

Message handlers are private

Although message handlers are just regular C functions, you normally do not want other code to call your message handlers. One of the goals of object-oriented programming is to hide the implementation of functionality from clients of that functionality. Clients should communicate with your objects by sending them messages, not by calling your functions. That way you can change the names and implementation of a message handler without affecting clients of your API.
Using debugger stream output

There are two main ways to debug programs in PenPoint:

- Send data to the debugger stream.
- Use the PenPoint source-level debugger.

Additionally, you can use the PenPoint mini-debugger, which is part of PenPoint, but is most useful when debugging kernel and device-interface code.

Note that you can't use debugging tools designed to run under DOS because these packages require your executable file to be running under DOS.

This section discusses sending data to the debugger stream. For a complete tutorial on how to use the PenPoint source-level debugger (DB) and mini-debugger (mini­DB), see the part on debugging in PenPoint Development Tools.

The debugger stream

You can send data to the debugger stream with Debugf() and DPrintf() statements in your code. This is much like debugging a DOS application by adding printf() statements to the code.

EMPTYAPP.C uses the system debugging output function Debugf() to print strings to the debug stream (Empty Application doesn't use its PenPoint windows to display anything).

Debugf() is much like the standard C function printf(). The %p formatting code in the format string means “print this out as a 32-bit hexadecimal pointer.” Because UIDs such as self are 32 bits, this is a quick and dirty way to print a UID value. The Class Manager defines routines that convert UIDs to more meaningful values that this application could have used instead; the message tracing and status warning debugging facilities use these fancier output formats.

Seeing debug output

There are several ways to view the information sent to the debugger stream:

- If you press Pause while running PenPoint, your screen will switch from graphics to text display and you will see strings that have been written to the debugger stream.
- If you have a second monitor and do not set monodebug=off in your MIL.INI file, debugger stream data is displayed on the second monitor.
- If you turn on the 8000 bit in the D debug flag, debugging strings will be copied to the file \PENPOINT\LOG on the BootVolume (the directory specified with PenPointPath in ENVIRON.INI).
- You can run the System Log application.

The System Log application is a PenPoint application that allows you to review data sent to the debugger stream. To use it, install it by uncommenting it in SYSAPP.INI or by installing from disk (just as you install any other application in PenPoint).
When the System Log application is installed, it adds its icon to the Accessories window. Tap on the icon to open the application.

Debug strings appear in the System Log application. You can scroll up and down to see its contents.

You can also check flags, see available memory, and set flags from the System Log application. To learn more about the System Log application, see the part on debugging in *PenPoint Development Tools*. 
Chapter 7 / Creating Objects (Hello World: Toolkit)

Although Empty Application shows that the Application Framework can do many things for an application, Empty Application is still rather boring, in that it doesn't contain anything or show anything on screen. This chapter describes how to create objects. It so happens that these objects also display things on screen.

A standard, simple test program is one that prints “Hello World.” With the PenPoint™ operating system, there are two different ways to approach this:

- Use PenPoint’s UI Toolkit to create a standard label that contains the text.
- Create a window and draw text in it using text and drawing services provided by the ImagePoint™ imaging model.

These two styles mirror two general classes of program. Programs such as database programs and forms can use standard user interface components to create dialogs with the user. Programs such as presentation packages and graphics editors do a lot of their own drawing. They need to create a special kind of window and draw in it.

This chapter shows the first approach; the application clsHelloWorld calls on the UI Toolkit to create a label object. The next chapter describes how to create a window and draw in it (and also discusses how to create a new class).

Even programs that do use custom windows will make heavy use of the UI Toolkit. Every application has a menu bar with standard menu buttons, a frame, and at least one option sheet, and most programs will add to these to implement other controls and dialogs with the user.

Moreover, using the UI Toolkit is much simpler than using a window. The toolkit component classes are all descendants of clsWin, the class that supports overlapping windows on the screen (and printer). But they know how and when to draw themselves and file themselves, so there's very little you need to do besides create them and put them in your application's frame.

HelloTK

Hello World (toolkit) uses UI Toolkit components to display the words “Hello World!” These components know how to draw themselves and position themselves. Consequently, it's extremely simple to create the application.

The directory PENPOINT\SDK\SAMPLE\HELLOTK actually contains two different versions of Hello World (toolkit). The first version, HELLOTK1.C, creates a single label in its frame. Usually you want to put several windows in a frame; this is more complex and is handled by HELLOTK2.C.
Compiling and installing the application

Both versions of Hello World (toolkit) (HELLOTK1.C and HELLOTK2.C) have a single C file. Consequently, compiling, downloading, and running it are the same as for Empty Application. Because there are multiple versions of the code, copy the version you want to run as HELLOTK.C before building the application.

This creates a PENPOINT\APP\HELLOTK directory and compiles a HELLOTK.EXE file in it. It uses STAMP to give the directory the long name Hello World (toolkit) and the .EXE the long name Hello World (toolkit).exe.

Install Hello World (toolkit) either by adding \BOOT\PENPOINT\APP\Hello World (toolkit) to PENPOINT\BOOT\locale\APP.INI (where locale is a locale such as JPN or USA) before starting PenPoint or by installing the application using the Installer.

Create Hello World (toolkit) application instances from the Stationery notebook, from the stationery quick menu, or from the Accessory palette.

Interesting things you can do with HelloTK

Alas, Hello World (toolkit) doesn't do much more than Empty Application besides display a label. It doesn't do anything less, so you can create multiple instances of it as accessories or as pages in the Notebook, you can trace messages to it (by setting the F flag to 0x20), and so on.

The only new thing to do is to notice how the label draws itself. Try zooming or resizing a Hello World (toolkit) document.

Code run-through for HELLOTK1.C

HELLOTK1.C creates a single label in its frame.

Highlights of HELLOTK1

The method table for Hello World (toolkit) only responds to one message, msgAppInit.

```c
msgAppInit, "HelloAppInit", objCallAncestorBefore,
```

In order to avoid clashing with other Hello World applications, HELLOTK1.C uses a different well-known UID.

```c
#define clsHelloWorld wknGDTb // avoids clashing with other HelloWorlds
```

Most of the work is done in the message handler `HelloAppInit()`, which responds to msgAppInit by creating the client window (a label).

So that it can use the same method table as HELLOTK2.C, HELLOTK1.C responds to msgAppOpen and msgAppClose as well as msgAppInit; however, it does nothing with these messages but return stsOK.

The only significant thing that happens in Hello World (toolkit) is that it responds to msgAppInit by creating a label. The code to do this is very simple, about 35 lines, but deciding what to do in those few lines introduces several key concepts in PenPoint application development:
• Choosing what classes to use.
• Deciding when to create objects.

It also involves some common programming techniques:
• Creating an instance of a class.
• Sending messages to self.

\section*{Sending messages}

Empty Application receives messages, but does not send messages. Often in responding to a message, your application must send other messages. It might send messages to other objects, or even send itself messages to get its ancestor classes to do things. Hello World (toolkit) shows how to send a few simple messages.

\subsection*{ObjectCall()}

Use \texttt{ObjectCall()} to pass a message to another object in your process. This works like a function call: the thread of control in your application's process continues in the message handler of the other object's class, and returns to your code when the other object's class returns a status value to your code.

There are other ways to send a message:
• Asynchronously
• Using the input queue
• Between processes

In a simple application, stick to \texttt{ObjectCall()}.

\subsection*{Testing return values and debugging}

Because messages return a status value, you should usually check their return values. This would ordinarily lead to lots and lots of constructs in your code, such as the following:

```c
if ((s = ObjectCall(msgXxx, someObject, &args) < stsOK) {
    // Print standard warning if DEBUG set
    // Handle error...
}
```

To save typing and code complexity, for every Class Manager function that returns a status value, there are macro versions of the function that jump to an error handler, or return true if there's an error, etc. For \texttt{ObjectCall()}, these are \texttt{ObjCallWarn()}, \texttt{ObjCallRet()}, \texttt{ObjCallJmp()}, \texttt{ObjCallChk()}, and \texttt{ObjCallOK()}.

The return value of \texttt{ObjCallWarn()} is the status value returned by \texttt{ObjectCall()}. If compiled with the \texttt{DEBUG} preprocessor variable set, then \texttt{ObjCallWarn()} prints out an error string if the status value is an error (that is, less than \texttt{stsOK}).

The other macros incorporate \texttt{ObjCallWarn()} into their behavior:

\texttt{ObjCallRet() Calls ObjCallWarn()} and then returns the status value if it is an error.
**ObjCallImp()**  Calls **ObjCallWarn()** and then jumps to a error label (where you can handle the error) if the status value is an error.

**ObjCallChk()**  Calls **ObjCallWarn()** and then returns the value true if the status value is an error.

**ObjCallOK()**  Calls **ObjCallWarn()** and then returns the value true if the status value is not an error (that is, greater than or equal to **stsOK**).

---

**Creating toolkit components**

HELLOTKI.C responds to **msgAppInit** by creating a **label**. Labels are one of the many components provided by the UI Toolkit. But why does it create this particular kind of component?

**What kind of component?**

It's worth taking a close look at the class hierarchy poster to see all the toolkit classes.

Most of the UI Toolkit classes are windows. **clsWin** implements the standard window behavior of multiple overlapping regions on a pixel device, but **clsWin** does not draw images in a window. The descendants of **clsWin** inherit **clsWin**'s behavior and add the ability to draw images, handle input, and so on. All of the UI toolkit components inherit from **clsBorder**, a special kind of window which knows how to draw a border.

*Tip* Some of the key decisions you make in any object-oriented programming system are choosing which built-in classes to use and which built-in classes to subclass.

**Part 4: UI Toolkit** of the *PenPoint Architectural Reference* explains the UI Toolkit in all its multilevel glory. For a hint of what it can do, Figure 7-1 shows a screen shot with all the different kinds of UI Toolkit components present.

There are many other classes in the UI Toolkit. There are several base classes that provide lower-level functionality. And there are many specialized components classes, such as date handwriting input fields.

For Hello World (toolkit), all we need is a class that can display a string, such as **clsLabel**.

To learn more about a class, you can try to:

- Use the class browser to get a brief description of it and all its messages.
- Read about it in its subsystem's part of the *PenPoint Architectural Reference*.
- Look up its "datasheets" in the *PenPoint API Reference*.
- Look at its header file in PENPOINT\SDK\INC.

The class Browser, the header, and the documentation all give you the information you need to create an instance of the class.

**msgNew arguments for clsLabel**

As you learned in Chapter 3, Application Concepts, you create objects by sending **msgNew** to their class. Different classes allow different kinds of initialization, so you pass different arguments to different classes. The documentation states what
message arguments a given class needs for msgNew. In the header file, the information is expressed as follows:

msgNew takes P_LABEL_NEW, returns STATUS

This says that you should pass in a pointer to a LABEL_NEW structure when you send msgNew to clsLabel. What you typically do is declare a LABEL_NEW structure in the routine which sends msgNew. You can give this any variable name you want; Hello World (toolkit) names it In, the first letter of each part of the structure name. The sample code follows this naming convention consistently.
HelloAppInit

Respond to msgAppInit by creating the client window (a label).

MsgHandler(HelloAppInit)
{
    APP_METRICS     am;
    LABEL_NEW      ln;
    STATUS         s;
}

Before you send msgNew to a class, you must always send msgNewDefaults to that class. This takes the same message arguments as msgNew (a pointer to a LABEL_NEW structure in this case). This gives the class and its ancestors a chance to initialize the structure to the appropriate default values. It saves your code from initializing the dozens of fields in a _NEW structure.

// Create the Hello label window.
ObjCallWarn(msgNewDefaults, clsLabel, &ln);

Note the use of ObjCallWarn() instead of ObjectCall(). As mentioned earlier, ObjCallWarn(), when compiled with DEBUG set, sends a warning message to the debugging output device when it returns a non-zero status value.

Now you’re ready to give values to those fields in the structure that you care about. Figuring out what’s in a _NEW structure is not easy. It contains initialization information for the class you are sending it to, along with initialization information for that class’s ancestor, and for its ancestor’s ancestor, all the way to initialization arguments for clsObject. Sometimes the only initializations you’re interested in are the ones for the class you’ve chosen, but in the case of the UI Toolkit, you often have to reach back and initialize fields for several of the ancestor classes as well.

ln.label.style.scaleUnits = bsUnitsFitWindowProper;
ln.label.style.xAlignment = lsAlignCenter;
ln.label.style.yAlignment = lsAlignCenter;
ln.label.pString = U_L("Hello World!");

You can look up the hierarchy for a class by looking in the PenPoint API Reference section for that class. The description of the _NEW structure for msgNew always gives the _NEW_ONLY structures that make up the _NEW structure. Thus, the hierarchy for clsLabel expands to:

LABEL_NEW {
    OBJECT_NEW_ONLY    object;
    WIN_NEW_ONLY       win;
    GWIN_NEW_ONLY      gWin;
    EMBEDDED_WIN_NEW_ONLY embeddedWin;
    BORDER_NEW_ONLY    border;
    CONTROL_NEW_ONLY   control;
    LABEL_NEW_ONLY     label;
}

When in doubt, rely on msgNewDefaults to set up the appropriate initialization, and modify as little as possible.
All you need to do to create a label is pass `clsLabel` a pointer to a string to give the string a label. However, the `LABEL_STYLE` structure contains various style fields that also let you change the way the label looks.

We want the text to fill the entire window, so the `scaleUnits` field looks promising. This is a bit field in `LABEL_STYLE`, but rather than hard-code numeric values for these in your code, `LABEL.H` defines the possible values it can take. One of these is `bsUnitsFitWindowProper`. This tells `clsLabel` to paint the label so that it fills the window, but keeping the horizontal and vertical scaling the same. Other style fields control the alignment of the text string within the label. In this example, we'd like to center the label.

By the way, one reason that `clsLabel` has so many style settings and other `msgNew` arguments is that many other toolkit components use it to draw their text, either by creating lots of labels or by inheriting from `clsLabel`. Thus `clsLabel` draws the text in tab bars, in fields, in notes, and so on:

```c
// Create the Hello label window.
ObjCallWarn(msgNewDefaults, clsLabel, &In);
In.label.style.scaleUnits = bsUnitsFitWindowProper;
In.label.style.xAlignment = IsAlignCenter;
In.label.style.yAlignment = IsAlignCenter;
In.label.pString = U_L("Hello World!");
ObjCallRet(msgNew, clsLabel, &In, s);
```

Now the label window object exists. The Class Manager passes back its UID in `In.object.uid`. But at this point it doesn't have a parent, so it won't show up on-screen.

**Where the window goes**

Empty Application appeared on-screen even though it didn't create any windows itself. The Application Framework creates a frame for a document. Frames are UI Toolkit components. A frame can include other windows within it. Empty Application's frame has a title bar, page number, and resize boxes; you've seen other applications whose frames also include tab bars, command bars, and menu bars.

Most importantly, a frame can contain a client window, the large central area in a frame. Empty Application didn't supply a client window (hence it looked pretty dull).

Hello World (toolkit) wants the label it creates to be the client window. The message `msgFrameSetClientWin` sets a frame's client window. But the label must have its frame's UID to send a message to its frame. Hello World (toolkit) didn't create the frame, its ancestor `clsApp` did.

`clsApp` does not define a specific message to get the main window. Instead, it provides a message to get diverse information about application instances, including the main window of that application. An application can have a different main window for itself other than a frame.
Information made public about instances of a class is often called metrics, and the message to get this information for an application is msgAppGetMetrics. msgAppGetMetrics takes a pointer to an APP_METRICS structure, one of the fields in the structure is mainWin. Here is how HelloApplnit() gets its main window:

```c
APP_METRICS am;
...
// Get the app’s main window (its frame).
ObjCallJmp(msgAppGetMetrics, self, &am, s, error);

// Insert the label in the frame as its client window.
ObjCallJmp(msgFrameSetClientWin, am.mainWin, (P_ARGS)ln.object.uid, s, error);
```

Note that the code sends msgAppGetMetrics to self. We have been talking loosely about Hello World (toolkit) doing this and that, but remember that this code is run as a result of an instance of clsHelloWorld receiving a message, and that clsHelloWorld is a descendant of clsApp. Thus, the document is the application object to which we want to send msgAppGetMetrics. In the middle of responding to one message (msgApplnit), we need to send a message to the same object that received the message. This is actually very common. The Class Manager provides a parameter to methods, self, which identifies the object that received the message.

**Why msgApplnit?**

Earlier you turned on message tracing to Empty Application. This causes the class manager to dump out every message received by instances of clsEmptyApp. You should have noticed that each Empty Application document receives dozens of messages during the course of a page turn to or from itself. These messages are sent to documents (application instances) by the PenPoint Application Framework.

If you want your application to do something, you must figure out when to do it. Your process can’t take over the machine and do whatever it wants, whenever it wants. It must do what it wants in response to the appropriate messages.

One of the hardest things in PenPoint programming is figuring out when to do things.

So, when should Hello World (toolkit) create its label? Because it inserts the label in its frame (using msgFrameSetClientWin), it can’t create the label before it has a frame. But it should have a label in its frame before it goes on screen.

It turns out that clsApp creates the document’s frame in response to msgApplnit. Thus Hello World (toolkit) can get its frame and insert the label in its msgApplnit handler, but it must do so after clsApp has responded to the message. This is why its method table tells the Class Manager to first send the message to its ancestor:

```c
MSG_INFO clsHelloMethods[] = {
  msgApplnit, "HelloApplnit", objCallAncestorBefore,
  msgAppOpen, "HelloOpen", objCallAncestorAfter,
};
```

Note that doing this relies on knowing what the ancestor class does. You’ll spend a lot of time reading Part 2: Application Framework of the PenPoint Architectural Reference to learn about the PenPoint Application Framework messages and how clsApp responds to them.
Why did the window appear?
If you're familiar with other window systems, you may be wondering how the label gets sized, positioned, and made visible on screen. These will be explained during the development of other tutorial programs. But here's a summary.

When the application is about to go on screen it receives msgAppOpen. clsApp inserts the main window (the frame) in the Notebook's window and tells it to lay out. clsFrame takes care of sizing and positioning its title bar, page number, move box, and client window (the label). Each of these windows is sent a message by the window system to repaint itself when it is exposed on screen. clsLabel responds to the repaint message by painting its label string. Thus all you need to do is put a toolkit window inside your frame, and the system takes care of the rest for you.

Possible enhancements
You can change the class of the window created in HelloAppInit() to be some other kind of window class by changing the class to which Hello World (toolkit) sends msgNewDefaults and msgNew. But different classes take different message arguments when they are created. You need to replace the declaration of a LABEL_NEW structure with the msgNew arguments of the new class.

If the class handling the message expects different arguments, it will blindly read past the end of the structure you passed it, and if it passes back values, it will overwrite random memory. A given class receiving a given message has to be given a pointer to the appropriate structure, otherwise unpredictable results will occur: but it can't enforce this.

There are many classes which inherit from clsLabel, consequently, if you used one of these, you wouldn't even have to change the initialization of the structure. For example, clsField inherits from clsLabel, and FIELD_NEW includes the same NEW_ONLY structures as LABEL_NEW, so it takes the same border and label specifications.

Warning Passing the wrong message arguments with a message is one of the more common errors in PenPoint programming. The C compiler will not catch the error.

Highlights of the second HelloTK
HELLOTK2.C is much like HELLOTK1.C. The big difference is that it supports more than one window. Most applications have many windows within their frame.

You compile and run it the same way. Just copy HELLOTK2.C to HELLOTK.C and follow the steps outlined above.

Only one client window per frame
Frames only support a single client window. But usually you'll want several windows in your application. You have two alternatives:
• Subclass clsFrame (which is very difficult).
• Create a client window, then insert all the windows you want into that client window (which is quite easy).
The toolkit provides two window classes that help you organize the windows within the client window. These are called layout windows. To understand why they're needed, you need to know a little bit about layout.

Layout

When you're using several windows, something is responsible for positioning them on the screen. You can set a window's position and size to some value with msgWinDelta. However, if the user changes the system font size, or resizes the frame, or changes from portrait to landscape mode, the numbers you pick are unlikely to still be appropriate. It's more convenient to specify window locations at an abstract level:

- "I want this window below that one, and extending to the edge of that other one."
- "Position these windows in two columns of equal width."

The UI Toolkit provides two layout classes that support these styles, clsCustomLayout and clsTableLayout. Both are packed with features. Both lay out their own child windows according to the constraints (for custom layout) or algorithm (for table layout) that you specify. The general way of using layout windows is to create one, specify the layout you want, and insert the windows in it.

HELLOTK2.C uses a custom layout window and positions a single label in its center using ClAlign(clCenter, clSameAs, clCenter).

```c
CstmLayoutSpecInit(&(cs.metrics));
cs.child = ln.object.uid;
cs.metrics.x.constraint = ClAlign(clCenterEdge, clSameAs, clCenterEdge);
cs.metrics.y.constraint = ClAlign(clCenterEdge, clSameAs, clCenterEdge);
cs.metrics.w.constraint = clAsIs;
cs.metrics.h.constraint = clAsIs;
ObjCallJmp(msgCstmLayoutSetChildSpec, cn.object.uid, &cs, s, error2);
```

Possible enhancements

You might consider trying to add one of the following to HELLOTK2.C.

Fields

Change the label to be an editable field. There are several ways of handling handwriting in PenPoint. One way is to use a UI component that allows editing, clsField. Since fields have similar behavior to labels (they display a string, have a length, font, and so on), clsField inherits from clsLabel. This makes it easy to update the application: replace the LABEL_NEW structure with FIELD_NEW, and clsLabel with clsField, and recompile. You can now hand-write into the field.

More components

Add some more controls, using different custom layout constraints. You should be able to put together a simple control panel.
**General model of controls**

You specify the **metrics** of each control when you create it, then you insert them in your layout window. The controls lay themselves out, repaint themselves, and support user interaction without any intervention on your part. When the user activates a control, the control sends its client (set in the **msgNew** arguments of **clsControl**, or by **msgControlSetClient**) a notification message.

For more information on controls, see Part 4: **UI Toolkit** of the **PenPoint Architectural Reference**.
Chapter 8 / Creating a New Class (Hello World: Custom Window)

This chapter describes how you create a new class. Along the way, the chapter also describes how to display the string “Hello World!” on screen by creating and drawing in custom windows.

**Hello World (Custom Window)**

Hello World (custom window) creates an instance of a custom window and uses the custom window to display some text.

It’s still not a very realistic application because it doesn’t file any data, but it does use an additional class, a descendant of clsWin, to do its drawing. Your application may be able to use only standard UI components from the UI Toolkit and other PenPoint™ subsystems; but if not, you will create new classes of windows to implement the special behavior you require.

So far, our example applications have been quite simple and have not needed to define their own classes (apart from creating a subclass of clsApp). One of the big advantages in object-oriented programming is that when you do define a class, other applications can create instances of the class (rather than defining new classes on their own).

So that other applications can use the new class, developers often define each class in a single C file and then compile and link one or more C files into a DLL. The C file that contains the application class (and has `main()`) is compiled into an executable file.

To show this coding style, Hello World (custom window) is implemented as an application and a separate DLL. There are two parts to Hello World (custom window): clsHelloWorld (the application class), and clsHelloWin (the window class). HELLO.C implements clsHelloWorld and HELLOWIN.C defines clsHelloWin. HELTBL.TBL contains the method table for clsHelloWorld; HELWTBL.TBL contains the method table for clsHelloWin.

**Compiling the code**

Compiling and linking the Hello World (custom window) executable is somewhat similar to compiling Empty Application. However, Hello World (custom window) is compiled and linked in two parts: an EXE file that contains the application, and a DLL file that contains the class of the client window (clsHelloWin).

You can build Hello World (custom window) by changing the directory to PENPOINT\SDK\SAMPLE\HELLO and running the make utility.
Note that because the application class, `clsHelloWorld`, and its window class are in different files, compiling is more efficient if they have separate method table files (HELTBL.TBL and HELWTBL.TBL).

**Linking DLLs**

When you link DLLs (dynamic link libraries), the information you provide to the linker is slightly different from the information you provide when linking an executable image. In addition to the object code, the linker requires a DLL.LBC file. This file lists all the exported functions defined in the DLL being linked. Usually, PenPoint DLLs only have the single entry point `DLLMain()`. The lines in the DLL.LBC file have the form:

```cpp
++entry_point.'lname'
```

Letter case doesn't matter in the DLL.LBC file.

The **entry-point** is the name of the exported function. In PenPoint, this is `DLLMain()`, the entry point for the DLL. The PenPoint Installer uses the `lname` to identify code modules. An `lname` is composed of a company ID, a project name, and a revision number. The revision number takes the form `Vmajor(minor)`, where `major` is the major revision number and `minor` is the minor revision number.

Thus, for Hello World (custom window), the DLL.LBC file contains the single line:

```cpp
++DLLMAIN.'GO-HELLO_DLL-V2'(0)
```

In this example, the entry point is `DLLMain()` and the `lname` is `GO-HELLO_DLL-V2(0)`. The `lname` indicates that the company is GO, the project is `HELLO_DLL`, and the version is 2(0).

**DLC files**

Because Hello World (custom window) requires that HELLO.DLL be loaded before HELLO.EXE can run, you need to have a HELLO.DLC file in the Hello World (custom window) application directory that expresses the relationship:

```cpp
GO-HELLO_DLL-V2(0) hello.dll
GO-HELLO_EXE-V2(0) hello.exe
```

The PenPoint installer uses this information when installing the Hello World (custom window) application. The first line indicates that the Hello World (custom window) application depends on the DLL file HELLO.DLL, version 2(0). Should this DLL already be loaded, PenPoint will not attempt to load it. The second line tells PenPoint to install the executable file HELLO.EXE.

Because the PenPoint name of the application directory is “Hello World,” the makefile must STAMP the .DLC file with the name “Hello World” so that the Installer will find it.
CHAPTER 8 / CREATING A NEW CLASS (HELLO WORLD: CUSTOM WINDOW)

Highlights of clsHelloWorld

The method table for clsHelloWorld (in HELTBL.TBL) handles two significant messages:
- msgAppOpen, "HelloOpen", objCallAncestorAfter,
- msgAppClose, "HelloClose", objCallAncestorBefore,

The handler for msgAppOpen creates an instance of clsHelloWin and inserts it as the frame's client window.

The handler for msgAppClose destroys the client window.

When processCount is 0, main() calls ClsHelloInit().

Highlights of clsHelloWin

The DLLMain() for clsHelloWin is the only thing defined in DLLINIT.C. The DLLMain() calls ClsHelloWinInit(), the initialization routine for clsHelloWin.

```
STATUS EXPORTED DLLMain (void)
StsRet(ClsHelloWinInit(), s);
```

The method table for clsHelloWin (in HELWTBL.TBL) handles three significant messages:
- msgInit, "HelloWinInit", objCallAncestorBefore,
- msgFree, "HelloWinFree", objCallAncestorAfter,
- msgWinRepaint, "HelloWinRepaint", 0,

clsHelloWin is the first sample application that defines its own instance data (in HELLOWIN.C).

```
typedef struct INSTANCE_DATA {
    SYSDC dc;
} INSTANCE_DATA, *P_INSTANCE_DATA;
```

clsHelloWin responds to msgInit by zeroing the instance data, creating a drawing context, initializing the drawing context, and storing the drawing context in the hello window object's instance data.

The class responds to msgDestroy by destroying the drawing context.

clsHelloWin responds to msgWinRepaint by calculating the text width and scaling the window so that it fits the text.

Graphics overview

To draw in a window you need to create a drawing context object (often abbreviated to DC). You send messages to the drawing context, not your window, to draw.

The drawing context's class knows how to perform these graphics operations. There could be different kinds of drawing contexts to choose from on PenPoint: For example, there might be one available from a third-party company which understands 3-D graphics, or you could create your own.
Part 1 / Application Writing Guide

System drawing context

The standard system drawing context (sometimes abbreviated to sysDC) supports the ImagePoint imaging model. You can draw lines, polygons, ellipses, Bezier curves, and text by sending messages to an instance of the system drawing context.

Each of these graphic operations is affected by the current graphics state of your DC. The system drawing context strokes lines and the borders of figures with the current line pattern, width, end style, and corner style, all of which you can set and get using system drawing context messages. Similarly, it fills figures with the current fill pattern. Most drawing operations involve both stroking and filling a figure, but by adjusting line width and setting patterns to transparent, you can only fill or only stroke a figure.

The pixels of figures on the screen are transformed according to the current rasterOp. This is a mathematical description of how the destination pixels on the screen are affected by the pixels in the source figure. To paint over pixels on the screen, you use the default rasterOp, sysDcRopCopy; another common rasterOp is sysDcRopXOR, which inverts pixels on the screen.

At this writing there are no PenPoint computers that support color, however, the system drawing context supports a full color model. You can set the background and foreground colors (on a black and white display, the resulting colors will always be black, white, or a shade of gray). The line and fill patterns are mixtures of the current foreground and background color, or sysDcInkTransparent.

Because the system drawing context is a normal Class Manager object, you create a new instance of it in the usual way, by sending msgNew to clsSysDrwCtx. Your drawing messages end up on some window on the screen, so at some point you must bind your DC to the desired window using msgDcSetWindow.

Coordinates in drawing context

Another vital property of the system drawing context is its arbitrary coordinate system. You can choose whether one unit in your drawing (as in "draw a line one unit long") is one point, 0.01 mm, 0.001 inch, 1/20 of a point, one pixel on the final device. You can then scale units in both the X and Y direction; one useful scaling is to scale them relative to the height and width of your window. You can even rotate your coordinate system. What this gives you is the precision of knowing that your drawing will be an exact size. It also gives you the freedom to use any coordinate system and scale that suits your drawing. The default coordinates are one unit is one point (approximately 1/72 of an inch), and the origin is in the lower left corner of your window.

Hello World (custom window) uses the default units, but scales its coordinate system so that its text output remains at a regular aspect ratio.

When to paint

Windows need to repaint themselves when they first appear on the screen, when they are resized, and when they are exposed after other windows have covered...
them. Windows receive msgWinRepaint when the window system determines that they need to repaint, and windows must respond to this.

clsHelloWin only paints in response to msgWinRepaint. The way most windows work is that they repaint dirty areas rather than paint new ones. When a window wants to draw something new, it can dirty itself and will receive msgWinRepaint. clsHelloWin has no need to dirty itself since it doesn't change what it paints.

**When to create things**

The need to manage a separate object (a drawing context) introduces two crucial questions you need to consider when designing an application:

- When do I create and destroy an object (or resource)?
- When do I file it, if at all?

An application can create objects at many stages in its life. It can create objects at installation, at initialization (or at restore time), when opening, or when painting its windows. If your application waits until it needs an object before it creates the object, it will use less memory before it creates the object. But creating objects takes time, so you may want to create the object at initialization time, before the user interacts with the application, to reduce the time it takes your application to respond to the user. As is often the case, you must strike a balance between memory and performance.

To decide when to create objects, you need to work backwards from when they are needed. In this case, Hello World only needs a drawing context in its window’s repaint routine. Creating a DC every time you need to repaint is OK, but it is a fairly expensive operation in terms of time. Besides, realistic applications often use a DC in input processing as well, to figure out where the user’s pen is in convenient coordinates. However, we do know that a DC will never be needed when the view doesn’t exist.

clsHello could create the DC and pass it to clsHelloWin, but it’s usually much more straightforward for the object that needs another object to create that object.

Hello World creates its window when it receives msgAppOpen and destroys its window when it receives msgAppClose. These are reasonable times for the window to create its DC, so clsHelloWin creates a DC when it receives msgInit and destroys the DC when it receives msgFree.

**Instance data**

In our example, clsHelloWin creates its DC in advance. This means that it has to store the UID of the DC somewhere so that it can use it during msgWinRepaint. In typical DOS C programs, you can declare static variables to hold information. It is possible to do this in PenPoint, but in general you should not do it in object-oriented code.

Instead, you should store the information inside each object, in its instance data. Up until now our classes have not had to remember state, so they haven’t needed
their own instance data. (Even if the class you create does not define instance data for its objects, its ancestors define some instance data, such as the document name and the label of the toolkit field.)

Specifying instance data is easy. You just tell the Class Manager how big it is (in the class.size field) when you create your class. You would typically define a typedef for the structure of your class's instance data, then give the size of this as the class.size. In the case of clsHelloWin, we define a structure called INSTANCE_DATA:

```c
typedef struct INSTANCE_DATA {
    SYSDC dc;
} INSTANCE_DATA, *P_INSTANCE_DATA;
```

and then in CIsHelloWinlnitO:

```c
STATUS CIsHelloWinInit (void)
{
    CLASS_NEW new;
    STATUS s;
    // Create the class.
    ObjCallWarn(msgNewDefaults, clsClass, &new);
    new.object.uid = clsHelloWin;
    new.cls.pMsg = clsHelloWinTable;
    new.cls.ancestor = clsWin;
    new.cls.size = SizeOf(INSTANCE_DATA);
    new.cls.newArgsSize = SizeOf(HELLO_WIN_NEW);
    ObjCallRet(msgNew, clsClass, &new, s);
}
```

**Is it msgNew or msgInit?**

As we discussed, clsHelloWin creates its DC when it is created. It does this by responding to msgInit.

Note that clsHelloWin responds to msgInit, not msgNew. When you create an object, you send its class msgNew. No classes intercept this message, so it goes up the ancestor chain to clsClass, which creates the new object. The Class Manager then sends msgInit to the newly created object, so that it can initialize itself.

**Window initialization**

Here's the HelloWinlnitO code that creates the Hello Window in response to msgInit:

```c
MsgHandler(HelloWinInit)
{
    SYSDC NEW dn;
    INSTANCE_DATA data;
    SYSDC_FONT_SPEC fs;
    SCALE fontStyle;
    STATUS s;
    clsHelloWinInit declares an instance data structure. It does this because the pointer to instance data passed to message handlers by the Class Manager (pData, unused in this routine) is read-only.
It then initializes the instance data to zero. It's important for instance data to be in a well-known state. This isn't necessary in the case of clsHelloWin, since the only instance data is the DC UID that it will fill in, but it is good programming practice.

```c
// Null the instance data.
memset(&data, 0, SizeOf(data));
```

clsHelloWin then creates a DC:

```c
// Create a dc.
ObjCallRet(msgNewWithDefaults, clsSysDrwCtx, &dn, s);
```

When msgNewWithDefaults returns, it passes back the UID of the new system drawing context. This is what clsHelloWin wants for its instance data:

```c
data.dc = dn.object.uid;
```

clsHelloWin sets the desired DC state (including the line thickness) and binds it to self (the instance that has just been created when HelloWinInit() is called):

```c
// Rounded lines, thickness of zero.
ObjectCall(msgDcSetLineThickness, data.dc, (P_ARGS)0);
if (DbgFlagGet('F', Ox40L)) {
    Dbg(Debugf(U_L("Use a non-zero line thickness.")));
    ObjectCall(msgDcSetLineThickness, data.dc, (P_ARGS)2);
}
// Open a font. Use the "user input" font (whatever the user has chosen for this in System Preferences.
fs.id = 0;
fs.attr.group = sysDcGroupUserInput;
fs.attr.weight = sysDcWeightNormal;
fs.attr.aspect = sysDcAspectNormal;
fs.attr.italic = 0;
fs.attr.monospaced = 0;
fs.attr.encoding = sysDcEncodeGoSystem;
ObjCallJmp(msgDcOpenFont, data.dc, &fs, s, Error);
// Scale the font. The entire DC will be scaled in the repaint // to pleasingly fill the window.
fontScale.x = fontScale.y = FxMakeFixed(initFontScale,0);
ObjectCall(msgDcScaleFont, data.dc, &fontScale);
// Bind the window to the dc.
ObjectCall(msgDcSetWindow, data.dc, (P_ARGS)self);
```

At this point, clsHelloWin has set up its instance data in a local structure. It calls ObjectWrite() to get the Class Manager to update the instance data stored in the Hello Window instance:

```c
// Update the instance data.
ObjectWrite(self, ctx, &data);
return stsOK
```

### Using instance data

Accessing instance data is easy. The Class Manager passes a read-only pointer to instance data into the class's message handlers.

The Class Manager has no idea what the instance data is, so it just declares the pointer as a mystery type (P_DATA, which is defined as P_UNKNOWN). The 

\[ \text{MsgHandler()} \] macro names the pointer pData. 

clsHelloWin needs to access its instance data during msgWinRepaint handling so it can use the DC. It knows that the instance data pointed to by pData is type INSTANCE_DATA, so it uses the MsgHandlerWithTypes() macro, which allows it to provide the types (or casts) for the argument and instance data pointers:

```
MsgHandlerWithTypes(HelloWinRepaint, P_ARGS, P_INSTANCE_DATA)
```

You can pass the pData pointer around freely within your code, but whenever you want to change instance data, you must de-reference it into a local (writable) variable, modify the local variable, and then call ObjectWrite(). clsHelloWin creates its DC when it is created, and never changes it, so it doesn't have to worry about de-referencing its instance data into local storage. But clsCnt, described in Chapter 9, does have to do this.

**No filing yet**

On a page turn, the process and all objects associated with a Hello World (custom window) document are destroyed. Normally this means that objects have to file their state. However, since clsHelloWin destroys its DC when it is destroyed and never changes its DC's state, it doesn't have to file its DC.

The application does not file its view—it creates it at msgAppOpen to draw, then destroys it at msgAppClose, and there's no useful state to remember from the DC. You could imagine an application that would want to remember some of the state of its DC. For example, if the user could choose the font in Hello World (custom window), then the program would need to remember what the font was so that when the user turns back to the application's page the application continues to use the same font.

**Drawing in a window**

Empty Application prints out messages, but it doesn't draw them in its window. Instead it uses the error output routine Debug() to generate output. Hello World (custom window) actually draws something in its window. Windows are separate objects from applications, and the window gets told to repaint, not the application. Hence, you need to create a window object. The window object will receive msg-WinRepaint messages whenever it needs to paint its window, either because the application has just appeared on-screen, or because another window was obscuring part of this window.

clsWin responds to msgWinRepaint by filling self with the background color and outlining the edge of the window. You could put an instance of clsWin inside your frame, but we want something more interesting to appear in the window. So clsHelloWin intercepts msgWinRepaint and draws its own thing. It draws the strings “Hello” and “World” and then draws an exclamation point using graphics commands. The most complex thing about its repaint routine is its scaling. It measures how long the strings “Hello” and “World” will be, then uses this information to scale its coordinate system so that the words and drawing fit in the window nicely.
Possible enhancements

Try drawing some other shapes using other msgDcDraw messages. Nest a clsHelloWin window in the custom layout window from HELLOTK2.C.

Debugging Hello World (custom window)

If you want to modify Hello World (custom window), you might need to use DB extensively as you make changes. This section explains techniques developers commonly use to speed up debugging with DB.

To save typing commands over and over to DB, you can store them in files and read them into DB using its < command, for example:

<\boot\proj\setbreak.txt

When it starts, DB looks for a start-up file called DBCUSTOM.DB. It tries to find this in \BOOT\PENPOINT\APP\DB, but you can specify the path to another file by specifying the path in a DBCustom line in PENPOINT\BOOT\ENVIRON.INI. You can use DBCUSTOM.DB to set up the ctx and srdir for your application's executables and DLLs, and set breakpoints. Here's how a DBCUSTOM.DB for Hello World (custom window) might look:

    sym "go-hello_exe-V2(0)" \boot\penpoint\sdk\sample\hello\hello.exe
    srcdir "go-hello_exe-V2(0)" \boot\penpoint\sdk\sample\hello
    sym "go-hello_dll-V2(0)" \boot\penpoint\sdk\sample\hello\hello.dll
    srcdir "go-hello_dll-V2(0)" \boot\penpoint\sdk\sample\hello
    bp HelloWinRepaint
    g

Whenever you start a new instance of Hello World (custom window)—either by choosing from the Accessory palette or by turning a page—DB will halt. At that point you can type t to step a line, g to continue, and so on.
Chapter 9 / Saving and Restoring Data (Counter)

The sample programs we have considered so far do not have any information to save. They always do the same thing in response to the same messages. However, real applications must be able to save and restore data.

PenPoint™ applications maintain information about what is on screen, how the user last interacted with the application, what options were set, what controls were active at the time, and so on. This information together with the application's data is called the application's state.

Because PenPoint is an object-oriented system, there is no real distinction between data and state information. An application is built from a series of objects. A scribble object might contain the scribbles that the user just drew, while a scroll window object contains the current scrolling position of the window. The former contains “user data” and the latter contains state information, but to PenPoint they are simply objects. This chapter discusses how applications save and restore their data.

The last part of this chapter describes how to create a menu using clsTkTable.

Saving state

Remember that as the user turns from page to page in the Notebook, the Application Framework is starting up and shutting down instances of clsApp. When you turn the page from Empty Application or Hello World, the Application Framework destroys the clsEmptyApp or clsHelloWorld application object. When you turn back to that page, the Application Framework creates a new application object.

This is fine, because these applications don't need to remember anything. They start from scratch each time they appear. However, if applications do change state, they must preserve this state, so that the user is not aware that the application instance is coming and going “behind” what is seen on-screen.

Counter application

The Counter Application saves data. Each time the application appears on-screen, it increments a counter and displays the counter's value. It also lets the user choose the format in which to display the counter (decimal, octal, or hexadecimal).

Based on the state filing rule, the application has two pieces of state that it should file:

- The value of the counter.
- The format in which it was told to display the counter.
clsCntrApp remembers the format in which it displays the counter value. clsCntrApp could also remember the value of the counter, but one of the benefits of an object-oriented system is that you can break up your application code into objects that model the natural structure of the system.

It's natural to think of the application displaying the value of a separate object, so that's the way we implement it: clsCntrApp creates and interacts with a separate clsCntr object. Because the format could be applied to all counter objects in the application, clsCntrApp remembers the format.

Note the difference between Counter Application and the two Hello World sample programs. The Hello World applications had to create other objects to get the behavior they needed. An application object is not a window, so they had to create window objects. In the case of Counter Application's counter object, we're not forced to use a separate object—we could have clsCntrApp remember the state of the counter, but for design reasons we choose to implement the counter as a separate object.

PenPoint has several classes that store a numeric value:

- clsIntegerField: A handwriting field that accepts numeric input.
- clsPageNum: The page number in floating frames.
- clsCounter: The page number with up and down arrows in the Notebook.

These are all window classes that display a numeric value. clsCntrApp creates a label to display the value of the counter, much like Hello World (toolkit). Hence none of these are quite right for Counter Application, so we create a separate counter class. Figure 9-1 shows the classes defined by Counter Application and their ancestors.

**Compiling and installing the application**

To compile Counter Application, change to the PENPOINT\SDK\SAMPLE\CNTRAPP directory and start the MAKE utility. This creates a PENPOINT\APP\CNTRAPP directory and compiles CNTRAPP.EXE in that directory.

Install Counter Application either by adding \BOOT\PENPOINT\APP\Counter Application to PENPOINT\BOOT\locale\APP.INI (where locale is USA for United States English or JPN for Japanese) before starting PenPoint or by installing the application using the Installer.

**Counter Application highlights**

The method table for clsCntrApp handles a number of interesting messages:

- msgInit
- msgSave
- msgRestore
- msgFree
- msgAppInit
- msgAppOpen
- msgAppClose
- msgCntrAppChangeFormat

```
msgInit,      "CntrAppInit", objCallAncestorBefore,
msgSave,      "CntrAppSave", objCallAncestorBefore,
msgRestore,   "CntrAppRestore", objCallAncestorBefore,
msgFree,      "CntrAppFree", objCallAncestorAfter,

**Counter Application objects**

PenPoint provides:

Objects in a running Counter Document

You must write:

![Diagram of Counter Application objects]

clsCntrApp creates an instance of clsCntr at msgAppInit time.

clsCntrApp responds to msgAppOpen by incrementing the counter, creating a label containing the counter value, making the label the client window, and creating the menu bar.

clsCntrApp responds to msgAppClose by destroying the client window.

The class responds to msgCntrAppChangeFormat, which is sent by its menu buttons, by changing its stored data format.

When processCount is 0, main() calls ClsCntrAppInit().

**Counter class highlights**

The method table for clsCntr is also defined in METHODS.TBL and handles these messages:

- msgNewDefaults,
- msgInit,
- msgSave,
- msgRestore,
- msgFree,
- msgCntrGetValue,
- msgCntrIncr,
- "CntrNewDefaults",
- "CntrInit",
- "CntrSave",
- "CntrRestore",
- "CntrFree",
- "CntrGetValue",
- "CntrIncr",

- 0,
- 0,
Instance data

The instance data for a clsCntr object contains the value of the counter:

```c
typedef struct CNTR_INST {
    S32 currentValue;
} CNTR_INST,
*P_CNTR_INST;
```

Make sure you notice the difference between CNTR_INST, the counter's instance data, and CNTR_INFO, the structure used for the arguments passed with msgCntr­GetValue. In this example, the two structures contain the same data; in a more complex example, the instance data would contain all the stateful information required by an instance of the object, while the message argument structure would only contain the data needed by a particular message.

Because the purpose of clsCntr is to maintain a value for its client, clsCntr must provide a means for its client to access the value. One common approach lets the client perform these tasks:

- Specify an initial value in msgNew.
- Get the value with a special message.
- Set the value with a special message.

clsCntr does all of these except set the value. The _NEW_ONLY information for clsCntr contains an initial value. Here is the CNTR_NEW_ONLY structure from CNTR.H:

```c
typedef struct CNTR_NEW_ONLY {
    S32 initialValue;
} CNTR_NEW_ONLY, *P_CNTR_NEW_ONLY;
```

In case its client doesn't specify an initial value when the client sends msgNew, clsCntr initializes the msgNew argument to a reasonable value (zero) in msgNew­Defaults:

```c
MsgHandlerArgType(CntrNewDefaults, P_CNTR_NEW)
{
    Dbg(Debugf(U_L("Cntr:CntrNewDefaults")));  
    // Set default value in new struct.
    pArgs->cntr.initialValue = 0;
    return stsOK;
    MsgHandlerParametersNoWarning;
} /* CntrNewDefaults */
```

In response to msgInit, clsCounter initializes the instance data to the starting value specified in the msgNew arguments:

```c
MsgHandlerArgType(CntrInit, P_CNTR_NEW)
{
    CNTR_INST inst;
    Dbg(Debugf(U_L("Cntr:CntrInit")));  
    // Set starting value.
    inst.currentValue = pArgs->cntr.initialValue;
    // Update instance data.
    ObjectWrite(self, ctx, &inst);
    return stsOK;
    MsgHandlerParametersNoWarning;
} /* CntrInit */
```
Getting and setting values

clsCntr defines messages to get and set the counter value, msgCntrGetValue and msgCntrInc. Note how we intentionally limit the API to suit the design of the object: the client can't directly set the counter value, it can only increment it. This makes the counter less general.

The (dubious) advantage of the approach used is that if the design of clsCntr changes so that it has more information, CNTR_INFO could change to include more information, and clients of it would only need to recompile.

Getting the value

The handler for msgCntrGetValue is straightforward. Note that the client must pass it a pointer to the structure in which clsCntr passes back the value.

```c
MsgHandlerWithTypes(CntrGetValue, P_CNTR_INFO, P_CNTR_INST)
{
    Dbg(Debugf(U_L("Cntr:CntrGetValue")));
    pArgs->value = pData->currentValue;
    return stsOK;
    MsgBoxParametersNoWarning;
} /* CntrGetValue */
```

In this case, passing a CNTR_INFO structure as the message arguments is not necessary. msgCntrGetValue could take a pointer to an S32, instead of a pointer to a structure that contains an S32. However, as soon as you need more than 32 bits to communicate the message arguments, you must define a structure and pass a pointer to the structure.

Incrementing the value

msgCntrIncr increments the value. It doesn't take any arguments.

```c
MsgHandlerWithTypes (CntrIncr, P_ARGS, P_CNTR_INST)
{
    CNTR_INST inst;
    Dbg(Debugf(U_L("Cntr:CntrIncr")));
    inst = *pData;
    inst.currentValue++;
    ObjectWrite(self, ctx, &inst);
    return stsOK;
    MsgBoxParametersNoWarning;
} /* CntrIncr */
```

There are a couple of things to note here. First, the instance data is stored in memory that only the Class Manager can write. When the Class Manager calls the message handler, it passes a pointer to this protected instance data. If the code had tried to update the protected pData->currentValue directly, PenPoint would have generated a general protection fault. That is why the code assigns the instance data (the implicit pData argument) to a variable (inst) before modifying it. After modifying the copy of the instance data, the code calls ObjectWrite(), which directs the Class Manager to update the protected instance data stored in the object.

Second, the code uses the MsgHandlerWithTypes() macro to define the function. MsgHandlerWithTypes() works like MsgHandler(), but lets you specify data types.
for the message argument (pArgs) and instance data (pData). In addition to the name of the method, the `MsgHandlerWithTypes()` macro takes two arguments that indicate the types of the message arguments (pArgs) and the instance data (pData).

In the `CntrIncr()` example above, the `MsgHandlerWithTypes()` casts the message argument as a `P_ARGS` pointer (the default for pArgs), and the instance data as a `P_CNTR_INST`, a pointer to a CNTR_INST structure.

### Object filing

The way objects preserve state is by filing it at the appropriate time. The Application Framework sends the application instance `msgSave` when the document should save its state and `msgRestore` when the document should recreate itself. The order in which applications receive these and other messages from the Application Framework is explained in Part 2: Application Framework of the PenPoint Architectural Reference manual.

The message arguments to `msgSave` and `msgRestore` include a handle on a **resource file**. Objects respond by writing out their state to this file and reading it back in. The objects do not care where the resource file is, nor do they care who created it.

The Application Framework creates and manages a resource file for each document. The file handle passed by `msgSave` and `msgRestore` is for this resource file. If you start up the disk viewer with the B debug flag set to 800 hexadecimal, and expand `\BOOT\PENPOINT\SYS\Bookshelf\Notebook\CONTENTS`, you should be able to see these files; look for a file called `DOC.RES` in each document directory.

At the level of `msgSave` and `msgRestore`, classes can just write bytes to a file (the resource file) to save state.

When it receives `msgSave`, `clsCntrApp` could get the value of the counter object (by sending it `msgCntrGetValue`) and just write the number to the file. However, this would introduce dependencies between the two objects, which in object-oriented programming is a bad thing. So, instead `clsCntrApp` tells the counter object to file itself. We'll cover exactly how this happens later, but for now just accept that the `clsCntr` instance receives `msgSave`.

### Handling `msgSave`

The message argument to `msgSave` is a pointer to an `OBJ_SAVE` structure:

```
MsgHandlerArgType(CntrSave, P_OBJ_SAVE)
```

If you look in `PENPOINT\SDK\INC\CLSMGR.H`, you will notice that one of the fields in the `OBJ_SAVE` structure is the handle of the file to save to. So all `clsCntr` has to do is write that part of its instance data that it needs to save to the file: basically, all of its instance data.

To write to a file, you send `msgStreamWrite` to the file handle. The message takes a pointer to a `STREAM_READ_WRITE` structure, in which you specify what to file and how many bytes to write.
MsgHandlerArgType(CntrSave, P_OBJ_SAVE)
{
STREAM_READ_WRITE fsWrite;
STATUS s;
Debugf("Cntr:CntrSave");
//
// Write instance to the file.
//
fsWrite.numBytes= SizeOf(CNTR_INST);
fsWrite.pBuf= pData;
ObjCallRet(msgStreamWrite, pArgs->file, &fsWrite, s);
return stsOK;
} /* CntrSave */

msgStreamWrite passes back information about how many bytes it actually wrote. A real application would check this information to make sure that it successfully filed all its state.

Handling msgRestore

msgRestore is similar to msgSave. The Class Manager handles msgRestore by creating a new object, so the ancestor must be called first. The message argument to msgRestore is a pointer to an OBJ_RESTORE structure:

MsgHandlerArgType(CntrRestore, P_OBJ_RESTORE)

Again, one of the fields in this structure is the UID of the file handle to restore from. clsCntr just has to restore self's instance data from the filed data. This is similar to initializing instance data in msgInit handling, except that the information has to be read from a file instead of from msgNew arguments. You declare a local instance data structure:

MsgHandlerArgType(CntrRestore, P_OBJ_RESTORE)
{
    CNTR_INST inst;
    STREAM_READ_WRITE fsRead;
    STATUS s;
}

To read from a file, you send msgStreamRead to the file handle, which takes a pointer to the same STREAM_READ_WRITE structure as msgStreamWrite. In the structure you specify how many bytes to read and give a pointer to your buffer that will receive the data:

Dbg(Debugf(U_L("Cntr:CntrRestore")));  
//
// Read instance data from the file.
//
fsRead.numBytes= SizeOf(CNTR_INST);
fsRead.pBuf= &inst;
ObjCallRet(msgStreamRead, pArgs->file, &fsRead, s);

You call ObjectWrite() to update the object's instance data.

//
// Update instance data.
//
ObjectWrite(self, ctx, &inst);
return stsOK;
MsgHandlerParametersNoWarning;
} /* CntrRestore */
Counter Application's instance data

clsCntrApp's instance data contains:
- The display format to use for the counter value.
- The UID of the counter object.
- A memory-mapped file handle (explained below).

When the user turns away from a Counter Application document's page, the Application Framework destroys the counter object (and the application instance). When the user turns back to the Counter Application document, the counter object is restored with a different UID. Hence clsCntrApp should not file the UID of the counter object, because it will be invalid upon restore. clsCntrApp only needs to file the display format and to tell the counter object to save its data.

Memory-mapped file

Counter Application could just write its data to the resource file created by the Application Framework, just as the counter object did. However, a disadvantage of filing data is that there are two copies of the information when a document is open: the instance data in the object maintained by the Class Manager and the filed data in the document resource file maintained by the file system.

One way to avoid this duplication of data is to use a memory-mapped file. Instead of reading and writing to a file, you can simply map the file into your address space; reading and writing to the file take place transparently as you access that memory. clsCntrApp stores its data (the current representation) in a memory-mapped file.

Opening and closing the file

Because you need to open the file both when creating the document for the first time, and when restoring the document after it has been filed, you need to open the file in two different places (msgAppInit and msgRestore), but you only need close it in one place (msgFree).

Why close the file in response to msgFree? Why not msgSave? Remember that when an application is created, it is sent msgAppInit (in response to which it creates and initializes objects) and then is immediately sent msgSave (which allows it to save its newly initialized objects before doing anything else). msgSave is also sent when the user checkpoints a document. In other words, receiving msgSave doesn't necessarily mean that we're about to destroy the application object.

Opening for the first time

When Counter Application receives msgAppInit, it creates the counter object:

```c
MsgHandler(CntrAppInit)
{
    CNTAPP_INST inst;
    Dbg(Debugf(U_L("CntrApp:CntrAppInit")));
    inst.counter = pNull;
    inst.fileHandle = pNull;
    inst.pFormat = pNull;
```
Opening to restore

CntrAppRestore() opens a file (called FORMATFILE) where it stores the document’s instance data, then maps the file to memory. This makes the format data available in inst.pFormat.

```c
MsgHandlerWithTypes(CntrAppRestore, P_OBJ_RESTORE, P_CNTRAPP_INST)
{
    FS_NEW   fsn;
    CNTRAPP_INST inst;
    STATUS   s;
    Dbg(Debugf(U_L("CntrApp:CntrAppRestore"));)
    // Get handle for format file, and save the handle. 
    // The default for fsn.fs.locator.uid is theWorkingDir, which
    // is the document's directory. 
    ObjCallWarn(msgNewDefaults, clsFileHandle, &fsn);
    fsn.fs.locator.pPath = U_L("formatfile");
    ObjCallRet(msgNew, clsFileHandle, &fsn, s);
    inst.fileHandle = fsn.object.uid;
    // Map the file to memory
    ObjCallRet(msgFSMemoryMapSetSize, fsn.object.uid, \ 
               (P_ARGS)(SIZEOF)cntrAppMemoryMapSize, s);
    ObjCallRet(msgFSMemoryMap, fsn.object.uid, inst.pFormat, s);
    // Restore the counter object.
    ObjCallJmp(msgResGetObject, pArgs->file, &inst.counter, s, Error);
    // Update instance data.
    ObjectWrite(self, ctx, &inst);
    return stsOK;
    MsgBoxHandlerParametersNoWarning;
} /* CntrAppRestore */
```

Using a memory-mapped file handle lets you maintain just one copy of the instance data when the document is open. The alternative is to create an instance data structure in memory when the document opens, copy the field data to the structure in memory, then copy changes from the in-memory data structure to the file before closing the document.

Closing on msgFree

When the application receives msgFree, it destroys the counter object, sends msgFSMemoryMapFree to unmap the file, and then sends msgDestroy to the file handle to close the file.

```c
MsgHandlerWithTypes(CntrAppFree, P_ARGS, P_CNTRAPP_INST)
{
    STATUS s;
    Dbg(Debugf(U_L("CntrApp:CntrAppFree"));)
    ObjCallRet(msgDestroy, pData->counter, Nil(P_ARGS), s);
```
Filing the counter object

The only thing that is left to do is to tell the counter object when to save and restore its data. For this, you send the resource messages msgResPutObject and msgResGetObject to the resource file handle created by the Application Framework. These messages are defined in RESFILE.H. You do not send msgSave and msgRestore directly to the counter object.

The resource file handle is an instance of clsResFile. When you send a message to the resource file handle, you tell it which object you want to put or get. In the case of msgResPutObject, clsResFile writes information about the object to the resource file, then sends msgSave to the object. In the case of msgResGetObject, clsResFile reads information about the object from the file, creates the object, which is essentially empty until clsResFile sends msgRestore to the object. This is how objects receive msgSave and msgRestore.

Saving the counter object

When Counter Application receives msgSave, it sends msgResPutObject to the file handle passed in with the msgSave arguments.

```c
MsgHandlerWithTypes(CntrAppSave, P_OBJ_SAVE, P_CNTRAPP_INST)
{
    STATUS s;
    Dbg(Debugf(U_L("CntrApp:CntrAppSave")));  // Save the counter object.
    ObjCallRet(msgResPutObject, pArgs->file, pData->counter, s);
    return stsOK;
    MsgHandlerParametersNoWarning;
} /* CntrAppSave */
```

Counter Application doesn't have to write the instance data to a file, because the data is a memory-mapped to a file.

Restoring the counter object

When Counter Application receives msgRestore, it sends msgResGetObject to the file handle passed in with the msgRestore arguments.

```c
MsgHandlerWithTypes(CntrAppRestore, P_OBJ_RESTORE, P_CNTRAPP_INST)
{
    FS_NEW fsn;
    CNTRAPP_INST inst;
    STATUS s;
```
Dbg(Debugf(U_L("CntrApp:CntrAppRestore")));  
// Get handle for format file, and save the handle.  
// The default for fsn.fs.locator.uid is theWorkingDir, which  
// is the document's directory.  
ObjCallWarn(msgNewDefaults, clsFileHandle, &fsn);  
fsn.fs.locator.pPath = U_L("formatfile");  
ObjCallRet(msgNew, clsFileHandle, &fsn, s);  
inst.fileHandle = fsn.object.uid;  
// Map the file to memory  
ObjCallRet(msgFSMemoryMapSetSize, fsn.object.uid, (P_ARGS)(SIZEOF)cntrAppMemoryMapSize, s);  
ObjCallRet(msgFSMemoryMap, fsn.object.uid, &inst.pFormat, s);  
// Restore the counter object.  
ObjCallJmp(msgResGetObject, pArgs->file, &inst.counter, s, Error);  
// Update instance data.  
ObjectWrite(self, ctx, &inst);  
return stsOK;  
MsgHandlerParametersNoWarning;  
return s;  
} /* CntrAppRestore */

**Menu support**

clsCntrApp creates a menu by specifying the contents of the menu statically in a toolkit table. clsTkTable is the ancestor of several UI components that display a set of windows, including choices, option tables, and menus. Instead of creating each of the items in a toolkit table by sending msgNew over and over to different classes, you can specify in a set of toolkit table entries what should be in the table. When you send msgNew to clsTkTable (or one of its descendants) it creates its child items based on the information you gave it.

When it receives msgAppOpen, clsCntrApp appends its menu to the SAMs (standard application menus) by passing its menu as an argument to msgApp­CreateMenuBar.

**Buttons**

The items in the menu are a set of buttons. When you create a button in toolkit table entry, you specify:

- The button's string, or a resource ID tag that refers to a string in a resource file.
- The notification message the button should send when the user activates it.
- A value for the button.
- If the string is specified as resource ID, the type of resource (usually tkLabel­StringID to specify a string resource).

There are other fields in a TK_TABLE_ENTRY, but you can rely on their defaults of 0.
The menu bar used in Counter Application is described by the TK_TABLE_ENTRY structure named CntrAppMenuBar() in CNTRAPP.C. CntrAppMenuBar() specifies user-readable strings, such as the name of the menu and the menu items, with resource ID tags.

```c
typedef enum CNTRAPP_DISPLAY_FORMAT {
    dec, oct, hex
} CNTRAPP_DISPLAY_FORMAT,
*P_CNTRAPP_DISPLAY_FORMAT;
...
/*
* Here we use tags that are associated with strings in a resource file
* for the name of our menu and the menu items.
*
* When using tags in a TKTable, the fifth field must be an id that gives
* the type of the tag. If there is an item already in the fifth field,
* you can 'or' the two field items, and the system will know which one
* to use.
*/
static const TK_TABLE_ENTRY CntrAppMenuBar[] = {
    {tagCntrMenu, 0, 0, 0, tkMenuPullDown | tkLabelStringId, clsMenuButton},
    {tagCntrDec, msgCntrAppChangeFormat, dec, 0, tkLabelStringId},
    {tagCntrOct, msgCntrAppChangeFormat, oct, 0, tkLabelStringId},
    {tagCntrHex, msgCntrAppChangeFormat, hex, 0, tkLabelStringId},
    {pNull},
    {pNull}
};
```

When the user taps one of the menu buttons, the menu button sends msgCntrAppChangeFormat to its client, which by default is the application. The message argument is the value of the button (dec, oct, or hex). clsCntrApp's message handler for msgCntrAppChangeFormat looks at the message argument to determine which button the user tapped.

```c
MsgHandlerWithTypes(CntrAppChangeFormat, P_ARGS, P_CNTRAPP_INST)
{
    APP_METRICS am;
    WIN thelabel;
    STATUS s;
    CHAR buf[MAXSTRLEN];
    Dbg(Debugf(U_L("CntrApp:CntrAppChangeFormat"));)
    // Update mmap data
    *(pData->pFormat) = (CNTRAPP_DISPLAY_FORMAT)(U32)pArgs;
    // Build the string for the label.
    StsRet(BuildString(buf, pData), s);
    // Get app metrics.
    ObjCallRet(msgAppGetMetrics, self, &am, s);
    // Get the clientWin.
    ObjCallRet(msgFrameGetClientWin, am.mainWin, &thelabel, s);
    // Set the label string.
    ObjCallRet(msgLabelSetString, thelabel, buf, s);
    return stsOK;
    MsgHandlerParametersNoWarning;
} /* CntrAppChangeFormat */
```
Tic-Tac-Toe is a large, robust application that demonstrates how to “play along” with many of the PenPoint™ protocols affecting applications:

- SAMs (standard application menus)
- Selections
- Move/copy protocol
- Keyboard input focus
- Stationery
- Help
- Option sheets

The rest of this chapter details the architecture of Tic-Tac-Toe, its files, classes, objects, etc, and describes some of the enhanced application features implemented in Tic-Tac-Toe.

**Tic-Tac-Toe objects**

No tutorial of this size can give you a course in object-oriented program design. It is an art, not a science. The books mentioned in Chapter 3 will be helpful. No matter what your experience level, you will find that you will probably have to redesign your object hierarchy at least once. (Here at GO, we redesigned our class hierarchy countless times in the first two years—now it is quite stable.) But there are some generally accepted techniques for breaking up an application into manageable components, and this tutorial will lead you through them.

Each section from now on will discuss the various design choices made.

**Application components**

A typical functional application does something in its application window, then saves data in the document working directory.

Tic-Tac-Toe does this: it displays a tic-tac-toe board in its window, then stores the state of the board. Its application class is clsTttApp. The application creates its own class to display the board, clsTttView. It also creates a separate object just to store the state of the board, clsTttData.
**Separate stateful data objects**

The Tic-Tac-Toe data object's set of Xs and Os are the main part of its state, which it must preserve.

The application and view also maintain some state, the application files its version, and the view remembers the thickness of the lines on the Tic-Tac-Toe board.

**Tic-Tac-Toe structure**

Table 10-1 lists the files in PENPOINT\SDK\SAMPLE\TTT that you use to build the Tic-Tac-Toe application (the directory also contains some text files that provide information about the application)
**Tic-Tac-Toe files**

<table>

**Tic-Tac-Toe window**

There is no pre-existing class that draws letters in a rectangular grid. So, some work is needed here. The PenPoint UI Toolkit provides labels that can have borders, along with clsTableLayout that lets you position windows in a regular grid. So, you could create the Tic-Tac-Toe board by creating nine one-character labels in a table layout window. However, there are some problems with this:

- Labels don't (ordinarily) scale to fit the space available.
- Each label is a window. A window in PenPoint is fairly lightweight (that is, it has a small system resource requirement), but if we were to change to a 16 x 16 board, it would use 256 single-character label windows.

A even more efficient way to draw the grid is to create a window and use the ImagePoint™ graphics system to draw the lines of the 3 x 3 grid.
Coordinate system

The obvious coordinate system is one unit is one square. However, this system makes it difficult to position characters within a square, since you specify coordinates for drawing operations in S32 coordinates.

The Tic-Tac-Toe view uses local window coordinates for its drawing.

Advanced repainting strategy

As explained in Hello World, the window system tells windows to repaint. When a window receives msgWinRepaint, it always self-sends msgWinBeginRepaint. This sets up the update region of the window—the part of the window where pixels can be altered—to the part of the window that needs repainting. After sending msgWinBeginRepaint, a window can only affect its pixels which the window system thinks need repainting, no matter where the window tries to paint.

Because the window system must calculate this dirty area, it makes the area available to advanced clients by passing it back in the message argument structure of msgWinBeginRepaint. In a fit of probable overkill, the Tic-Tac-Toe view is such an advanced client. Tic-Tac-Toe looks at the RECT32 structure passed back and figures out what parts of the grid lines and which squares it needs to repaint. It wants to do this in its own coordinate system, so it sends msgWinBeginRepaint to its DC.

View and data interaction

The Tic-Tac-Toe view displays what’s in the data object, so it needs access to the data maintained by the data object. There are various ways that a view can get to this state. It could share memory pointers with the data object, or it could use the specialized function ObjectPeek() to look directly at the data object’s instance data memory. However, both of these methods compromise the separation of view and data into two objects. A purer approach is to have the view object send the data object a message when it needs to know the data object’s state, but you still have to decide whether the data object should pass the view its internal data structures or a well-defined public data structure.

These are the classic problems of encapsulation and abstraction faced in object-oriented program design.

Data object design

Tic-Tac-Toe’s data object class, clsTttData, is similar to Counter Application’s clsCntr. It lets its client perform these tasks:

- Specify an initial board layout in msgNew.
- Get the value of all the squares (msgTttDataGetMetrics).
- Set the value of all the squares (msgTttDataSetMetrics).
- Set the value of a particular square (msgTttDataSetSquare).

clsTttData gets and sets the square values as part of getting and setting all of its metrics. The theory is that any client that wants to set and get this probably wants
all the information about the data object. (In fact, \texttt{clsTttData}'s instance metrics comprise only its square values.)

\textbf{Instance data by value vs. by reference}

The instance data for each of \texttt{clsTttApp}, \texttt{clsTttView}, and \texttt{clsTttData} is a pointer that points to a data structure outside the instance. The outside data structure is where the class stores the information. Storing instance data by reference in this way has some advantages:

- You don't have to use \texttt{ObjectWrite()} to update instance data every time state changes, since the pointer never changes.
- The size of the instance data can vary.

It does mean that the class has to allocate space for the instance information. The Tic-Tac-Toe classes do this using \texttt{OSHeapBlockAlloc()} in \texttt{msgInit} processing.

\textbf{Saving a data object}

\texttt{clsTttApp} tells its view to file, and an instance of \texttt{clsView} automatically files its data object.

\textbf{Handling failures during \texttt{msgInit} and \texttt{msgRestore}}

\texttt{msgInit} and \texttt{msgRestore} both create objects. It is vital that the handlers for these messages guarantee that the object is initialized to some well-known state, even if your handler or some ancestor failed in some way, because after a failed creation, the object will in fact receive \texttt{msgDestroy}.

Note how \texttt{clsTttData} writes appropriate data into its instance data even in the case of an error.

```c
MsgHandlerWithTypes(TttDataInit, P_TTT_DATA_NEW, PP_TTT_DATA_INST)
{
    P_TTT_DATA_INST
    STATUS s;
    DbgTttDataInit((U_1("")))
    // Initialize for error recovery.
    //
    pInst = pNull;
    // Allocate, initialize, and record instance data.
    //
    StsJmp(OSHeapBlockAlloc(osProcessHeapId, SizeOf(*pInst), &pInst), \s, Error);
    pInst->metrics = pArgs->tttData.metrics;
    ObjectWrite(self, ctx, &pInst);
    DbgTttDataInit((U_L("return stsOK")))
    return stsOK;
    MsgHandlerParametersNoWarning;
    Error:
    if (pInst) {
        OSHeapBlockFree(pInst);
    }
    DbgTttDataInit((U_L("Error; returns Ox%lx"), s))
    return s;
} /* TttDataInit */
```
The selection and keyboard input

When a computer permits multiple windows on-screen, it must decide which window receives keyboard input. PenPoint uses a selection model, meaning that it sends keyboard input to the object holding the selection (along with all the other move/copy/options/delete messages that the selected object may receive). So, to allow typing, the Tic-Tac-Toe view must “be selectable.”

How selection works

There can only be one primary selection in the Notebook UI at a time. The user usually selects something on-screen by tapping on it. In response to holding the selection, the selected thing is highlighted. Depending on what is selected, the user can then operate on the selection by deleting it, copying it, asking for its option sheet, and so on.

PenPoint’s Selection Manager keeps track of which object has the selection. However, it is up to the class implementor to support selections, to highlight the selection, and to implement whatever operations on that selection make sense. Text fields and text views support selections, but clsWin and clsObject do not.

Which object?

Because the Tic-Tac-Toe view is the object that draws the Tic-Tac-Toe board, it makes sense for it to track selections. The selection does not change the board contents, so the Tic-Tac-Toe data object need not care.

When the user selects in the Tic-Tac-Toe view, the action selects the entire view. A more realistic class would figure out which of its squares the user selected, but the principles used by clsTttView are the same.

clsTttView responds to selection messages sent by the Selection Manager. It asks theSelectionManager if it holds the selection, and if so, repaints differently to indicate this fact.

What event causes selections?

The application developer must decide what input event causes a selection in the Tic-Tac-Toe view: the usual is a pen-up event or a pen-hold timeout. On receiving this input event, the object wishing to acquire the selection should send msgSelSetOwner to the special Selection Manager object. Since the Tic-Tac-Toe view also supports keyboard input, it also calls the routine InputSetTarget() to acquire the keyboard focus. From this point on, the view receives keyboard input events, and may receive other messages intended for the selection, such as options, move, and copy.

The object which has acquired the selection should highlight the selected “thing” on-screen. clsTttView draws the board in gray when it has the selection, and in white when it does not have the selection. It determines whether it has the selection by sending msgSellsSelected to self. Here is the code from TttViewRepaint() (msgSellsSelected returns stsOK if the receiver of the message has the selection):
More on view and data interaction

When a Tic-Tac-Toe view receives a `msgPenHoldTimeout` input event, `clsTttView` self-sends `msgTttViewTakeSel` telling it to acquire the selection, and self-sends `msgWinUpdate`, which forces it to repaint the entire board. (If the view supported square-by-square selection, it would convert the input event X-Y coordinates to a square location on the board).

**Move/copy protocol**

The selection holder receives a variety of messages, including `msgSelYield` and the move/copy protocol messages. Because `clsTttView` inherits from `clsEmbeddedWin`, it can rely on `clsEmbeddedWin's` default handling of many selection messages.

**More on view and data interaction**

Thus far the data maintained by the data object has been static; now the user can change the data. But the user interacts with the view, not the data object. It's the view that knows what characters the user entered. The view must tell the data object about the change as well as draw the new data.

The natural way to do this might seem to be for the view to draw the new letter in the square, and then tell the data object about the new letter. However, this is not the view-data model. Instead, the view tells the data object about the changed letter by sending it `msgTttDataSetSquare`. When the data object receives this message, it updates its state, then broadcasts `msgTttDataChanged` to all its observers. When the view receives `msgTttDataChanged`, it knows it needs to repaint the board. The advantages of this model are that the data object can remain in control of its data: it could reject the update message from the view, and the view would not display bad data. Also, it allows for several views to display the same data object, since if any of them updates the data object, they all are told about the change.

To actually draw the new square, `clsTttView` dirties the rectangle of the square that changed. This also may seem odd—why not paint the square immediately with the new value when notified by the data object of the new value? But the Tic-Tac-Toe view already knows how to repaint itself; it's nice to take advantage of the batching provided by the window system's repaint algorithm.
The Text subsystem is a more compelling argument for the view-data model used by Tic-Tac-Toe. Using the same kind of message flow to update text views and text data objects, Text does indeed allow several views of the same underlying object, and it has a very intelligent window repainting routine.

**Handwriting and gestures**
Views inherit from clsGWin, so there is little extra work required to make clsTttView respond to input events and gestures.

**Input event handling**
There is one input message in PenPoint, `msgInputEvent`. Within the message arguments of this is a device code that indicates the type of input event. Device codes all begin with `msgKey` or `msgPen`, which is slightly confusing because objects never receive these messages, they always receive `msgInputEvent`. clsTttView's handles `msgInputEvent` with a routine called `TttViewInputEvent()`.

`TttViewInputEvent()` calls a routine to process keyboard events, and lets clsTttView's ancestor, clsEmbeddedWin, handle pen events. clsEmbeddedWin includes code for handling many pen input events. For example, clsEmbeddedWin watches for pen-hold timeouts and, if `self` is moveable or copyable, `self`-sends `msgSelSelect` and `msgSelBeginMoveCopy`.

```c
MsgHandlerWithTypes(TttViewInputEvent, P_INPUT_EVENT, PP_TTT_VIEW_INST)
{
    STATUS s;
    switch (ClsNum(pArgs->devCode)) {
    case CIsNum(clsKey):
        s = TttViewKeyInput(self, pArgs);
        break;
    default:
        s = ObjectCallAncestorCtx(ctx);
        break;
    }
    return s;
    MsgHandlerParametersNoWarning;
} /* TttViewInputEvent */
```

**Gesture handling**
When clsTttView's ancestor gets a pen event, the event ends up being handled by clsGWin. If clsGWin recognizes the pen event as a gesture, it sends `msgGWinGesture` to `self`. In other words, when the user draws a gesture on the Tic-Tac-Toe view, the view receives `msgGWinGesture`.

The arguments for `msgGWinGesture` are different in PenPoint 1.0 than in PenPoint 2.0 Japanese. For PenPoint 1.0, the arguments include the gesture in the form of a message identifier. The class for the message is clsXGesture. The number of the message encodes the actual gesture detected by clsGWin. In PenPoint 2.0 Japanese, the arguments include the gesture in the form of a Unicode character that represents the gesture.
Handwriting and gestures

TttViewGesture(), the handler for msgGWInGesture, uses a switch statement to take appropriate action based on the gesture argument. Because the msgGWInGesture API is different in PenPoint 1.0 than in PenPoint 2.0 Japanese, the code uses an #ifdef directive that lets you compile the correct switch statement for PenPoint 1.0 by defining PP1_0, or setting it on the compiler command line. The switch statement handles the gestures that are meaningful to clsTttView, and lets the ancestor class handle all other gestures:

```c
MsgHandlerWithTypes(TttViewGesture, P_GWIN_GESTURE, PP_TTT_VIEW_INST)
{
    STATUS s;
    #ifdef PP1_0
    switch(pArgs->msg) {
    #else
    switch(pArgs->gesture) {
    #endif
        case xgslTap:
            ObjCallJmp(msgTttViewToggleSel, self, pNull, s, Error);
            break;
        case xgsCross:
            StsJmp(TttViewGestureSetSquare(self, pArgs, tttX), s, Error);
            break;
        case xgsCircle:
            StsJmp(TttViewGestureSetSquare(self, pArgs, tttO), s, Error);
            break;
        case xgsPigtailVert:
            StsJmp(TttViewGestureSetSquare(self, pArgs, tttBlank), s, Error);
            break;
        case xgsCheck:
            // Make sure there is a selection.
            s = ObjectCall(msgSelIsSelected, self, pNull);
            if (s == stsNoMatch) {
                ObjCallJmp(msgTttViewTakeSel, self, pNull, s, Error);
                ObjCallJmp(msgWinUpdate, self, pNull, s, Error);
            }
            // Then call the ancestor.
            ObjCallAncestorCtxJmp(ctx, s, Error);
            break;
        default:
            DbgTttViewGesture((U_L("Letting ancestor handle gesture")))
            return ObjCallAncestorCtxWarn(ctx);
        }
    #ifend
    DbgTttViewGesture((U_L("return stsOK"))) return stsOK;
    MsgHandlerParametersNoWarning;
    Error:
    DbgTttView Gesture((U_L( "Error; return 0x%lx"), s)) return s;
} /* TttViewGesture */
```
clsTttView's keyboard input routine handles multikey input, for example, when
the user presses two keys at once or in rapid succession. The device code for this is
msgKeyMulti, and the input event data includes the number of keystrokes and an
array of their values. The keyCode of a key value is a simple ASCII number.

clsTttView handles the X, O, and Space keys on the keyboard.
Chapter 11 / Refining the Application (Tic-Tac-Toe)

Tic-Tac-Toe has many of the niceties expected of a real application. Many of these enhancements are independent of the program, and could be added to Empty Application as easily as to Tic-Tac-Toe.

**Debugging**

You can use DB, the PenPoint™ source-level debugger, to step through code. In an object-oriented system, your objects receive many messages from outside sources, many of which you may not expect. It’s useful to be able to easily track the flow of messages through your routines, and to turn this on and off while your program is running. As you’ve noticed if you’ve looked at the code, Tic-Tac-Toe has extensive support for debugging. It uses the following facilities for debugging:

- `msgTrace` to trace messages.
- `Debugf()` to print debugging messages.
- `msgDump` to dump the state of objects.
- `ClsSymbolsInit()` to give the Class Manager symbolic names for Tic-Tac-Toe’s objects, messages, and status values.

The complexity in Tic-Tac-Toe arises because it lets you turn features on and off while the program is running.

**Tracing**

It’s very useful to have a log of what messages are coming in. You can get a message log by turning on message tracing; you can either turn it on for a class or for a single instance of that class.

In DEBUG mode, TTTMBAR.C defines a debug menu which can turn tracing on or off for the various classes. All the menu items send `msgTttAppChangeTracing` to the application. The message argument encodes the target object to trace and whether to trace it or not:

```c
static TK_TABLE_ENTRY traceMenu[] = {
    {"Trace App On", msgTttAppChangeTracing, MakeU32(0,1)},
    {"Trace App Off", msgTttAppChangeTracing, MakeU32(0,0)},
    {"Trace View On", msgTttAppChangeTracing, MakeU32(1,1)},
    {"Trace View Off", msgTttAppChangeTracing, MakeU32(1,0)},
    {"Trace Data On", msgTttAppChangeTracing, MakeU32(2,1)},
    {"Trace Data Off", msgTttAppChangeTracing, MakeU32(2,0)},
    {pNull}
};
```
Note that the strings in this `TK_TABLE_ENTRY` array, unlike the one used for the menu bar in Counter Application, are not specified with resource IDs. That's acceptable programming practice in this case, because the user will never see the trace menu. That means that you'll never have to translate the strings to another language, so there is no benefit to putting the strings into a resource file (and no cost to hard-coding them).

The `TtDbgChangeTracing()` routine is implemented in `TTTDBG.C`. It simply sends `msgTrace` to the target object, with an argument of true or false.

**Debugf() statements and debug flags**

Going beyond message tracing, it's useful to print out what your application is doing at various stages. One approach is to add simple `Debugf()` statements as you debug various sections. However, in a large program you can quickly get overwhelmed by debugging statements you're not interested in. Tic-Tac-Toe leaves all the `Debugf()` statements in the code, and controls which statements show up by examining a debugging flag set. It uses `DbgFlagGet()` to check whether a flag is set, the same as Empty App and the other simpler applications. What Tic-Tac-Toe provides is an easy way to print out a string identifying the routine, followed by whatever `printf()`-style parameters you want to use. Thus this code:

```c
if (s == stsFSNodeNotFound) {
    DbgTttAppCheckStationery((U_L("file not found; s=0x%lx"),s))
    goto NormalExit;
}
```

will print out

```
TttAppCheckStationery: file not found; s=0xnum
```

but only if the appropriate debugging flag is set.

So, how is it implemented? A definition of its debug routine precedes each function for which you want to print debugging information, for example, `DbgTttAppCheckStationery()`.

```c
#define DbgTttAppCheckStationery(x) \
    TttDbgHelper(U_L("TttAppCheckStationery"),tttAppDbgSet,0x01,x)
```

Call this macro anywhere that you might want to display a debugging string. The parameter to the macro (x) is the Unicode format string and any arguments `((U_L("file not found; s=0x%lx"),s))`. In order to treat multiple parameters as one, they must be enclosed in a second set of parentheses.

The `TttDbgHelper()` routine checks if the specified flag (0x0001) is set in the specified debugging flag set (`tttAppDbgSet`), and if so prints the identifying string `U_L("TttAppCheckStationery")` together with any `printf()`-style format string passed in (x).
There are 256 debugging flag sets, each with a 32-bit value. GO uses some of them for its applications—see PENPOINT\SDK\INC\DEBUG.H for a full list. TTTPRIV.H defines the debugging flag sets used in Tic-Tac-Toe, such as tttAppDbgSet:

```c
// Debug flag sets
#define tttAppDbgSet 0xC0
#define tttDataDbgSet 0xC1
#define tttUtilDbgSet 0xC2
#define tttViewDbgSet 0xC3
#define tttViewOptsDbgSet 0xC4
#define tttViewXferDbgSet 0xC5
```

Other routines use other flags.

In case you're interested, here's the definition of TttDbgHelper():

```c
#define TttDbgHelper(str,set,flag,x) 
    Dprintf("%s: ",str); Debugf x)
```

Dprintf() is the same as Debugf(), except that Dprintf() doesn’t insert an automatic new line at the end of the function.

### Dumping objects

One of the messages defined by the Class Manager is msgDump. A class should respond to it by calling its ancestor, then printing out information about self's state. Most classes only implement msgDump in the DEBUG version of their code.

Tic-Tac-Toe lets you dump its various objects from its Debug menu. In TTTMBAR.C, it defines the menu:

```c
static TK_TABLE_ENTRY debugMenu[] = {
    {"Dump View", msgTttAppDumpView, 0},
    {"Dump Data", msgTttAppDumpDataObject, 0},
    {"Dump App", msgDump, 0},
    {"Dump Window Tree", (U32)dumpTreeMenu, 0, 0, tkMenuPullRight},
    {"Trace", (U32)traceMenu, 0, 0, tkMenuPullRight | tkBorderEdgeTop},
    {"Force Repaint", msgTttAppForceRepaint, 0, 0, tkBorderEdgeTop},
    {pNull}
};
```

The client of the menu is the application, so to dump the application all the menu item needs to do is send msgDump. For the view and data object, you would either have to change the clients of the menu items, or have the application class respond to special msgTttAppDumpView or msgTttAppDumpData messages by sending msgDump to the appropriate target. Tic-Tac-Toe does the latter; the handlers for these messages are in TTTDBG.C.

### Dumping any object

Another approach is to have a generic dump-object function in the DEBUG version of your code which sends msgDump to its argument. When running DB, you can call this routine directly, passing it the UID of the object you want dumped.
Symbol names

All the Class Manager's macros (ObjCallRet(), ObjCallWarn(), ObjCallAncestorChk(), and so on) print a string giving the message, object, and status value if they fail (in DEBUG mode). You can also ask DB to print out messages, objects, and status values. Ordinarily the most the Class Manager and DB can do is print the various fields in the UID, such as the administrated field and message number. However, if you supply the Class Manager a mapping from symbol names to English names, it and DB will use the English names in their debugging output.

The Class Manager routine you use is ClsSymbolsInit(). The routine takes three arrays, one for objects, one for messages, and one for status values. Each array is composed of symbol-string pairs. Tic-Tac-Toe sets up these arrays in the file S_TTT.C:

```c
const CLS_SYM_STS tttStsSymbols[] = {
    0, 0);
const CLS_SYM_MSG tttMsgSymbols[] = {
    msgTttAppChangeDebugFlag, U_L("msgTttAppChangeDebugFlag"),
    msgTttAppChangeDebugSet, U_L("msgTttAppChangeDebugSet"),
    ...
    msgTttViewTakeSel, U_L("msgTttViewTakeSel"),
    0, 0);
const CLS_SYM_OBJ tttObjSymbols[] = {
    clsTttApp, U_L("clsTttApp"),
    clsTttData, U_L("clsTttData"),
    clsTttView, U_L("clsTttView"),
    0, 0);
```

(Tic-Tac-Toe doesn't define any STATUS values.) ClsSymbolsInit() also takes a fourth parameter, a unique string identifying this group of symbolic names. Here's the routine in S_TTT.C that calls ClsSymbolsInit():

```c
STATUS EXPORTED TttSymbolsInit(void)
{
    return ClsSymbolsInit(
        U_L("ttt"),
        tttObjSymbols,
        tttMsgSymbols,
        tttStsSymbols);  
}
```

At installation (from process instance 0), TTT.EXE calls TttSymbolsInit() to load these arrays. To save space, all of this code is excluded if DEBUG is not set.

Generating symbols automatically

It's cumbersome to type in and update the arrays of UID-string pairs. At GO we have developed scripts that automatically generate files like S_TTT.C. These scripts require the MKS toolkit and other third-party utilities, so they are on the unsupported SDK Goodies disk.

Printing symbol names yourself

Tic-Tac-Toe just prints UIDs as long integers when it needs to print them out. You can also print them in hexadecimal format using the %p format code. If you want to print out the long names within your own code, the Class Manager defines
several functions to convert objects, messages, and status values to strings, such as 
ClsObjectToString().

Installation features
During installation, PenPoint automatically creates several application enhance­
ments based on the contents of the application’s installation directory:

- Stationery.
- Help notebook documents.
- Quick-help for the application’s windows.
- Application icons.

The nice thing about these enhancements is that you can create and modify them 
separately from writing and compiling the application. In fact, all of these features 
could have been added to Empty Application, the very simplest application.

General details on application installation are covered in detail in Part 12: Installa­
tion API of the PenPoint Architectural Reference. This section only covers what Tic­
Tac-Toe does.

Stationery
The user can pick a Tic-Tac-Toe board to start with from a list of Stationery. The 
user can draw a caret \ over the table of contents to pop up a Stationery menu, or 
can open the Stationery auxiliary notebook (see Figure 11-1).

Creating stationery
The Installer looks for Stationery in a subdirectory called STATNRY. Each Stationery 
document should be in a separate directory in STATNRY. You can stamp the directo­
ries with long PenPoint names, and in PenPoint 2.0 Japanese you can stamp the 
directory with a locale and read the long name from a resource file. You can also 
stamp the directories with attributes indicating whether the Stationery should 
appear in the Stationery menu and whether it should appear in the Stationery 
notebook.

How Tic-Tac-Toe handles stationery
Stationery directories can contain a filed document—a regular instance of the 
application. To build such Stationery you copy a document from the Notebook to 
the installation volume. One disadvantage of this is that it could make the Statio­
nery take up more space, since it’s an entire filed document.

Instead, clsTttApp always checks for a file called TTTSTUFF.TXT in the document’s 
directory when a document is first run (during msgApplnit). The routine is Ttt­
AppCheckStationery() in TTTAPPC. If it finds a TTTSTUFF.TXT file, clsTttApp 
opens it and sends msgTTTDataRead to its data object. This tells the data object to 
set its state from the file.
clsTTData simply reads the first nine bytes of the file and sets its value from those; for example, the TTTSTUFF.TXT file for "Tic-Tac-Toe (filled)" (in PENPOINT\APP\ TTT\STATNRY\TTTSTAT1) is simply

xoxoxoxox stationery for tttapp

This saves a lot of space over a filled Tic-Tac-Toe document; however, note that this form of Stationery doesn't include things like the thickness of the grid in the view. The user can always make Stationery that is a full document by moving or copying a Tic-Tac-Toe document to the Stationery notebook.

The makefile for Tic-Tac-Toe creates the STATNRY directory in PENPOINT\APP\ TTT, and then creates the two directories TTTSTAT1 and TTTSTAT2. The makefile copies the file FILLED.TXT to TTTSTAT1 and names it TTTSTUFF.TXT; it then copies the file XSONLY.TXT to TTTSTAT2 and also names it TTTSTUFF.TXT

**Help notebook**

Tic-Tac-Toe has its own Help information, which the user can view in the Help auxiliary notebook. Each page in the Help notebook is a separate document.

Tic-Tac-Toe doesn't have to do anything to support this.
Creating help documents

During installation, if there is anything in the HELP subdirectory of the application home, the Installer creates a subsection for the application in Applications section of the Help notebook. The Installer automatically installs help documents in this section of the Help notebook. Like stationery, you put help documents in subdirectories of a special subdirectory in the Tic-Tac-Toe installation directory, called HELP. You can stamp the directories with long PenPoint names, these are the names of the pages in the Help notebook.

The Tic-Tac-Toe makefile creates a HELP directory in PENPOINT\APP\TTT and creates TTTHELP1 and TTTHELP2 directories in TTTHELP. The makefile copies STRAT.TXT to TTTHELP1 and names it HELP.TXT; it then copies RULES.TXT to TTTHELP2 and names it also HELP.TXT.

Help documents can either be complete instances of filed documents (of any type, such as MiniText or MiniNote, even a help version of your application), or a simple text file. If the directory contains a simple text file, the Help notebook will run a version of MiniText on that page, displaying the contents of the file. This is the approach Tic-Tac-Toe uses.

Quick Help

Quick Help is the other form of help in PenPoint. The Quick Help window appears when the user makes the question mark ? gesture in a window, or taps on a window when Quick Help is up (see Figure 11-2).

clsGWin, the gesture window class, automatically handles the Quick Help gesture. It will invoke the Quick Help window, if it knows what to display. Instead of specifying to clsGWin what strings to display, you create your strings in a separate resource, and just give clsGWin an ID which it uses to locate the strings. In the msgNewDefaults handling of clsTttView:

```c
MsgHandlerWithTypes(TttViewNewDefaults, P_TTT_VIEW_NEW, PP_TTT_VIEW_INST)
{
    DbgTttViewNewDefaults((U_L("self=0x%lx"),self))
    pArgs->win.flags.input |= inputHoldTimeout;
    pArgs->gWin.helpId = tagTttView;
    ...
    pArgs->view.createDataObject = true;
    ...
}
```

This is the only thing clsTttView must do to handle Quick Help.

Creating Quick Help resources

One way to create resources is to tell a resource file to file an object, using say msgResPutObject. This is what happens when an application is told to save a document.

However, one goal of resources is to separate the definition of a resource from the application that uses it. So you can also compile resources under DOS, putting them
in a resource file, and read them from within PenPoint applications. These resources aren't objects, they are basically predefined data structures.

In the case of Quick Help, a Quick Help resource consists of three parts:

- The strings that contain the Quick Help text.
- A tagged string array resource (type RC_TAGGED_STRING) that associates each text string with a tag. The tags are used by the gesture window helpIds to associate a gesture window with its Quick Help text.
- An RC_INPUT structure containing:
  - A list resource ID created from the administered portion of the Quick Help ID (in this case clsTttView) and the Quick Help group (usually resGrpQhelp).
  - A pointer to the tagged string array resource for the class.
  - A length field (updated by the resource compiler).
  - The identifier for the string array resource agent (resTaggedStringArrayResAgent).
Each Quick Help string has two parts, which are separated by two vertical line characters (||). The first part is the title for the Quick Help card; the second part is the Quick Help text. The vertical line characters are not printed when Quick Help displays.

These are the United States English Quick Help strings for the Tic-Tac-Toe application, defined in USA.RC (there is also a Japanese version in JPN.RC):

```c
// Define the Quick Help resource for TTT.
static RC_TAGGED_STRING tttViewQHelpStrings[] = {
    // Quick help for TTT's option card to change the line thickness.
    tagTttViewCard,
    U_L("TTT Card||")
    U_L("Use this option card to change the thickness of the lines ")
    U_L("on the Tic-Tac-Toe board.")
    // Quick help for the line thickness control in TTT's option card.
    tagCardLineThickness,
    U_L("Line Thickness||")
    U_L("Change the line thickness by writing in a number from 1-9.")
    // Quick Help for the TTT window.
    tagTttView,

    0,
    resTaggedStringArrayResAgent
};
```

See Part 11: Resources, in the PenPoint Architectural Reference, for more information on resource compiling and the specifics of Quick Help resources.

To compile resource definitions into a resource file, you use the PenPoint Resource Compiler (PENPOINT/SDK/UTIL/DOS/RC).

The Installer copies the application resource file during installation. Hence the makefile tells the resource compiler to append the Quick Help resources to the application resource file. The name of the application resource file includes a three-letter code that indicates the locale for which you've compiled the resource file. For example, for the United States, the resource file is called USA.RES; for Japan, it is called JPN.RES. You define in the makefile which locales to compile resource files for.
Standard message facility

The PenPoint standard message facility, \texttt{StdMsg()}, provides a standard way for your application to display modal dialog boxes, error messages, and progress notes without requiring it to create UI objects. \texttt{StdMsg()} uses \texttt{clsNote} (see \texttt{NOTE.H}) to display its messages. Notes have a title, a message body, and zero or more command buttons at the bottom.

Message text and command button definitions are stored in resource files. \texttt{StdMsg()} supports parameter substitution for the message text and button labels (see \texttt{CMPSTEXT.H}). A 32-bit value (a tag in the case of dialog boxes and a status code in the case of errors) is used to select the appropriate resource.

\texttt{StdMsg()} provides the following routines for when the programmer knows exactly which message is to be displayed:

\begin{itemize}
\item System and application dialog boxes use \texttt{StdMsg(tag, ...)}
\item Application errors use \texttt{StdError(status, ...)}
\item System errors use \texttt{StdSystemError(status, ...)}
\item Progress notes use \texttt{StdProgressUp(tag, &token, ...)}
\end{itemize}

With \texttt{StdMsg()}, \texttt{StdError()}, \texttt{StdSystemError()}, and \texttt{StdProgressUp()}, any parameter substitutions are supplied with the argument list, much like \texttt{printf()}. Like \texttt{printf()}, there is no error checking regarding the number and type of the substitution parameters. The first three functions return an integer, which indicates the command button that the user tapped. Progress notes, which use \texttt{StdProgressUp()}, don't have a command bar.

\texttt{StdMsg()} also provides support for the situation where an unknown error status is encountered: \texttt{StdUnknownError()}. This function does not provide parameter substitution or multiple command buttons, it always displays a single “OK” command button. \texttt{StdUnknownError()} replaces any parameter substitution specifications in the text with “???”.

Using \texttt{StdMsg()} facilities

To use \texttt{StdMsg()}, you first define the message text strings. These strings are held in string array resources, like Quick Help. A single resource holds all the strings for a given class. There is a separate string array for dialog boxes and error messages. You should store the application message resources in the application’s resource file.

Here’s the resource file definition of all of the error notes for the \texttt{CLOCK} sample application:

\begin{verbatim}
static RC_TAGGED_STRING errorStrings[] = {
  // Error: user has set alarm to before the current time
  stsClockAlarmInvalid,
  U_L("You can’t set the alarm date and time to be earlier 
       than the current date and time.")
  /* Error: user has specified an out-of-bounds number, like 12:72 */
  stsClockFieldRangeError,
  U_L("The time you specified is invalid. Choose a number 
       between 2d and 3d.")
};
\end{verbatim}
You must define a tag or error status for each string. The string's position in the string array determines its tag or status index (starting from 0). Here are the definitions for the example above:

```c
#define stsClockAlarmInvalid MakeStatus(clsClockApp, 0)
#define stsClockFieldRangeError MakeStatus(clsClockApp, 1)
#define stsClockIntFieldInvalid MakeStatus(clsClockApp, 2)
#define stsClockDateFieldInvalid MakeStatus(clsClockApp, 3)
```

To create a note from the items defined above, simply call `StdMsg()` or `StdError()`.

```c
if ( (low <= value ) && (value <= high) ) {
    return stsOK;
} else {
    // else field out of range
    StdMsg(stsClockFieldRangeError, pFieldName, low, high);
    return stsFailed;
}
```

Progress notes are slightly different from the message functions. Your application displays a progress note when it begins a lengthy operation, and takes the note down when the operation completes. PenPoint 1.0 does not support cancellation of the operation. Here's an example of progress note usage:

```c
SP_TOKEN token;
StdProgressUp(tagFooProgress1, &token, param1, param2);
... Lengthy operation ...
StdProgressDown(&token);
```

**Substituting text and defining buttons**

The message strings can contain substituted text and definitions for buttons. String substitution follows the rules defined by the compose text function (defined in CMPSTXT.H). A button definition is a substring enclosed in square brackets at the beginning of the message string. You can define any number of buttons, but you must define all buttons at the beginning of the string. The button substrings can contain text substitution. If the string doesn't define any buttons, `StdMsg()` creates a single “OK” button.
StdMsg(), StdError(), and StdSystemError() return the button number that the user tapped when dismissing the note. Button numbers start with 0. For example, this string definition would result in a return value of 1 if the user tapped **Button1**:  
`U_L("[Button0] [Button1] [Button2] Here's your message!")`

Be aware that these functions might also return a negative error status, which indicates that a problem occurred inside the function.

You can break your message up into paragraphs by putting two newline characters at the paragraph breaks. For example:  
`U_L("Here's the first paragraph.\n\nHere's the second one.")`

### StdMsg() and resource files or lists

There are variations of StdMsg() and StdError() that allow you to specify the resource file handle or resource list to use. These are most useful for PenPoint Services, where there is no default resource list available. These messages are:

+ `StdMsgRes(resource_file, tag, ...)`
+ `StdErrorRes(resource_file, status, ...)`

### StdMsg() customization function

The function StdMsgCustom() allows you to customize a StdMsg() note. The function returns the UID of the note object (created by clsNote), without displaying it. You can modify this object as you wish and then display it yourself using the messages defined by clsNote.

### Bitmaps (icons)

PenPoint uses icons to represent applications in the table of contents and in Browsers. You can also use icons in your own applications. In PenPoint terminology, the icon includes optional text as well as a bitmap picture. There are default bitmaps for applications and documents, but you can create your own using the bitmap editor (see Figure 11-3).

When it needs a bitmap, the Application Framework searches for it by resource ID in your application's resource list. If you do not specify an application icon in your application's resource file, the search gets the default bitmap in the system resource file. However, if you put a different icon in your application's resource file, it will be used instead. You don't need to make any changes to your application to support this.
Creating icons

The bitmap editor application is available in the PENPOINT\APP\BITMAP directory. It is also available on the PenPoint Goodies disk.

The bitmap editor needs to generate a bitmap as a resource and put it in a resource file. However, it conforms to the PenPoint document model, so it has no Save command. Instead, you use the About... menu item in the Document menu to bring up the Export option card to specify the type of bitmap resource, and then use the Export... command to actually generate the bitmap resource. You generally export four bitmaps, two each for the application and document in 16 x 16 and 32 x 32 sizes. Although you can export them to the APP.RES file in your application’s installation directory, it is often preferable to create separate SMICON.RES and LGICON.RES files for the large and small icons and use the resource compiler to append these to your application’s resource file.

For more information on using the bitmap editor, see Part 3: Tools in PenPoint Development Tools.
Chapter 12 / Releasing the Application

You're almost done, but not quite. Before you make your application available to the larger world of PenPoint™ users, you must complete these tasks:

- Register your classes with GO.
- Document the application.
- Prepare your distribution disks.

You should also consider making your classes available to other developers. If you do so, you need to document the API for those classes.

Registering your classes

While developing an application, you can identify your classes with the well-known UIDs wknGDTa through wknGDTg. Of course, if you use these UIDs in a published application, they will conflict with other developers who use your application and attempt to use these well-known UIDs to test their own applications.

When you are fairly sure that you will publish your application, you must obtain an administered value for each of your public classes. Remember that a UID consists of an administered object value, a version number, and a scope (global or local, well-known or private). Contact GO Customer Services at 1-415-358-2040 (or by Internet electronic mail at gocustomer@go.com) for information on how to get a unique administered value.

Documenting the application

The need for quality documentation cannot be over-emphasized. There are three ways in which you should document your application:

- Manuals or other form of separate documentation.
- Pages in the Help notebook.
- Quick Help text.

Writing manuals

For more information on documenting your application, contact GO Customer Services at 1-415-358-2040 (or by Internet electronic mail at gocustomer@go.com) and ask for Tech Note #8, Documenting PenPoint Applications. This technical note, written by GO's end-user documentation group, provides information about how GO writes and produces its end-user documentation. The Tech Notes also give print specifications, if you want your documentation to appear similar to GO's.
Screen shots

The S-Shot utility enables you to capture TIFF images of PenPoint computer screens. You can then incorporate your images into your documentation. S-Shot is on the SDK Goodies disk.

Gesture font

For developer and end-user documentation, GO created an Adobe Type 1 font that depicts the PenPoint gesture set. If you use a PostScript printer, you can incorporate this font into your documentation and on-line help.

Registered developers may request a copy of the PenPoint Gesture font from GO by contacting GO Customer Services.

On-disk structure

When developing your application, the PenPoint file organization requires you to place your files in certain specific directories under the PENPOINT directory. This is described in detail in Chapter 3 of Part 12: Installation API in the PenPoint Architectural Reference.

Before distributing your application, you should ensure that all your auxiliary files, such as Help notebook pages, Stationery, Resource files, and so on are in their correct directories.

Sharing your classes

If you have created a component class that might be useful to other PenPoint developers, you should consider licensing the class.

Chapter 13 / Introduction

The worldwide software market is growing at an exciting rate. Recognizing this trend, GO Corporation has designed PenPoint™ to be a global operating system. Specifically, the PenPoint operating system provides many objects, functions, and tools that help you prepare your application for an international market.

Modifying an application for use in a specific country (or locale, because countries like Canada, Switzerland, and Singapore use more than one language) is called localization. The process of preparing an application so that it is ready to localize is called internationalization.

This handbook provides a step-by-step guide through the process of internationalizing your code. The result is code that is ready to be adapted to particular markets.

This handbook does not contain specific guidelines on how to design a successful version of your application for a particular market. It does not, for example, offer specific suggestions on how to design an appropriate user interface for Japan or Germany or Italy.

Because this handbook does not discuss localization, you may want to work with your marketing and sales departments, local software partners, localization houses, users, and other resources to create an appropriate product for a given locale. Also, Chapter 19, Additional Resources, lists resources that may help you with the localization process.

The PenPoint operating system currently supports only American English and Japanese. Future releases will support more languages and countries.

**Intended audience**

This handbook is for developers designing original PenPoint applications for an international market and for developers porting existing PenPoint 1.0 applications to PenPoint 2.0 Japanese. When used in this document, the terms “PenPoint 2.0” or “PenPoint SDK 2.0” refer to “PenPoint 2.0 Japanese” or “PenPoint 2.0 SDK Japanese.”

Many issues that you need to consider while designing international applications are less important if you are developing only for a local market. For example, consider an icon designed to signal “stop.” American users might expect such an icon to look like a traffic light with a red light on top. This icon would be inappropriate in many countries outside of the United States. In Japan, for example, traffic lights are horizontal so that the red light is on the far left.
This handbook assumes that you are familiar with PenPoint programming. \textit{Part 1: PenPoint Application Writing Guide} is the best place to start if you are new to PenPoint programming. You will also get the most out of this handbook if you understand what your target locale is and what kind of application you plan to market there. Once you’ve identified the target locales for your application, you can tailor the general recommendations in this handbook to your specific needs.

This handbook also assumes you have installed PenPoint SDK 2.0 Japanese. See \textit{Installing and Running the PenPoint SDK 2.0}, a document included with the SDK, for details on how to install the SDK.

For details on localizing your application to Japan, read \textit{Part 3: PenPoint Japanese Localization Handbook}. This part assumes you have internationalized your code according to the guidelines in this handbook.

\section*{Handbook structure}

This chapter describes the handbook’s purpose and organization.

Chapter 14, Overview, describes the general process of how to write an international application.

Chapter 15, PenPoint Support for International Software, describes PenPoint’s routines, functions, and utilities that support international applications.

Chapter 16, Procedures, provides step-by-step instructions on how to write code for international applications.

Chapter 17, Porting to PenPoint 2.0, discusses how to port existing PenPoint 1.0 code to the latest version of PenPoint.

Chapter 18, Localization Guidelines, lists general issues to consider while localizing your application.

Chapter 19, Additional Resources, describes other helpful resources, including dictionaries, books, and contacts for standards organizations.

\section*{How to use this handbook}

If you are new to internationalization issues, begin with Chapter 14, Overview. If you are familiar with internationalization issues and want to learn how the PenPoint operating system helps you produce internationalized applications, read Chapter 15, PenPoint Support for International Software. Both of these conceptual chapters place the procedures covered in Chapter 16, Procedures, in perspective.

If you are looking for specific directions on how to perform a task such as supporting Unicode, see “Supporting Unicode” on page 209 in Chapter 16, Procedures. Each procedure refers to other information, usually in this handbook, that you need to understand before doing the procedure.
Chapter 14 / Overview

This chapter provides a general overview of how to write international software. Chapter 15, PenPoint Support for International Software, provides specific details on how some special features of the Japanese localization of PenPoint™ operating system 2.0 help you write international software.

Many books and organizations may also help you internationalize your application. Chapter 19, Additional Resources, lists some of these resources.

Overview of international software

The goal of internationalization is to make an application easily adaptable for a target locale. The internationalized version of your source code must support international character sets and behave appropriately for different locales.

In this handbook, we usually use the term locale to identify a particular country, language, and dialect. Often, as with the USA and Japan, the country name is enough to identify a locale because the country uses only one language and no major dialects. Sometimes, however, as in Canada, Switzerland, and Singapore, countries use multiple languages and even dialects. In such cases, a locale represents both a country and a language (and sometimes a dialect) such as French-speaking Canada or Chinese-speaking Singapore.

In the best case, you can maintain a single code base for your application and create localized versions by simply creating different resource files. Figure 14-1 shows this optimum design. Remember that resource files are collections of data, such as strings, that are cleanly separated from your application code.

Think of resource files as modular pieces that can be snapped in and out of your application as the locale requires. What kind of pieces might be stored as resource files? Anything that the user sees is a likely candidate. These include user interface strings, window layouts, icons, and bitmaps.

You can also use resource files to store binary data that your application interprets. For example, you might use a flag in a resource file to tell your application whether to calculate in English or metric units. Another set of flags might represent user preferences.

Sometimes local versions of your application differ too much for you to maintain a common code base. For example, a Japanese version of your application might need to provide context-sensitive handwriting recognition that a German version of your application does not need to provide.
When local versions of your application differ too much for you to maintain a common code base, create different DLLs from different source code files as shown in Figure 14-2. In the example above, you might write all the code that provides additional Japanese handwriting support in one source file, compile the code into a DLL, and then link that library with the rest of your application's object files.

If you must resort to separate code bases for each locale, keep the differences isolated to as few files as possible. This strategy makes it easier to test and maintain your code.

**Writing international software**

This section introduces the process of writing international software. After this overview, you may want to look through Figure 14-1. This checklist is a detailed, step-by-step description of how to implement the general tasks described here.

Internationalizing an application requires these four general steps:

1. Prepare to handle international character sets by supporting Unicode.
2. Write locale-independent code.
3. Move application components that vary with locale like strings, window layouts, and bitmaps into resource files.
4. Update your project files.
Notice that steps 1 and 2 involve producing the block of common code at the top of Figure 14-1. Step 3 creates the resource files in the middle tier, and step 4 brings all the pieces together.

Consider the example of a word processor. A U.S. version of the word processor should provide functionality and an interface tailored for U.S. users. This application would:

- Display, read, and write Roman characters.
- Delimit English words, sentences, and paragraphs based on U.S. English grammatical conventions.
- Sort words based on the order of the English alphabet.

A Japanese version of the word processor, on the other hand, should use an interface tailored to Japanese users, and support Japanese functionality:

- Display, read, and write Japanese characters.
- Delimit Japanese phrases, sentences, and paragraphs based on Japanese grammatical conventions.
- Sort characters based on Japanese sorting conventions.

See Figure 14-3 for a MiniText document that shows how this might look.
Again, the goal is to have a single code base for both local versions of your application. This single code base combined with an appropriate resource file yields a localized version of your application. The four general steps you must take to write an international version of your application or service are described in more detail below.

**Step 1. Support Unicode**

Your application must support multiple character sets such as Roman letters and Japanese characters. In order to maintain a single code base for all local versions of your application, you need a single character coding scheme that handles all the character sets you plan to support. The PenPoint operating system, beginning with version 2.0 Japanese, uses Unicode as its character coding scheme. Your first task is to provide Unicode support in your code.

- The Unicode character encoding scheme is discussed beginning with the section “International character sets” on page 183.
- The process of supporting Unicode is discussed beginning with the section “Supporting Unicode” on page 209.

**Step 2. Write locale-independent code**

The next step is to make your application behave correctly for a particular locale. Rather than rewriting major parts of your code to perform local functions (sorting, formatting, and filing, for example), write a single block of internationalized source code that behaves as expected in a given locale.

For example, rather than write separate formatting algorithms for English and Japanese dates, you can use a single PenPoint function called `IntlFormatDate()` in your code that appropriately formats English or Japanese dates depending on the locale. PenPoint provides a collection of functions whose behavior changes according to the locale (specified as an argument). These functions are discussed in detail in Chapter 15, PenPoint Support for International Software.
Whenever possible, your application should also use PenPoint-defined objects because these objects behave appropriately for any currently supported locale. For example, an input pad (clsIP) in the Japanese version of PenPoint handles Japanese handwriting recognition.

- The PenPoint international functions are discussed in Chapter 15, PenPoint Support for International Software.
- For step-by-step instructions on how to use the international functions, see Chapter 16, Procedures.

✿ **Step 3. Use resource files**
Next, move application elements that vary with locale into resource files. The strings in your user interface are a good example, though other elements, such as bitmaps, may also belong in resource files.

Having strings and other elements that vary with locale in resource files makes it easier to localize your application.

- Resource files are discussed in the section “Resource files” on page 189.
- The process of moving things to resource files is discussed beginning with the section “Using the DOS utility INTLSFCAN” on page 210. The discussion continues in “Moving strings to resource files” on page 216.

✿ **Step 4. Create your application**
Finally, update your project directory and makefile to create localized versions of your application or service.

Makefiles are discussed in detail in Chapter 29 of Part 4: PenPoint Development Tools Supplement. For more details on how to update your makefiles, see “Updating your makefile” on page 224.

For recommendations on how to organize your project files, see “Managing your project” on page 205.
Internationalization checklist

These are the steps you should take to prepare your application for an international market. Don't worry if some of the terms in the checklist are unfamiliar. They will be explained in the section shown in the checklist.

- Understand the steps involved in the internationalization process by reading this chapter.
- Use INTLSCAN to help internationalize your code ("Using the DOS utility INTLSCAN" on page 210).
  - Declare character and string data as 16 bits long ("Supporting Unicode" on page 209).
  - Use 16-bit routines to handle Unicode characters ("Using the DOS utility INTLSCAN" on page 210).
  - Make literal strings Unicode strings ("Creating Unicode strings" on page 215).
  - Move most literal strings to resource files ("Moving strings to resource files" on page 216).
- Use resource files to store locale-dependent components ("Resource files" on page 189).
  - Use predefined Application Manager tags ("Using predefined AppMgr tags" on page 219).
  - Use tags in your source code ("Using tags in source code" on page 222).
  - Use utility functions to read data out of resource files ("Using resource utility functions" on page 220).
- Write locale-independent code ("Locale-independent code" on page 196).
  - Take advantage of PenPoint's international functions ("PenPoint's international functions" on page 197).
- Manage your project files ("Updating your makefile" on page 224).
- If necessary, handle porting from 1.0 details (Chapter 17, Porting to PenPoint 2.0).
  - Update your code to reflect new PenPoint APIs ("Changed APIs" on page 229).
  - Update your gesture handling code ("Gesture handling code" on page 230).
  - Use the bitmap editor to design special characters ("Special characters" on page 231).
  - File class version information with your data ("File version data" on page 233).
  - Maintain a single code base ("Single code base" on page 233).
Chapter 15 / PenPoint Support for International Software

This chapter introduces the messages, functions, and utilities the PenPoint™ operating system provides to support international software. Currently, the PenPoint operating system 2.0 Japanese supports only Japanese and U.S. English. Future releases of PenPoint will support more locales.

International character sets

English text is composed of letters derived from the Roman alphabet. The Roman writing system is the most common in the modern world. Some 70 percent of the world’s literate population write or understand a language based on the Roman writing system.

Languages based on Roman letters are relatively simple to represent. Indeed, 8-bit ASCII-based encoding schemes are sufficient to encode most European alphabets, Roman and non-Roman, as well as a large collection of punctuation marks.

Not all countries, of course, use letters from these European alphabets. The Cyrillic and Hebrew alphabets are two familiar examples.

Some languages do not use alphabets at all, or do not use them as the primary building blocks of language. Instead, these languages use ideographs (literally "idea symbols") to represent a thing or idea rather than letters to represent words.

Chinese, Japanese, and Korean are the most common of these ideographic writing systems, and these languages are written by almost a billion people in the world today. These character sets contain thousands rather than dozens of characters.

Multibyte and wide characters

The problem with large character sets, from a programmer’s point of view, is that they are difficult to represent. Clearly, 8 bytes are insufficient because you can represent only $2^8$ or 256 characters if you use a one-to-one mapping between code points and represented characters. A code point is a number that represents a particular character. For example, the ASCII code point for the letter ‘A’ is 0x41.

Two possible solutions to this problem are multibyte characters and wide characters.

Multibyte character encoding schemes use one or more bytes to represent a single character. A good example of this scheme is the Japanese Industrial Standards (JIS) encoding of Japanese.
JIS encoding involves two states. In one state, a single byte represents a single ASCII character. In the other state, two bytes represent a single Japanese character. A special sequence of codes shifts a text stream between the two states.

Because many of the world’s existing computer devices deal with bytes of information, such a scheme takes advantage of existing byte-sized system designs.

On the other hand, there are drawbacks to multibyte encoding. One of the obvious disadvantages is that you must know what state a given byte is in before you can manipulate it. For example, in an arbitrary stream of JIS text, you cannot be sure if a given byte is a single ASCII character or half a Japanese character without scanning for the “shift-in” and “shift-out” codes.

Because code that processes these multibyte character sets is complex and error-prone, programmers have developed an alternative scheme: using fixed-length codes wide enough to accommodate the required characters.

These wide codes allow more characters to be encoded without ambiguity. Character manipulation code is thus easier to write.

However, no widely adopted standard of wide character encoding has been established. Implementation of wide character sets has been private to a particular company. Though systems could depend on their internal characters being of some fixed length longer than a byte, they could not depend on other systems using the same fixed length in the same way.

Introduction to Unicode

The PenPoint operating system, beginning with version 2.0 Japanese, encodes its character using Unicode, a character encoding system that offers advantages of both multibyte and wide character schemes. It uses a wide, 16-bit code to encode each character, regardless of the language to which it belongs. For example, Roman letters and Japanese characters are both 16-bits long.

The uniform 16-bit length frees the programmer from the difficulties of multibyte encoding: a 16-bit Unicode code always represents a single character.

The Unicode standard aims to be comprehensive. Because Unicode characters are uniformly 16-bits long, there are $2^{16}$ or roughly 65,500 possible characters. Currently, some 34,400 characters and symbols have been assigned as part of Unicode 1.0. According to the Unicode Consortium, these characters are “more than sufficient for modern communication.”

For more information on Unicode, see Chapter 19, Additional Resources, for more details on the two-volume book titled *The Unicode Standard, Version 1.0*.

Minor changes have been made to the Unicode standard since the publication of the two volumes. This revised standard is Unicode 1.0.1, and PenPoint uses this most current version of the Unicode standard.
**Unicode architecture**

The complete Unicode character set is divided into four major zones, as shown in Figure 15-1.

![Unicode Architecture Diagram](image)

The character set is laid out in successive blocks of 256 code points. A Unicode code point is a unique 16-bit number representing a particular character. For example, the code point 0x0041 represents the Latin letter 'A'.

Each block (or group of blocks) of 256 code points forms a linguistic or functional category. For example, there are blocks representing ASCII characters, Cyrillic letters, Arrows, Mathematical Operators, and Chinese, Japanese, and Korean (CJK) ideographs.

Each block is identified by the value of its upper byte. For example, ASCII characters are in block 00, Arabic is in block 06, and Thai is in 0E.

Chinese, Japanese, and Korean ideographs occupy the 76 blocks from hex 40 to 8B, representing a total of approximately 19,500 characters.

For more details on how Unicode compares with existing double-byte character sets, notably the popular JIS and Shift-JIS used in Japan, please see *The Unicode Standard 1.0* and the *Part 3: PenPoint Japanese Applications Handbook*. 

**FIGURE 15-1**

The four zones in Unicode contain the following:

- **Alphabets** contain all alphabets and all other nonideographic script characters, as well as miscellaneous symbols.
- **CJK** contain all Chinese, Japanese, and Korean ideographs.
- **Reserved** is a currently unassigned zone reserved for future use.
- **Private Use Area** contains areas that corporations can use to define their own characters. For example, GO's gesture glyphs are in the private use area. This private area also includes characters retained for compatibility with previous character encoding standards.
Providing Unicode support in your code is straightforward, one-time procedure. Once your code supports Unicode, you never need to rewrite substantial portions of your code to support different character sets.

ASCII-based encoding systems use 8 bits to encode characters while Unicode uses 16 bits. Supporting Unicode requires you to write code that deals with 16-bit rather than 8-bit characters. The PenPoint SDK 2.0 Japanese provides tools to help you make the transition, which impacts the following categories of code:

- Character types.
- String functions.
- Character and string constants.
- String formatting.

Each of these categories is discussed below. Table 15-1 below gives you a flavor of how the new code will look compared to the old.

### How to work with strings

<table>
<thead>
<tr>
<th>Attribute</th>
<th>8-bit strings</th>
<th>16-bit strings</th>
<th>Both 8- and 16-bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Character types</td>
<td>CHAR8</td>
<td>CHAR16</td>
<td>CHAR</td>
</tr>
<tr>
<td>Character/string constants</td>
<td>“John”</td>
<td>L “John”</td>
<td>U_L(“John”)</td>
</tr>
<tr>
<td>String functions</td>
<td>strlen(&amp;aString)</td>
<td>strlen16(&amp;aString)</td>
<td>Ustrlen(&amp;aString)</td>
</tr>
<tr>
<td>String formatting</td>
<td>“%hs”</td>
<td>“%ls”</td>
<td>“%s”</td>
</tr>
<tr>
<td>Library functions</td>
<td>isupper(aChar)</td>
<td>_uisupper(aChar)</td>
<td>Uisupper(aChar)</td>
</tr>
</tbody>
</table>

The last column is labelled “Both 8- and 16-bit.” The code shown in this column works with 8-bit characters in PenPoint 1.0 and 16-bit characters in PenPoint 2.0 Japanese (and beyond).

For example, declaring a variable of type CHAR declares an 8-bit character (CHAR8) character in PenPoint 1.0 and a 16-bit character (CHAR16) in PenPoint 2.0 Japanese. Future releases of the PenPoint operating system will continue to use 16-bit Unicode characters. Use these hybrid functions and types whenever possible.

Most of the hybrid types are defined CTYPE.H. The hybrid functions are defined in the same C header file as the equivalent C function. For example, the Ustrlen() function is defined in STRING.H. The U_L() macro is defined in INTL.H.

Several procedures in Chapter 16, beginning with “Examples” on page 210, list step-by-step directions for writing code that supports Unicode. Read the following sections for an overview of the process.

The SDK includes a DOS utility called INTLSCAN that flags code that may need to be changed to support Unicode. The utility is on the Goodies disk in the directory "SDK\UTIL\DOS." See “Using the DOS utility INTLSCAN” on page 210 for more information.
Character types

The PenPoint operating system provides three type declarations for character data: CHAR8, CHAR16, and CHAR. The first two declare 8- and 16-bit characters, respectively. The CHAR type is defined for code portability: it is 8 bits wide in PenPoint 1.0 and 16 bits wide in PenPoint 2.0 Japanese.

If you have PenPoint 1.0 code that uses the char (lower case) type, convert all of your character data to use the CHAR (upper case) type. You may not need to change declarations of noncharacter data. Use types such as U8 to declare variables of fixed size.

Where noncharacter data depends on the size of CHAR being 1 byte, you need to update your code because CHAR is 2 bytes longs in PenPoint 2.0 Japanese.

The DOS utility INTLSCAN, included on the Goodies disk in \SDK\UTIL\DOS, flags lines of code that may need to change to support Unicode. See “Using the DOS utility INTLSCAN” on page 210 for information on how to use INTLSCAN.

String functions

The familiar C string library functions (strcmp(), strcpy(), and so on) still exist in PenPoint 2.0, but they work only on 8-bit characters. A set of PenPoint macros such as Ustrlen() and Ustrcmp() allows you to work with 8-bit and 16-bit strings, depending on the PenPoint version. These macros are defined in STRING.H.

In PenPoint 2.0 Japanese, the macros are defined to call new functions provided by the WATCOM C compiler to work with 16-bit data. These functions all have the character _u prepended to the equivalent C function name. For example, the header file STRING.H defines prototypes for a set of string functions named _ustrcmp(), _ustrcpy(), and so on.

These 16-bit functions are defined in the same C header file you would find the equivalent 8-bit C function. Prototypes for strlen() and _ustrlen(), for example, are both defined in STRING.H.

One note before you replace all your 8-bit functions with the 16-bit or hybrid functions like Ustrlen(). Some functions like isupper() not only have 16-bit equivalents, but they also have equivalents in the PenPoint international package. In this particular case, the equivalent to isupper() is IntlCharIsUpper() defined in CHARTYPE.H.

The international functions also work on 16-bit characters or strings, but these functions are more likely to provide behavior appropriate for a particular language. Use these functions, discussed beginning with the section “Locale-independent code” on page 196, whenever you are processing linguistically meaningful text.

In summary, GO recommends that you use the following functions, in order of preference:

- Use the PenPoint international functions such as IntlStrConvert() when you are processing text the user sees.
- Use the U...() macros such as Ustrcmp() when an international function is unavailable or when you are processing internal data.
• Use the _u...() functions such as _ustrlen() provided by WATCOM when you are sure your data is 16-bits long.
• Use the C library functions such as strlen() when you are sure your data is 8-bits long.

**Character and string constants**

When you use CHAR8, you can use the standard C conventions for forming character and string constants. For example:

```
CHAR8 *s = "string";
CHAR8 c = 'c';
```

When you use the CHAR16 type, you must wrap the L"" modifier around your literal character or strings. This tells the compiler you are using a 16-bit (or Long) character, as in:

```
CHAR16 *s = L"string";
CHAR16 c = L'c';
```

When you use the CHAR type, you must put the character or string constant in the macro U_L().

```
CHAR *s = U_L("string");
CHAR c = U_L('c');
```

Again, the U_L() macro is a hybrid. In PenPoint 1.0, U_L() tells the compiler to use 8-bit characters; in PenPoint 2.0, it tells the compiler to use 16-bit characters. GO recommends that you use the U_L() macro around all of your literal strings.

The L"" modifier is part of the C language, and the U_L() macro is defined in INTL.H.

You can specify particular Unicode characters in literal strings by typing \x value in the string, where value is a four-digit hexadecimal number. For example, here are some Quick Help strings from the TextView class:

```
U_L"\xF61F \tab Pigtail. Delete a character.\par"
U_L"\xF60A \xF609 \xF60C \xF60B \tab Flicks. Scroll up, down, left, or right.\par"
```

This code uses the Unicode value for GO's gesture glyphs to specify them in a literal string. See Table 15-6 for a list of the Unicode value for all of the gesture glyphs.

**String formatting**

When you use the standard C formatting codes to format strings, make sure you use the correct format code. Note that the Uprintf() function requires the U_L() macro wrapped around its format code, as shown below

```
Uprintf(U_L("%hs"), "I am an 8-bit string.");
Uprintf(U_L("%ls"), L"I am a 16-bit string.");
Uprintf(U_L("%s"), U_L("I can be either kind of string."));
```

**Memory and file space**

You may be concerned about the additional memory and file space required to support Unicode. Rest assured that your data files will not automatically double their size as a result of supporting Unicode.
Unicode does not demand much more storage space than popular multibyte encoding schemes like Shift-JIS, a standard popular in Japan. Japanese text requires 2 bytes in JIS and Shift-JIS just as it does in Unicode.

Although a Unicode representation of English-only text requires twice the memory space as an ASCII representation, you can compress the data efficiently when writing it to a file. In practice, a compressed Unicode file containing English-only text is less than 1% larger than the identical file stored in ASCII.

**Compressing Unicode**

You can compress Unicode strings with the PenPoint functions `IntlCompressUnicode()`, defined in `\2_0\PENPOINT\SDK\INC\ISRH`. The function implements a compression scheme called **packed Unicode**. This scheme adds 1 byte to every 255 bytes of ASCII data and compresses a typical Shift-JIS file by roughly a quarter. You can compress data before writing it to a file.

You can also buy commercial compression algorithms to compress fielded data. Be aware, however, that many commercially available compression algorithms are optimized for 8-bit data, and Unicode is 16 bits long. On the other hand, algorithms like the 16-bit Huffman algorithm that are optimized for 16-bit characters are often memory intensive.

Of course, the data in your application that does not represent text does not require any additional memory.

**Resource files**

PenPoint resource files store objects and data in a structured way that is isolated from source code. If you are unfamiliar with PenPoint resource files, read Part 11 of the *PenPoint Architectural Reference* for an overview.

You can use resource files to store elements of your application that vary from locale to locale. The most typical example of this is using resource files to store translated user interface strings.

The following list gives examples of when you might use resource files to store elements that differ between localized versions of an application.

- Text for menus, Quick Help, and StdMsg...() messages.
- Different, locally appropriate versions of a bitmap representing “stop.”
- Two different window layouts for two different locales.
- Flags that your application reads and writes as binary data to save user preferences.

Resource files usually store user interface elements like strings, window layouts, and bitmaps. You can, however, use resource files to store things other than UI elements. The last example, for example, is binary data that influences how your application behaves.
Think of resource files as a place to store modular elements that can be plugged in and out of your application as appropriate to the locale.

GO recommends that you use a strategy for naming resources files to represent the specific localization. All of the PenPoint 2.0 sample code, for example, has a USA.RC file for the American localization and a JPN.RC file for the Japanese localization.

You must use the exact names JPN.RC and USA.RC if your makefile uses the standard makefile rules included with the sample applications (_0\PENPOINT\SDK\SAMPLE\SRULES.MIF). The standard makefile rules look for particular strings in USA.RC or JPN.RC to stamp the application directory with PenPoint information.

Resource files existed in PenPoint 1.0, although they were not used extensively in sample code. Resource file architecture in PenPoint 2.0 Japanese is unchanged, and there are additional utilities for working with resources in RESUTIL.H. The resource file architecture supports 16-bit strings.

Strings in resource files

If you have literal strings in your source code, consider moving the strings to resource files. The DOS utility INTLSCAN flags literal strings (as well as lines that may not be appropriate for international applications) in your code. See “Using the DOS utility INTLSCAN” on page 210 for details on how to use INTLSCAN.

While you may not need to move literal strings to resource files for a successful compile, we strongly encourage you to do so. The trade-offs involved in the move are described in the following sections.

Advantages of moving strings to resource files

- Strings in resource files are easier to translate because all the strings are in one place. You can simply pass the resource file to translators, and they can translate the strings without any programming knowledge.

- Applications with strings in resource files are easier to maintain because all user interface strings are in one place rather than scattered throughout various source and header files.

- Having strings in resource files makes it easier to maintain a single code base even if you have many localized versions of your application. Ideally, you can create new localized versions of your application by simply providing new resource files.

Disadvantages of moving strings to resource files

Moving strings to resource files makes your code harder to read. People who want to understand what your code does must follow the tag reference to another file. Some of the sample code included with the SDK, like EmptyApp, leaves strings in the source files for exactly this reason.

GO recommends that you use one resource file to contain all the strings for a particular localization. The resource file name should describe the locale, as in USA.RC and JPN.RC.
Resource file structure

This section describes the recommended structure for resource files. Before we describe the structure, you should understand the following about strings in resource files.

- Each string is associated with a tag that is defined in a header file. You use this tag in your source code when you need to use the string.
- Each string can be part of a group. In the resource file, the entire group is considered a single resource. The four predefined groups for each class are:
  - Toolkit strings.
  - Quick Help strings.
  - Miscellaneous strings (such as format strings for ComposeText functions).
  - Standard Message strings.
You can define your own groups as needed.
- Each group can have up to four arrays that identify lists of indexed resources. Each array or list is identified as a well-known list resource ID. Because each array may contain up to 256 entries, your class can have up to 1,024 tags and corresponding strings just using the predefined groups.

The resource file from the sample Counter Application clearly shows the recommended file structure. You can find this code in `\2_0\PENPOINT\SDK\SAMPLE\CNTRAPP`.

Creating tags in header files

You must define a tag for each string you want to use. Remember that tags are just 32-bit numbers with a fixed structure. Define these tags in the header file that your source code includes. For example, `CNTRAPP.H` defines these tags:

```c
#define tagCntrMenu MakeTag(clsCntrApp, 0)
#define tagCntrDec MakeTag(clsCntrApp, 1)
#define tagCntrOct MakeTag(clsCntrApp, 2)
#define tagCntrHex MakeTag(clsCntrApp, 3)
```

When you use resource utility functions from `RESUTIL.H` to read these strings from a resource file, use these tags when the functions expect a variable of type `IX_RES_ID`. See “Tags in source code” on page 193 for an example.

You must also define a `RES_ID` for each group. A `RES_ID` is a 32-bit number, defined in `CLSMDR.H`, that identifies a resource. Use a `RES_ID` to identify a particular resource in a resource file. The header file `CNTRAPP.H` defines these `RES_IDs`:

```c
#define resCntrTK MakeListResId (clsCntrApp, resGrpTK, 0)
#define resCntrMisc MakeListResId (clsCntrApp, resGrpMisc, 0)
```

Defining tags and strings in resource files

You put the literal strings and their associated tags in a resource file. GO recommends that you put U.S. English strings in `USA.RC`, and Japanese strings in `JPN.RC`. 
The data structure that contains a tag and its corresponding string is an array of structures of type RC_TAGGED_STRING.

```c
static RC_TAGGED_STRING tkStrings[] = {
   // Representation menu
   tagCntrMenu, U_L("Representation"),
   // Decimal menu item
   tagCntrDec, U_L("Dec"),
   // Octal menu item
   tagCntrOct, U_L("Oct"),
   // Hexagonal menu item
   tagCntrHex, U_L("Hex"),
   Nil (TAG)
};
```

Notice that the literal strings are surrounded by the U_L() macro which indicates the string contains 8-bit character data in PenPoint 1.0 and 16-bit character data in PenPoint 2.0 Japanese.

An RC_INPUT structure immediately follows the RC_TAGGED_STRING array.

```c
static RC_INPUT tk = {
   resCntrTK,
   tkStrings,
   0,
   resTaggedStringArrayResAgent
};
```

The macro resCntrTK, defined in CNTRAPP.H, is a 32-bit number that identifies the resource, in this case the group of strings defined in tkStrings.

```c
#define resCntrTK MakeListResId(elsCntrApp, resGrpTK, 0)
```

The RC_INPUT structure also indicates how the Counter Application should interpret the tkStrings array. In this case, the tagged string array resource agent interprets the array. Every group has both of these structures: the RC_TAGGED_STRING structure and the RC_INPUT structure.

Finally, after all the groups have been similarly defined, one more structure of type P_RC_INPUT is required to identify all the groups.

```c
P_RC_INPUT resInput[] = {
   &app, // the Application Framework strings
   &tk,  // the TK strings for CNTRAPP
   &misc, // the Misc strings for CNTRAPP
   pNull  // End of list.
};
```

Note that Counter Application uses only three out of the four standard groups. This is fine. Groups may be left empty except for toolkit strings belonging to the Application Framework. The Application Framework uses those strings to display information about your application to the user.
Look at the sample code provided with the SDK for more examples of resource files. The Goodies disk also contains three files in `\SDK\UTIL\TEMPLATE`. The files, `TEMPLATE.C`, `TEMPLATE.H`, and `TEMPLATE.RC`, are examples of resource files and source code that uses resources.

**Tags in source code**

After defining tags in your resource file, you use them in one of three ways.

- Use tags directly if a function or message expects a tag as a parameter. Standard toolkit elements that inherit from `clsTkTable` often expect tags. This code sets up a standard toolkit menu, again in Counter Application.

```c
static const TK_TABLE_ENTRY CntrAppMenuBar[] = {
    {tagCntrMenu, 0, 0, 0, tkMenuPullDown | tkLabelStringId, clsMenuButton},
    {tagCntrDec, msgCntrAppChangeFormat, dec, 0, tkLabelStringId},
    {tagCntrOct, msgCntrAppChangeFormat, oct, 0, tkLabelStringId},
    {tagCntrHex, msgCntrAppChangeFormat, hex, 0, tkLabelStringId},
    {pNull},
    {pNull}
};
```

When you use tags instead of literal strings in a `TK_TABLE_ENTRY`, you must set (or add, using the bitwise OR operator) the `tkLabelStringId` flag. This flag directs the code to read the required string out of a resource file.

- Use tags instead of literal strings. Many user interface objects that inherit from `clsLabel` allow you to use tags in the place of literal strings. Let the object know that you are supplying a tag rather than a string by setting the `infoType` field of the `LABEL_STYLE` structure to `lsInfoStringId`. This constant is defined in `LABEL.H`.

- Use resource utility functions to read the required string out of your resource file. A variety of resource utility functions are defined in `RESUTIL.H`.

```c
size = sizeof(resStr) / sizeof(CHAR);
ResUtilGetListString(resStr, size, resGrpMisc, tagCntrMessage);
```

The `ResUtilGetListString()` function expects a `RES_ID` to identify the group in which the string is defined; in the example shown here, `resGrpMisc` is the group defined in `CNTRAPP.H`. The function also expects a `IX_RES_ID`.

See "Using tags in source code" on page 222 for more detailed instructions and code samples.

**Predefined tags**

The Application Manager has predefined tags that you use to identify your company, application name, and copyright information.

In PenPoint 1.0, you did this by filling in fields of the `APP_MGR_NEW` structure. In PenPoint 2.0 Japanese, you must put these strings in a resource file and associate them with the predefined tags defined in `APPTAG.H`. Although this was not described in detail in the 1.0 documentation, you can use tags instead of strings in both PenPoint 1.0 and PenPoint 2.0 Japanese.
The strings defined in this resource file are used in two ways:

- The Application Framework reads these strings from your resource file when it needs to display information about your application to the user.
- Standard makefiles (such as those provided with the sample applications) use the application name and type to stamp your project directory.

This example is from the Counter Application.

```c
static RC_TAGGED_STRING appStrings[] = {
    // Default document name
    tagAppMgrAppDefaultDocName,
    U_L("Counter Application"),
    // The company that produced the program.
    tagAppMgrAppCompany,
    U_L("GO Corporation"),
    // The copyright string.
    tagAppMgrAppCopyright,
    U_L("\x00A9 Copyright 1992 by GO Corporation, All Rights Reserved."),
    Nil(TAG)  // end of list marker
};
```

See "Makefiles" in Chapter 29 of Part 4: PenPoint Development Tools Supplement for more information on how the standard makefile rules use these tags. As usual, a RC_INPUT structure follows the RC_TAGGED_STRING structure.

```c
static RC_INPUT app = {
    tagAppMgrAppStrings,  // standard resource ID for APP strings
    appStrings,           // pointer to string array
    0,                    // data length; ignored for string arrays
    resTaggedStringArrayResAgent // How to interpret the data pointer
};
```

**Working with resource files**

The PenPoint operating system provides three DOS utilities to work with compiled resource files (for example, USA.RES). With these utilities, you can append (RESAPPND), view (RESDUMP), and delete (RESDEL) resources from a resource file.

For example, here is output of the utility RESDUMP on the Counter Application's resource file USA.RES. The DOS utilities work only on compiled resource files, so the following example shows the entire application being compiled and created in an application directory under `\2_0\PENPOINT\APP`.
Each group defined in CNTRAPP.H is a separate resource with its own RES_ID. Notice that the Application Manager group has a different administered number (Admin=69) than the Counter Application's groups (Admin=555). Look in CNTRAPP.H to see that 555 is the well-known UID identifying clsCntrApp.

#define clsCntrAppMakeWKN(555, 1, wknGlobal)

See Part 4: PenPoint Development Tools Supplement for more information on these DOS utilities.
Locale-independent code

Your application's behavior will likely vary between locales. Formatting, for example, is a behavior that varies between locales. Table 15-2 shows some examples of different formatting conventions.

### Formatting differences between countries

<table>
<thead>
<tr>
<th>Attribute</th>
<th>American English example</th>
<th>Different country example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number formatting</td>
<td>1,234,567.89</td>
<td>Germany: 1.234.567.89</td>
</tr>
<tr>
<td>Time formatting</td>
<td>11:45 p.m.</td>
<td>Italy: h 23:45</td>
</tr>
<tr>
<td>Date formatting</td>
<td>3/31/92</td>
<td>Sweden: 92-03-31</td>
</tr>
<tr>
<td>Currency formatting</td>
<td>$1995.95</td>
<td>Norway: Kr. 1,995</td>
</tr>
<tr>
<td>Address formatting</td>
<td>John Smith</td>
<td>Denmark: Administrerende direktør</td>
</tr>
<tr>
<td></td>
<td>Vice-President, Sales</td>
<td>Acme Corp.</td>
</tr>
<tr>
<td></td>
<td>Acme Widgets Corporation</td>
<td>Sandtoften 39</td>
</tr>
<tr>
<td></td>
<td>123 Industrial Boulevard</td>
<td>DK-2820 Gentofte</td>
</tr>
<tr>
<td></td>
<td>Providence, RI 02913</td>
<td>Danmark</td>
</tr>
<tr>
<td></td>
<td>U.S.A.</td>
<td></td>
</tr>
<tr>
<td>Phone numbers</td>
<td>(416) 325-2061</td>
<td>France: (16) 2.25.20.61</td>
</tr>
<tr>
<td>Paper sizes</td>
<td>Letter, 8.5&quot; x 11&quot;</td>
<td>England: A4, 210 cm x 297 cm</td>
</tr>
<tr>
<td>Sort order begins</td>
<td>a A b B c C d D e E</td>
<td>Portugal: a À ã À ã À ã À</td>
</tr>
</tbody>
</table>

The following categories of behavior vary from locale to locale. If your application supports any of these behaviors, make sure local versions of your application implement the behavior appropriately. This list is not comprehensive.

- Formatting conventions
  - Number formatting.
  - Currency handling.
  - Time and date formatting.
  - Numbered items (for example, “3 files”).

- Phone number formats.

- Fax dialing formats, cover sheets, and form letters.

- Paper sizes.

- Sorting and comparison rules.

- Word and sentence.

- Linguistic packages.
  - Dictionaries.
  - Heuristics for text processing.
  - Local handwriting translation engines.

Rather than write different code for each country, take advantage of PenPoint’s collection of international functions. These international functions behave appropriately for a particular language or country. Using these functions frees you from implementing the locally appropriate version of a function yourself.
In the ideal case, the international functions allow you to write and maintain a single code base no matter how many local versions you create. This single code base would be locale-independent code.

Sometimes, you cannot write a single block of code to implement all the local variants your application requires. You have two alternatives in this case:

- You can create different DLLs from different source. You then load a different DLL for each local version of your application. See Figure 14-2 for a diagram of this situation.
- You can write a service to implement a specific function for a locale.

**PenPoint's international functions**

The PenPoint operating system provides a host of types, data structures, and functions that simplify your task of writing locale-independent code.

Consider a concrete example. Notice from Table 15-2 that Germans write 1.234.567,89 while the Americans prefer 1,234,567.89.

Rather than write your own formatting algorithm, you can simply call a function called `IntlFormatS32()` in your code. The functions accepts, among other arguments, a locale identifier (see “Locales” on page 199 for a discussion of locale identifiers), and returns the correctly formatted string.

Currently, PenPoint supports only U.S. English and Japanese versions of these international functions. Future releases of PenPoint will support more countries, languages, and functionality.

Table 15-3 describes the international functions PenPoint provides. The next section describes the most important functions, most of which are in ISR.H. For details on particular functions, see the on-line header files in \_2\_0\PENPOINT\SDK\INC.

### PenPoint international functions

<table>
<thead>
<tr>
<th>Header file to include</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISR.H</td>
<td>Types and functions such as word, sentence, and paragraph delimiting; line break calculation; time, date, number, and currency formatting; sorting and comparison; and Unicode manipulation. These functions deal primarily with strings.</td>
</tr>
<tr>
<td>ISRSTYLE.H</td>
<td>Styles that used to control how international functions behave. For example, styles control how to format date and negative numbers, how to sort a list (whether to consider spaces or not), and how to delimit words.</td>
</tr>
<tr>
<td>GOLOCALE.H</td>
<td>Constants for country, language, and currency names, as well as names for commonly used strings like days of the week, months of the year, time zones, and units of measurement.</td>
</tr>
<tr>
<td>CHARTYPE.H</td>
<td>Types, macros, and functions that work on individual characters. Sample operations include checking for spaces and uppercase letters.</td>
</tr>
<tr>
<td>INTL.H</td>
<td>Types and macros used by international functions.</td>
</tr>
</tbody>
</table>
PenPoint international functions

<table>
<thead>
<tr>
<th>Header file to include</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>GLPYH.H</td>
<td>Macros for Unicode code points, such as GO gesture glyphs, commonly used in PenPoint applications and services.</td>
</tr>
<tr>
<td>CMPSTEXT.H</td>
<td>Functions that compose text from strings and variable values, allowing free placement of the parameters throughout the text.</td>
</tr>
</tbody>
</table>

Remember to link the appropriate library with your source code if you use any of these functions. All of the functions described below are defined in INTL.LIB with the exception of ComposeText() functions, which are defined in SYSUTIL.LIB.

International functions in ISR.H

Most of PenPoint’s international functions are defined in the header file ISR.H. Table 15-4 shows some of the most commonly used functions and their behavior.

Some functions from ISR.H

<table>
<thead>
<tr>
<th>Function</th>
<th>Default behavior</th>
</tr>
</thead>
<tbody>
<tr>
<td>IntlDelimitWord()</td>
<td>Delimits a word (or word-equivalent in languages with no words).</td>
</tr>
<tr>
<td>IntlDelimitSentence()</td>
<td>Delimits a sentence.</td>
</tr>
<tr>
<td>IntlBreakLine()</td>

</tbody>
</table>

Many of the functions come in pairs that reverse each other’s functionality:

- The formatting functions such as IntlFormatDate() have parsing equivalents such as IntlParseDate().
- The conversion functions such as IntlMBToUnicode() have functions that reverse the conversion such as IntlUnicodeToMB().

Many of the functions also have counted and uncounted version. Counted versions have the letter N in their names. For example, the counted version of
IntlDelimitWord() is IntlNDelimitWord(). The uncounted functions work on null-terminated strings. The counted versions work on strings with known length. Most of the functions require a 32-bit argument that identifies a locale. Locales are explained in the next section.

**Locales**

This handbook uses the term locale rather than country or language because countries vary a great deal within their borders. Canada, Switzerland, and Singapore, for example, are countries that use more than one language. Even within a language, there are distinct variations called dialects. All of these differences influence the localization process.

The PenPoint international functions take these factors into account by introducing a type called LOCALE_ID. This 32-bit number contains three byte-long “fields” that correspond to the language, dialect, and country of a particular locale. Thus, a variable of type LOCALE_ID unique identifies a locale as a 32-bit number. LOCALE_ID uses only 3 bytes of data. The remaining bits are reserved for future use. Fill those bits with 0s if you do custom manipulation of these identifiers. Usually, just use predefined macros in GOLOCALE.H to manipulate variables of type LOCALE_ID.

The following code uses a macro defined in INTL.H to create locale identifiers for two familiar locales. The arguments are constants defined in GOLOCALE.H.

```
#define locUSA intlLIDMakeLocaleId(ilcEnglish, 0, iccUnitedStates)
#define locJpn intlLIDMakeLocaleId(ilcJapanese, 0, iccJapan)
```

The types and macros for creating locale identifiers are defined in INTL.H. Languages, dialects, and countries are assigned an 8-bit code and a corresponding mnemonic (like iccUnitedStates) in GOLOCALE.H.

**Predefined locale identifiers**

The PenPoint operating system identifies the current system locale by setting the a LOCALE_ID called systemLocale. This initialization is done at boot time, so by the time your application is running, systemLocale has been set.

If your application must behave differently in different locales, your code can check the value of systemLocale to control its behavior. The Clock sample application, for example, checks the value of systemLocale to determine how it should format the time. See “Checking the system locale” on page 227 for a code sample.

Most commonly, though, your application needs to behave appropriately for only a single locale. To accomplish this single-locale behavior, use a series of macros whose names begin with Loc...(). For example, use the macro called LocDelimitWord() to provide word selection functionality appropriate to PenPoint’s current locale. Here is the definition of LocDelimitWord in ISR.H:

```
#define LocDelimitWord(tx, s, st) IntlDelimitWord(tx, s, intlDefaultLocale, st)
```
Notice that the macros simply call the related international function with the pre-defined locale identifier `intlDefaultLocale` as an argument.

The international functions provide behavior to support Japanese and U.S. English. As shown above, two locale identifiers, `locUSA` and `locJpn`, are defined in `GOCALE.H`. You can send these identifiers as arguments to the international functions.

**Styles**

Often, even a `LOCALE_ID` is not enough to specify how a function should behave. There are, for example, at least four different ways to display a date in each Western language.

PenPoint introduces a 32-bit number called a *style* to control how functions should behave within locales. For example, the various styles associated with displaying a date are defined in `ISRSTYLE.H` as:

```c
// Flags used with all Date format styles
#define intlFmtDateSpaceFill flag16 // Space fill numeric fields
#define intlFmtDateZeroFill flag17 // Zero fill numeric fields

// International Date format styles
#define intlFmtDateStyleNumeric 0x0001 // e.g. 1/14/92
#define intlFmtDateStyleAbbrv 0x0002 // e.g. 14-JAN-92
#define intlFmtDateStyleShort 0x0003 // e.g. Jan. 14, 1992
#define intlFmtDateStyleFull 0x0004 // e.g. January 14, 1992
```

You use these styles when calling the function `IntlNFormatDate()`. Note that the function expects, among other things, a locale and a style, as parameters:

```c
S32 EXPORTED IntlFormatDate(
    P_INTL_TIME pTimeVal,      // Time to format
    P_CHAR pString,            // Out: converted string
    U32 length,                // Length of buffer
    IX RES_ID format,          // Optional explicit format
    LOCALE_ID locale,          // Locale to use, intlDefaultLocale for default
    U32 style                  // Conversion style to use, or styleDefault
);
```

**Styles**

- A flag is a major variation that affects all the functions in a given category. You can specify only one flag at a time.
- A format style is a more subtle variation. You can sometimes use multiple variants simultaneously using the bitwise OR operator. If you specify an unsupported collection of styles, an international function returns the status `stsRequestNotSupported`.

The flag `intlFmtDateSpaceFill` is a good example of a major style. It directs the date formatting function to use spaces as a placeholder in dates, as in `12/3/92`. Because you can only specify one flag at a time, you cannot specify `intlFmtDateSpaceFill` and `intlFmtDateZeroFill` at the same time.

Unlike flags, you can specify a collection of format styles. For example, you can specify `intlFmtTimeStyleStandard` and `intlFmtTimeForce24Hour` simultaneously.
to format a time that looks like 13:57. Use the bitwise OR operator to specify multiple styles simultaneously. For example, define `myStyle` as follows to specify the two styles above:

```c
U32 myStyle = intlFmtTimeStyleStandard | intlFmtTimeForce24Hour;
```

Use the predefined style `intlStyleDefault` as a parameter to an international function when you want to use what GO expects to be the most common variation for a given locale. Comments in ISRSTYLE.H identify the default style for a particular locale.

**Query capability**

Many of the PenPoint international functions require a buffer as an argument. A function that requires a buffer often offers clients a query capability in which the client requests the function to recommend a size for the buffer to pass in. For example, if you pass `pNull` as two of the arguments to the `IntlDelimitWord()` function, the function returns the recommended size of buffer to pass in.

```c
U32 size;
U32 style = intlStyleDefault;
size = LocDelimitSentence(pNull, pNull, style);
```

Use the `size` returned by the function to determine how much of your buffer to send when you call the function again. See the procedure on delimiting words in Part 3: PenPoint Japanese Localization Handbook for a more detailed code sample.

**International function structures**

The international functions use three new structures as shown in Table 15-5. All of the structures are defined in ISR.H.

### Table 15-5: International function structures

<table>
<thead>
<tr>
<th>Structure name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTL_CNTD_STR</td>
<td>Contains a string and its count. Used by IntlNSort() to sort a collection of counted strings.</td>
</tr>
<tr>
<td>INTL_TIME</td>
<td>A time structure that is a superset of the standard <code>tm</code> structure. It contains two additional members to represent an era (for example, A.D., heisei) and time zone. The <code>year</code> member represents the year of an era rather than years since 1900. Valid eras are defined in GOLOCALE.H.</td>
</tr>
<tr>
<td>INTLBREAK_LINE</td>
<td>Contains information on how to break a line, including the position of the break, the characters to delete from the end and start of the line, and the character to insert at the and start of the line.</td>
</tr>
</tbody>
</table>

The new time structure `INTL_TIME` introduces a new `era` member to accommodate international calendars. Many calendar systems use era information more heavily than the Western Gregorian calendar. For example, the Japanese imperial calendar specifies dates relative to the reign of the current emperor. The year 1992 is represented as heisei 4, the fourth year of the current emperor’s reign.

There are international functions to convert between this international time structure and the system time structure `OS_DATE_TIME`. 
The line break structure INTL_BREAK_LINE is used by the IntlBreakLine() (and its counted equivalent) to contain information about how a line should break. Different languages use different rules about how lines should break.

For example, English permits words to break roughly at each syllable. A hyphen is used to indicate that a word continues to the next line. So running becomes run-ning.

In Japanese, on the other hand, characters simply follow each other sequentially across lines. The only restriction is that certain characters, such as an open parenthesis, cannot end or begin a line.

As another example, when the German word backen breaks across lines, it becomes bak-ken. Notice that the trailing c becomes a trailing k. The IntlBreakLine() function uses the INTL_BREAK_LINE structure to return the necessary line break information. The structure is defined in ISR.H as follows:

```c
typedef struct INTL_BREAK_LINE {
    U32 breakAt; // position of line break
    U32 deleteThis; // chars to delete from end of this line
    CHAR insertThis[intlBreakLineMaxInsert]; // chars to insert at end of this line
    U32 deleteNext; // chars to delete from start of next line
    CHAR insertNext[intlBreakLineMaxInsert]; // chars to insert at start of next line
} INTL_BREAK_LINE, *P_INTL_BREAK_LINE;
```

**Unicode glyphs**

The file GLYPH.H defines mnemonics for the Unicode values of various standard glyphs. Included are PenPoint user interface glyphs, GO gesture glyphs, Unicode control characters, and the Unicode values of PenPoint's standard gestures.

For example, you might use the mnemonics to assign the value of a character.

```c
CHAR myGlyph = glyphCheckMark;
```

After you make this assignment, use the standard drawing context messages to draw the gesture glyph on the screen. See Part 3 of the Architectural Reference for more information on drawing PenPoint graphics.

Table 15-6 lists the Unicode values of GO's gesture glyphs. The abbreviation "na" means the gesture glyph was undefined in PenPoint 1.0.

</table>

This table shows only some of the names defined in GLYPH.H. See the on-line header file for a complete listing.

**Composed strings**

Because strings created dynamically differ between locales, you need to be careful composing them. Many of the messages you display to the user are composed dynamically. For example, the file system dynamically composes the message “Delete MYFILE.DOC?” when the user makes the cross-out gesture over the file MYFILE.DOC.

The rules for composing strings differ between locales. Punctuation, word order, and capitalization rules, for example, vary between locales.

Because the familiar C library functions such as `sprintf()` and `printf()` fix the order of their parameters, they are not appropriate for composing strings where word
Managing your project

Your project consists of a collection of files that comprise your application. It includes header files, source code, resource files, makefiles, and supporting files like Stationery and help documents. The following sections discuss strategies and tools you use to create localized versions of your application.

See Chapter 29 of Part 4: PenPoint Development Tools Supplement for more information on this topic.

Project organization

GO suggests that you keep all your project files in a single directory, including all the different resource files for your various localizations. Notice in the sample code, for example, that every application contains a USA.RC and a JPN.RC file. Each file corresponds to a particular localization.

When you build your application, compile the appropriate resource files and copy the compiled file into your application directory along with the executable image.
The makefiles provided with the sample applications show you how to set up a makefile to coordinate the process of producing different localizations of your application.

**Makefiles**

The makefiles provided with the sample applications contain a few lines that help create localized versions of your application. The information in this section applies only if you are using the WATCOM WMAKE application to make your application.

First, you can add a **LOCALE** flag to the command line to make a particular localized version of your application. For example, type one of the following to create the Japanese or American version of your application:

```
wmake LOCALE=jpn
wmake LOCALE=usa
```

Inside the makefile, you can use three resource variables to identify which resource files to include with the executable image:

<table>
<thead>
<tr>
<th>Makefile variables</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES_FILES</td>
<td>For resource files that are the same for all locales</td>
</tr>
<tr>
<td>USA_RES_FILES</td>
<td>For resource files unique to the U.S. localization</td>
</tr>
<tr>
<td>JPN_RES_FILES</td>
<td>For resource files unique to the Japanese localization</td>
</tr>
</tbody>
</table>

See “Updating your makefile” on page 224 for details on how to use these makefiles.

**Scanning your source code**

**INTLSCAN.EXE** is a DOS utility located on the Goodies disk. It scans source code files and flags lines that may not be appropriate for international applications. The flagged lines fall into one of three categories.

- Code that deals with ASCII. These lines of code usually need to change as follows:
  - Code that performs ASCII (8-bit) manipulation must be changed to code that performs Unicode (16-bit) manipulation.
  - Literal ASCII strings must become literal Unicode strings.
  - Strings, including all the strings users see, should be moved into resource files to facilitate translation.

- Functions that are locale-dependent. Using these locale-dependent functions will make it difficult for you to localize your application. Consider replacing your locale-dependent function with a locale-independent equivalent.

- PenPoint 1.0 code that will no longer work under the latest PenPoint version because of API changes. Calls to the old APIs must be changed to reflect the new APIs.
INTLSCAN searches for particular declarations and function calls in your code. Because it cannot tell what you are doing with a particular variable or function, it may flag a line that does not need to be changed. If you are certain the code INTLSCAN flagged will work in all the locales you plan to market your application, leave it alone.

Conversely, do not assume that because INTLSCAN did not flag any lines in your code that your application is ready for localization. There are many internationalization issues that INTLSCAN cannot possibly detect. For example, INTLSCAN cannot tell you whether a particular piece of your application’s functionality is appropriate to a particular locale.

Working with local users and getting familiar with popular local applications may help you understand the needs of a locale.

See “Using the DOS utility INTLSCAN” on page 210 for step-by-step directions on using INTLSCAN.

**Other DOS utilities**

Other utilities included with the PenPoint SDK 2.0 Japanese help you create localized versions of your application. See Chapter 31 of Part 4: PenPoint Development Tools Supplement for details on these utilities.

**Missing functions**

If your want to maintain a single code base for multiple local versions of your application, you need the international package unless you plan to implement a function not already in PenPoint.

If you do implement a new function, and you think the function you implement would be useful to many developers, contact GO Technical Services with your suggestion.
Chapter 16 / Procedures

This chapter provides step-by-step details on how to write internationalized code. To help you use this chapter more efficiently, each procedure begins with a list of references to prerequisite information and ends with a list of related information. If you have read the previous chapters already, don't worry about the prerequisite information.

The prerequisite information discusses the concepts and motivations for doing a particular procedure. If possible, an example is included with each task.

Supporting Unicode

Read this section if you want to support Unicode in a new application. If you want to add Unicode support to an existing PenPoint 1.0 application, see “Using the DOS utility INTLSCAN” on page 210.

Prerequisite information

Read the following for an overview of Unicode and the code required to support it:

- “International character sets” on page 183.
- “Multibyte and wide characters” on page 183.
- “Unicode architecture” on page 185.
- “Code supporting Unicode” on page 186.

Procedure

1. Declare character and strings (pointer to characters) as CHAR, which is a 16-bit type in PenPoint 2.0 Japanese.

2. When you process text that a user sees, use the PenPoint international functions such as IntlCharIsUpperO and IntlFormatS32O. These functions are guaranteed to behave appropriately for the specified locale.

3. When no international functions are available, use the PenPoint macros U…() functions UstrcpyO and UisupperO rather than the standard C library functions to manipulate text. These functions work on 16-bit data in PenPoint 2.0 and on 8-bit data in PenPoint 1.0.

4. Use the WATCOM C compiler _u…() functions such as _ustrcpyO and _uisupperO for 16-bit data only. These functions may not be locale-independent, so use the PenPoint international functions whenever you are processing readable text.
Wrap the U_LO macro around literal strings, including format strings in the PenPoint U...() functions. See “Creating Unicode strings” on page 215 for details.

Do not depend on CHAR being 1 byte long because CHAR is 2 bytes long in PenPoint 2.0 Japanese.

Run INTLSCAN to help ensure your code supports Unicode. See “Using the DOS utility INTLSCAN” on page 210 for details.

**Examples**
See the following sections for code samples:
- “Unicode: 8-bit type—consider CHAR or P_CHAR” on page 212.
- “Unicode: 8-bit function—consider 16-bit replacement” on page 212.
- “Unicode: check mem size for sizeof(CHAR) != 1” on page 213.
- “CHAR8: fixed 8-bit type—are you sure?” on page 215.

**Related procedures**
- “Using the DOS utility INTLSCAN” on page 210.
- “Interpreting INTLSCAN messages” on page 211.

**Using the DOS utility INTLSCAN**
This procedure helps you use the DOS utility INTLSCAN.EXE. The utility identifies lines of code that may not be internationalized.

**Prerequisite information**
Read the following to understand why you should use INTLSCAN.
- “Overview of international software” on page 177.
- “Writing international software” on page 178.
- “International character sets” on page 183.
- “Resource files” on page 189.
- “Locale-independent code” on page 196.
- “Managing your project” on page 205.
- “Scanning your source code” on page 206.

**Procedure**
1. Copy INTLSCAN.EXE to your \_\_0\PENPOINT\SDK\UTIL\DOS directory from the \SDK\UTIL\DOS directory on the Goodies disk.
2. If necessary, use the CONTEXT.BAT batch file to update your PATH variable to include \_\_0\PENPOINT\SDK\UTIL\DOS in your DOS path. See *Installing and Running PenPoint SDK 2.0* for more information on the batch file.
Run INTLSCAN on your source (.C) files by typing:
intlscan *.C

List the error files generated by INTLSCAN:
dir *.ERR

Open any .ERR file with a non-zero size. The file contains a list of line numbers and corresponding INTLSCAN messages.

Make any necessary changes to your source code. The next procedure "Interpreting INTLSCAN messages" on page 211 shows you how to make the changes INTLSCAN recommends.

Repeat steps 4 through 6 for all of your project’s header (.H) files.

Repeat steps 4 through 6 for all of your project’s resource (.RC) files.

Related information

- "Interpreting INTLSCAN messages" on page 211.
- "Moving strings to resource files" on page 216.
- "Updating your makefile" on page 224.

Interpreting INTLSCAN messages

If INTLSCAN detects a line of code that may need to be changed, it writes the line number and one of the following messages to the file FILENAME.ERR. This section helps you interpret the message and make the recommended changes to your code.

Here is a list of INTLSCAN’s messages. Each of these is discussed below.

- Unicode: 8-bit type—consider CHAR or P_CHAR.
- Unicode: Check mem size for sizeof(CHAR) != 1.
- Unicode: 8-bit function—consider 16-bit replacement.
- CHAR8: Fixed 8-bit type—are you sure?
- Resource: Literal string.
- Resource: Literal character.
- ISR: USA function—consider ISR equivalent.

ISR stands for International Services and Routines.

Prerequisite information

Read the following to understand why INTLSCAN flags certain lines of code.

- "International character sets" on page 183.
- "Code supporting Unicode" on page 186.
- "Locale-independent code" on page 196.
- "Resource files" on page 189.
Procedure

1. Open the FILENAME.ERR file generated by INTLSCAN.
2. If your editor supports multiple windows, open your source file, FILENAME.C.
3. If appropriate, make the first recommended change. Remember, the changes are only recommendations. Some of the flagged lines may not need to change.
4. If your editor supports a "next error" function, use it to move to the next line INTLSCAN flagged.
5. You may want to run INTLSCAN after finishing your changes to make sure you responded to all of INTLSCAN's recommendations.

Examples

Each of the possible INTLSCAN messages is listed and described below along with old and rewritten code examples. The first sentence of each section describes why INTLSCAN flagged your code.

Unicode: 8-bit type—consider CHAR or P_CHAR

You see this message when your code contains a 8-bit variable with a type such as U8, P_STRING, or char. If appropriate, redeclare these variables as 16-bit strings or characters (using types such as CHAR or P_CHAR). Any text processing should be done in 16 bits. Actual byte-sized data should remain 8-bits long.

Remember that CHAR is 16-bits long in PenPoint 2.0 and 8-bits long in PenPoint 1.0. If you want 16-bit data all the time, use CHAR16.

Here are some examples of old and rewritten code. Old code is on top and grayed out.

```c
typedef char   AM_PM_STR[5];
typedef CHAR   AM_PM_STR[5];
P_STRING       tmpDate;
P_CHAR         tmpDate;
```

Note that declarations like:

```c
U8    fontSize;
```

need not change because fontSize is real 8-bit data.

Unicode: 8-bit function—consider 16-bit replacement

You see this message when your code calls a function that works only with 8-bit data. You may want to replace the function with its 16-bit equivalent. Table 16-1 outlines some of your options.
8- and 16-bit functions

<table>
<thead>
<tr>
<th>If you want...</th>
<th>Use...</th>
</tr>
</thead>
<tbody>
<tr>
<td>A specific 8-bit function</td>
<td>A function from the standard C library such as <code>isupper()</code>.</td>
</tr>
<tr>
<td>A function that will work on 8-bit data in PenPoint 1.0 and 16-bit data in PenPoint 2.0.</td>
<td>A PenPoint macro such as <code>Uisupper()</code>.</td>
</tr>
<tr>
<td>A function that works on 16-bit data only.</td>
<td>A WATCOM <code>_u...()</code> function such as <code>_uisupper()</code>.</td>
</tr>
<tr>
<td>A function that works on 16-bit data and whose behavior is appropriate to any locale PenPoint supports.</td>
<td>A PenPoint international function such as <code>IntlCharIsUpper()</code>.</td>
</tr>
</tbody>
</table>

If you want to maintain a single code base that compiles under PenPoint 1.0 and PenPoint 2.0, use the `U...()` functions rather than the `_u...()` functions. The `U...()` functions are 8-bit in PenPoint 1.0 and 16-bit in PenPoint 2.0. For more details on maintaining a single code base, see “Single code base” on page 233.

Here are some examples of old and new code:

```c
int strnlen(const char *str, size_t n)
```

Notice the last code example contains the `U_L()` macro. This macro, defined in `INTL.H`, makes the literal string inside a 16-bit string in PenPoint 2.0. In PenPoint 1.0, it allows strings to remain 8-bits long.

**Unicode: check mem size for sizeof(CHAR) != 1**

You see this message when your code calls a function like `OSHeapBlockAlloc()` that takes a size in bytes. When you call such functions, remember that 16-bit strings require twice the memory of 8-bit strings. Hence, if you depend on `CHAR` being 1 byte long, multiply your former memory request by the size of `CHAR`. For example:

```c
#define MAX_DT_STR 60
P_CHAR pBuf;
OSHeapBlockAlloc(osProcessSharedHeapId,
    (sizeof) (MAX_DT_STR), &pBuf);
#define MAX_DT_STR 60
P_CHAR pBuf;
OSHeapBlockAlloc(osProcessSharedHeapId,
    (sizeof) (sizeof(CHAR)*MAX_DT_STR), &pBuf);
```
You need to do this multiplication for CHAR types only. You do not need to change the following code because the SizeOf() macro correctly computes the size of the structure CLOCK_APP_DATA, taking into account any 16-bit characters or strings it might have.

```c
OSHeapBlockAlloc(osProcessHeapId, SizeOf(CLOCK_APP_DATA), &pInst);
```

The SizeOf() macro is defined in G0.H.

### Resource: literal string

You see this when your code contains a literal quoted string. Consider putting these strings in a resource file, unless the string falls into one of these categories:

- Strings that are meaningful in all languages and in all countries. Universally recognized names like “Disneyland” or “Coca-Cola” might be examples.
- Debugging strings that you display using Debugf().
- Hidden filenames that users will never see.

If you leave the literal string in your code because it falls into one of these three categories, consider wrapping the U_L() macro around the string. This makes it a 16-bit string in PenPoint 2.0 Japanese.

Move all other strings to resource files. See “Moving strings to resource files” on page 216 for the procedure.

Here are samples of old and new code that may help you change your code:

```c
strcpy((*pData)->token.buf, "Error");
// where token.buf in pData is defined as CHAR[maxDigits]
ResUtilGetListString((*pData)->token.buf, maxDigits, resGrpMisc, tagCalcAppError);
// Where tagCalcAppError is a tag with a corresponding string in a // resGrpMisc string array
SYSDC_TEXT_OUTPUT tx;
tx.pText = "Hello";
SYSDC_TEXT_OUTPUT tx;
P_CHAR helloStr;
helloStr =
    ResUtilAllocListString(osProcessHeapId, resGrpMisc, tagHelloStr);
// where tagHelloStr is a tag with a corresponding string in a // resGrpMisc string array
// Free the string when you are finished
OSHeapBlockFree(helloStr);
```

### Resource: literal character

You see this message when your code contains a literal character. Consider moving the literal character to a resource file, unless you are certain this character is valid in every language and every country in the world (and on all hardware, too). If a character stays literal, consider wrapping the U_L() macro around characters so that they are 16-bit.
For example, change this code:

```c
#define BACK_SLASH_CHAR '\\'
```

to this:

```c
#define BACK_SLASH_CHAR U_L(\\)
```

Typically, you may leave backslashes (in a filename, for example) as literals, but most other characters probably need to go into a resource file.

**ISR: USA function—consider ISR equivalent**

You see this message when your code uses a locale-dependent function. Unless you are sure this function will work in all the locales you sell this application, replace the function with a locale-independent function from PenPoint's international package.

See “Writing locale-independent code” on page 225 for details. Table 16-3, which lists locale-dependent functions and their locale-independent equivalents, may also be helpful.

**CHAR8: fixed 8-bit type—are you sure?**

You see this message when your code declares an 8-bit data type by declaring something to be of type CHAR8 or P_CHAR8. Make sure you intend the variable to contain only 8-bit data. If the variable stores the value of a Unicode character, use a 16-bit type like CHAR.

For example,

```c
CHAR8 internalString = "private";
```

should be changed to

```c
CHAR internalString = U_L("private");
```

Remember to make sure the user does not see this string. If the user does see the string, it should go in a resource file.

**Related information**

- “Moving strings to resource files” on page 216.
- “Updating your makefile” on page 224.

**Creating Unicode strings**

This procedure writes Unicode characters and strings in your code.

**Prerequisite information**

- “International character sets” on page 183.
- “Code supporting Unicode” on page 186.

**Procedure**

1. Declare all characters and pointer to characters as a 16-bit type. Use CHAR16 for data that is always 16 bits and CHAR for data that will be 8 bits long in PenPoint 1.0 and 16 bits in later releases.
Wrap the U_L() macro around literal characters and strings. Use the L"" modifier only if you are certain your character data will always be 16 bits long.

To specify special Unicode characters, use a \x followed by its Unicode value, a 4-digit hexadecimal number.

**Examples**

These code fragments show examples of the U_L() macro and L"" modifier.

```c
Uprintf(U_L("I am 8 bits long in PenPoint 1.0; 16 bits in PenPoint 2.0");
P_CHAR16 pTheString = L"I am always a 16-bit string."
static RC TAGGED_STRINGqHelpStrings[] = {
    tagTextView, U_L("\xF61F \tab Pigtail. Delete a character.\par "),
    Nil (TAG)
};
```

**Related procedures**

- “Using the DOS utility INTLSCAN” on page 210.
- “Interpreting INTLSCAN messages” on page 211.

**Moving strings to resource files**

This procedure explains how to put strings in a resource file and use those strings in source code.

**Prerequisite information**

- Part 11: Resources in PenPoint Architectural Reference.
- “Resource files” on page 189.
- “Strings in resource files” on page 190.
- “Resource file structure” on page 191.
- “Tags in source code” on page 193.

**Procedure**

1. Copy a resource file named USA.RC or JPN.RC from one of the sample applications into your project directory. Alternatively, copy the file \SDK\UTIL\TEMPLATE\TEMPLATE.RC from the Goodies disk. For example, type the following:
   ```
   copy \2_0\penpoint\sdk\sample\cntrapp\usa.rc c:\myapp
   ```

2. Name the resource file to remind you of which localization the file is for: USA.RC and JPN.RC, for example.

3. Identify the file in which you plan to use a particular string, say PROJECT.C.

4. Define tags for each string in the corresponding header file, PROJECT.H. If you want to use an array of strings in a group such as the Toolkit group, you need a RES_ID for each group.
5 Replace the template resource file's strings and tags with your own strings and tags.

6 Modify your implementation in PROJECT.C to use your new tags rather than the literal string. See “Using tags in source code” on page 222 for details.

7 Update your makefile to identify which resources should be included with your application. See “Updating your makefile” on page 224 for more information.

**Example**

The following code comes from the Counter Application in 2_0\PENPOINT\SDK\SAMPLE\CNTRAPP. It shows the result of moving strings to resource files.

The following tags are defined in the header file CNTRAPP.H. The macro MakeListResldO is defined in RESFILE.H, and the macro MakeTag() is defined in G0.H. Each group must be identified by a RES_ID created by the MakeListResldO() macro, and each string must be defined by a TAG created by the MakeTag() macro.

```c
#define resCntrTK
#define resCntrMisc
MakeListResld (clsCntrApp, resGrpTK, 0)
MakeListResld (clsCntrApp, resGrpMisc, 0)

#define tagCntrMenu
#define tagCntrDec
#define tagCntrOct
#define tagCntrHex
MakeTag(clsCntrApp, 0)
MakeTag(clsCntrApp, 1)
MakeTag(clsCntrApp, 2)
MakeTag(clsCntrApp, 3)
```

The next code fragment comes from the resource file USA.RC. The file uses three groups of strings, Application Framework strings, toolkit strings, and miscellaneous strings. Note that all the literal strings are enveloped in the U_L() macro, making them 16-bit Unicode strings.

```c
static RC_TAGGED_STRING appStrings[] = {
    // Default document name
    tagAppMgrAppDefaultDocName,
    U_L("Counter Application"),
    // The company that produced the program.
    tagAppMgrAppCompany,
    U_L("GO Corporation"),
    // The copyright string.
    tagAppMgrAppCopyright,
    U_L("\x00A9 Copyright 1992 by GO Corporation, All Rights Reserved."),
    // User-visible filename. 32 characters or less.
    tagAppMgrAppFilename,
    U_L("Counter Application"),
```
// User-visible file type. 32 characters or less.
tagAppMgrAppName,
   U_L("Application"),
   Nil(TAG) // end of list marker
};

static RC_INPUT app = {
tagAppMgrAppStrings,
   appStrings, // pointer to string array
   0, // data length; ignored for string arrays
   resTaggedStringArrayResAgent // How to interpret the data pointer
};

static RC_TAGGED_STRING tkStrings[] = {
   // Representation menu
tagCntrMenu, U_L("Representation"),
   // Decimal menu item
tagCntrDec, U_L("Dec"),
   // Octal menu item
tagCntrOct, U_L("Oct"),
   // Hexagonal menu item
tagCntrHex, U_L("Hex"),
   Nil(TAG)
};

static RC_INPUT tk = {
   resCntrTK,
   tkStrings,
   0,
   resTaggedStringArrayResAgent
};

static RC_TAGGED_STRING miscStrings[] = {
   // Message used to display counter value. The ^ls argument allows
   // the code to fill in the appropriate value based on the user's menu
   // choice.
   //
tagCntrMessage, U_L("The counter value is: ^ls"),
   // Message indicating an unknown representation type.
   //
tagCntrUnknown, U_L("Representation type unknown."),
   Nil(TAG)
};

static RC_INPUT misc = {
   resCntrMisc,
   miscStrings,
   0,
   resTaggedStringArrayResAgent
};
Using predefined AppMgr tags

After each of the groups is defined with a `RC_TAGGED_STRING` and `RC_INPUT` structure, a `P_RC_INPUT` structure identifies all the groups. Each of the groups is a separate resource in the resource file.

```c
P_RC_INPUT resInput[] = {
    &app,          // the Application Framework strings
    &tk,           // the TK strings for CNTRAPP
    &misc,         // the Misc strings for CNTRAPP
    pNull          // End of list.
};
```

Finally, Counter Application's source code needs to use these tags. Here is the code that creates the application's menu bar:

```c
static const TK_TABLE_ENTRY CntrAppMenuBar[] = {
    {tagCntrMenu, 0, 0, 0, tkMenuPullDown | tkLabelStringId, clsMenuButton},
    {tagCntrDec, msgCntrAppChangeFormat, dec, 0, tkLabelStringId},
    {tagCntrOct, msgCntrAppChangeFormat, oct, 0, tkLabelStringId},
    {tagCntrHex, msgCntrAppChangeFormat, hex, 0, tkLabelStringId},
    {pNull},
    {pNull}
};
```

**Related information**

- “Using the DOS utility INTLSCAN” on page 210.
- “Updating your makefile” on page 224.

**Using predefined AppMgr tags**

The Application Manager has predefined tags that you should use to identify your company, application name, and copyright information. In PenPoint 1.0, you did this by filling in fields of the `APP_MGR_NEW` structure. You should now put these strings in a resource file and use the new predefined tags that are part of the Application Manager's toolkit group.

**Prerequisite information**

- “Resource files” on page 189.
- “Strings in resource files” on page 190.
- “Resource file structure” on page 191.
- “Tags in source code” on page 193.
- “Predefined tags” on page 193.

**Procedure**

1. If you have PenPoint 1.0 code that uses the fields of the `APP_MGR_NEW` structure to identify your company, application name, and copyright information, remove these lines.
Place this information in a resource file appropriate to the localized version. For example, American strings might go in USA.RC, Japanese strings into JPN.RC, and so on.

Your strings must be 32 characters or less.

**Example**

Remove these lines from PenPoint 1.0 code:

```c
strcpy(new.appMgr.company, "GO Corporation");
strcpy(new.appMgr.defaultDocName, "Counter Application");
ObjCallRet(msgNew, clsAppMgr, &new, s);
```

and simply call:

```c
ObjCallRet(msgNew, clsAppMgr, &new, s)
```

Then put these lines in your resource file:

```c
APP framework strings

static RC_TAGGED_STRING appStrings[] = {
    // Default document name
    tagAppMgrAppDefaultDocName,
    U_L("Counter Application"),

    // The company that produced the program.
    tagAppMgrAppCompany,
    U_L("GO Corporation"),

    // The copyright string.
    tagAppMgrAppCopyright,
    U_L("\xA9 Copyright 1992 by GO Corporation, All Rights Reserved."),

    // User-visible filename. 32 characters or less.
    tagAppMgrAppFilename,
    U_L("Counter Application"),

    // User-visible file type. 32 characters or less.
    tagAppMgrAppClassName,
    U_L("Application"),
    Nil(TAG) // end of list marker
};
```

```c
static RC_INPUT app = {
    tagAppMgrAppStrings,
    appStrings,
    0,
    resTaggedStringArrayResAgent // How to interpret the data pointer
};
```

**Related information**

- “Moving strings to resource files” on page 216.
- “Updating your makefile” on page 224.

**Using resource utility functions**

This procedure uses functions defined in RESUTIL.H to read data out of resource files.
Prerequisite information

- "Resource files" on page 189.
- "Resource file structure" on page 191.
- "Tags in source code" on page 193.

Procedure

1. Find code where you use msgResReadObject or msgResReadData to read data out of a resource file.
2. Call Resource Utility functions as shortcuts to reading objects and strings out of resource files. Table 16-2 lists the available functions.
3. Call one of the first four functions in Table 16-2 to read a single object or string from theProcessResList, the application’s standard list of resources stored in USA.RES or JPN.RES.

1. Call one of the last three functions in Table 16-2 to read a string from a group. The functions expect you to specify the group (RES_ID) and the string’s location (IX_RES_ID) in that group. Use the RES_ID and TAGs you defined in your header file with the MakeTag() and MakeListResID() macros. See “Strings in resource files” on page 190 for details on strings in groups.

2. In most cases, avoid the load utilities ResUtilLoadObject() and ResUtilLoadListString() because these functions allocate their own memory.

3. Link RESFILE.LIB with your code if you use any of these functions.

Resource utility functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ResUtilLoadString</td>
<td>Loads a string from theProcessResList into a buffer or a heap.</td>
</tr>
<tr>
<td>ResUtilGetString</td>
<td>Same as ResUtilLoadString except that you provide a buffer and its size.</td>
</tr>
<tr>
<td>ResUtilAllocString</td>
<td>Loads a string from theProcessResList into a heap you specify.</td>
</tr>
<tr>
<td>ResUtilLoadListString</td>
<td>Loads an item from a string list in theProcessResList into a buffer or a heap.</td>
</tr>
<tr>
<td></td>
<td>You pass in the desired string’s group and its index in that group.</td>
</tr>
<tr>
<td>ResUtilGetListString</td>
<td>Loads a string from a string array in theProcessResList into a buffer you specify. You pass in the desired string’s group and index.</td>
</tr>
<tr>
<td>ResUtilAllocListString</td>
<td>Loads a string from a string array in theProcessResList into a heap you specify.</td>
</tr>
</tbody>
</table>

Example

Replace this code:

```c
#define sampleResId MakeWknResId(clsSample, 17)
readObj.resId = sampleResId;
readObj.mode = resReadObjectMany;
ObjCallRet(msgNewDefaults, clsObject, &readObj.objectNew, status);
status = ObjCallWarn(msgResReadObject, file, &readObj);
object = readObj.objectNew.uid;
```
with this code:
```c
#define sampleResId MakeWknResld(clsSample, 17)
status = ResUtilLoadObject(sampleResId, &object);
```

**Related information**
- “Moving strings to resource files” on page 216.
- “Updating your makefile” on page 224.

**Using tags in source code**
This procedure shows you two ways to use tags that you have defined in resource and header files in your code.

**Prerequisite information**
- “Resource files” on page 189.
- “Resource file structure” on page 191.
- “Tags in source code” on page 193.

**Procedure**
You can choose any one of these steps as needed:

1. Use the tag directly when the function or message expects a tag as a parameter.
2. Use a tag in place of a literal string with any UI component that inherits from clsLabel. Set the label style to IsInfoStringId to let the object know you are using a tag rather than a literal string.
3. Use ResUtil functions to read the required string out of the resource file. Pass the tag as a parameter to the function to let it know which string you want.

**Examples**
The three examples below show the different ways to use a tag in source code.

**In toolkit tables**
Code from `\2_0\PENPOINT\SDK\SAMPLE\CNTRAPP\CNTRAPP\C` uses tags to set up Counter Application's standard toolkit menu.
```c
static const TK_TABLE_ENTRY CntrAppMenuBar[] = {
    {tagCntrMenu, 0, 0, 0, tkMenuPullDown | tkLabelStringId, clsMenuButton},
    {tagCntrDec, msgCntrAppChangeFormat, dec, 0, tkLabelStringId},
    {tagCntrOct, msgCntrAppChangeFormat, oct, 0, tkLabelStringId},
    {tagCntrHex, msgCntrAppChangeFormat, hex, 0, tkLabelStringId},
    {pNull},
    {pNull}
};
```
When you use tags instead of strings in a TK_TABLE_ENTRY, you must set the flag tkLabelStringId flag. Notice that the bitwise OR operator is used to add the flag to another flag, tkMenuPullDown.
In place of a literal string

The toolkit demo sample application in 2_0\PENPOINT\SDK\SAMPLES\ICONS.C shows the use of tags in place of literal strings. Note that clsIcon inherits from clsLabel.

```c
ICON_NEW in;

// Set the icon's label
in.label.style.infoType = lsInfoStringId;
in.label.pString = (P_CHAR)tagIconGoLogo;
```

Using resource utility functions

You can also use tags to fetch the required string out of your resource file.

```c
size = sizeof(resStr) / sizeof(CHAR);
ResUtilGetListString (resStr, size, resGrpMisc, tagCntrMessage);
```

Note that one of the parameter ResUtilGetListString() expects is the group in which the string is defined; in this case, resGrpMisc.

Using ComposeText functions

This procedure uses ComposeText functions to compose strings while your application is running. These functions are described in CMPSTEXT.H. Remember to link SYSUTIL.LIB if you any of these functions.

Prerequisite information

- "Resource files" on page 189.
- "Strings in resource files" on page 190.
- "Composed strings" on page 204.

Procedure

1. Identify strings that you compose dynamically from variable values and pieces of text.
2. Unless these composed strings are never displayed to the user, move these strings to resource files (if you have not already done so).
3. Include ComposeText parameters in each string, making sure you place the parameter in the appropriate place.
4. Call ComposeText functions in your source code when you need to create this string.

Example

This code is from the sample Counter Application. First, here is the entry in the resource file:

```c
// Message used to display counter value. The '^ls' argument allows
// the code to fill in the appropriate value based on the user's menu
// choice.
	tagCntrMessage, U_L("The counter value is: ^ls"),
```
Here is the code that retrieves the string along with formatting information from the resource file. The next block of lines composes the string.

```c
P_CHAR p;
U32 size;
CHAR buffer[MINSTRLEN];
...
// Retrieve format string from resource file, and construct display
   // string from format string and counter value.
size = MAXSTRLEN;
SComposeTextL(&p, &size, pNull, resGrpMisc, tagCntrMessage, buffer);
```

**Related information**

- “Using resource utility functions” on page 220.
- “Updating your makefile” on page 224.

**Updating your makefile**

This procedure shows you how to update your makefile to handle multiple resource files. This applies only if you are using the WATCOM WMAKE tool.

**Prerequisite information**

- “Managing your project” on page 205.
- “Makefiles” on page 206.

**Procedure**

1. Specify a locale in the command line. If you don't specify a locale, the standard makefile rules assume it is JPN.
2. Specify the resource files needed to build a localized version of your application by setting the RES_FILES, USA_RES_FILES, and JPN_RES_FILES variables in your makefile.
3. Add `${APP_DIR}\${TARGET_RESFILE}` to your "all" line.
4. Set the variable RES_STAMP to yes. This directs the makefile to use the application name and type defined in the resource file USA.RC or JPN.RC (depending on the value of LOCALE).

**Example**

From the command line, you can type either:

```bash
wmake LOCALE=usa
wmake LOCALE=jpn
```

to make the appropriate version of your application.

This sample makefile comes from NotePaper App, one of the sample applications included with the SDK. You can find the code in `\2_0\PENPOINT\SDK\SAMPLE\NPAPP`
Writing locale-independent code

This procedure helps make your code general enough to behave appropriately for a given locale. The goal is to maintain a single code base for all local versions of your application.

Prerequisite information

- "Writing international software” on page 178.
- "Locale-independent code” on page 196.
- "Using the DOS utility INTLSCAN” on page 210.
- "Interpreting INTLSCAN messages” on page 211.

Procedure

1. Run INTLSCAN on your source files to identify code that may be locale-dependent by typing:
   ```
   intlscan -r -u PROJECT.C
   ```
   The flags -r and -u force INTLSCAN to suppress messages about Unicode and resource files. See “Using the DOS utility INTLSCAN” on page 210 for details on using the INTLSCAN.

2. Identify other functionality that your application performs that may vary between locales. See “Locale-independent code” on page 196 for a partial listing of functionality categories that tend to vary tremendously between locales.

3. Replace locale-dependent function calls with calls to PenPoint international functions. Table 16-3 lists all the functions INTLSCAN flags and suggests PenPoint replacements.

4. If the required function does not exist in the PenPoint international package, write your own locale-independent code. Usually this means your function or message accepts a locale (and, optionally, a style) as a parameter. If you think the function you are writing would be widely useful to PenPoint developers, contact GO Technical Services with your suggestion.
Example

Table 16-3 lists locale-dependent functions and their suggested replacements from the PenPoint international package. This table should orient you to the problem of locale-dependent code and suggest further areas of code that may be locale-dependent.

Ellipses (…) in the chart indicate that there are a number of related functions with similar names. For example, IntlFormat... means that there are a variety of functions like IntlFormatS32(), IntlFormatDate(), and so on whose names begin with IntlFormat.

Checking the system locale

This procedure shows you how to check systemLocale to control your application's behavior.

Prerequisite information

- "Locale-independent code" on page 196.
- "Locales" on page 199.
- "Predefined locale identifiers" on page 199.

Procedure

1. Compare the value of systemLocale with the locale you are interested in.
2. Write the code to perform the special function.
3. Use the comparison to control whether the code executes.
Example

The following code comes from the Clock sample application. The fragments come from \2_0\OPENPOINT\SDK\SAMPLE\CLOCK\CLOCKAPP\CLOCKAPP.C. Here are the relevant type and macro definitions:

```
#define bothUp(timeUp | dateUp)
#define oneRow 4
#define oneCol 8
#define sideBySide 32
#define alarmOnTime 64
#define timeAndDate (bothUp | oneRow | sideBySide | timeFirst)
#define dateOverTime (bothUp | oneCol | alarmOnTime)
...
#define defaultFmtUSA timeAndDate
#define defaultFmtJPN dateAndTime
#define filedData \U8
   fmt;
...
   BOOLEAN alarmSnoozeEnable;
```

typedef struct CLOCK_APP_DATA {
   filedData // the filed portion of the instance data must come first
   ...
   OBJECT self;
} CLOCK_APP_DATA, *P_CLOCK_APP_DATA;

The code that uses these macros and types checks the system locale and selects an appropriate date format.

```
#ifdef PPI_0
   // Assume a USA locale for PenPoint 1.0
   pInst->fmt = defaultFmtUSA;
#else
   {
      // Choose different defaults depending on locale
      SYS_LOCALE currentLocale;
      currentLocale.localeString=pNull;
      // get the current locale
      ObjCallWarn(msgSysGetLocale, theSystem, &currentLocale);
      if (currentLocale.localeId==locUSA)
         pInst->fmt=defaultFmtUSA;
      else if (currentLocale.localeId==locJpn)
         pInst->fmt=defaultFmtJPN;
      else
         pInst->fmt=defaultFmt;
   }
#endif
```

Like most of the sample applications, the Clock application has been written to be compiled under both PenPoint 1.0 and PenPoint 2.0 Japanese. The symbol PPI_0 is defined to mark code that is for PenPoint 1.0 only.

To maintain a single source code base, you must use the PenPoint bridging package included with the PenPoint SDK 2.0 Japanese. See “Single code base” on page 233 in Chapter 17 for more information.

Related procedures

- “Writing locale-independent code” on page 225.
Chapter 17 / Porting to PenPoint 2.0

This chapter discusses the changes you need to make if you are porting an existing PenPoint™ 1.0 application to PenPoint 2.0 Japanese. You must perform these four steps:

1. Make changes required by changed PenPoint APIs.
2. Update your gesture handling code.
3. Use bitmaps rather than fonts to display special characters.
4. If you have not already done so, file version information as part of your instance data.

You must also make the changes discussed in the first four chapters of this handbook. For example, your 8-bit character should now be 16-bit data, your strings should be in resource files, and your locale-dependent functions should have been replaced with locale-independent functions.

**Changed APIs**

This procedure shows you how to update your PenPoint 1.0 code to reflect the new PenPoint 2.0 APIs.

**Prerequisite information**

Various categories of API changes have been made. Many of the fundamental changes have been discussed in this handbook, such as 8-bit to 16-bit character data. The PenPoint SDK 2.0 Release Notes describes most of the general API changes, and the Part 5: Architectural Reference Supplement provides more message and structure-level details.

The DOS utility INTLSCAN flags lines of code that use PenPoint 1.0 APIs.

**Procedure**

1. Run the utility to identify the lines in your code that contain PenPoint 1.0 APIs. See “Using the DOS utility INTLSCAN” on page 210 for details.
2. Replace the PenPoint 1.0 APIs with their updated APIs.

**Related information**

- “Single code base” on page 233.
Gesture handling code

This procedure updates your PenPoint 1.0 gesture handling code so that it compiles under PenPoint 2.0.

Prerequisite information

In PenPoint 1.0, gestures were encoded as 32-bit numbers. Beginning in 2.0, gestures are encoded as Unicode characters.

The change is simple. The msg member of the GWIN_GESTURE data structure has been renamed to gesture. So the declaration used to look like:

```c
typedef struct GWIN_GESTURE {
    MESSAGE msg;
    RECT32 bounds;
    XY32 hotPoint;
    OBJECT uid;
    U32 reserved;
} GWIN_GESTURE, *P_GWIN_GESTURE;
```

and now looks like this:

```c
typedef struct GWIN_GESTURE {
    CHAR gesture;
    RECT32 bounds;
    XY32 hotPoint;
    OBJECT uid;
    U32 reserved[2];
} GWIN_GESTURE, *P_GWIN_GESTURE;
```

Procedure

To change your code, simply:

1. Search your .C files for instances of the msg member of the GWIN_GESTURE structure.
2. Replace them with references to the gesture member.
3. Anywhere you have declared msg to be of type TAG, MESSAGE, or U32, make sure to change the field name to be gesture of type CHAR.
4. Replace the following obsolete code fragments with their newer counterparts. Unless you are maintaining a very old code base, you should not have to worry about this last step.
   - Replace MsgNew(pg->msg) with pg->gesture.
   - Replace TagNum(xgsGestureName) with xgsGestureName.

Examples

This sample comes from the Tic-Tac-Toe application. You can find the code listed here in $2_0\PENPOINT\SDL\SAMPLE\TTT\TTTVIEW.C.

This code is from the TttViewGesture message handler. The old version reads:

```c
MsgHandlerWithTypes(TttViewGesture, P_GWIN_GESTURE, PP_TTT_VIEW_INST) {
    STATUS s;
    // OBJECT owner;
```
switch(MsgNum(pArgs->msg)) {
    case MsgNum(xgslTap):
        ObjCallJmp(msgTttViewToggleSel, self, pNull, s, Error);
        break;
    case MsgNum(xgsCross):
        StsJmp(TttViewGestureSetSquare(self, pArgs, tttX), s, Error);
        break;
    case MsgNum(xgsCircle):
        StsJmp(TttViewGestureSetSquare(self, pArgs, tttO), s, Error);
        break;
    ...
}

The new code instead looks like this. Notice pArgs->msg is now pArgs->gesture.

MsgHandlerWithTypes(TttViewGesture, P_GWS_GESTURE, PP_TTT_VIEW_INST) {
    STATUS s;
    // OBJECT owner;

    switch(pArgs->gesture) {
        case xgslTap:
            ObjCallJmp(msgTttViewToggleSel, self, pNull, s, Error);
            break;
        case xgsCross:
            StsJmp(TttViewGestureSetSquare(self, pArgs, tttX), s, Error);
            break;
        case xgsCircle:
            StsJmp(TttViewGestureSetSquare(self, pArgs, tttO), s, Error);
            break;
        ...

\section*{Special characters}

PenPoint 2.0 no longer supports the 1.0 font editor. If you used the font editor to
design special glyphs to display in your application's user interface, these glyphs will
not display under 2.0.

\section*{Prerequisite information}

You might have designed certain user interface elements with the font editor. For
example, you might have designed a special interface that allows your application to
control a CD-ROM player. Its buttons are the familiar buttons found on most CD
players, and the icons representing play, skip track, and so on are actually special
glyphs of a font.

If you need to design special screen elements, use the bitmap editor instead of the
font editor.

If you have already created outline fonts with the font editor and need them in your
PenPoint 2.0 Japanese applications, contact GO Technical Services to see if your
fonts can be translated.
Also contact GO Technical Services if you need a particular Unicode glyph for your application that is currently unsupported. Given enough demand, it is possible that future releases of PenPoint will support the glyph you need.

**Procedure**

1. Install the bitmap editor as you would any other PenPoint application. It is available in `\PENPOINT\APP\BITMAP`.

2. Create the special symbols your application needs. Documentation on the bitmap editor is in Chapter 31, Bitmap Editor, of *Part 4: PenPoint Development Tools Supplement*. The bitmap editor saves your bitmap as a resource file with the extension .RES.

3. Use messages from `clsIcon` or `clsBitmap` to read the bitmap out of the resource file and display it on the screen.

**Example**

This code comes from the toolkit demo sample application. You can find this code in `\2_0\PENPOINT\SDK\SAMPLE\TKDEMO\ICONS.C`. The first thing to do is create an instance of `clsIcon`.

```c
ObjCallRet(msgNewDefaults, clsIcon, &in, s);
in.control.client = app;
in.win.tag = tagIconResource;
in.label.style.infoType = lsInfoStringId;
in.label.pString = (P_CHAR)tagIconResource;
ObjCallRet(msgNew, clsIcon, &in, s);
in.win.parent = parent;
ObjCallRet(msgWinInsert, in.object.uid, &in.win, s);
```

Notice no bitmap is specified here. When it needs the bitmap, `clsIcon` sends the icon's client `msgIconProvideBitmap`. In this case, the client is the application itself. When the application receives this message, it responds by passing the message to its ancestor which provides the bitmap.

When you make `TKDEMO`, the resource compiler appends the ICON.RES file created by the bitmap editor into either USA.RES or JPN.RES (depending on which localization you are working on). The application class `clsApp` knows how to read the icon out of the compiled resource file, so it responds appropriately to the message `msgIconProvideBitmap`.

**Notes**

There are several reasons GO requires you to create special symbols with the bitmap editor rather than the font editor.

- Bitmaps can be local to an application, whereas fonts are a global resource available to all applications.
- You can manipulate gray pixels with the bitmap editor.
* clsIcon will scale bitmaps with respect to screen resolution and the window layout, while fonts scale mathematically without regard for the surrounding visual context. A 10-pt font scaled 120% is 12 points, regardless of whether this is visually appropriate.

**File version data**

Remember to file a version number with the instance data of your application. This will make it possible for future versions of your application to read documents created by previous versions of your application. One possible way to file version data is to set aside the first byte of your filed instance data for a version number.

In general, you cannot read documents created by PenPoint 1.0 applications with applications created for PenPoint 2.0 Japanese. This is because many PenPoint objects are filing different data than they did in PenPoint 1.0.

**Single code base**

GO provides a bridging package that allows you to maintain a single code base that compiles and runs under both PenPoint 1.0 and PenPoint 2.0 Japanese. Your code must be written in a special way and must make use of the header files, makefiles, and library files provided with the bridging package.

See the *PenPoint Bridging Handbook* included with the PenPoint SDK 2.0 Japanese for more details on how to use the bridging package. Most of all, the PenPoint sample applications are specially written to compile and run under both versions of PenPoint. Use these samples as templates for the applications and services you want to create to run under both versions of PenPoint.
Chapter 18 / Localization Guidelines

After you finish internationalizing your application, the only step remaining is to prepare your application for a specific locale.

Remember that your product is much more than code. The released product should include translated documentation, appropriate packaging, a support plan, and other marketing and sales preparation.

The goal of localization is to produce a software product that respects a particular culture's language, customs, and traditions. Though this may seem obvious, a localized software product should behave similarly to applications developed by people native to your target locale.

This handbook does not cover specific details on how to localize to a particular country. However, here are a few guidelines to consider as you begin the localization process:

- Does the application support the local writing system? Your application should read, write, render, process, and receive user input for all the characters needed for communicating in the local writing system. The PenPoint™ operating system provides much, if not all, of the required support. Make sure your application takes advantage of the provided support.

- Does the application respect local text formatting conventions? Numbers, times, dates, currencies, and other text should display as the local user expects.

- Does the application behave as expected? Localized applications, for instance, should sort and compare using locally accepted precedence rules, calculate mortgage and interest payments using local formulas, and select words, sentences, and paragraphs using local grammatical rules.

- Does the application support standards popular in the local computing environment? File and communication standards are particularly important.

- Does the application respect local customs, taboos, and traditions? For example, make sure that any gestures, icons, and strings the application uses are appropriate, meaningful, and nonoffensive.

- Is the user interface graphically pleasing? What one country considers attractive may not be attractive in another country. Japanese characters, for instance, usually require more space than Roman characters. Does your interface make more room elegantly?
- Is the documentation translated in a way local users find informative and appropriate? Japanese users, for instance, tend to read documentation from cover to cover rather than referring to the documentation only when needed. Is your translation appropriate for such reading?
- Is your packaging appropriate to the locale?
- Has your software and documentation been tested by quality assurance personnel as well as local users?
Chapter 19 / Additional Resources

This appendix contains references to resources you may find helpful as you prepare your code for an international market.

**Texts**

These books may be helpful to you as you plan and design your application. Some are general guidebooks; others provide specific information on particular countries.

*PenPoint Application Writing Guide: Expanded Edition*  GO Corporation, 1992. An introduction to PenPoint programming updated from the original edition to discuss new sample code and other changes to the PenPoint SDK since PenPoint SDK 1.0.

*Do's and Taboos* Roger Axtell, John Wiley & Sons, 1989 Similar to *Do's and Taboos Around the World*, this book is aimed at small businesses. It includes discussions of planning for international markets, pricing, shipping, managing and motivating distributors, and communication. It also includes an entire chapter on Japan.

A set of general guidelines and specific details on how to support national languages. Volume 1 is an overview, and volumes 2 through 4 cover technical details on implementing “left-to-right and double-byte character set languages” (vol. 2), Arabic scripts (vol. 3), and Hebrew (vol. 4).

*The Standard C Library* P.J. Plauger, Prentice Hall, 1992. Although this book discusses the entire library, it also discusses the C library functions that deal with multibyte and wide character encoding. See “Large Character Sets for C” by P.J. Plauger in the August 1992 issue of *Dr. Dobb's Journal* for an overview.

Chapter 25 / Resources

Chapter 26 / Japanese Character Set

How the list was created
Chapter 20 / Introduction

Japan is an exciting market for PenPoint™ applications. The Japanese localization of the PenPoint 2.0 Japanese operating system provides many building blocks you can use to create high-quality, innovative Japanese applications. These building blocks include:

- A highly accurate handwriting recognition engine.
- An innovative font rendering engine.
- Functions that provide high-level support for Japanese, such as sorting and date formatting and parsing.
- Support for various ways of accepting Japanese input.

This handbook introduces concepts that help you localize your application to Japan. It discusses the changes you may need to make to your code, the development environment, and other issues that may influence the design of your Japanese product.

Intended audience

This handbook assumes the following about its readers:

- You are a developer planning to localize your application or service to Japan.
- You are familiar with PenPoint programming. Part 1: PenPoint Application Writing Guide is the best place to start if you are new to PenPoint programming.
- You have code that is ready to localize. Specifically, this handbook assumes that you have applied the procedures described in the Part 2: PenPoint Internationalization Handbook to internationalize your code. For example, your application should support Unicode, use resource files to store strings, and contain locale-independent code.

Organization of this handbook

Chapter 20, Introduction, describes the organization of this handbook.

Chapter 21, Japanese Characters, describes the Japanese language from a developer's point of view. It describes the official Japanese character set and how PenPoint 2.0 Japanese represents the character set internally. This chapter includes a discussion of the popular Shift-JIS (Japanese Industrial Standards) character encoding standard and how it compares with Unicode.
Chapter 22, Processing Japanese Text, builds on the previous chapter on Japanese characters and discusses more global issues about processing Japanese text. Topics include formatting conventions, sorting, and other text-related issues.

Chapter 23, Development Environment, describes the PenPoint 2.0 Japanese development environment. It describes the tools, utilities, and sample files that are designed specifically to help you create Japanese applications and services.

Chapter 24, Procedures, gives step-by-step instructions on how to perform common tasks such as creating Shift-JIS strings, supporting kana-kanji conversion, and using Japanese fonts.

Chapter 25, Resources, lists some books that may help you design, translate, and market your Japanese application.

Chapter 26, Japanese Characters, contains a chart that shows the JIS character set and the Unicode values of each character.
Chapter 21 / Japanese Characters

This chapter and Chapter 22, Processing Japanese Text, explain concepts that you should understand when writing a Japanese application. This chapter discusses the Japanese language and how the PenPoint™ operating system encodes Japanese characters. Topics include:

- Overview of Japanese.
  - Kanji.
  - Kana.
  - Romaji.
- Character encoding.
  - The Japanese character set.
  - Half- and full-width variants.
  - Unicode.
- Fonts.
- JIS and Shift-JIS encoding.
  - JIS encoding details.
  - Shift-JIS encoding details.
  - Converting to and from Shift-JIS.
  - Gaiji.

The next chapter discusses more general issues about handling user text input and processing Japanese text. If you are new to the Japanese language and its encoding, we recommend you read these two chapters in order.

Overview of Japanese

The Japanese writing system is among the most complicated in the world. Where most writing systems use fewer than 255 symbols, Japanese uses over 6,000 symbols.

Fortunately, you do not need to write any code to support this complex language. Many PenPoint 2.0 Japanese classes and objects already support Japanese behavior. For example, clsTextView can manipulate and display Japanese text in a window.

Use PenPoint 2.0 Japanese classes and objects whenever possible to implement this behavior. See Part 4: UI Toolkit and Part 5: Input and Handwriting Recognition of the PenPoint Architectural Reference for details.

Furthermore, the PenPoint 2.0 Japanese operating system provides a large set of international functions that have been localized to manipulate Japanese characters. For example, the IntlSort() function can correctly sort Japanese characters.
Use these international functions whenever available to provide behavior Japanese users expect. See Chapter 22, Processing Japanese Text, for details.

Most languages are written with a single set of symbols. English, for example, uses a single set of characters from a 26-letter alphabet and a collection of numerals and punctuation marks. Japanese writing, in contrast, uses four different sets of symbols called kanji, hiragana, katakana, and romaji. Each of these sets is discussed below. Table 21-1 summarizes the discussion.

**Kanji**

Kanji is a collection of more than 6,000 characters derived from Chinese. Kanji is the core of Japanese, representing nouns, verbs, adverbs, and adjectives. When a PenPoint 2.0 Japanese term has a good kanji translation, the kanji is used in the user interface. An official list of 6,355 characters, representing more than 99 percent of kanji in common use, has been published by the Japanese Industrial Standards (JIS) organization. See “Character encoding” on page 247 for more details.

**Kana**

Kana are two sets of symbols that represent syllables of spoken Japanese. These sets are called syllabaries because each symbol represents a syllable of spoken language. Each syllabary contains 46 basic characters. You can apply vocalization markings to these basic characters to represent a possible total of 104 syllables. These vocalization markings indicate how to pronounce a syllable. Not all of the possible characters are used in practice.

Hiragana is a set of 83 characters used mainly to write inflections. Both verbs and adjectives are inflected in Japanese. Pure hiragana words are rare in computer interfaces. Sometimes, though, you may see hiragana following kanji to form a complete word, as shown in the examples for “Apply” and “Close” in the margin.

Katakana is a set of 86 characters used mainly to write words borrowed from foreign languages. These borrowed terms are called loanwords. For example, the Japanese word for truck is written in katakana and pronounced teruku; similarly, the word for baseball is written and pronounced besubaru. A popular Japanese dictionary lists more than 13,000 loanwords. Katakana words, because of their foreign origin, are often used in computer interfaces. The katakana equivalents of PenPoint (penpointo), notebook (noto), and printer (purinda) are shown in the margin.

**Romaji**

Romaji is the set of characters of the Latin alphabet. Ji means character in Japanese, so romaji is literally “roman character.” Romaji includes both uppercase and lowercase letters, numerals, and English punctuation marks. Japanese uses romaji to represent expressions without turning them into loanwords.

The Japanese localization of the PenPoint 2.0 Japanese operating system provides a great deal of support for Japanese language processing. For example, the operating

The 7-bit ASCII character encoding scheme is too small to accommodate the thousands of Japanese characters. The most popular encoding system commonly used to encode Japanese in personal computers is called Shift-JIS. See “Shift-JIS encoding details” on page 252 for details on this encoding system.

Because code that processes Shift-JIS text can be quite difficult to write, the PenPoint 2.0 Japanese operating system uses Unicode to encode Japanese characters. The following sections discuss Unicode and how it compares with Shift-JIS.

PenPoint 2.0 Japanese provides simple facilities to work with Japanese encoded characters in either Shift-JIS or Unicode, although your application must process Unicode characters internally.

**The Japanese character set**

PenPoint 2.0 Japanese supports a standard list of characters published by the JIS organization in 1990. The characters are listed in a document called JIS C 0208-1990 and include the following:

- 6,355 kanji in Level 1 and Level 2.
- 86 katakana characters.
- 83 hiragana characters.
- 10 numerals.
- 52 Roman characters.
- 147 symbols.
- 66 Cyrillic characters.
- 48 Greek characters.
- 32 line elements for making charts.
The kanji are divided into two levels. The Level 1 kanji contains 2,965 of the most commonly used kanji sorted by pronunciation. The Level 2 kanji includes 3,390 less-frequently used characters sorted by radical. A radical is the most important part of a kanji, somewhat analogous to a Latin or Greek root word in English. Within each radical, characters are sorted by the number of strokes required to write the character (excluding the radical).

Together, these levels define 6,355 characters, or more than 99 percent of the kanji in common use.

The 1990 JIS standard derives from two previous JIS standards: one published in 1978 and the other in 1983. New kanji were added and existing characters rearranged in each edition, so that the standards are not strict supersets. Conversion between sets, however, is straightforward.

PenPoint 2.0 Japanese has glyphs for all of the characters in the 1990 character set. See “Fonts” on page 250 for more information.

The handwriting recognition engine that comes with the PenPoint SDK 2.0 Japanese can recognize a large fraction of the characters in the 1990 list. See “Handwriting recognition” on page 255 for details.

\section*{Supplemental characters}

In 1990, JIS also published a supplemental character list in a document called JIS X 0212-1990. It specifies an additional 5,801 kanji, a collection of 245 Latin-based characters, and 21 miscellaneous symbols and diacritical marks. These characters are called the JIS Supplemental Characters. Because they are not part of the JIS Level 1 or 2 kanji, these characters are sometimes called \textit{gaiji}, literally characters (ji) which are outside (gai) the standard.

These supplemental characters are rarely used variants of characters primarily used in proper names. The fonts shipped with PenPoint 2.0 Japanese do not contain glyphs for these supplemental characters, although Unicode does assign each character a code point. Thus you can represent any of these supplemental characters internally, but PenPoint 2.0 Japanese cannot display the appropriate glyph.

Because there was no standard way of encoding these characters prior to Unicode, PenPoint 2.0 Japanese files containing these supplemental characters are incompatible. See “Gaiji” on page 254 for information on how PenPoint imports and exports files containing these characters.
**Half- and full-width variants**

Any katakana character may be half- or full-width. In Japanese, this is translated as **hankaku** (half-width) or **zenkaku** (full-width). PenPoint 2.0 Japanese can represent and display these half- and full-width variants.

This width distinction is not an inherent part of the language. Rather, it is a historical convention from the JIS standard. To allow more characters to fit per line, the original JIS standard allowed a variant of the katakana characters to be as wide as a monospaced Roman letter. Because kanji were twice as wide as Roman characters, these katakana variants were called half-width characters.

In PenPoint 2.0 Japanese, a normal Roman character remains roughly half the width of a kanji character. Because Roman characters are often proportional while Japanese kana and kanji are always fixed-width, the comparison is a rough estimate. In addition to these normal-width (hankaku) ASCII characters, PenPoint can also represent and display double-width (zenkaku) ASCII characters.

The double-width Roman characters are monospaced, so they line up evenly with kanji characters. You might use these double-width characters in a title or table that contains mixed kanji and roman characters.

To see these zenkaku and hankaku variants, select some text in a MiniText document and select To Zenkaku or To Hankaku from the Convert menu.

PenPoint 2.0 Japanese provides a function called **IntlStrConvert()** that can convert between the half- and full-width characters. Remember that only katakana and ASCII characters have these half-and full-width variants. See “Converting between character variants” on page 287 for more information.

**Unicode**

PenPoint 2.0 Japanese uses the 16-bit Unicode encoding standard to represent Japanese characters. Your source code should already support 16-bit Unicode characters. If it does not, see Part 2: PenPoint Internationalization Handbook for details on how to support Unicode.

The Unicode standard assigns all the characters discussed above a unique 16-bit number, sometimes called a **code point**. All the characters specified in the most current 1990 list, the 5,801 supplemental kanji characters, as well as the half- and full-width versions of katakana and Roman alphanumerics are assigned unique Unicode code points.

Thus, your application can represent and manipulate any of these characters internally.

Table 21-2 shows how various Japanese characters are encoded in Unicode. One of the design goals of Unicode was to eliminate redundant coding of characters common to Chinese, Japanese, and Korean (CJK). If all three languages use the same character, that character is assigned a single Unicode value.
The space allotted to these unified characters is labelled CJK ideographs. All of the JIS kanji fall into this range. Also, because Chinese, Japanese, and Korean share many punctuation marks, many of the Japanese punctuation marks are encoded as ideographic punctuation.

**Unic ode encoding of Japanese characters**

<td>U+E000→U+F7FF</td>
<td>Not applicable</td>
</tr>
</tbody>
</table>

Unicode encodes half-width katakana and double-width ASCII in an area called the Compatibility zone. It is called the Compatibility zone because the characters in this zone exist in Unicode solely to be compatible with other character sets like Shift-JIS. Remember that the half- and full-width distinction for katakana is not inherent in Japanese, so these characters would not need code points if they did not exist in the JIS standard.

Because files created on Japanese computers may contain characters outside of the official JIS list, PenPoint 2.0 Japanese must map them to some location in the Unicode code space. The Unicode Private Use Zone is used for this purpose. See “Gaiji” on page 254 for details.

**Fonts**

The PenPoint operating system 2.0 Japanese currently provides two Japanese fonts, Heisei Mincho and Heisei Gothic. Use the Mincho font in roughly the same way you use a Roman serif font, and use Gothic as you would a Roman sans-serif font. Note that all kanji and kana are monospaced.

The Mincho and Heisei fonts contain glyphs for JIS levels 1 and 2 kanji as well as all of the other JIS C 0208-1990 characters. This includes the hankaku and zenkaku versions of ASCII and katakana characters, but does not include the supplemental characters.

The default system font, used by the system and text applications, is 12-point Mincho. The default user font used in fields is 12-point Gothic.

Users can set either of these defaults to Gothic, Roman, Sans Serif, or Mincho in the Preferences section of the Settings notebook. If Roman is the chosen default font, Japanese characters appear in Mincho. If Sans Serif is chosen, Japanese characters appear in Gothic.
Again, the standard fonts do not contain glyphs for any of the 5,801 supplemental kanji. So while your application can represent internally any Unicode character, the only kanji that appear on the screen are JIS levels 1 and 2 characters.

If your application tries to display one of the 5,801 JIS Supplemental Characters, it will appear as a hex quad. A hex quad is a collection of four hex numbers that represent a single 16-bit code. The first (high) byte is on top, and the second (low) byte is on the bottom. The first example in the margin represents the hexadecimal number 0x001B.

The fonts are divided into several files, as shown in Table 21-3.

### JIS and Shift-JIS encoding

JIS and Shift-JIS are two popular character encoding schemes used by current Japanese computer systems. Think of JIS encoding as the standard on larger computers and Shift-JIS as the personal computer standard. For example, IBM DOS J5.0/V and KanjiTalk, the Japanese version of the Macintosh operating system, use the Shift-JIS encoding standard.

Do not confuse the JIS encoding standard with the JIS character list. The JIS encoding standard maps characters in the JIS character list to a particular code point.

Both JIS and Shift-JIS are multibyte encoding systems. That is, both use two bytes to represent Japanese characters. The only exception is a hankaku character, the half-width version of katakana. Each hankaku character requires one byte.

Both schemes also use a single byte to represent ASCII characters. This allows a text file to mix ASCII and Japanese characters.

### JIS encoding details

JIS encoding overlaps with the printable ASCII characters; that is, its codes fall between decimal 33 and 126 (hex 21 through 5F). ASCII codes still represent ASCII characters, and each Japanese character is represented as a sequence of 2 byte-long ASCII codes. Hankaku characters are represented by a single byte between 0xA1 and 0xDF.
To distinguish a single-byte ASCII character from a double-byte Japanese character, applications must search for a shift state. The shift state indicates whether a given text stream is in one-byte-per-character mode (ASCII) or two-bytes-per-character mode (Japanese).

A shift is indicated by a particular escape sequence like ESC $ @ (hex 1B 24 40). “Shift out” marks the beginning of a series of double-byte JIS characters, while “shift in” marks the return to single-byte ASCII characters. Different shift states are used for each different character set (1978, 1983, 1990).

The shift state can make text-processing code quite complex. If the application needs to process text in the middle of a sentence or page, for example, the code may be required to read backwards to determine the state.

Because the JIS encoding system is not widely used by Japanese personal computers, PenPoint 2.0 Japanese does not provide any support of the JIS encoding. If necessary, convert any JIS files to Shift-JIS before importing them into PenPoint 2.0 Japanese.

Shift-JIS encoding details

Shift-JIS, sometimes abbreviated XJIS, is a variation of JIS encoding used widely by Japanese personal computers. It eliminates state information by shifting the code of the first byte of a Japanese character to above hex 80.

The second byte falls between decimal 64 and 126 (hex 40 and 7E). This range contains both printing and nonprinting ASCII characters. So while the first byte of a Shift-JIS character cannot be confused with a standard 7-bit ASCII character, the second byte can be. As in the JIS encoding, hankaku characters are represented by a single byte between 0xA1 and 0xDF.

Although the ASCII standard itself is only 7 bits, most vendors use the high ASCII characters above hex 80 for special characters. For example, IBM uses codes above hex 80 for line drawing elements, European alphabets, and other glyphs. Thus even the first byte of a Shift-JIS character overlaps with codes that are previously assigned code points.

This overlap makes processing text difficult even without explicit state information embedded in the text stream.

For example, say your code encounters a character with code value below hex 80. It might be an ASCII character, but it might also be the second byte of a Japanese character. You can check the code of the previous character, but this check does not always resolve the ambiguity.

If the previous character is above hex 80, it can still be the first or second byte of a Japanese character. To determine the state of the current character, your code must scan through the stream backwards until two sequential ASCII characters appear. This algorithm is complex, error-prone, and computationally expensive.

**Character set code spaces**

Figure 21-1 shows what codes the different character encoding systems occupy. Each of the two-dimensional charts shows the high byte along the left edge and the low byte along the top edge. Notice that the original JIS encoding completely overlaps with 7-bit ASCII; all bytes fall between hex 20 and 80.

Although Shift-JIS solves this overlap problem for 7-bit ASCII, most 8-bit ASCII code points still overlap with Shift-JIS code points.

Unicode code points are shown on the left side. The four labelled zones contain the following characters:

- **Alphabets** contains alphabets, syllabaries, and symbols.
- **CJK** contains Chinese, Japanese, and Korean characters, including all the JIS Level 1, Level 2, and supplemental kanji.
- **Private Use** area contains compatibility zone characters and characters for private, corporate use. GO’s gesture glyphs are in the corporate use zone. The hankaku, katakana, and zenkaku ASCII characters are the in compatibility zone.
- **Reserved** area is reserved by the Unicode Consortium for future use.

### Character code spaces

<table>

</tbody>
</table>

![Figure 21-1](image)

**Shift-JIS**

- High byte: 81-9F, EO-EF
- Low byte: 40-7E, 80-FC
- Zenkaku: AO-EO

**JIS**

- High byte: 21-7E
- Low byte: 21-7E
- Zenkaku: AO-EO

**Unicode**

See Table 21-2 for the ranges of Unicode code points.
Converting to and from Shift-JIS

PenPoint 2.0 Japanese provides various conversion facilities between Shift-JIS and Unicode:

- Convert Shift-JIS files to and from Unicode with the DOS utility UCONVERT. This utility is included with the SDK in `\2_0\SDK\UTIL\DOS\UCONVERT`. See “Converting Unicode and Shift-JIS files” on page 285 for details on using the utility.

- Directly import Shift-JIS files into MiniText. See “Working with Shift-JIS in text files” on page 283 for details.

- Use the functions `IntlMBToUnicode()` and `IntlUnicodeToMB()` to translate text programmatically. The default behavior of this function in PenPoint 2.0 Japanese converts between Unicode and the 1990 Shift-JIS encoding.

- Use `clsText` messages `msgTextRead` and `msgTextWrite` to read and write Shift-JIS strings. These messages are documented in `TXTDATA.H`. Specify `fileTypeASCII` as the format. Because Shift-JIS uses 8-bit characters, `fileTypeASCII` works for both Shift-JIS and 8-bit extensions to ASCII. File types are defined in `FILETYPE.H`.

Gaiji

Gaiji literally means characters (ji) that are outside (gai) of the standard. There are thousands of characters that are not included in JIS levels 1 or 2, many of which are rarely used characters or rare forms of characters used in proper names.

Many of these characters have been defined as part of the 5,801 supplementary kanji added to JIS in 1990. Unicode assigns each of these characters a unique 16-bit code.

Before Unicode, however, implementation of these gaiji varied tremendously. Consequently, files are often incompatible between applications and computer systems. For example, the AX Consortium, NEC, and Fujitsu each support mutually incompatible gaiji encoding schemes.

When you import a file containing gaiji encoded by one of these three schemes, PenPoint 2.0 Japanese automatically maps the characters into parts of the Unicode Private Use Area. The characters are displayed as hex quads because the fonts shipped with PenPoint 2.0 Japanese do not contain glyphs for gaiji. When you export the documents, all the gaiji characters are mapped to their original values.

Note that if the computer from which you are importing does not use the same gaiji mapping as the computer to which you are exporting, the gaiji are not mapped correctly. In other words, PenPoint 2.0 Japanese does not translate between different gaiji encodings.
Chapter 22 / Processing Japanese Text

This chapter discusses how Japanese text is typically processed and how your application can use the PenPoint™ operating system's support for high-level text processing. Topics include:

- Japanese text entry.
  - Handwriting recognition.
  - Kana-kanji conversion.
  - Romaji-kanji conversion.
  - Supporting KKC and RKC.
  - Using keyboards.
- Handling Japanese text.
  - Delimiting words.
  - Delimiting sentences.
  - Comparing and sorting.
  - Converting between Shift-JIS and Unicode.
  - Compressing Unicode.
- Formatting Japanese text.
  - Line breaks.
  - Dates.
  - Times.
  - Numbers.

**Japanese text entry**

Using a keyboard to enter Japanese kanji is a cumbersome and time-consuming process. One of the most exciting features of PenPoint 2.0 Japanese is Japanese handwriting recognition.

With PenPoint 2.0 Japanese, users can simply write Japanese characters on their PenPoint machine and the handwriting recognition engine translates the characters into a machine-readable form. You do not have to write any code to support this feature.

**Handwriting recognition**

The handwriting engine shipped with PenPoint 2.0 Japanese recognizes all of the JIS kana, romaji, and almost all of the JIS levels 1 and 2 kanji. See “Character recognition” on page 256 for more details on which characters the handwriting engine recognizes.
Here are a few tips that help the handwriting recognizer achieve higher accuracy. You might mention these tips in your user documentation:

- Use the correct stroke order. Each Japanese character has a standard stroke order. Although the engine recognizes popular variations on the stroke order, recognition is better with the standard stroke order.
- Print neatly. Highly curved and joined strokes take more time to recognize.
- Keep radicals separate. Many Japanese characters are composed of two or more radicals. Do not overlap them when writing.
- Do not add extra strokes. The engine tolerates missing strokes but not additional strokes.
- Experiment with simplified forms of a character. The engine recognizes traditional as well as some of the simplified forms of a character.

**Character recognition**

The handwriting engine recognizes all of the JIS Level 1 kanji (2,965) and roughly 2,900 of the 3,390 Level 2 kanji. The unrecognized characters fall into three categories:

- Radicals that are not complete characters in themselves, such as 興.
- Rarely used characters, such as 鍾.
- Rare variants of a character whose common style is recognized, such as 閱.

Users can enter characters not recognized by the handwriting engine in one of three ways:

- Kana-kanji conversion (KKC) allows users to “spell” the kanji character in either hiragana or katakana. The user then converts the kana sequence into a kanji character. See “Kana-kanji conversion” on page 257 for more details on KK.
- Romaji-kanji conversion (RKC) allows users to type in the English romanization for a kanji character. PenPoint 2.0 Japanese uses the Hepburn system of romanization. See “Romaji-kanji conversion” on page 258 for more information.
- The Unicode Browser, a PenPoint accessory, allows users to enter these characters from a collection of pop-up lists. See “Unicode Browser” on page 279 for details. The document *New UI Features in PenPoint 2.0* shows you how to use the Unicode Browser.

Because the fonts shipped with PenPoint 2.0 Japanese contain glyphs for all Level 1 and 2 characters, your application can display these characters even though the handwriting recognition engine cannot recognize them. The limitation discussed here applies only to the character recognition engine.
**Punctuation recognition**

The handwriting engine recognizes the following Japanese punctuation marks and symbols. ASCII punctuation marks are used primarily with romaji, although there is some overlap. Japanese, for example, uses the English question mark.

See the *Unicode Standard, Volume 1*, pages 332 through 338, for representative glyphs.

</tbody>
</table>

**Kana-kanji conversion**

The typical method of entering Japanese with a personal computer is called *kana-kanji conversion* (KKC). The approach is as follows.

The user types kana with a Japanese keyboard. The user then presses a special key to convert a sequence of kana to a single kanji character.

Japanese has many homophones, words that sound alike. Consequently, a single sequence of kana specifies a number of possible kanji. After the user presses the convert key, a list of possible matches appears, and the user then selects the desired character.

PenPoint 2.0 Japanese supports this method of entering kanji in addition to the direct handwriting recognition discussed above. Users can type or write kana characters, and then initiate KKC by pressing a special key (the space bar on American keyboards and a dedicated KKC key on Japanese keyboards) or by using the right up − gesture.
The easiest way to provide KKC support in your application is to use a PenPoint 2.0 Japanese object that implements the behavior. Instances of clsIP or clsField automatically support KKC without any additional code.

To provide KKC support with your own custom objects, read the protocol described below in “Supporting KKC and RKC.” Also see “Supporting kana-kanji conversion” on page 296 for a code sample.

Romaji-kanji conversion

A process similar to KKC called romaji-kanji conversion (RKC) allows users to enter Japanese characters by typing English letters. The letters are first translated into kana, which then undergo KKC to specify a list of possible kanji.

For example, if the user types the word nihongo and hits the convert key, the insertion pad replaces nihongo with Japanese characters.

Users can use an attached keyboard or PenPoint’s virtual keyboard to type Japanese characters. The space bar initiates RKC on the English keyboard. The Japanese keyboard has a dedicated conversion key, as well as extra keys for scrolling through alternatives and reversing the conversion.

See “Using keyboards” on page 261 for tips on using the keyboards to type Japanese.

Supporting KKC and RKC

The easiest way to support KKC and RKC is to create an instance of clsIP or clsField because these objects already support both character conversions. In general, only sophisticated text-processing applications, such as word processors, need create their own classes to handle KKC and RKC.

If you create your own class to support KKC and RKC, it should follow the protocol described below. Before we describe the protocol, you should know about three new PenPoint 2.0 Japanese classes.

The first new class, called clsCharTranslator, is an intermediary between clients that want to support character translation and services that provide character translation functionality. Because clsCharTranslator is an abstract class, its descendant clsKKCT serves as the actual intermediary.

Both these classes receive messages from the client (often via clsGwin, as described below), and then request services from clsKKC. Because clsKKC is a descendant of clsService, it provides APIs for requesting services to perform actual character translations. This architecture permits you to replace the translation engine provided with PenPoint 2.0 Japanese with your own engine.

Because the character translator requests gesture information, its clients are almost always subclasses of clsGWIN. Every instance of clsGWIN creates a character translator (during msgInit) to which it sends translation requests.

You can specify which translator clsGWIN sends the message to by filling in the LOCALE_ID field of GWIN_NEW ONLY. If you do not specify a translator, clsGWIN
creates a translator appropriate to the system locale. The default translator for Japan (locJpn) is an instance of clsKKCT.

Here is an example of the protocol in action, described as clsIP implements it:

1. The user writes a few kana characters in an insertion pad, then requests KKC with the right up → gesture, as shown in Figure 22-1. When the pad receives a gesture, it self-sends the message msgCharTransGesture.

Handling the KKC gesture

2. Rather than handling the message itself, clsIP allows the message to be handled by clsGWin. In turn, clsGWin sends the message to the character translator it created as part of its response to msgInit. Again, for PenPoint 2.0 Japanese, the default translator is an instance of clsKKCT.

3. When the character translator (an instance of clsKKCT) receives the gesture information it determines if the gesture is relevant to character translation. Since the right-up gesture explicitly requests KKC, it sends the msgCharTransGetClientBuffer to the client (clsIP) requesting a portion of its buffer.

4. The client sends the requested characters in response to msgCharTransGetClientBuffer.

5. The translator communicates with clsKKC, the front-end to the actual service that provides KKC. In this case, a translation is needed, so the translator sends msgCharTransModifyBuffer with the translation to the client.

6. Using information sent with msgCharTransModifyBuffer, the insertion pad updates its internal buffer and user interface to display the translated character. Note that in the result, shown in Figure 22-2, the translated characters are highlighted. The arguments sent with msgCharTransModifyBuffer contain information on which characters to highlight. See Part 6: PenPoint User Interface Design Reference Supplement for details on how character highlighting should behave during KKC.

Displaying the translated characters
The user then requests a list of alternatives by tapping on the highlighted character. The insertion pad self-sends `msgCharTransGesture`, again allowing the message to be handled by `clsGWin`.

The translator receives the message from `clsGWin` and queries `clsKKC` for character alternatives. It also asks the client where the character alternatives pop-up box should be placed by sending `msgCharTransProvideListXY`. The insertion pad calculates the coordinates of the upper-left corner of the pop-up box. The pop-up box should appear directly below the original character.

### Handling a character alternatives request

If the user selects an alternative from the pop-up box, the translator sends `msgCharTransModifyBuffer` to the insertion pad. The insertion pad then updates its buffer and user interface.

When the user taps OK to dismiss insertion pad, the pad self-sends `msgCharTransGoQuiescent` to reset the translator in preparation for the next character translation request.

The description above does not exhaust the messages involved in the character translation protocol. For example, it did not mention any of the messages involved for supporting keyboard input. The following paragraphs describe the most important messages involved in the protocol.

The client should self-send the following four messages when appropriate. However, the client should not define a method to handle the message. Rather, the client should allow the message to be passed up to `clsGWin`.

1. Self-send `msgCharTransKey` each time the user presses a key.
2. Self-send `msgCharTransChar` each time the user edits an existing buffer (for example, when the user inserts or deletes a character). Normally, you need not send this message as the user writes a new character. See step 4 below for handling this case.
3. Self-send `msgCharTransGoQuiescent` to cancel the current translation. When the user taps outside an insertion pad, for example, `clsIP` self-sends `msgCharTransGoQuiescent`.
4. Self-send `msgCharTransGesture` each time the user makes a gesture on your text.
The client should respond to the following messages sent by the character translator:

- **msgCharTransModifyBuffer**, which contains information on how to translate characters. The client should respond by updating its text buffer and user interface, including updating strong and weak highlighting. The character translator sends the client a CHAR_TRANS_MODIFY structure containing all the relevant information.

- **msgCharTransGetClientBuffer**, which asks the client for some text from its buffer. Pass the requested text to the character translator as part of a CHAR_TRANS_GET_BUF structure.

- **msgCharTransProvideListXY**, which asks the client where to put the character alternative list. The client should compute root window coordinates so that the pop-up box appears below the original character.

See “Supporting kana-kanji conversion” on page 296 for more details and a code sample.

### Using keyboards

The PenPoint operating system 2.0 Japanese supports a number of keyboards including:

- IBM Japanese A01.
- IBM U.S. keyboard (IBM AT).
- Toshiba laptop keyboards (Toshiba Dynabook 386/20).
- Toshiba desktop keyboards (Toshiba J3100ZS).
- AX Consortium keyboard (OkiData 486 VX530)

Set the **Keyboard** variable in MIL.INI to identify your keyboard. Valid values are shown in MIL.INI.

Here are some tips when using the American keyboard:

- The keyboard has two modes: One lets you type English characters, the other Japanese characters. Press Ctrl-Shift-L to toggle between modes.
- If you are having problems toggling modes, cancel the insertion pad, press Ctrl-Shift-L, and then open another pad.
- Press the space bar to initiate KKC or RKC.
- In Japanese mode, alphabetic keys map to hiragana. Hold down the Shift key to enter katakana.
- Use the up and down arrows to scroll through the character alternatives pop-up box.

The Japanese keyboard has dedicated keys to initiate character conversion, scroll through character alternatives, and adjust the current selection.
The virtual keyboard included as a PenPoint 2.0 Japanese accessory emulates both American and Japanese keyboards. Bring up the keyboard from the Accessories notebook and make the check gesture √ on the keyboard title bar to select an emulation mode. See "Japanese virtual keyboard" on page 279 for more information.

**Handling Japanese text**

PenPoint 2.0 Japanese provides a collection of international functions to perform tasks like formatting dates and times, sorting, and word and paragraph selection. Because the desired behavior of these functions varies widely between locales, the international functions accept an argument that identifies a locale. The value of this argument determines the function's behavior.

Remember that in this context, a locale identifies a country, a language, and an optional dialect. The default locale in PenPoint 2.0 Japanese is Japan, which is defined as the 32-bit locale identifier loe[pn in GOLOCALE.H.

See Table 22-2 for a summary of the default behavior of the most important international functions for Japan. The rest of this chapter provides more details by describing how Japanese is typically processed. Topics include line breaking, selecting words, sorting, and more.

See Part 2: PenPoint Internationalization Handbook for general information on these international functions and locales. Most of the international functions are defined in C:2:0\PenPoint\SDK\INC\ISR.H.

Chapter 24, Procedures, describes how to use PenPoint's international functions to give your applications the behavior described here.

If your application needs to provide appropriate behavior in just the default locale loe[pn, use the Loc...() macros rather than the Intl...() functions. For example, here is the definition of LocDelimitWordO from ISR.H. Calling LocDelimitWord() in PenPoint 2.0 Japanese delimits the Japanese equivalent of a word.

```c
#define LocDelimitWord(tx,s,st) IntlDelimitWord(tx,s,intlDefaultLocale,st)
```

Notice that it calls the equivalent international function, sending intlDefaultLocale as an argument.

**Japanese behavior of international functions**

<table>
<thead>
<tr>
<th>Function</th>
<th>Default behavior</th>
</tr>
</thead>
<tbody>
<tr>
<td>IntlDelimitWord()</td>
<td>Delimits a bunsetsu.</td>
</tr>
<tr>
<td>IntlDelimitSentence()</td>
<td>Delimits a sentence ended by an ideographic period or other punctuation mark.</td>
</tr>
<tr>

<tr>
<td>IntlParseTime()</td>
<td>Parses A.M./P.M., hours, minutes, with kanji separators.</td>
</tr>
<tr>
<td>IntlCompare()</td>
<td>Compares Unicode values of two characters.</td>
</tr>
<tr>
<td>IntlSort()</td>
<td>Sorts characters by Unicode value.</td>
</tr>
<tr>
<td>IntlMBToUnicode()</td>
<td>Converts latest Shift-JIS encoding (1990) to Unicode.</td>
</tr>
<tr>
<td>IntlUnicodeToMB()</td>
<td>Converts Unicode to latest Shift-JIS encoding (1990) to Unicode.</td>
</tr>
</tbody>
</table>

Many of these functions are discussed in detail in the rest of this chapter.

**Delimiting words**

The Japanese equivalent of an English word is called a bunsetsu, which literally means a phrase.

**Text with selected bunsetsu**

The rules for delimiting an English word are relatively straightforward because English uses spaces and punctuation to separate words. Japanese does not use spaces, so the rules for locating a bunsetsu are quite complicated.

Call the PenPoint 2.0 Japanese function LocDelimitWord() to locate a bunsetsu. The prototype for the international function follows. Remember that the Loc...() macro calls the Intl...() function, passing intlDefaultLocale as the LOCALE_ID.

```c
S32 EXPORTED IntlDelimitWord(
    P_CHAR   pString,    // Beginning of text region
    P_U32    pStart,     // In/Out: seed position/start of word
    LOCALE_ID locale,    // Locale to use -- from golocale.h
    U32       style      // Delimit style -- from isrstyle.h
);
```

This function and the IntlDelimitSentence() function both take a start position and return the start and length of the requested item (a word or sentence). The length is returned by the function, and the start position is returned as one of its out parameters pStart.

Use the intlDelimitExpandLeft or intlDelimitExpandRight flags to extend the selection in a single direction one bunsetsu at a time. See the file ISRSTYLE.H for more details and other valid styles.

See “Delimiting words” on page 289 for more details on how to locate bunsetsu in your application.
**Delimiting sentences**

Japanese uses a mark called a **maru** to end a sentence. It works similarly to the English period. Unicode calls the symbol the ideographic period (U+3002) because it is common to Chinese, Japanese, and Korean.

**Text with sentence selected**

![Text example](image)

Use the `LocDelimitSentence()` macro to find a sentence in a text stream. Here is the prototype:

```c
EXPORTED IntlDelimitSentence(
    P CHAR pString,  // Beginning of text region
    P U32 pStart, // In/Out: seed position/start of sentence
    LOCALE_ID locale, // Locale to use -- from golocale.h
    U32 style // Delimit style -- from isrstyle.h
);
```

See “Delimiting sentences” on page 290 for details on how to locate sentences in your application.

**Comparing and sorting**

There is a well-established ordering for the kana characters. The characters are arranged according to the sounds of the “Fifty Sounds Table.” You can find the table in any Japanese dictionary or introduction to Japanese writing. See Chapter 25, Resources, for references to some of these texts.

The kanji characters, however, are more difficult to order. Popular dictionaries sort characters by radical. Within radicals, they sort characters by the number of additional strokes, not including the radical, it takes to write the character.

The JIS character list, unfortunately, is not uniformly ordered this way. The Level 1 kanji are ordered phonetically (that is, by their kana equivalents), while the Level 2 kanji are ordered by the radical-stroke scheme.

In a Shift-JIS text that contains both Level 1 and Level 2 kanji, sorting characters is quite a challenge. Fortunately, the Unicode encoding already puts Japanese characters in sorted order. Thus PenPoint 2.0 Japanese can sort Japanese characters simply by their Unicode value. Specify the `intlSortStyleDictionary` style when you call `IntlCompare()` or `IntlSort()` to sort by radicals and number of strokes.

For more information on how Unicode orders Japanese characters, see *The Unicode Standard: Version 1.0, Volume 1*.

The other available sort and compare style is `intlSortStylePhoneBook`. If you specify this style, the sort and compare functions use the JIS ordering for Level 1 kanji; that is, comparing and sorting is done phonetically. There are various complicated comparison rules for characters outside of the Level 1 kanji.
Here is the prototype for the IntlSort() function:

```c
STATUS EXPORTED IntlSort(
    PP_CHAR ppString,  // list of strings to sort
    U32 count,         // number of strings in list
    LOCALE_ID locale, // Locale to use -- from g_locale.h
    U32 style          // Collation style -- from isrstyle.h
);
```

See “Comparing strings” on page 291 and “Sorting strings” on page 292 for details on how to give your application comparison and sort capabilities.

### Converting between character variants

There are four typical character conversions you may want to support:

- Katakana to hiragana.
- Hiragana to katakana.
- Zenkaku (full-width) to hankaku (half-width).
- Hankaku to zenkaku.

The width conversion functions work with the ASCII and katakana characters. The normal size for katakana is full-width (zenkaku), and the normal size for alphanumerics is half-width (hankaku).

You can convert individual characters or strings. Functions that work on individual characters are in CHARTYPE.H, and have names that begin with IntlChar…(), as in IntlCharToUpper(). The string conversion functions, defined in ISR.H. are IntlStrConvert() and IntlNStrConvert().

All of these functions convert a Unicode character or string to another Unicode character or string. They do not convert between character sets. For more information on conversions between character sets, see the next section, “Converting between Shift-JIS and Unicode.”

The Unicode representation of zenkaku and hankaku are in a special area called the **Unicode Compatibility Zone**, which extends from U+FE00 to U+FFE6. The zone contains character variants that exist in Unicode solely to be compatible with other characters sets like Shift-JIS.

The string conversion functions also support conversions to and from the Compatibility Zone. Your application might, for example, import a Shift-JIS text, convert it to Unicode, and then convert all the characters in the Compatibility Zone to their equivalents outside of the Compatibility Zone. This would convert any half-width katakana characters to full-width katakana. It would also convert any full-width alphanumerics to half-width. Think of conversions out of the Compatibility Zone as converting characters to their most typical form.

The string and character conversion functions also handle conversions between upper and lowercase and between composed characters and their base character plus diacritical mark equivalent.

See “Converting between character variants” on page 287 for details on how to provide character conversion support in your application.
Converting between Shift-JIS and Unicode

Many existing Japanese files are in Shift-JIS format. Therefore, your application may want to provide import capabilities for Shift-JIS files. PenPoint 2.0 Japanese provides functions named IntlMBToUnicode() and IntlUnicodeToMB() to convert between Shift-JIS to Unicode strings. The default translation converts to and from the latest (1990) Shift-JIS encoding.

See “Converting Unicode and Shift-JIS strings” on page 286 for details on how to use these functions.

If you are converting a string that contains a filename, set the intlCharSetFileNameMapping flag. Because operating systems use different characters to represent path and file names, the string conversion function must know whether the string to be converted is (or contains) a filename. For example, most Japanese versions of DOS use the yen (¥) character to separate path names, while most U.S. English versions of DOS use the backslash (\) character.

To convert entire files between different character sets, use the DOS utility UCONVERT. See “Converting Unicode and Shift-JIS files” on page 285 for details.

Compressing Unicode

Unicode can be efficiently compressed when written to a file, especially if all the characters in the text stream are from the same character set (for example, all ASCII text).

All Unicode characters are 16-bits long. Shift-JIS, on the other hand, uses a single byte to encode hankaku, katakana, and ASCII characters, and two bytes to encode all other Japanese characters. Thus, the two character encodings require roughly the same amount of memory with mostly Japanese text.

When filed, however, Unicode data can be compressed. PenPoint 2.0 Japanese provides functions that allow you to compress Unicode strings before filing them. Typically, these compressed Unicode files store Japanese text using less space than the identical Shift-JIS file.

Call IntlCompressUnicode() and IntlUncompressUnicode() to compress and decompress Unicode strings. See the header file ISR.H for more information.

Formatting Japanese text

The following sections describe Japanese text formatting conventions. Table 22-3 shows some of these conventions.

PenPoint 2.0 Japanese provides many formatting functions that provide appropriate formatting behavior for Japanese text. Your application should simply call these functions whenever they are available.

The only formatting convention shown in Table 22-3 that does not have native PenPoint 2.0 Japanese support is phone number formatting. Your application should provide its own formatting functions to handle phone numbers. Note that the number of digits in a Japanese area code varies with geographical location.
**Default Japanese Formatting**

<table>
<thead>
<tr>
<th>Formatting area</th>
<th>American English formatting</th>
<th>Default Japanese formatting</th>
</tr>
</thead>
<tbody>
<tr>
<td>Date Formatting</td>
<td>3/31/92</td>
<td>1992年3月31日</td>
</tr>
<tr>
<td>Time Formatting</td>
<td>11:45 P.M.</td>
<td>午後3時51分</td>
</tr>
<tr>
<td>Number Formatting</td>
<td>1,234,567.89</td>
<td>1,234,567.89</td>
</tr>
<tr>
<td>Currency Formatting</td>
<td>$1995.95</td>
<td>¥199500</td>
</tr>
<tr>
<td>Phone Numbers</td>
<td>(415) 358-2000</td>
<td>(045) 472-6000</td>
</tr>
<tr>
<td>Paper Sizes</td>
<td>Letter, 8.5 in. x 11 in.</td>
<td>A4, 210 cm x 297 cm</td>
</tr>
</tbody>
</table>

Table 22-3 shows the default format for a Western-style (Gregorian) date. See Table 22-5 for the default formatting of an Imperial calendar date.

### Line breaks

Japanese, like most other languages, does not permit certain characters to appear at the beginning or end of a line. For example, in both English and Japanese, you cannot begin a line with a close parenthesis or end a line with an open parenthesis.

Japanese characters do not use hyphens when they break across lines. Either a break is permitted and the subsequent characters continue onto the next line, or no break is permitted.

When romaji appears in text, Japanese uses the same rules as English for line breaks.

Call `IntlBreakLine()` to ensure your text breaks correctly. The function uses an `INTL_LINE_BREAK` structure to contain information about how to break a line.

Here is the structure, defined in `ISR.H`:

```c
typedef struct INTL_BREAK_LINE {
    U32 breakAt;       // position of line break
    U32 deleteThis;    // chars to delete from end of this line
    CHAR insertThis[INTL_LINE_BREAK_MAX_INSERT]; // chars to insert at end of this line
    U32 deleteNext;    // chars to delete from start of next line
    CHAR insertNext[INTL_LINE_BREAK_MAX_INSERT]; // chars to insert at start of next line
} INTL_BREAK_LINE, *P_INTL_BREAK_LINE;
```

Because Japanese does not need hyphens to indicate a line break, you do not need to use the fields when dealing with Japanese characters. However, because Japanese follows the same rules as English when text contains romaji, your code should be prepared to handle these fields. Here is the prototype for `IntlBreakLine()` itself:

```c
S32 EXPORTED IntlBreakLine(
    PCHAR pString,    // Line to break
    U32 pos,          // 1st char that won't fit
    P_INTL_BREAK_LINE pBreak, // Out: how to break it
    LOCALE_ID locale, // Locale to use
    U32 style         // breaking style
);```

The line break function does not currently support hyphenation, so the various insert and delete fields in `INTL_BREAK_LINE` are empty. Hyphenation support is planned for future releases of PenPoint.

See "Delimiting words" on page 289 for details.
Dates

Japanese uses two different date formats. One is based on the Western-style Gregorian calendar, the other on the Japanese imperial calendar. In the Japanese imperial calendar, the year 1992 is called Heisei 4, the fourth year of the reign of the current emperor. Otherwise, the two calendar systems are identical.

The international functions use the structure INTL_TIME, defined in ISR.H, to represent the current time. The INTL_TIME structure contains a field to represent the era. Use macros defined in GOLOCALE.H to fill in this field if you use the era field to represent, for example, a Japanese imperial date.

Table 22-4 shows the four Japanese eras that PenPoint 2.0 Japanese supports, along with the macro that represents the era.

<table>
<thead>
<tr>
<th>Era name</th>
<th>Macro in GOLOCALE.H</th>
<th>Years</th>
</tr>
</thead>
<tbody>
<tr>
<td>Meiji</td>
<td>itcEraMeiji</td>
<td>1868–1912</td>
</tr>
<tr>
<td>Taisho</td>
<td>itcEraTaisho</td>
<td>1912–1926</td>
</tr>
<tr>
<td>Showa</td>
<td>itcEraShowa</td>
<td>1926–1989</td>
</tr>
<tr>
<td>Heisei</td>
<td>itcEraHeisei</td>
<td>1989–present</td>
</tr>
</tbody>
</table>

Call IntlFormatDate() to get a formatted date string from an INTL_TIME structure. The functions accept a number of style flags that can present dates in various formats, examples of which are shown in Table 22-5.

Date formats

<table>
<thead>
<tr>
<th>Date</th>
<th>Locale and style</th>
</tr>
</thead>
<tbody>
<tr>
<td>1992年3月31日</td>
<td>locJpn, IntlFmtDateStyleFull</td>
</tr>
<tr>
<td>平成4年3月31日</td>
<td>locJpn, IntlFmtDateStyleFull; IntlSecToTimeStructStyleJapanese</td>
</tr>
<tr>
<td>1990.1.15</td>
<td>locJpn, IntlFmtDateStyleAbbrv</td>
</tr>
<tr>
<td>90/1/15</td>
<td>locJpn, IntlFmtDateStyleNumeric</td>
</tr>
<tr>
<td>January 15, 1990</td>
<td>locUSA, IntlFmtDateStyleFull</td>
</tr>
<tr>
<td>Jan. 15, 1990</td>
<td>locUSA, IntlFmtDateStyleShort</td>
</tr>
<tr>
<td>1/15/90</td>
<td>locUSA, IntlFmtDateStyleNumeric</td>
</tr>
<tr>
<td>15-Jan-90</td>
<td>locUSA, IntlFmtDateStyleAbbrv</td>
</tr>
</tbody>
</table>

You use the IntlSecToTimeStructStyleJapanese style with the IntlSecToTimeStruct() function. All the other styles shown work with IntlFormatDate().

If you cannot create the date string you want, IntlFormatDate() also accepts an explicit format string. The string represents a date string constructed from its constituent parts. PenPoint 2.0 Japanese allows you to construct a date string using any of the following parts: day, month, year, day of the week, day of the year, and an era. See the header file ISRSTYLE.H for more information.
You can also format a date according to user-specified system preferences. The function `PrefsIntlDateToString()` returns a pointer to the string containing a formatted date when you pass it a `P_INTL_TIME` structure. The function is defined in `PREFS.H`.

See Chapter 107 in the *PenPoint Architectural Reference* for more general information on how to observe system preferences.

**Times**

Japanese uses almost the same time formats as American English. The only difference is that kanji characters are used to distinguish hours, minutes, seconds, and whether the time is A.M. or P.M. Table 22-6 shows some of the time formats you can create by specifying the appropriate styles when calling `IntlFormatTime()`. All of the examples below assume the locale is `locJpn`.

### Time Formats

<table>
<thead>
<tr>
<th>Time</th>
<th>Locale and styles</th>
</tr>
</thead>
<tbody>
<tr>
<td>15時51分</td>
<td><code>IntlFmtTimeStyleLocal</code></td>
</tr>
<tr>
<td>15時51分34秒</td>
<td><code>IntlFmtTimeStyleLocal, IntlFmtTimeDispSeconds</code></td>
</tr>
<tr>
<td>午後3時51分</td>
<td><code>IntlFmtTimeStyleLocal</code></td>
</tr>
<tr>
<td>午後3時51分34秒</td>
<td><code>IntlFmtTimeStyleLocal, IntlFmtTimeDispSeconds</code></td>
</tr>
<tr>
<td>3:51午後</td>
<td><code>IntlFmtTimeStyleStandard</code></td>
</tr>
<tr>
<td>3:51:34午後</td>
<td><code>IntlFmtTimeStyleStandard, IntlFmtTimeDispSeconds</code></td>
</tr>
<tr>
<td>13:51:34</td>
<td><code>IntlFmtTimeStyleStandard, IntlFmtTimeDispSeconds, IntlFmtTimeForce24Hour</code></td>
</tr>
<tr>
<td>13:51</td>
<td><code>IntlFmtTimeStyleStandard, IntlFmtTimeForce24Hour</code></td>
</tr>
</tbody>
</table>

**Numbers**

Japanese uses Arabic numerals to represent numbers for most purposes. In more formal settings, however, Japanese text uses kanji to represent numbers. PenPoint 2.0 Japanese currently supports only Arabic numerals, although ISRSTYLE.H defines a style `IntlFmtNumStyleKanji` for future use.

Numbers like 1,234,567 are split every thousand with commas as they are in English. Specify the default style `IntlStyleDefault` when you call one of the number formatting functions to format numbers this way.

Japanese occasionally uses an older style of formatting that puts a comma after every ten thousand, as in 12,3456. You must provide your own formatting function if you want to support the older style.

Remember that Japanese currency amounts can get quite large. Billions of yen are not uncommon in typical texts. Remember to set aside screen space to display all the necessary digits.
Call IntlFormatS32() or IntlNFormatS32() to format a signed integer. The equivalent functions IntlNFormatNumber() and IntlFormatNumber() work on floating point numbers.

You can specify many styles that control how numbers are formatted. The following listing comes from ISRSTYLE.H.

```c
/*
 * The style flags for number formatting give you extensive control of how the number is formatted. They work for both the FormatS32 and the FormatNumber (double) functions.

   intFmtNumLeftJustify: Add padding spaces on the left so that the decimal points align. This is based on the number of characters not their widths, so it only works with fixed width fonts.

   intFmtNumRightJustify: Add padding spaces on the right so that the decimal points align. This is based on the number of characters not their widths, so it only works with fixed width fonts.

   intFmtNumDropTrailZeros: Drop trailing zeros after the decimal point. E.g. 23.020 would become 23.02 with this set.

   intFmtNumScale: Move the decimal place to the left by the number of digits specified by the 'scale' parameter. E.g. a scale of two would cause 1234. to come out as 12.34 when this flag is set.

   intFmtNumSpaceFill: Force the fill character to be a space. So if the results of a format would have been "***23.4" it would instead be "23.4".

   intFmtNumZeroFill: Force the fill character to be a zero. So if the results of a format would have been "***23.4" it would instead be"00023.4".

   intFmtNumForceDecimal: Force a decimal point to be displayed even if it would not normally be shown. E.g. "123" would become "123." with this set. This is usually used with a scale of 0 or if intFmtNumDropTrailZeros is set.

   intFmtNumDisplayPositive: Force the display of the sign on positive numbers. E.g. "123" would become "+123" with this set.
*/
#define intFmtNumLeftJustify flag16 // Pad to align on left side
#define intFmtNumRightJustify flag17 // Pad to align on right side
#define intFmtNumDropTrailZeros flag18 // Drop trailing zeros in fraction
#define intFmtNumScale flag19 // Move decimal by scale
#define intFmtNumSpaceFill flag20 // Use space character for fill
#define intFmtNumZeroFill flag21 // Use 0 digit for fill
#define intFmtNumForceDecimal flag22 // Use decimal even if not needed
#define intFmtNumDisplayPositive flag23 // Sign on positive num. (e.g. +5)
*/
```

Each style specifies a general way of formatting a number. The details depend on the locale and the style flags you give. Also some of the styles are specific to some regions of the world, and do not make sense everywhere.

intFmtNumStylePlain: The simplest format for the locale. No thousands separators or other fancy stuff. In USA & Japan you get results like "1000.0" and "-1000.0" with this.

intFmtNumStyleSimple: Default! This is the standard format used in the locale. It normally includes the thousands separators. In USA & Japan you get results like "1,000.0" and "-1,000.0" with this.
intValueAccounting: This is the typical style of numbers used by accountants and such for the locale. In USA & Japan you get results like "1,000.0" and "(1,000.0)" with this. This format always uses some non-blank form of fill by default. For example "**3.45" is used in USA and Japan.

intValueFillSign: A common style in some places is to put the space fill between the sign and the number. This style is only defined for locales where this makes sense. In USA & Japan you get results like "- 1,000.0" with this.

intValueKanji: <Not implemented> This style indicates you want Kanji digits instead of the normal 0-9.

*/

// International styles
#define intValuePlainOx0001 // e.g. 1000.0 & -1000.0
#define intValueSimpleOx0002 // e.g. 1,000.0 & -1,000.0
#define intValueAccountingOx0003 // e.g. 1,000.0 & (1,000.0)

// Common European/North American styles
#define intValueFillSignOx0004 // e.g. "- 1,000.0"

// Japanese Number Format styles, NOT supported at this time
#define intValueKanjiOx0005 // Use Kanji digits
Chapter 23 / Development Environment

The Japanese localization of the PenPoint™ 2.0 Japanese operating system development environment contains many tools, utilities, and sample files that help you edit, compile, link, and debug Japanese applications. This chapter highlights the available tools, but does not discuss them in detail. More detailed information can be found in PenPoint Development Tools and Part 4: PenPoint Development Tools Supplement, in this book.

This chapter assumes that you are familiar with the process of creating PenPoint applications. For more information on these topics, consult the PenPoint Application Writing Guide, Expanded Edition and the two manuals mentioned above. Chapter 28 of Part 4: PenPoint Development Tools Supplement contains a visual overview of the entire process of creating PenPoint 2.0 Japanese applications and services.

Development tools

This section describes the tools you should use to edit, compile, and make applications.

Text editors

Your source code consists mostly of ASCII files since it is mostly C code. Sometimes, though, your code contains literal Japanese strings. For example, the Japanese version of your application resource file, JPN.RC, must contain Japanese strings encoded as a combination of ASCII and Shift-JIS. Your application uses the Japanese strings in JPN.RC in its user interface.

The easiest way to work with Shift-JIS files is with a Shift-JIS editor. Most editors popular in the U.S. have Japanese versions that allow you to edit Japanese text.

You can use MiniText as a Shift-JIS and Unicode editor. First, make sure the PenPoint system locale is JPN by specifying it when you run the GO batch file:

```
go jpn
```

When MiniText imports a DOS file, it assumes high ASCII characters are part of a Japanese character; that is, it assumes the file contains Shift-JIS data. See “Working with Shift-JIS in text files” on page 283 for details.

Keep the number of files that contain Shift-JIS characters at a minimum. This will make your project easier to maintain because all your Japanese strings are in one place. In the best case, only your application resource file JPN.RC will contain Shift-JIS characters.
Compilers

Make sure your compiler can compile code containing 16-bit characters. You must set the compiler flag that enables this feature when compiling code that contains 16-bit Unicode or multibyte Shift-JIS strings.

For example, if you are using the WATCOM C compiler, you must set the compiler flag /ZK0U. The standard makefile rules provided with the sample applications as SDEFINES.MIF automatically set this flag.

The PenPoint 2.0 Japanese resource compiler RC.EXE also uses this flag because your resource files often contain Shift-JIS characters.

Debuggers

PenPoint 2.0 Japanese allows you to display Japanese strings in the debugger stream. You can specify which character set you want to display using the DebugCharSet variable in ENVIRON.INI discussed in the next section.

You can view the debugger stream on a second monitor only if your debugger stream contains ASCII characters.

To view kanji in the debugger stream, use the System Log application or save the debugger stream to a file. See Chapter 10 of PenPoint Development Tools and Chapter 30 of PenPoint Development Tools Supplement for information on saving the debugger stream to a file.

The value of DebugCharSet also controls the interpretation of the mini-debugger memory dump commands (d, da, db, dd, and dw). See Chapter 30 of PenPoint Development Tools Supplement for details on debugging.

DebugCharSet

The DebugCharSet variable in ENVIRON.INI controls the character set of your debugging output. Table 23-1 shows the currently permissible values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASCII</td>
<td>Standard 7-bit ASCII</td>
</tr>
<tr>
<td>XJIS</td>
<td>1990 Shift-JIS character set</td>
</tr>
<tr>
<td>437</td>
<td>IBM Code Page 437 used in U.S. IBM PCs</td>
</tr>
<tr>
<td>850</td>
<td>IBM Code Page 850 used in European IBM PCs</td>
</tr>
</tbody>
</table>

If you are sending debugging information to your PenPoint monitor or a second debugging monitor, make sure it can display characters in the specified DebugCharSet. GO does not support using Shift-JIS monitors as second debugging monitors. See Chapter 30, Debugging, of Part 4: PenPoint Development Tools Supplement for information about how to see Shift-JIS in your files.
Literal strings in `DebugfO` and `DPrintfO` appear in the specified character set. Unsupported Unicode characters display as hex quads in PenPoint 2.0 Japanese. On your monitor, they display as `\xnnnn`, where `nnnn` is a four-digit hex number.

The default value of `DebugCharSet` depends on the value of `LOCALE`, another `ENVIRON.INI` variable. If `LOCALE=JPN`, the default is Shift-JIS. The default is ASCII if `LOCALE=USA`.

If `DebugCharSet` is set to an invalid value, the default character set is assumed.

### Makefiles

The standard makefile rules provided with the sample applications help you make different localized versions of your application. If you write your makefile by tailoring a makefile from a sample application, you can add a `LOCALE` argument to the command line to make a particular localized version of your application. For instance, type:

```
wmake LOCALE=jpn
wmake LOCALE=usa
```

to create the Japanese and American versions of your application, respectively. If you do not supply a `LOCALE` argument, JPN is the default locale.

You must create a file called `JPN.RC` to contain your application's Japanese strings. The file should at least contain strings for the `tagAppMgrAppFilename` and `tagAppMgrAppClassName`. The standard makefile rules stamp the application directory with the strings associated with these tags.

In your makefile, you can use three new variables to identify which resource files to compile and copy into the application directory with the executable image.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES_FILES</td>
<td>Resource files to be included with all versions of your application.</td>
</tr>
<tr>
<td>USA_RES_FILES</td>
<td>Resource files to be included with only the American version.</td>
</tr>
<tr>
<td>JPN_RES_FILES</td>
<td>Resource files to be included only with the Japanese version of your application.</td>
</tr>
</tbody>
</table>

See Chapter 29 of *PenPoint Development Tools* for details on creating PenPoint applications and services.

### DOS utilities

PenPoint 2.0 Japanese provides a collection of DOS utilities that help you work with resource files, PenPoint file names, and international character sets. See Chapter 14 of *PenPoint Development Tools* and Chapter 31 of Part 4: *PenPoint Development Tools Supplement* for detailed information on how to use the utilities.
The following table briefly summarizes the purpose of each utility.

**DOS utilities**

<table>
<thead>
<tr>
<th>Name</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>PSTAMP.EXE</td>
<td>Adds special PenPoint information to a DOS file or directory. Replaces STAMP from PenPoint 1.0.</td>
</tr>
<tr>
<td>PDEL.EXE</td>
<td>Deletes specific directory entries from PENPOINT.DIR files.</td>
</tr>
<tr>
<td>PCOPY.EXE</td>
<td>Recursively copies files and directories to other PenPoint directories.</td>
</tr>
<tr>
<td>PDIR.EXE</td>
<td>Lists the PenPoint names and file systems attributes for all the files and directories in a DOS directory. Replaces GDIR from the utilities included with PenPoint 1.0.</td>
</tr>
<tr>
<td>PSYNC.EXE</td>
<td>Scans the current directory and removes any entries from PENPOINT.DIR for which there are no corresponding files.</td>
</tr>
<tr>
<td>RC.EXE</td>
<td>Compiles resource files.</td>
</tr>
<tr>
<td>RESAPPND.EXE</td>
<td>Appends resources from one resource file into another.</td>
</tr>
<tr>
<td>RESDUMP.EXE</td>
<td>Shows the contents of a compiled resource file.</td>
</tr>
<tr>
<td>RESDEL.EXE</td>
<td>Deletes specified resources from a compiler file.</td>
</tr>
<tr>
<td>UCONVERT.EXE</td>
<td>Converts files between character sets, for example from Shift-JIS to Unicode.</td>
</tr>
<tr>
<td>CONTEXT.BAT</td>
<td>A DOS batch file that sets the required DOS environment variables PenPoint requires. Takes an argument to indicate which version of PenPoint (1.0 or 2.0).</td>
</tr>
<tr>
<td>GO.BAT</td>
<td>Boots PenPoint on your development machine, allowing choice of the system and user locales.</td>
</tr>
<tr>
<td>LOCALE.BAT</td>
<td>Switches the system and user locales that PenPoint uses.</td>
</tr>
</tbody>
</table>

In PenPoint 2.0 Japanese, the PENPOINT.DIR file is in Unicode format, although the utilities that deal with PenPoint information can still read ASCII files. For additional information on each utility, type -? or /? after most of these commands to see a help message. For example, type PDIR /? for help on the PDIR utility.

See PenPoint Development Tools and its supplement for more information.

You can set two DOS environment variables to notify the utilities which character set or locale you typically work with.

- **CHARSET** can be one of ASCII, 437, LATIN1, or 850 to denote a character set.
- **LOCALE** can be either USA or JPN.

For example, if you specify a LOCALE of JPN, then the DOS utility PDIR will interpret your PenPoint names as a Shift-JIS string.

Do not confuse the DOS environment variable with the LOCALE in ENVIRON.INI. Only the DOS utilities are sensitive to the DOS environment variable. PenPoint itself is sensitive to the LOCALE in ENVIRON.INI.

If you want, set these environment variables in your AUTOEXEC.BAT with the DOS command SET. Other character sets and locales are supported, but the ones listed here are the relevant values for Japan.
Running PenPoint

You must remove any terminate-and-stay-resident (TSR) programs before booting PenPoint 2.0 Japanese. Some TSRs use the same interrupts as PenPoint. This conflict causes boot error 106 (unknown boot error).

The easiest way to remove TSRs is to remove the programs in GO.BAT and reinstall them, if necessary, after PenPoint exits. Comments in GO.BAT indicate where you should remove and reload your TSRs.

The GO.BAT batch file now takes two optional parameters to specify the locales to boot with:

`go system_locale user_locale`

When you specify a system locale, PenPoint’s behavior and user interface are changed to be appropriate to the specified locale (U.S. or Japanese).

When you specify both a system and user locale, the batch file directs PenPoint to change its behavior to match the system locale, but to change its user interface strings to match the target locale.

When you type GO with no parameters, PenPoint boots in the same state as it was last booted. If you type GO with no parameters and you are in Debug Tablet mode, PenPoint warm boots. See Chapter 30 of Part 4: PenPoint Development Tools Supplement for more information about debugging modes and warm booting. For example:

* To boot with Japanese behavior and strings, type
  
  `go jpn`

* To boot with Japanese behavior, but English strings, type
  
  `go jpn usa`

Because the batch file only controls the resource files PenPoint loads, the stamped application and service names appear in the system locale language.

GO.BAT relies on LOCALE.BAT to do the locale switch. Make sure \\2_0\PENPOINT\SDK\UTIL\DOS is in your DOS PATH. Both GO.BAT and LOCALE.BAT require utilities in that directory to switch locales.

When you specify a locale with GO.BAT (or LOCALE.BAT) the batch file recursively deletes your PENPOINT\SS directory. This deletes any documents that you had saved in your PenPoint 2.0 Japanese file system. Make sure to save the files to your hard drive if you need them.

Currently, only two locales are supported: JPN and USA. See page 45 of PenPoint Development Tools for more information about the GO batch file. The manual describes the PenPoint boot process, including the order in which files are read and the actions that are taken as a result.

See Chapter 31 of Part 4: PenPoint Development Tools Supplement for details on how the batch file coordinates the locale switching.
PenPoint environment

This section describes the PenPoint 2.0 Japanese environment variables relevant for developing Japanese applications.

ENVIRON.INI

There are two important variables new to PenPoint 2.0 Japanese that you should set when running Japanese applications.

- **Locale** can be set to USA or JPN. Its value controls PenPoint’s behavior and appearance. Different locales use different fonts, dynamic link libraries, applications, and services. See Chapter 32 of *PenPoint Development Tools Supplement* for details.

- **DebugCharSet** can be set to ASCII, XIS, 437, or 850, controls the interpretation of characters you send to the debugger stream. See Chapter 4 of *PenPoint Development Tools Supplement* for details.

Remember to set your **PenPointPath** to \\2_0 if you are working with PenPoint 2.0 Japanese development.

MIL.INI

PenPoint supports many different U.S. and Japanese keyboard models. Set your **Keyboard** variable in MIL.INI to identify your keyboard.

The value of **Keyboard** determines how the keyboard behaves throughout PenPoint. For example, clsField and clsKKCT observe this variable to determine how it should handle character input. To change keyboards, you must warm or cold boot. Swap booting does not change keyboard behavior.

See “Using keyboards” on page 261 for tips on using your keyboard to type Japanese and English characters.

Initialization files

PenPoint 2.0 Japanese uses a collection of control files to set up its environment. Since these files can sometimes contain Japanese filenames, some of these control files can contain Shift-JIS or Unicode characters. The following table shows which combinations are permitted.

<table>
<thead>
<tr>
<th>Filename</th>
<th>Permissible character sets</th>
</tr>
</thead>
<tbody>
<tr>
<td>MIL.INI</td>
<td>ASCII only</td>
</tr>
<tr>
<td>ENVIRON.INI</td>
<td>ASCII only</td>
</tr>
<tr>
<td>BOOT.DLC</td>
<td>ASCII, Unicode</td>
</tr>
<tr>
<td>CONSOLE.DLC</td>
<td>ASCII, Unicode</td>
</tr>
<tr>
<td>APP.INI</td>
<td>ASCII, Shift-JIS</td>
</tr>
<tr>
<td>SERVICE.INI</td>
<td>ASCII, Shift-JIS</td>
</tr>
<tr>
<td>SYSAPP.INI</td>
<td>ASCII, Shift-JIS</td>
</tr>
<tr>
<td>SYSCOPY.INI</td>
<td>ASCII, Shift-JIS</td>
</tr>
</tbody>
</table>

**TABLE 23-4**
**PenPoint tools**

The SDK includes some PenPoint 2.0 Japanese applications and accessories that can help you write Japanese applications.

**MiniText**

You can use MiniText as a Shift-JIS and Unicode editor. It supports Japanese handwriting recognition, KKC, and RKC. Although insertion pads only let you enter hankaku, you can convert between hankaku and zenkaku by selecting the To Hankaku or To Zenkaku commands under the Convert menu.

MiniNote assumes any imported text file contain Shift-JIS when the Locale variable in ENVIRON.INI is set to JPN. Your Shift-JIS file can also contain RTF keywords. Before you import an RTF file, run the file through the DOS utility RTFTRIM before importing it. RTFTRIM removes RTF keywords that PenPoint's text component does not use from an RTF file. See Chapter 31 of Part 4: PenPoint Development Tools Supplement for more information on RTFTRIM.

MiniText assumes that any file with a .UNC extension imported into PenPoint is a Unicode file. Be sure your Unicode files have the .UNC extension before you import them into your PenPoint notebook.

See “Working with Shift-JIS in text files” on page 283 for details on how to create, import, and export Shift-JIS files between PenPoint 2.0 Japanese and your development machine.

**Unicode Browser**

The Unicode Browser is a PenPoint 2.0 Japanese accessory that allows users to send characters to the text stream by tapping on them in a table of possible characters. See Using PenPoint for instructions on using the Unicode Browser.

**Japanese virtual keyboard**

The virtual keyboard is another PenPoint 2.0 accessory that allows you to send characters to the text stream. It offers various emulations, including American and Japanese IBMJ-A01 keyboard modes.

Bring up the keyboard by tapping on its icon in the Accessories notebook. Change modes by making the check ✓ gesture over the title bar to switch modes.

With the Japanese keyboard, you can type romaji, hiragana, or katakana. There are keys that toggle the keyboard between the character sets.

**Sample code**

The sample code included with the SDK is a good starting point for your own applications. Here are a few details to note about the sample code included with the 2.0J SDK in \2_0\PENPOINT\SDK\SAMPLE.
Japanese versions of sample code

Most of the sample applications have two resource files, USA.RC and JPN.RC. As their names suggest, these files contain U.S. English and Japanese strings. Use these files to help write your own resource files.

All of the sample applications except the Keisen Table application make use of the Bridging Package. This package allows you to maintain a single code base that compiles under both PenPoint 1.0 and 2.0. See the PenPoint Bridging Handbook included with the 2.0 SDK for details on how to do this.
"Japanese virtual keyboard"

FIGURE 23-2

Use the virtual keyboard to enter characters into the text stream. You can simulate both American and Japanese keyboards.

Keisen Table application

The Keisen Table sample application uses hard-coded Japanese strings because the application is designed exclusively for Japan. It shows how to use toolkit tables to create a complex Keisen Table, a popular way of gathering data in Japan.

All the hard-coded strings are in Shift-JIS format.
Chapter 24 / Procedures

This chapter contains step-by-step instructions on how to take advantage of the PenPoint™ operating system’s support for Japanese applications. It describes in detail how to perform several of the common procedures that developers use to write Japanese applications.

Working with Shift-JIS in text files

This procedure shows you one way of creating and editing Shift-JIS strings in a text file.

Prerequisite information

The easiest way to work with Shift-JIS is to edit it with a Shift-JIS editor. This procedure shows you how to use MiniText as a Shift-JIS editor.

Shift-JIS strings are most commonly used in control files like APP.INI and the Japanese version of your resource file, JPN.RC.

- “Character encoding” on page 247.
- “Shift-JIS encoding details” on page 252.
- “Text editors” on page 273.
- “Initialization files” on page 278.

Procedure

1. Set the B800 debugging flag so that you can access your hard drive with the Connections notebook. You can do this one of two ways:
   - Add /B800 to the DebugSet line in ENVIRON.INI.
   - While in PenPoint, press Break to drop into the mini-debugger. Type fs B +800 to set the flag, and then g to resume PenPoint.

2. Create a new MiniText document or import an existing document. You can import by opening the Connections notebook and choosing Directory under the View menu. Then browse through your disk and copy a Shift-JIS file to your PenPoint notebook. Import the file as a MiniText document.

3. Turn to your new or imported MiniText document to edit it.

4. When you are done editing the file, turn back to your table of contents.

5. Open the Connections notebook and choose Directory under the View menu.

6. Move or copy the file to your hard drive.

7. Select Text File as the export type.
Related information

- “Working with Unicode in source code” on page 284.
- “Converting Unicode and Shift-JIS files” on page 285.
- “Converting Unicode and Shift-JIS strings” on page 286.

Working with Unicode in source code

This procedure shows you how to create Unicode strings in your source code.

Prerequisite information

- Chapter 15, Part 2: PenPoint Internationalization Handbook.
- “Character encoding” on page 247.
- “Unicode” on page 249.

Procedure

1. Declare your character or pointer to characters as a 16-bit type. Use CHAR16 for data that is always 16 bits and CHAR for data that will be 8-bits long in PenPoint 1.0 and 16 bits long in 2.0 and later releases.

2. Wrap the U _LO macro around literal characters and strings. Use the L" " modifier if you do not need your code to compile under PenPoint 1.0.

3. Type ASCII characters between the quotation marks.

4. To specify special Unicode characters, use a \x followed by a Unicode code point, which has 4 hexadecimal digits.

Examples

The following code uses the U _LO macro to indicate that the declared character or strings are 8 bits long in PenPoint 1.0 and 16 bits long in PenPoint 2.0 Japanese.

The second example declares character data that is always 8 bits long.

```
Uprintf(U_1("I am 8 bits long in PenPoint 1.0; 16 bits in PenPoint 2.0"));
P_CHAR8 pTheString = L"I am always a 16-bit string."
static RC _TAGGED_STRING qHelpStrings[] = {
    tagTextView,  U_1("xF61F \tab Pigtail. Delete a character.\par "),
    Nil(TAG)
};
```

This last example specifies Unicode values directly because they cannot be typed with the keyboard.

Related information

- “Working with Shift-JIS in text files” on page 283.
- “Converting Unicode and Shift-JIS files” on page 285.
- “Converting Unicode and Shift-JIS strings” on page 286.
Converting Unicode and Shift-JIS files

This procedure converts files between Unicode and Shift-JIS formats.

Prerequisite information

- “Character encoding” on page 247.
- “Unicode” on page 249.
- “Shift-JIS encoding details” on page 252.
- “Converting to and from Shift-JIS” on page 254.

Procedure

1. If necessary, run CONTEXT.BAT to put your system in the 2_0 context. The batch file adds \2_0\SDK\UTIL\DOS to the beginning of your PATH.

2. Run UCONVERT.EXE on the file to be converted. The syntax for this DOS utility is:

   `UCONVERT s[-d] [-m] source-file dest-file [source CharSet] [dest CharSet]`

You can specify a character set as either a code page or a locale as follows:

- Specify ASCII with one of the following: ASCII, 437, or USA.
- Specify Shift-JIS with XJIS or JPN.
- Specify Unicode with UNI.

Examples

Table 24-1 shows sample runs of the UCONVERT utility.

Using UCONVERT

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>uconvert mytext.doc mytext.unc</td>
<td>Puts a Unicode copy of ASCII document MYTEXT.DOC in the file MYTEXT.UNC. ASCII-to-Unicode is the default conversion.</td>
</tr>
<tr>
<td>uconvert mytext.unc mytext.jis uni xjis</td>
<td>Puts a Shift-JIS version of the Unicode document MYTEXT.UNC in the file MYTEXT.JIS</td>
</tr>
<tr>
<td>uconvert -d myfiles.doc myfiles.jis xjis uni</td>
<td>Puts a Shift-JIS version of the file MYFILES.TXT containing filenames in the file MYFILES.JIS. The -d flag is necessary when the input Shift-JIS file contains filenames.</td>
</tr>
<tr>
<td>uconvert letter.jis letter.unc jpn uni</td>
<td>Puts a Unicode copy of the Shift-JIS file LETTER.JIS in the file LETTER.UNC.</td>
</tr>
<tr>
<td>uconvert -m longfile.437 longfile.unc</td>
<td>Puts a copy of the extended ASCII file LONGFILE.437 in the Unicode file LONGFILE.UNC, converting all CR/LF combinations to the Unicode line separator character (U+2028).</td>
</tr>
</tbody>
</table>

Related information

- “Working with Shift-JIS in text files” on page 283.
- “Working with Unicode in source code” on page 284.
- “Converting Unicode and Shift-JIS strings” on page 286.
Converting Unicode and Shift-JIS strings

This procedure allows your code to convert between Unicode and Shift-JIS strings.

Prerequisite information

- “Unicode” on page 249.
- “Shift-JIS encoding details” on page 252.
- “Converting to and from Shift-JIS” on page 254.

Procedure

1. Include ISR.H in your source file. Link INTL.LIB with your code by listing it in your makefile.

2. Call IntlNUnicodeToMB() to convert a Unicode string to a Shift-JIS string. Use one of these styles to indicate which JIS character set to convert to:
   - intlCharSetStyleXJIS maps to the most recent character set (currently JIS X0208-1990)
   - intlCharSetStyleXJIS1978 for JIS C6226-1978
   - intlCharSetStyleXJIS1983 for JIS X0208-1983
   - intlCharSetStyleXJIS1990 for JIS X0208-1990

3. Call IntlMBToUnicode() to convert a Shift-JIS string to a Unicode string. Use the same styles to indicate which character set you are converting from. The default style uses the most current (1990) Shift-JIS standard.

4. Specify the style IntlCharSetFileNameMapping if the string you want to convert contains a filename.

Example

This code fragment converts the multibyte string pStr8 to the Unicode string pStr.

```c
MsgHandlerArgType(MyHandler, P_MY_ARGS)
{
    STATUS s;
    U32 oLength, length;
    P_CHAR pStr;
    P_CHAR8 pStr8;
    length = pArgs->len;
    pStr8 = (P_CHAR8) pArgs->pData;
    oLength = length;
    if (sizeof(CHAR) > 1)
    {
        StsWarn(OSHeapBlockAlloc(osProcessHeapId,
                        length*sizeof(CHAR), &pStr));
        StsWarn(oLength=IntlNMBToUnicode(pNull, 0, pStr8, &length,
                        intlStyleDefault));
        StsWarn(length=IntlNMBToUnicode(pStr, oLength, pStr8, &length,
                        intlStyleDefault));
    }
}```
Related information

- “Working with Shift-JIS in text files” on page 283.
- “Working with Unicode in source code” on page 284.

Converting between character variants

This procedure converts between various character sets, such as from zenkaku (full-width) to hankaku (half-width), and from katakana to hiragana.

Prerequisite information

- “Kana” on page 246.
- “Half- and full-width variants” on page 249.
- “Converting between character variants” on page 265.

Procedure

1. Include ISR.H in your source file. Link INTL.LIB with your code by listing it in your makefile.
2. Allow the user to specify a string to be converted. Collect the string in a buffer with a terminating null.
3. Call the IntlStrConvert() function.
4. Update your memory and user interface.

Example

This code sample uses clsTextView to support string conversion requested by the user. The functions convert the selected text to all upper-case, all lower-case, or initial capitals.

```object
OBJECT myTextObject;
int desiredState;
U32 attrLimit, startLen, amtRemain, newLen, style;
TEXT_BUFFER textBuffer;
P_TV_SELECT pTarget;
...
switch (desiredState) {
  case 1:
    style = intlStrConvertStyleToUpper;
    break;
  case 2:
    style = intlStrConvertStyleToProper;
    break;
  case 3:
    style = intlStrConvertStyleToLower;
    break;
  }
...```
while (pTarget->length)
{
    // ensure buffer size is less than maxbufferlen
    if (pTarget->length > MAXBUFFERLEN)
    {
        amtRemain = pTarget->length - MAXBUFFERLEN;
        pTarget->length = MAXBUFFERLEN;
    }
    else
        amtRemain = 0;

    // Get selected chars into buffer
    textBuffer.first = pTarget->first;
    textBuffer.length = pTarget->length;
    textBuffer.bufUsed = 0;
    textBuffer.buf = pSrc;
    textBuffer.bufLen = pTarget->length;
    ObjCallWarn(msgTextGetBuffer, myTextObject, &textBuffer);
    startLen = pTarget->length;
    if (pTarget->length)
    {
        if (amtRemain)
            style |= intlStrConvertMoreText;
        else
            style &= -intlStrConvertMoreText;

        // Do conversion with result in pDest
        newLen = IntlStrConvert(pDest, MAXBUFFERLEN * 2, pSrc,
                                &(pTarget->length), &ctx, intlDefaultLocale, style);
    }
}

Notes

The function prototype for IntlStrConvert() is as follows:

S32 EXPORTED IntlStrConvert(
    P_CHARpDest,       // Out: converted string
    U32    destLen,    // Max space available in pDest
    P_CHARpSrc,        // Null-terminated string to be converted.
    LOCALE_IDlocale,  // Locale to use -- from glocale.h
    U32    style       // Conversion style -- from isrstyle.h
);

The relevant flags are:

// Flags used with string conversion styles.
#define intlStrConvertMoreText flag16     // More text than was passed.

// String Conversion styles
#define intlStrConvertStyleToUpper 0x0001   // All characters
#define intlStrConvertStyleToProper 0x0002  // 1st letter of words only
#define intlStrConvertStyleToLower 0x0003   // All characters
#define intlStrConvertStyleToHiragana 0x0004 // from katakana, not kanji
#define intlStrConvertStyleToKatakana 0x0005 // from hiragana, not kanji
#define intlStrConvertStyleToComposed 0x0006 // minimize floating forms
#define intlStrConvertStyleToClean 0x0007   // maximize floating forms
#define intlStrConvertStyleToCompatibility 0x0008 // Map to C-Zone
#define intlStrConvertStyleFromCompatibility 0x0009  // Map from C-Zone
#define intlStrConvertStyleToHankaku 0x000A    // Map to half-width chars
#define intlStrConvertStyleToZenkaku 0x000B    // Map to full-width chars
Related information

See ISR.H for more information about how to convert large chunks of text extending over multiple buffers (such as converting an entire file).

Delimiting words

This procedure locates a bunsetsu, the Japanese equivalent of an English word or phrase, in a text stream.

Prerequisite information

“Delimiting words” on page 263.

Procedure

1. Include ISR.H in your source file. Link INTL.LIB with your code by listing it in your makefile.
2. Locate where the user has requested a phrase selection.
3. Call LocDelimitWordO or LocNDeliminateWord().

Example

The following code demonstrates the query capabilities of the delimit word and sentence functions. The code queries a function by calling it with pNull where it expects a buffer. The function responds to the query by returning the size of the buffer that the code needs to send to the function. The returned size is used in the GetSpanBuf() call that fills the buffer with nCharToCopy characters.

```c
#define atomSentence 4
...
typedef struct SPAN_BUF {
    P_CHAR buf;
    TEXT_INDEX len;
    U32 pos;
    BOOLEAN freeBuf;
} SPAN_BUF, *P_SPAN_BUF;
...
SPAN_BUF spanBuf;
TEXT_INDEX oldPos, first, baLen;
TEXT_SPAN span, savNChToCopy, nCharToCopy;
STATUS s;
S32 style;
if (span.type == atomSentence)
    savNChToCopy = nCharToCopy = LocDelimitSentence(pNull, pNull, style);
else
    savNChToCopy = nCharToCopy = LocDelimitWord(pNull, pNull, style);
```
while (TRUE) {
    spanBuf.pos = first;
    s = GetSpanBuf(pB, &spanBuf, nCharToCopy);
    if (s < stsOK) goto CleanUp;
    oldPos = spanBuf.pos;
    style = (first - spanBuf.pos) > 0 ?
        FlagSet(intlDelimitMoreLeft, style) :
        FlagClr(intlDelimitMoreLeft, style);
    style = (first + nCharToCopy) < baLen ?
        FlagSet(intlDelimitMoreRight, style) :
        FlagClr(intlDelimitMoreRight, style);
    if (span.type == atomSentence)
        s = LocNDelimSentence(spanBuf.buf, spanBuf.len, &spanBuf.pos, style);
    else
        s = LocNDelimWord(spanBuf.buf, spanBuf.len, &spanBuf.pos, style);
}

The code uses two class manager macros `FlagSet()` and `FlagClr()` to set and clear style flags. The macros are defined as follows in CLSMGR.H:

```c
#define FlagSet(f,v) ((v) | (f))
#define FlagClr(f,v) ((v) & (~f))
```

**Notes**

The function prototype looks like this:

```c
S32 EXPORTED IntlNDelimWord(
    P_CHAR pString,    // Beginning of text region
    U32 length,        // Length of text region.
    P_U32 pStart,      // In/Out: seed position/start of word
    LOCALE ID locale,  // Locale to use -- from g_locale.h
    U32 style          // Delimit style -- from isrstyle.h
);
```

The function expects a counted string, a locale, and a style. Remember that calling `LocDelimitWord()` sends `intlDefaultLocale` and `intlDefaultStyle` as parameters.

Pass in a position you want to search from as `pStart`. When the function returns, `pStart` contains the start of the bunsetsu, and the function itself returns the length of the bunsetsu.

**Related information**

- "Delimiting sentences" on page 290.
- The header files ISR.H and ISRSTYLE.H contain more information about different ways to call the delimit word and sentence functions.

**Delimiting sentences**

This procedure locates a sentence in a text stream.

**Prerequisite information**

"Delimiting sentences" on page 264.
Procedure

1. Include ISR.H in your source file. Link INTL.LIB with your code by listing it in your makefile.
2. Locate the position in your text stream where the user requested a sentence selection.
3. Call LocNDelimSentence() or LocDelimitSentence().

Example

See example for “Delimiting words” on page 289.

Notes

Here is the function prototype:

```
S32 EXPORTED IntlDelimitSentence(
    P_CHAR pString,   // Beginning of text region
    P_U32 pStart,     // In/Out: seed position/start of sentence
    LOCALE_ID locale, // Locale to use -- from golocale.h
    U32 style         // Delimit style -- from isrstyle.h
);
```

Specify intlDlmntSntcStyleSentence as a style to select a sentence without any punctuation.

Related information

“Delimiting words” on page 289.

Comparing strings

This procedure compares two null-terminated strings and returns their sort order.

Prerequisite information

“Comparing and sorting” on page 264.

Procedure

1. Find two null-terminated strings you want to compare.
2. Send the characters to IntlCompare().

Example

This code compares two literal strings. It is intended as an example of how to call IntlCompare() rather than as good coding practice. Do not use literal strings in your code unless absolutely necessary.

```
P_CHAR firstString = L"First string";
P_CHAR secondString = L"Second string";
LocCompare(firstString, secondString, intlSortStyleDictionary);
```
Notes

The function prototype follows:

```c
S32 EXPORTED IntlCompare(
    P CHAR pLeft,         // left string of comparison
    P CHAR pRight,        // right string of comparison
    LOCALE_ID locale,     // Locale to use -- from golocale.h
    U32 style             // Collation style -- from isrstyle.h
);                     
```

The function returns:

- `-1` when `pLeft` precedes `pRight` (left < right)
- `0` when `pLeft` is the same as `pRight` (left == right)
- `1` when `pLeft` follows `pRight` (left > right)
- `stsRequestNotSupported` if the locale or style is unsupported.

The following styles apply with sorting and comparing.

```c
#define intlSortIgnoreCase
#define intlSortStyleDictionary
#define intlSortStylePhoneBook
```

flag 16 0x0001 // (*) Ignore case
        // e.g. treat space as first character
flag 16 0x0002 // e.g. ignore spaces altogether

Remember that `intlSortStyleDictionary` uses the JIS order for Level 1 kanji and various rules for other characters, while `intlSortStylePhoneBook` sorts in Unicode order, which is a good approximation of the radical and number of stroke sort orders used in Japanese dictionaries.

Related information

"Sorting strings" on page 292.

Sorting strings

This procedure sorts an array of null-terminated strings.

Prerequisite information

"Comparing and sorting" on page 264.

Procedure

1. Include ISR.H in your source file. Link INTL.LIB with your code by listing it in your makefile.
2. Encode the strings you want sorted as an array of null-terminated strings.
3. Pass in the array as a pointer to a string (type PP_CHAR) as a parameter to IntlSort().

Example

No example available.
Notes

The function prototype follows:

```
STATUS EXPORTED IntlSort(
    PP_CHAR ppString,  // list of strings to sort
    U32 count,         // number of strings in list
    LOCALE_ID locale, // Locale to use -- from glocale.h
    U32 style         // Collation style -- from isrstyle.h
);
```

See the Notes under “Comparing strings” on page 291 for details on the valid styles.

Related information

“Comparing strings” on page 291.

Handling line breaks

This procedure breaks lines of text, ensuring that no character that is not allowed to begin or end a line does so.

Prerequisite information

“Delimiting words” on page 289.

Procedure

1. Include ISR.H in your source file. Link INTL.LIB with your code by listing it in your makefile.

2. When displaying text that wraps, send the text stream to IntlBreakLineO(). The result is returned in an INTL_BREAK_LINE structure.

3. Check the breakAt field of INTL_BREAK_LINE for the position of the line break.

4. If the position is at or before the start of a line, the function could not find an appropriate break point. You should provide a default method to handle this case. In most cases, you can just include all the characters that will fit on the line and break when necessary.

Example

The following code checks to see if the text in pMetrics fits on the current line. If the text does not fit, LocNBreakLineO() is called to find an appropriate place to break the line. If the function returns a break position at the beginning of the line, no appropriate place was found to break the line, and hence the line need not be remeasured. Otherwise, the line is remeasured and the buffer updated with the correct line break information.

```
P_TEXT_LINE pMetrics;
P_POSSIBLE_LINE maybeMetrics;
TEXT_INDEX savePos, pos, posInBuf;
CHAR charBufMem[MAX_BUF_SIZE];
CHAR *charBuf;
BOOLEAN wordWrap;
```
Notes

The IntlBreakLine() function requires a special structure as a parameter. When the function returns, the information on how to break the line is passed out in this structure. The following structure definition is in ISR.H:

```c
typedef struct INTL_BREAK_LINE {
    U32 breakAt; // position of line break
    U32 deleteThis; // chars to delete from end of this line
    CHAR insertThis[intlBreakLineMaxInsert]; // chars to insert at end of this line
    U32 deleteNext; // chars to delete from start of next line
    CHAR insertNext[intlBreakLineMaxInsert]; // chars to insert at start of next line
} INTL_BREAK_LINE, *P_INTL_BREAK_LINE;
```

The constant intlBreakLineMaxInsert is also defined in ISR.H. Its current value is 8.

Because Japanese simply breaks lines with no changes to the text stream, the fields deleteThis, insertThis, deleteNext and deleteNext are typically empty.

The current version of this function does not support hyphenation, although such support is planned. When hyphenation support is provided, and you use this function to check line breaks for romaji, the fields deleteThis and deleteNext are typically empty, while insertThis contains a hyphen.

The prototype for IntlBreakLine() is as follows:

```c
S32 EXPORTED IntlBreakLine(
    P_CHAR pString, // Line to break
    U32 pos, // 1st char that won't fit
    P_INTL_BREAK_LINE pBreak, // Out: how to break it
    Locale_ID locale, // Locale to use -- from golocale.h
    U32 style // Break style -- from isrstyle.h
);
```

Related information

- “Delimiting words” on page 289.
- “Delimiting sentences” on page 290.
Using Japanese fonts

This procedure describes various methods you can use to specify a particular Japanese font.

Prerequisite information

- "Fonts" on page 250

Procedure

There are a variety of ways your application can work with fonts.

- Use the default system fonts. Set the group field of SYSDC_FONT_ATTR structure to sysDcGroupDefault or sysDcGroupUserInput. The default fonts are Mincho for the system and Gothic for the user.

- Use clsPopUpChoice to display currently installed fonts in a scrolling window from which the user may select a font. See the example below for sample code.

- Set the drawing context with the desired font. The short font string for Mincho is MC55; for Gothic, the string is GT55. You can convert the string to a 16-bit font identifier with the SysDcFontID() function. Note that if you specify sysDcGroupTransitional, the group for Roman fonts, the system displays Japanese characters in the Mincho font. Similarly, the system displays Gothic characters when you specify the group as sysDcGroupSansSerif. See Chapter 26 of the Architectural Reference for details.

Examples

The first example is from the Hello World application. It sets the font to be the default user font by creating a drawing context in which the font group is sysDcGroupUserInput.

```
// Create a dc.
ObjCallRet(msgNewWithDefaults, clsSysDrwCtx, &dn, s);
data.dc = dn.object.uid;

// Open a font. Use the "user input" font (whatever the user has
// chosen for this in System Preferences.
fs.id = 0;
fs.attr.group = sysDcGroupUserInput;
fs.attr.weight = sysDcWeightNormal;
fs.attr.aspect = sysDcAspectNormal;
fs.attr.italic = 0;
fs.attr.monospaced = 0;
fs.attr.encoding = sysDcEncodeGoSystem;
ObjCallJmp(msgDcOpenFont, data.dc, &fs, s, Error);

// Scale the font. The entire DC will be scaled in the repaint
// to pleasingly fill the window.
fontScale.x = fontScale.y = FxMakeFixed(initFontScale, 0);
ObjectCall(msgDcScaleFont, data.dc, &fontScale);

// Bind the window to the dc.
ObjectCall(msgDcSetWindow, data.dc, (P_ARGS)self);
```
You can find this code in \2_0\PENPOINT\SDK\SAMPLE\HELLO\HELLOWIN.C.

The second example comes from the Clock Application. You can find the code in \2_0\PENPOINT\SDK\CLOCK\CLOCKAPP.C.

You can set up a TK_TABLE that allows the user select from the available fonts. To do so, include tkPopupChoiceFont as part of the flags field of a clsPopupChoice. This notifies the popup filed to get the list of available fonts from the system.

```c
static const TK_TABLE_ENTRY clockDisplayCardEntries[] = {
    ....
    {hlpClkAppDisplayFont, 0, 0, 0, tkLabelStringId, 0, hlpClkAppDisplayFont},
    {fontPrune, 1, 0, tagFont, tkNoClient | tkPopupChoiceFont, hlpClkAppDisplayFont},
    ....
    {pNull}
};
```

When the user taps Apply and this control is dirty, the Clock application must rewrite each of its labels in the new chosen font.

```c
StsRetNoWarn(ReadControl(pArgs->win, tagFont, &value, 0, 0, pNull, false), s);
if (s == stsDirtyControl) {
    plnst->fontld = (UI6)value;
    SysDcFontString((UI6)value, fontName);
    Dbg(Debugf(U_L("ClockApp: new font id is Ox%lx, 
    
    "), value,fontName);
    SetLabelFont(plnst->timeWin, plnst->fontld);
    SetLabelFont(plnst->amPmWin, plnst->fontld);
    SetLabelFont(plnst->dateWin, plnst->fontld);
    SetLabelFont(plnst->alarmWin, plnst->fontld);
    *pAppLayout = true;
}
```

SetLabelFont() is an internal function that updates the current font specs with the new font ID.

```c
STATUS SetLabelFont(OBJECT win, U16 fontld) {
    SYSDC_FONT_SPEC spec;
    STATUS s;
    if (win) {
        ObjCallRet(msgLabelGetFontSpec, win, &spec, s);
        spec.id = fontld;
        ObjCallRet(msgLabelSetFontSpec, win, &spec, s);
    }
    // SetLabelFont
}
```

**Supporting kana-kanji conversion**

The easiest way to support KKC or RKC in your application is to create an instance of clsIP or clsField, because these classes already support character conversion.

This procedure describes how to make your own class the client of clsCharTrans. The easiest way to do this is to make your class a subclass of clsGWin or one of its descendants.
Prerequisite information

- "Kana-kanji conversion" on page 257.
- PenPoint Architectural Reference, Part 4, Chapter 32.

Procedure

1. Subclass clsGWin or one of its descendants.
2. Create your window as an instance of this subclass.
3. When appropriate, self-send the following messages to your window instance. Do not handle the messages. Rather, allow them to pass up to clsGWin, which sends the messages to its associated character translator. In PenPoint 2.0 Japanese, this translator is clsKKCT.
   - Send msgCharTransKeyEvent whenever the user presses a key.
   - Send msgCharTransChar whenever the user changes the buffer (for example, when the user inserts or deletes a character).
   - Send msgCharTransGesture when the user makes a gesture. If the gesture is relevant to character translator, be prepared to handle msgCharTransGetClientBuffer (described below).
   - Send msgCharTransGoQuiescent to abort any current translations.
4. Your class should respond to the following messages sent by the character translator.
   - msgCharTransModifyBuffer, which contains information on how to update your buffer with the newly translated characters. Respond by updating your text buffer and user interface, including updating strong and weak highlighting. The character translator passes you a CHAR_TRANS_MODIFY structure.
   - msgCharTransGetClientBuffer, which asks your window instance for some text. Pass the requested text to the character translator as part of a CHAR TRANS_GET_BUF structure.
   - msgCharTransProvideListXY, which asks your class where to put the character alternative list. Compute the coordinates so that the list pops up below the character.
   - msgCharTransSetMark, which notifies your class that the translator is collecting characters. This message is sent for historical reasons. You can largely ignore it.
Notes

The following structures are used or required by the messages that the character translator sends your class.

The character translator sends the CHAR_TRANSFORM.MODIFY structure to let the client know how to modify its buffer. The structure is sent with msgCharTransModifyBuffer. Note that the markRelative, setActiveLenTo0, popupEvent, and user fields are used internally and you generally do not need to worry about them.

```
typedef struct CHAR_TRANSFORM.MODIFY {
    CHAR_TRANSLATOR ct;  // in: originating translator
    S32 first;             // in: 1st char to modify
    S32 length;            // in: # of chars to replace
    S32 buflen;            // in: # of chars in buf
    P_CHAR buf;            // in: chars to replace with
    CHAR_TRANSFORM HIGHLIGHT highlight;
    U32 markRelative:1,  // unused (reserved)
        setActiveLenTo0:1,
        popupEvent:1,
        reserved:29;  // unused (reserved)
    U32 user;
    U32 spare1;            // unused (reserved)
} CHAR_TRANSFORM.MODIFY, *P_CHAR_TRANSFORM.MODIFY;
```

The CHAR_TRANSFORM.HIGHLIGHT structure contains information on how to highlight characters in the current buffer. The character translator sends you this structure as part of the P_ARGS for msgCharTransModifyBuffer.

```
typedef struct CHAR_TRANSFORM.HIGHLIGHT {
    S32 weakStart;
    S32 weakLen;
    S32 strongStart;
    S32 strongLen;
    S32 oldWeakLen;
    S32 oldStrongStart;
    S32 oldStrongLen;
} CHAR_TRANSFORM.HIGHLIGHT, *P_CHAR_TRANSFORM.HIGHLIGHT;
```

The character translator requests part of its client’s buffer with msgCharTransGetClientBuffer. The CHAR_TRANSFORM.GET_BUF structure describes what portion of the buffer the character translator requires.

```
typedef struct CHAR_TRANSFORM.GET_BUF {
    P_CHAR buf;
    S32 startPosition;
    S32 length;
    U32 reserved;
} CHAR_TRANSFORM.GET_BUF, *P_CHAR_TRANSFORM.GET_BUF;
```

When the user requests an alternative to the current translation, the translator requests the client to provide the location for the pop-up box by sending msgCharTransProvideListXY. The client fills in the requested information as part of a CHAR_TRANSFORM_LIST_XY structure.

```
typedef struct CHAR_TRANSFORM_LIST_XY {
    S32 charPosition;  // character position in client buffer
    XY32 xy;           // root window coordinates for list
    U32 reserved1;
    U32 reserved2;
} CHAR_TRANSFORM_LIST_XY, *P_CHAR_TRANSFORM_LIST_XY;
```
Examples

The following code fragments illustrate different parts of the character translation protocol. The first fragment shows a typical response to the user pressing a key.

```
const P_INPUT_EVENT pEvent,
const OBJECT self,
P_KEY_DATA pKeyData;
P_MY_TEXT_STRUCTURE pText;
U16 key;
CHAR_TRANS_CHAR ctChar;

switch MsgNum(pEvent->devCode) {
    case MsgNum(msgKeyChar):
        pKeyData = (P_KEY_DATA) (pEvent->eventData);
        key = pKeyData->keyCode;
        ctKeyEvent.keyCode = key;
        ctKeyEvent.scanCode = pKeyData->scanCode;
        ctKeyEvent.shiftState = pKeyData->shiftState;
        s = ObjectCall(msgCharTransKeyEvent,self,&ctKeyEvent);
        if ( s < stsOK)
            break;
        s = HandleAnyKey(self, pText, pKeyData->shiftState,
            key, pKeyData->repeatCount);
}
```

The client self-sends `msgCharTransKeyEvent` each time the user presses a key. If the translator does not use the key, the message returns a status less than `stsOK`. In this case, the client responds by sending the key event to the internal function `HandleAnyKey()`.

The second fragment is part of the `HandleAnyKey()` function. It shows a typical instance of sending `msgCharTransChar`. Remember that you send `msgCharTransChar` to `self` when a character in your buffer changes (for example, when the user inserts or deletes a character). This particular code responds to the user pressing the backspace key.

```
CHAR_TRANS_CHAR ctChar;
U16 repeatCount;
switch (key) {
    ...
    case uKeyBackSpace:
        ctChar.c = (CHAR) key;
        ctChar.position = r.first-1;
        ctChar.operation = ctDeleteChar;
        for (i = 0, sts==OK && i < repeatCount && ctChar.position >= 0; i++)
            { ObjCallWarn(msgCharTransChar,self,&ctChar);
                ctChar.position--;
            }
    ...}
```
The third fragment shows the entire handler for `msgTransCharGetClientBuf`. The character translator sends you this message to request a part of your buffer.

```c
MsgHandlerArgType(SampleTextCharTransGetClientBuf, P_CHAR_TRANS_GET_BUF)
{
    const P_MY_TEXT_STRUCTURE pText = IDataDeref(pData, P_MY_TEXT_STRUCTURE);
    TEXT_BUFFER myText;
    myText.buf = pArgs->buf,
    myText.first = pArgs->startPosition;
    myText.length = text.bufLen = pArgs->length;
    ObjCallWarn(msgTextGetBuffer, pText->tb, &myText);
    return (stsOK);
    MsgHandlerParametersNoWarning;
}
```
Chapter 25 / Resources

Here are some texts that may help you during your localization process. Though not listed here, there are also consulting, translation, and marketing companies that can help you design, test, and translate your Japanese application and documentation.

*Electronic Handling of Japanese Text* Ken Lunde. Describes how Japanese text is handled electronically. Includes a superb history of Japanese character encoding. Available through the Internet via anonymous FTP at MSI.UMN.EDU (128.101.24.1). The files, which include various utility programs, are in the /PUB/LUNDE directory.

Chapter 26 / Japanese Character Set

The following pages list all the kanji defined by the 1990 JIS character set listed in Shift-JIS order. The Unicode value for each character is listed underneath each character as a 4-digit hexadecimal number.

We used PenPoint 2.0 Japanese to print this list with a standard 300 dots per inch (dpi) laser printer.

The fonts shipped with PenPoint 2.0 Japanese contain glyphs for all the characters listed. The characters that the handwriting recognition engine cannot recognize are marked with an asterisk (*).

Shift-JIS is ordered by a system called **ku-ten**. Most Japanese characters require two bytes of memory (half-width katakana characters, which require a single byte, are the exception).

Shift-JIS identifies the first byte with a string between ku 1 and ku 94, and the second byte with a string between ten 1 and ten 94. The kanji begin with ku 16 (hexadecimal 0x81).

Each ku is printed on a separate page that contains characters running from ten 1 to ten 94 for a given ku.

**How the list was created**

The list was created as follows:

1. A C program generated an RTF file containing the characters in the proper order and with the Unicode values.
2. The RTF file was passed into the DOS utility RTFTRIM. The result is a legal RTF file stripped of the RTF keywords that PenPoint's text component does not use.
3. The trimmed file was imported as a MiniText document and printed to a spool file. See Chapter 32 of *Part 4: PenPoint Development Tools Supplement* for information on printing to a spool file.
4. The spooler output was copied to a laser printer.

Part 4 / PenPoint Development Tools Supplement
Chapter 27 / Introduction

375 Organization of this supplement

Chapter 28 / Road Map

377 Creating a PenPoint application
  One time only tasks
  Preliminary design
  Creating an application
  Preparing for distribution

Chapter 29 / Creating Applications and Services

381 Overview
382 Where to put your files
382 Makefiles
  Compiling
  Linking
  Stamping
  Building a resource file
386 Changes from 1.0
  Stamping changes
  Specifying locales
387 Compiler details
  16-bit character flag
  DOS environment variables
  Working with the method table compiler
388 PenPoint libraries
  PenPoint applications
388 Installing PenPoint applications
  Installing automatically
  Installing applications in \2_0\PENPOINT\APP
  Installing applications from any connected disk
  Using the Settings notebook
  Copying files to the application directory
390 Working with supporting files
  Preparing distribution disks
  Using short DOS path and file names
  Stamping stationery with different names

Chapter 30 / Debugging

395 Overview
  Debug version of PenPoint
  Sending text to the debugger stream
  Viewing the debugger stream
  DebugCharSet
  System Log
398 Debug modes
  DebugTablet
  DebugRAM
  Running PenPoint 1.0 and 2.0
  Warm booting
401 Using the mini-debugger
  Displaying Unicode
  Disabling the mini-debugger
  Turning flag bits on and off
  Getting help

Chapter 31 / Tools and Utilities

403 Locales and character sets
404 PenPoint attribute utilities
  PSTAMP
  PCOPY
  PDIR
408 Resource file utilities
  RESDEL
409 Other DOS utilities
  UCONVERT
  RTFTTRIM
  CONTEXT batch file
  GO batch file
  LOCALE batch file
  Bitmap editor
  Font editor
413 PenPoint tools
  MiniText
  Unicode Browser
  Japanese virtual keyboard

420 Long DOS file names
  Do not use CHKDSK /F
421 Changes to QuickHelp
421 Working with different locales
422 Corrections to previous documentation
Chapter 27 / Introduction

This manual contains updated information about the PenPoint™ development environment. It describes tools you use to create applications for the Japanese localization of the PenPoint operating system.

Much of the information in the PenPoint Development Tools manual is still accurate. Where information in the PenPoint Development Tools manual is outdated, this manual provides updates. This manual also describes new tools and utilities available in the PenPoint SDK 2.0 Japanese.

Consult the following sources for more information on the PenPoint development environment:

- PenPoint Development Tools
- PenPoint Application Writing Guide: Expanded Edition
- About PenPoint 2.0 SDK

To make information easy to find, this manual closely follows the organization of the original PenPoint Development Tools manual.

Organization of this supplement

This chapter, Introduction, describes the purpose and organization of this manual. Chapter 3, Running PenPoint on a PC, from the original PenPoint Development Tools has moved to a separate document called Installing and Running PenPoint SDK 2.0.

Chapter 28, Road Map, describes the general process of writing PenPoint applications. This chapter also points out which volumes of the PenPoint documentation will help you in this process.

Chapter 29, Creating Applications and Services, covers topics related to creating a PenPoint application or service.

Chapter 30, Debugging, describes PenPoint debugging techniques, including new tools for debugging PenPoint 2.0 Japanese applications.

Chapter 31, Tools and Utilities, describes various tools that you use to work with PenPoint directories, resource files, and bitmaps.
Chapter 28 / Road Map

This chapter describes the typical process of creating a PenPoint™ application. The steps involved are discussed below, and Figure 28-1 is a visual representation of part of the process. Although applications are explicitly discussed here, the process of creating a PenPoint service are nearly identical.

Creating a PenPoint application
Creating a PenPoint application or service typically follows these steps. Indicated after each step is where you can find more information on a particular process.

One time only tasks
You only need to perform the following steps once.

1  Install the PenPoint SDK 2.0 Japanese.
   - See Installing and Running the PenPoint SDK 2.0 Japanese for more information.

2  Learn PenPoint programming and user interface concepts. See the following for more information.
   - PenPoint Application Writing Guide: Expanded Edition, Parts 1 and 6
   - PenPoint Development Tools
   - PenPoint User Interface Design Reference

Preliminary design
You need to perform the following preliminary design tasks each time you create a PenPoint application or service.

1  Design your application taking advantage of PenPoint’s extensive class library.
   - PenPoint Architectural Reference
   - Part 2: PenPoint Internationalization Handbook
   - Part 5: PenPoint Architectural Reference Supplement

2  Plan, design, and begin writing user documentation.
   - Using PenPoint
   - New UI Features in PenPoint

3  Plan, design, and begin producing supporting documents such as Help notebook documents, stationery, and sample documents.
   - PenPoint Development Tools Supplement, Chapter 29

4  If necessary, plan for translation and other localization services.
Creating an application

You take the following steps to create a PenPoint application. The steps here correspond to the steps in Figure 28-1.

1. Write C code, including source code (.c), header files (.H), resource files (.RC), a method table (METHODS.TBL), and a makefile (MAKEFILE). Name your resource file (one for each localization) to remind you of the localization the file corresponds to. For example, name your resource files JPN.RC and USA.RC for the Japanese and U.S. English localizations.
   - PenPoint Architectural Reference
   - PenPoint Application Programming Interface
   - PenPoint Development Tools
   - On-line header files in \2\0\PENPOINT\SDK\INC

2. Compile and link your code. This involves compiling source code, resource files, and your method table, as shown in Figure 28-1. You then link your object files with PenPoint libraries.
   - PenPoint Application Writing Guide: Expanded Edition
   - PenPoint Development Tools
   - Compiler documentation

3. Build your PenPoint application in its own directory underneath the PenPoint application directory (\2\0\PENPOINT\APP) or service directory (\2\0\PENPOINT\SERVICE). You must put in your application directory the necessary executable file (.EXE), dynamic link libraries (.DLL), compiled resource files (.RES), dependency identifier file (.DLC), and supporting documents.
   - PenPoint Development Tools

4. Stamp your application directory with PenPoint information, including the application name, the file type (application, service, font, and so on), and the linker name.
   - PenPoint Development Tools

Preparing for distribution

As you prepare for distribution, remember to take the following steps to

1. Contact GO Technical Services to register your classes.

2. Verify user documentation, translations, and other localization issues
   - Part 2: PenPoint Internationalization Handbook, Chapter 18

3. Create distribution disks.
   - PenPoint Development Tools Supplement, Chapter 29

Typically, use a makefile based on one of the sample application makefiles to coordinate steps 3 and 4.

Different releases of PenPoint use different root directories. For example, PenPoint 1.0 uses \1\01 as its root.
Creating an application

1 Write C code

2 Compile and link

3 Build application directory

4 Stamp application directory
Chapter 29 / Creating Applications and Services

This chapter describes the process of compiling, linking, and preparing your application or service to work under the PenPoint™ operating system.

Overview

You typically take the following steps to create a PenPoint application. Although this discussion centers on applications, the process of creating services is similar.

1 Compile your source code, resource files, and method table.
2 Link your object code with PenPoint libraries to create an executable image and dynamic link libraries.
3 Build your application by placing the executable image, dynamic link libraries, resource files, and supporting files in a directory within the PenPoint application directory. In PenPoint 2.0 Japanese, the application directory is \\2\0\PENPOINT\APP.
4 Stamp your application directory and the PenPoint application directory with PenPoint file names and attributes.

Rather than performing all these steps manually, you typically create a makefile that your compiler uses to perform each of these steps. The sample applications included with the SDK all build on three standard makefiles that work with the WATCOM WMAKE utility.

- SDEFINES.MIF contains standard definitions used to compile and link PenPoint applications and services.
- SRULES.MIF contains standard rules for creating PenPoint applications.
- SVCRULES.MIF contains standard rules for creating PenPoint services.

Use these makefiles as building blocks. Namely, define variables and add rules for your own project, but do not make any changes to the sample makefiles. Probably the easiest way to write your own makefile is to modify one that comes with a sample application such as Tic-Tac-Toe.

So that you can see the steps involved in creating a typical PenPoint application, the section “Makefiles” on page 382 steps through the most important parts of SRULES.MIF.
Where to put your files

Don’t use the SDK trees (for example, \2_0\PenPoint\SDK) for your own projects.

GO reserves the right to change the organization of the SDK trees. Also, GO may provide tools for moving, copying or otherwise manipulating these trees. If you store your projects in the SDK trees, we cannot guarantee that these tools will work, nor can we guarantee that they will preserve your sources.

You might use a directory in your root directory such as \MYAPP or in a special directory containing all your applications such as \APPS\MYAPP.

Makefiles

Most of the complexity of creating a PenPoint application is contained in the file SRULES.MIF. Stepping through the key parts of this file is a good way to understand the steps involved in creating an application.

Compiling

First, the makefile compiles your source code, method table, and resource files. Compiler errors are saved in files with a .ERR extension. After the makefile finishes creating your application, list all the .ERR files in your directory to make sure there are no compiler errors.

These commands in the makefile compile your source code, method table, and resource files.

```plaintext
  .c.obj:
    set WCC386=$(WCC386)
    wcc386p /Fo$*.obj $*.c > $*.err
    type $*.err

  # Method table
  .tbl.obj:
    set WCC=$(WCC)
    set WCC386=$(WCC386)
    $(PENPOINT_PATH)\sdk\util\clsmgr\mt $(MT_FLAGS) $< -Fo=$*.obj > $*.err
    type $*.err

  # Resource compiler file
  .rc.res:
    $(RC) $*.rc > $*.err
    type $*.err
```

Some variables that are common to all projects are defined in SDEFINES.MIF. For example, the variable WCC386 lists all the compiler flags required to create the appropriate object files.

Sometimes old object files get linked to your new project. This happens when the compiler encounters errors in your updated source code and aborts compilation. Type WMAKE CLEAN to delete old object files during your compile, test, debug, and recompile cycles.
Linking

After the source code is compiled into object code, it must be linked with PenPoint libraries. The makefile accomplishes this by creating a temporary WLINK file. The `%create` command creates this file, and the `%append` command adds the required lines to the file.

These lines link object files with PenPoint libraries to create executable code or dynamic link libraries.

```
$(APP_DIR) : .SYMBOLIC
    mkdir $(APP_DIR)
    # The following complexity is needed to build a WLINK command file.

$(APP_DIR)$(PROJ).exe : $(APP_DIR) $(EXE_OBJS)
    %create $(PROJ).eln
    %append $(PROJ).eln SYSTEM PenPoint
    %append $(PROJ).eln NAME $(APP_DIR)$(PROJ).exe
    %append $(PROJ).eln$(LINK_DEBUG)
    for %i in ($(EXE_OBJS)) do %append $(PROJ).eln FILE %i
    for %i in ($(EXE_LIBS)) do %append $(PROJ).eln LIBRARY %i
    %append $(PROJ).eln $(EXE_DATA_DIRECTIVE)
    %append $(PROJ).eln OPTION Quiet, Map=$(PROJ).mpe, NOD, Verbose, &
    Stack=$(EXE_STACK), MODNAME='$(EXE_LNAME)'
    wlinkp @$$(PROJ).eln
    del $(PROJ).eln
    copy $(PROJ).mpe $(APP_DIR)
```

Your makefile must define some of the variables used by SRULES.MIF. For example, the `EXE_OBJS` variable lists all of your object files that are needed to create the final executable image (.EXE). Again, the easiest way to write a makefile is to tailor the makefile of a sample application to your own project.

The makefile links the method table object code at this step in the process, but it does not link the resource object code. The resource object code stays separate from the executable code so that resource file data is cleanly separated from the rest of your application. See "Building a resource file" on page 385 for more information on how the resource file is built later in the process.

The loops in the code above adds a line to the temporary file for each of the object files and PenPoint libraries needed to create this application. The WLINKP command uses the information in the temporary file to link all the necessary object files together, and the temporary file is deleted when the linker finishes.

Finally, the makefile copies a file with an .MPE extension to your application directory. The linker creates this so-called map file to provide details about line numbers and symbol addresses created by the compiler and linker. You can view this file with a text editor to see details of how the linker created your executable file.
Stamping

The makefile uses a similar strategy for stamping the application directory. It first creates a temporary file that contains information about how to stamp your directory, passes that temporary file to the PSTAMP utility, and deletes the file when the utility is done. The following makefile rules accomplish this:

```makefile
%create $(PROJ).stm
%append $(PROJ).stm $(APP_DIR)\..
%append $(PROJ).stm /u
%append $(PROJ).stm /n
! ifeq RESStamp yes
    %append $(PROJ).stm /l $(LOCALE)
    %append $(PROJ).stm /r "$(LOCALE).rc" ""
! else
    %append $(PROJ).stm /g "$(EXE_NAME)"
! endif
%append $(PROJ).stm /d $(PROJ)
%append $(PROJ).stm /a imAttrVersion "$(APP_VERSION)"
%append $(PROJ).stm /a cmAttrProgramName "$(EXE_LNAME)"
%append $(PROJ).stm /a appAttrClassName "Application"
%append $(PROJ).stm /a appAttrClass 1001a0
-$(STAMP) -s $(PROJ).stm
del $(PROJ).stm
%create $(PROJ).stm
%append $(PROJ).stm $(APP_DIR)
%append $(PROJ).stm /u
%append $(PROJ).stm /n
! ifdef EXE_DLC
! ifeq RESStamp yes
    %append $(PROJ).stm /l $(LOCALE)
    %append $(PROJ).stm /r "$(LOCALE).rc" "dlc"
! else
    %append $(PROJ).stm /g "$(EXE_NAME).dlc"
! endif
%append $(PROJ).stm /D $(PROJ).dlc
! else
! ifeq RESStamp yes
    %append $(PROJ).stm /l $(LOCALE)
    %append $(PROJ).stm /r "$(LOCALE).rc" "exe"
! else
    %append $(PROJ).stm /g "$(EXE_NAME).exe"
! endif
%append $(PROJ).stm /D $(PROJ).exe
! endif
-$(STAMP) -s $(PROJ).stm
del $(PROJ).stm
```

The makefile first stamps a user-visible PenPoint name for your application. The standard rules use the string associated with `tagAppMgrAppFilename` as your application name. The tag and string are defined in the localized version of your resource file USA.RC or JPN.RC. If you need to stamp PenPoint names yourself, use the -g or -r option with the PSTAMP utility.

The makefile also stamps the directory with the following four attributes:

- A user-visible string describing the file type such as `Application`, `Font`, or `Service`. SRULES.MIF uses the string associated with `tagAppMgrAppNameClassName` in the appropriate version of your resource file.
The linker name of your application. Define this in your makefile with the 
EXE_LNAME variable.

The version number of your application. Define this in your makefile as the 
APP_VERSION.

A special 7-digit hexadecimal number that identifies the file as an application. 
SRULES.MIF stamps this number for you. You don’t need to set this in either 
your makefile or your resource file.

Table 29-1 shows more details about the information the makefile stamps. The 
middle column shows the tags (in lower case) or makefile variables (in upper case) 
you should define.

Attributes stamped by the makefile

<table>
<thead>
<tr>
<th>Attribute label</th>
<th>Makefile variable / Resource file tag</th>
<th>Example attribute value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Not an attribute</td>
<td>tagAppMgrDefaultDocName</td>
<td>Counter Application</td>
</tr>
<tr>
<td>appAttrClassName</td>
<td>tagAppMgrAppName</td>
<td>Application</td>
</tr>
<tr>
<td>imAttrVersion</td>
<td>APP_VERSION</td>
<td>2.0</td>
</tr>
<tr>
<td>cimAttrProgramName</td>
<td>EXE_LNAME</td>
<td>GO-CNTRAPP-V2(0)</td>
</tr>
<tr>
<td>appAttrClass</td>
<td>None (automatically stamped)</td>
<td>10001A0</td>
</tr>
</tbody>
</table>

Use the DOS program PSTAMP to manually stamp the directory with this required 
information. See “PSTAMP” on page 405 for more information.

Notice that the makefile checks the value of RES_STAMP several times. You must 
define this variable in your own makefile. Set it to YES if the makefile should stamp 
your project with the application name and type in your resource file.

If you do not set RES_STAMP to YES, the makefile directs PSTAMP to use the 
EXE_NAME from your makefile and stamp the type as Application.

Building a resource file

By now, the makefile has created an executable in your project directory and 
stamped your directory with PenPoint attributes. The next step is to build your 
application resource files, as shown in the following makefile rules:

```makefile
# Build the app's .res file
#
$(APP_DIR)/$(TARGET_RESFILE) : $(APP_DIR) $(LOCALE)_RES_FILES $(RES_FILES)
  for %i in $(LOCALE)_RES_FILES do -$(RESAPPND) %i temp.res
!ifdef RES_FILES
  for %i in $(RES_FILES) do -$(RESAPPND) %i temp.res
!endif
!ifdef DISTRIBUTED_DLLS
  for %i in DISTRIBUTED_DLLS do -$(RESAPPND)
  $(PENPOINT_PATH)/sdk\dll\%i$(LOCALE).res temp.res
!endif
  copy temp.res $(APP_DIR)/$(TARGET_RESFILE)
  -del temp.res
```
The exact resource file that gets built depends on the LOCALE variable. You can specify the value of LOCALE when you call WMAKE. See “Specifying locales” on page 386 for details.

**Changes from 1.0**
The following things have changed in SRULES.MIF since PenPoint 1.0.

**Stamping changes**
In 1.0, SRULES.MIF stamped an application's name and its type (“Application”) onto the executable.

In 2.0, the rules changed to allow both the name and the type to be localized. The new version of SRULES.MIF reads the application name and type from a resource file. The resource file must have a name of the form *Locale.RC* where *Locale* is JPN or USA.

All you need to do is provide `tagAppMngrAppName` and `tagAppMngrAppNameClassName` in the resource file for each localization. For example, if you are making a Japanese version of your application, these strings must be in JPN.RC.

**Specifying locales**
The WATCOM make utility (WMAKE.EXE) helps you make different localized versions of your application. When you call WMAKE, specify a LOCALE argument in the command line to make a localized version of your application. For instance, you can type:

```
wmake LOCALE=jpn
wmake LOCALE=usa
```

to create the Japanese and American versions of your application.

The LOCALE variable tells the compiler which resource files to compile and then copy to your application directory. Specifying JPN as the LOCALE directs the makefile to use the resource files specified by the variable JPN_RES_FILES. For example, with the Counter Application, the only resource file specified is JPN.RC.

You need a resource file for each of the localizations you create. If you have both American English and Japanese versions of your application, you must have files named USA.RC and JPN.RC.

In your makefile, use the three variables shown in Table 29-2 to identify which resource files to compile and copy into the application directory with the executable image.

**Makefile variables**

<table>
<thead>
<tr>
<th>Variable</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES_FILES</td>
<td>Resource files to be included with all versions of your application.</td>
</tr>
<tr>
<td>USA_RES_FILES</td>
<td>Resource files to be included with only the American version.</td>
</tr>
<tr>
<td>JPN_RES_FILES</td>
<td>Resource files to be included only with the Japanese version of your application.</td>
</tr>
</tbody>
</table>
For example, this fragment comes from the makefile for the NotePaper application in \2_0\PENPOINT\SDK\NPAPP:

```makefile
# The .res files for your project. If you have resources, add
# $(APP_DIR)$(TARGET_RESFILE) to the "all" target.
RES_FILES = bitmap.res
USA_RES_FILES = usa.res
JPN_RES_FILES = jpn.res

# Targets
all: $(APP_DIR)$(PROJ).exe $(APP_DIR)$(TARGET_RESFILE) .SYMBOLIC
```

### Compiler details

GO uses the WATCOM C 9.01d/386 compiler to compile PenPoint 2.0 Japanese code. Although other compilers may work, GO does not support them.

### 16-bit character flag

When you compile code containing 16-bit (Unicode) or double-byte (Shift-JIS) characters, set a compiler flag so that the compiler works for 16-bit characters. For example, if you are using the WATCOM C compiler, set the compiler flag /ZKOU. All PenPoint 2.0 Japanese applications should support the 16-bit Unicode character standard. For more information, see Chapter 15 of Part 2: PenPoint Internationalization Handbook.

The standard makefile rules set this flag automatically in SDEFINES.MIF. The PenPoint 2.0 Japanese resource compiler RC.EXE also sets this flag because your resource files almost certainly contain Shift-JIS or Unicode strings.

### DOS environment variables

You must identify the DOS PATH containing your WATCOM C compiler files. For example, you might put the following line in your AUTOEXEC.BAT:

```bash
path=c:\watcom\bin;
```

Use the CONTEXT batch file to set up the other DOS environment variables required to created PenPoint applications. See "CONTEXT batch file" on page 410 for more details on how to use this batch file.

### Working with the method table compiler

The method table compiler, (\2_0\PENPOINT\SDK\UTIL\DOS\MT.EXE), creates a header file named METHODS.H from your source file METHODS.TBL. If METHODS.H already exists, the compiler checks if the first line of the file matches the following:

```
"// WARNING: DO NOT EDIT ...
```

If that is the first line of the file, or if the file does not exist, the compiler creates a new METHODS.H.

If a METHODS.H file exists, but the first line is not the one above, the compiler exists with the error message:

```
mtcom ERROR: Failed while opening intermediate file (.h file exists)
```
PenPoint libraries

All the PenPoint 2.0 Japanese libraries are located in `\2_0\PENPOINT\SDK\LIB`. To direct the makefile to link a given PenPoint library with your code, you must include the name of the library as part of the definition of `EXE_OBJS` in your makefile.

The PenPoint 2.0 Japanese header files tell you which libraries you need to link. Remember to include the header file using the `#ifndef`, `#include`, and `#endif` preprocessor directives. The directives prevent files from being included more than once. For example, to use the PenPoint code that deals with memory allocation, you must have:

```
#ifndef OS_HEAP
#include <osheap.h>
#endif
```

in one of your header files. Then put the following line in your makefile:

```
EXE_OBJS = PENPOINT.LIB
```

Note that INTL.LIB and BRIDGE.LIB are new to PenPoint 2.0 Japanese.

- INTL.LIB contains all the international functions that are described in more detail in Part 2: PenPoint Internationalization Handbook.
- BRIDGE.LIB is virtually empty in PenPoint 2.0 Japanese. You can link this file with specially written code to allow the code to compile and run under both PenPoint 1.0 and 2.0. See the PenPoint Bridging Handbook for more information.

PenPoint applications

Many applications and services are stamped with their Japanese names in the 2.0 SDK. This is because no local application directory exists for each localization. Applications and services are usually found in `\2_0\PENPOINT\APP` and `\2_0\PENPOINT\SERVICE`.

To see the Shift-JIS names of these applications and services, type

```
\2_0\penpoint\sdk\util\dos\pdir -c XJIS \2_0\penpoint\app
```

This also shows you how the Japanese file names relate to DOS names.

Installing PenPoint applications

Section 3.15 of the PenPoint Development Tools suggests using the Installer to install your application. The Installer no longer exists. Here are some ways to install your application.

Installing automatically

To have PenPoint automatically install your application at boot time:

1. Add its PenPoint name and path to the appropriate APP.INI file.
2 If the application name contains characters you cannot type with your keyboard, just copy the application name from the application's resource file Locale.RC (USA.RC or JPN.RC) into APP.INI. The appropriate file depends on whether you are installing your application for the Japanese (\2_0\PENPOINT\BOOT\JPN\APP.INI) or American English (\2_0\PENPOINT\BOOT\USA\APP.INI) localization.

**Installing applications in \2_0\PENPOINT\APP**

To install an application in the \2_0\PENPOINT\APP directory:

1. Open the Connections notebook.
2. Make sure you are on the Disks page.
3. Choose Applications from the View menu.
4. Tap on the Install box next to the application you want to install.

**Installing applications from any connected disk**

To install an application from any connected disk:

1. Open the Connections notebook.
2. Make sure you are on the Disks page.
3. Choose Layout under the Options menu.
4. Select Install in the option sheet that appears.
5. Navigate to an application on any connected disk.
6. Tap on the Install box next to the application you want to install.

**Using the Settings notebook**

To install an application by copying it into the Settings notebook:

1. Open the Settings notebook, and tap on the Applications button. This shows the currently installed applications.
2. To install an application, tap on the Install menu item. This brings up a screen that shows you all the applications in \2_0\PENPOINT\APP. Tap on the Install box for the application you want to install.
3. If you want to install an application not shown in this window, turn to the Disks page of the Connections notebook.
4. Select View by Directory.
5. Navigate to the application you want to install.
6. Copy the application into the Installed Applications page of the Settings notebook. Use the tap press gesture to initiate the copy, then drag the application on top of the Settings notebook.

Using the Settings notebook is easier if you also want to set preferences for software, remove software, or save any changes you have made.
Using the Connections notebook is more convenient if you also plan to set up a printer, transfer files to and from the computer, format a floppy disk, or use network resources. It also lets you install applications from any directory, not just `\PenPoint\App`.

Aside from these differences, using the Settings notebook is identical to using the Connections notebook. They are merely different user interfaces for the same process.

**Copying files to the application directory**

On page 51 in *PenPoint Development Tools*, the last section instructs you to create a directory called `\PenPoint\App\EMPTYAPP`, and copy `EMPTYAPP.EXE` into that directory.

Simply creating the directory and copying the executable file into that directory does not create a PenPoint application. You need to copy in any resource files, supporting documents, and stamp the directory with PenPoint information. See “Stamping” on page 384 for more information on how the standard makefile rules stamp PenPoint information on application directories.

**Working with supporting files**

In addition to the executable image and compiled resource files, your application might require supporting files such as Quick Start documents, Help notebook documents, and stationery. This section describes strategies for working with these supporting documents.

**Preparing distribution disks**

Each of your distribution disks for an application or service should contain certain directories. Table 29-3 shows the structure for the sample Tic-Tac-Toe application. You should put similar directories and files beginning at the root of your distribution disk.

**Sample distribution disk structure**

<table>
<thead>
<tr>
<th>Directory and contents</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>\PenPoint\App\TTT</code></td>
<td>Application directory</td>
</tr>
<tr>
<td><code>\PenPoint\App\TTT\PenPoint.Dir</code></td>
<td>PenPoint directory and application information.</td>

<td>Directory containing first stationery document.</td>
</tr>
<tr>
<td><code>\PenPoint\App\TTT\HELP\TTTStat2\TTTFUE.TXT</code></td>
<td>Actual contents used by stationery document.</td>
</tr>
</tbody>
</table>
See Chapter 11 of this manual for more information on how Tic-Tac-Toe creates and uses its supporting files. You may also want to examine the makefile for Tic-Tac-Toe to learn how to set up the \HELP and \STATNRY directories.

There is one more file in the Tic-Tac-Toe directory called TTT.MPE. This map file is created by the linker and is for debugging purposes only. You should not copy the file to your distribution disks.

**Using short DOS path and file names**

DOS imposes a 64-character limit on the total length of a path and file name.

The PenPoint document model creates a separate directory for each file. Furthermore, each embedded document contains a separate subdirectory beneath the directory of its parent document.

This recursive structure can create DOS file names longer than the maximum of 64 characters. For example, here is the full path to a stationery document that is part of a stationery notebook for a typical application:

```
C:\2_0\PENPOINT\APP\MY_APP\STATNRY\MY_APP_QU\NOTEBOOK\CONTENTS\USQ1SALES\DOC.RES
```

You can work around the 64-character limit by using the short, 2-character path name PenPoint creates for each directory. PenPoint can then translate the short file names into full PenPoint names using information in PENPOINT.DIR. Using this technique shortens the long path name above to the shorter path name:

```
C:\2_0\PENPOINT\APP\MY_APP\STATNRY\MQ\NB\CS\US\DOC.RES
```

To create these short DOS directory names, you must copy the document to a \PENPOINT directory in the root of any volume.

For example, follow this procedure to save a MiniNote document as a Quick Start stationery item. The sample application is called MyApp.

1. Before starting PenPoint, set the B flag to 800 by adding /DB800 to the DebugSet line in ENVIRON.INI as follows:
   ```
   DebugSet=/DD8000 /D+1 /DB800
   ```
   You can also type FS B 800 in the mini-debugger to set the flag.

2. Start PenPoint and create a MiniNote document named something like **MyApp Quick Start**. When you have finished the Quick Start document, open the Connections notebook and set the View to Directory.

3. Open the \PENPOINT directory in the root of any volume except RAM.

4. Copy the Quick Start document into \PENPOINT. Make sure you are copying into the \PENPOINT directory directly off the root of your volume. For example, the \2_0\PENPOINT directory will not work.

5. Shut down PenPoint.
Navigate into your application directory, and create a `\STATNRY` subdirectory. For example, the following creates the subdirectory in `C:\\2_0\PENPOINT\APP\MYAPP`:

```
cd c:\2_0\penpoint\app\myapp
md statnry

cd statnry
```

Use the DOS utility `PDIR` to list the PenPoint names of the files in the `\PENPOINT` directory: See “`PDIR`” on page 407 for more information.

```
pdir c:\penpoint
```

Note the DOS name of the directory containing `MyApp Quick Start`. In this example, the DOS directory name is `MT`.

Copy the PenPoint document to your application's `\STATNRY` directory. For example, if the document is in the DOS directory `MT`, type the following:

```
xcopy c:\penpoint\mt mt /s/e
```

Append PenPoint attributes from the Quick Start document to the `\STATNRY` directory. See “PenPoint attribute utilities” on page 404 for details.

```
pappend penpoint.dir c:\penpoint\penpoint.dir /g "Myapp Quick Start"
```

Stamp the document to put a check in its menu check box. This forces the stationery document to appear in the Create menu.

```
pstamp /g "MyApp Quick Start" /A anmAttrStationeryMenu 1
```

Boot PenPoint and install `MyApp`. Verify that the only two stationery items for the application are `MyApp` and `MyApp Quick Start` by opening the Stationery Notebook.

GO uses this technique to save the Sample notebook and Help notebook. These files are in the `\\2_0\\PENPOINT\\BOOT\\DOC` directory.

**Stamping stationery with different names**

When you create localized versions of your application, you may want to ship different versions of your supporting documents, such as stationery and Quick Start documents. Use the procedure described above in “Using short DOS path and file names” to create the supporting documents.

However, some supporting documents you create are not language-specific. For example, the Tic-Tac-Toe sample application uses a piece of stationery to fill in a Tic-Tac-Toe board. Its stationery files are simply filled with a pattern of Xs and Os. The only difference between localized versions of the stationery is the stamped information (containing, among other things, the user-visible file name).

To create this kind of supporting document (which differs only by the stamped information), create the document in your development directory as described above.
When you build your application directory, copy the stationery files to \2_0\PENPOINT\APP\MYAPP\STATNRY and stamp the files as appropriate to the locale.

For example, the following procedure stamps locally appropriate names onto stationery:

1. Add a tag and an associated string to the resource file for each localization. For example, you might use the tag tagMyStationeryName and add the appropriate strings to each resource file.

2. Add lines to your makefile that stamp your stationery with the string associated with the tag. Specify the name that should be stamped by prefixing the tag name with the & (ampersand) symbol. For example, the following makefile commands stamp the string associated with tagMyStationeryName on your stationery:

   %create statnry.stm
   %append statnry.stm -u
   %append statnry.stm -n
   %append statnry.stm $(PENPOINT_PATH)\app\MyApp\statnry
   %append statnry.stm -l $(LOCALE)
   %append statnry.stm -r $(LOCALE) .rc ""
   %append statnry.stm -g &tagMyStationeryName
   %append statnry.stm -d $(DOSNAME)
   %append statnry.stm -a anmAttrStationeryMenu 1
   -$(STAMP) -s statnry.stm
del statnry.stm

3. Specify a locale when you call WMAKE to create your stationery. For example, the following commands create U.S. English versions of Tic-Tac-Toe stationery.

   wmake stationery LOCALE=usa
   wmake help LOCALE=usa

   If you do not specify a locale, the makefile rules assume JPN.
Chapter 30 / Debugging

You can use a variety of tools to debug your PenPoint™ applications. This chapter provides an overview of those tools and discusses changes and improvements to the debugging tools for PenPoint 2.0 Japanese.

See Part 2 of PenPoint Development Tools for more information on using PenPoint’s debugging tools.

Overview

There are a variety of ways to debug your application. Some common strategies are:

- Running the debug version of PenPoint 2.0 Japanese.
- Using Debugf() or DPrintf() to send text strings to the debugger stream. You can display these strings on your PenPoint screen or a second monochrome screen dedicated to displaying the debugger stream. You can also use the System Log application to write the debugger stream to a file.
- Using the PenPoint source debugger or the mini-debugger.
- Handling msgDump, which requests an object to format its instance data in a readable format to send it to the debugger stream.

Each of these strategies is discussed in more detail below.

Debug version of PenPoint

The PenPoint SDK 2.0 Japanese includes two versions of PenPoint, the production and debug versions. Each version contains its own set of DLLs, services, and applications.

The production version is what the end-user sees. Its files are in \...\PENPOINT\BOOT\DLL, \...\PENPOINT\BOOT\APP, and \...\PENPOINT\BOOT\SERVICE. The file PENPOINT.OS is also part of the production version. The ellipses (...) represent either 1_01 or 2_0, depending on which version of PenPoint you are developing for.

The debug version lets you see and use the following information in your debugger stream:

- Warnings from ObjCallWarn/Ret/Jump and StsWarn/Ret/Jump.
- Symbolic names for objects, classes, messages, and status values.
- Additional debugging information that may be helpful for reporting bugs to Developer Technical Services.
- Special debugging features documented in DEBUG.H.
The debug version files are in \PENPOINT\BOOT_DLL, \PENPOINT\BOOT_APP, and \PENPOINT\BOOT_SERVICE. The debug version of PENPOINT.OS is _PP.OS.

The drawbacks to using the debug version are:

- It requires more memory.
- PenPoint 2.0 Japanese runs more slowly.
- It is unlike the final end-user environment.
- Some debug warning messages are benign, and these may cause you undue worry about your own code.

You can modify the GO.BAT file to run either the debug or production version of PenPoint 2.0 Japanese. The default is the production version.

**Sending text to the debugger stream**

You can write debug information to the debugger stream using the Debugf() and DPrintf() functions. The sample code often uses this strategy to identify when a particular method handler executes. For example, here is the CntrNewDefaults method from the Counter Application:

```
MsgHandlerArgType(CntrNewDefaults, P_CNTR_NEW)
{
    Dbg(Debugf(U_L("Cntr:CntrNewDefaults"))); // Set default value in new struct.
    pArgs->cntr.initialValue = 0;
    return stsOK;
    MsgHandlerParametersNoWarning;
} /* CntrNewDefaults */
```

You can find this code in \2_0\PENPOINT\SDK\SAMPLE\CNTRAPP\CNTR.C.

Responding to msgDump is another way to send text to the debugger stream. Because your shipping product should not handle msgDump, use the #IFDEF and #ENDIF preprocessor directives to surround code that handles msgDump (and all other debugging code). For example, here are excerpts from the Tic-Tac-Toe method table showing how to use the directives:

```
MSG_INFO clsTttDataMethods[] = {
    msgNewDefaults, "TttDataNewDefaults", objCallAncestorBefore,
    #ifdef DEBUG
    msgDump, "TttDataDump", objCallAncestorBefore,
    #endif
};
```

Put a line in your makefile to define the name DEBUG when your application compiles. When DEBUG is defined, all the debugging code surrounded by the #IFDEF and #ENDIF preprocessor directives is compiled, so debugging information is sent to the debugger stream. Here is the line in Tic-Tac-Toe's makefile that defines the name:

```
MODE = debug
```
Look in SDEFINES.MIF to see how the MODE line influences which compiler and debugging flags are set.

See Chapter 10 in *PenPoint Development Tools* for more details on the functions that send data to the debugger stream.

**Viewing the debugger stream**

There are a variety of ways to view the debugger stream. Here are some of your options. See Chapter 10 in *PenPoint Development Tools* for more information.

**On the PenPoint screen**

To view the debugger stream on the same monitor as your PenPoint screen, you must uncomment the following line in MIL.INI:

```
MonoDebug=off
```

**On a second monitor**

Make sure the line above is commented out if you want to see the debugger stream on a second, monochrome monitor. This configuration is called two- or dual-headed debugging. Be sure to set the appropriate `DebugCharSet` to indicate which character set should be used to interpret the debugger stream codes. See “DebugCharSet” on page 398 for more details.

GO does not support viewing Shift-JIS on this second debugging monitor.

**Using the System Log application**

This PenPoint application saves the debugger stream to its own internal buffer. You can use the application to see the stream in a variety of ways. See “System Log” on page 398 for details.

**Using a serial port**

Assign a serial port to the `SerialDebugPort` variable in MIL.INI to send the debugger stream to that serial port. The port should be connected to a terminal emulator that can display the required character set. Most likely, this is another computer running a terminal emulation package. See “MIL.INI” on page 415 for details.

**As a file**

You can set variables in ENVIRON.INI to send the debugger stream to a file on your PC’s hard drive. For example, set the following variables to save the stream to the file PENPOINT.LOG in the root directory of your PC’s hard drive. The stream is flushed to the file after every 10 characters written to the stream.

```
DebugSet=/DD8000
DebugLog=PENPOINT.LOG
DebugLogFlushCount=10
```
**DebugCharSet**

The DebugCharSet variable in ENVIRON.INI controls the character set of your debugging output. Table 30-1 shows the currently permissible values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASCII</td>
<td>Standard 7-bit ASCII</td>
</tr>
<tr>
<td>XJIS</td>
<td>1990 Shift-JIS character set</td>
</tr>
<tr>
<td>437</td>
<td>Extended ASCII used in American PCs</td>
</tr>
<tr>
<td>850</td>
<td>Extended ASCII used in European PCs</td>
</tr>
</tbody>
</table>

If you are sending debugging information to your PenPoint monitor or a second debugging monitor, make sure it can display characters in the specified DebugCharSet. If you don’t, you will see unmeaningful characters.

Literal strings in Debug() and DPrintf() appear in the specified character set.

Unicode characters that do not have glyphs display as hex quads in PenPoint 2.0 Japanese. Outside of PenPoint, Unicode characters without glyphs display as /x value, where value is a 4-digit hexadecimal number. For example, the first hex quad in the margin would be displayed as /x001B.

The default value of DebugCharSet depends on the value of Locale, another ENVIRON.INI variable. If Locale is JPN, the default is Shift-JIS. The default is ASCII if Locale is USA.

If DebugCharSet is set to an invalid value, the default character set is assumed.

**System Log**

The System Log application writes the debugger stream to a file.

See Chapter 11 of *PenPoint Development Tools* for information on using the application. Contrary to the text on page 141 of that chapter, you cannot get or set debug flags with the System Log application.

In PenPoint 2.0 Japanese, the System Log application can display Shift-JIS characters as well as ASCII text.

Note that the Device List command under View menu is not supported in the production version of PenPoint 2.0 Japanese.

**Debug modes**

You can run the debug version of PenPoint in either DebugRAM or DebugTablet mode. The DebugRAM mode is convenient for early application testing because it is much faster, while the DebugTablet mode is more appropriate for more refined testing because it more closely simulates a notebook computer. For example, in DebugTablet mode, files created in PenPoint persist between boots.

Because the DebugTablet mode most closely matches a real pen computer, GO encourages you to run in DebugTablet mode as you get closer to shipping your product.
### DebugTablet

The **DebugTablet** mode, the default mode in PenPoint 2.0 Japanese, simulates a pen computer most closely. For example, files that you create will persist across boots. Also, when applications are installed, PenPoint copies executable code to a special system directory called the loader database. See Section 3.6 of *PenPoint Development Tools* for more information on DebugTablet mode.

If you set `SwapBoot` to 2 in `ENVIRON.INI`, PenPoint writes the content of your simulated notebook, complete with its documents and applications, to a swap file called `\PENPOINT.SWP`. The next time you boot, PenPoint reads the swap file to restore your simulated notebook. This considerably speeds up the boot process.

You specify the size of the swap file by setting `SwapFileSize` in `ENVIRON.INI`.

### DebugRAM

In the **DebugRAM** mode, PenPoint creates its run-time file system (the Bookshelf, Notebook, and document directories) in RAM. If you use the complete Japanese font set in PenPoint 2.0 Japanese, this mode requires 12 megabytes of RAM. See *Installing and Running the PenPoint SDK 2.0* for strategies on reducing the required amount of RAM.

In DebugRAM mode, PenPoint does not create the loader database of executable system code, application executables, and DLLs. Instead, PenPoint pages them in from the original files. Thus, PenPoint starts from a fresh state each time you boot in DebugRAM mode.

You can still preserve files by copying them to your DOS disk by using the Connections notebook.

If you install an application or service from a floppy disk, and remove the disk while the application or service is running, PenPoint 2.0 Japanese may page fault. This is true only in DebugRAM mode.

### Running PenPoint 1.0 and 2.0

If you are developing PenPoint 1.0 and 2.0 Japanese applications on the same PC, make sure only one environment uses DebugTablet mode. This protects you from crashes that occur if the PenPoint operating system tries to read a swap file created by a different version of PenPoint.

Because DebugTablet is the default mode in PenPoint 2.0 Japanese, set DebugRAM as your PenPoint 1.0 mode, or change the 2.0 default.

### Warm booting

When you are debugging, you frequently want to replace the existing code with the most recent version. In DebugTablet mode, you may be able to replace the changed .EXE and .DLL files in the loader database (in \2_0\PENPOINT\SS\LR), thereby bypassing the PenPoint installer. This technique, called warm booting, saves about 100 seconds during boot.
Warm booting works only when you have:

- Cold booted with your .DLL or .EXE running.
- Made no structural changes to your project's destination directory.
- Not enabled swap booting.

The DLLs and EXEs in the loader database are the same as the files in `\2_0\PENPOINT\APP` or `\2_0\PENPOINT\BOOT\DLL`, except that:

- They are stamped with PenPoint attributes.
- Their PenPoint names are in the linker form rather than the DOS directory names. The syntax for the linker name is as follows:
  
  `company-project-VmajorVersion(minorVersion)`

  For example, the linker form of the dynamic link library required by the Calculator sample application is `GO-CALC_ENG-V2(0)`.

Leave the PenPoint attributes unchanged in `\2_0\PENPOINT\SS\LR\PENPOINT.DIR`, and just copy in the new version of the DOS file.

The name of the files to copy are the DOS forms of your application's PenPoint name. The DOS names are usually the first eight letters of the linker name. For example, `GO-CALC_` is the DOS version of the linker name `GO-CALC_ENG-V2(0)`.

If you can guarantee that the first eight characters identify the files you want, write a makefile to perform the required copying automatically. You might write your makefile so that typing `make warmboot` from the DOS prompt takes the required steps. Your makefile might look something like this:

```bash
WARMEXES = $(WARMEXES)
  ifneq DLL_OBJS
    ifeq DLL_DIR
      WARMEXES += $(APP_DIR)\$(PROJ).dll
    endif
  endif
  only get the init.dll or the executable if they are built here
  ifneq INIT_OBJS
    WARMEXES += $(APP_DIR)\init.dll
  endif
  ifneq EXE_OBJS
    WARMEXES += $(APP_DIR)\$(PROJ).exe
  endif
warmboot :: \penpoint\ss\lr\penpoint.dir $(WARMEXES) .SYMBOLIC
  ifneq DLL_OBJS
    ifeq DLL_DIR
      -copy $(APP_DIR)\$(PROJ).dll \penpoint\ss\lr\$(DLL_LNAME)
    endif
  endif
```
Using the mini-debugger

This section contains more detailed information about how to use the mini-debugger. See Chapter 12 of *PenPoint Development Tools* for more information.

Displaying Unicode

Table 12-1 on page 146 of *PenPoint Development Tools* shows a series of mini-debugger commands (d, da, db, dd, and dw) that display the contents of particular memory addresses as ASCII text.

In PenPoint 2.0 Japanese, the same commands display the memory contents as either multibyte (Shift-JIS) or Unicode characters. The interpretation is controlled by the `mdb` command, which controls various aspects of the mini-debugger.

Table 30-2 shows the currently defined controls. Simply type `mdb` followed by one of these numbers to activate a control. For example, `mdb 6` turns on Unicode interpretation of memory dumps.
Mini-debugger controls

<table>
<thead>
<tr>
<th>Control</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Turn off page fault protection</td>
</tr>
<tr>
<td>2</td>
<td>Turn on page fault protection</td>
</tr>
<tr>
<td>3</td>
<td>Turn off symbolic translation during stack traces (st)</td>
</tr>
<tr>
<td>4</td>
<td>Turn on symbolic translation during stack traces (st)</td>
</tr>
<tr>
<td>5</td>
<td>Turn off symbolic translation when displaying address information (ai)</td>
</tr>
<tr>
<td>6</td>
<td>Interpret memory contents as Unicode characters.</td>
</tr>
<tr>
<td>7</td>
<td>Interpret memory contents as multibyte (Shift-JIS) characters.</td>
</tr>
</tbody>
</table>

Disabling the mini-debugger

In the end-user version of PenPoint, the mini-debugger is disabled. You can explicitly disable the mini-debugger by setting the /DD10000 flag. When the mini-debugger is disabled, applications or services that crash are simply terminated, and operation continues.

Also, set the /DD40000 flag to disable the keys that drop you into the mini-debugger. Without this flag, CTRL-C and BREAK drop you into the mini-debugger.

A PenPoint machine set up for a user has both flags set; namely, /DD50000 is set.

Turning flag bits on and off

The mini-debugger fs command accepts + and - to enable and disable flags. The operators toggle the value of the flag specified. For example, the following lines toggle the B 800 flag.

```
fs B +800
fs B -800
```

These commands are much simpler than the source-level debugger commands, where you are responsible for the addition and subtraction of the appropriate bits.

Getting help

Type H or h to see the list of valid commands. Press the space bar to scroll through the list one line at time; press Return to scroll through an entire screen at once.

Table 12-1 in PenPoint Development Tools erroneously states that you can type the question mark (?) character to get help.
Chapter 31 / Tools and Utilities

This chapter describes various DOS utilities and PenPoint™ accessories that help you create PenPoint 2.0 Japanese applications and services. Many of these utilities are updates of tools found in the 1.0 SDK, so you should look in PenPoint Development Tools for information on how to use these tools.

The old command-line syntax is still accepted for all utilities. You only need to rename GDIR and STAMP in your 1.0 scripts, since these utilities have been renamed.

Most of the new and updated DOS utilities are in \2_0\PENPOINT\SDK\UTIL\DOS. Type -? or /? after any of these DOS utilities to see a help message.

Locales and character sets

Because you are likely to use different character sets while developing your PenPoint 2.0 Japanese application, most of the DOS utilities are sensitive to two DOS environment variables.

- CHARSET can be one of the values in Table 31-1.
- LOCALE, a combination of a country, language, and dialect, can be either USA or JPN. The locale maps to a default character set. The USA locale maps to code page 437, while JPN maps to XJIS.

Valid values for CHARSET

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASCII</td>
<td>Standard 7-bit ASCII.</td>
</tr>
<tr>
<td>XJIS</td>
<td>Shift-JIS encoding of the 1990 JIS character set.</td>
</tr>
<tr>
<td>437</td>
<td>IBM code page 437 used in U.S. PCs.</td>
</tr>
<tr>
<td>850</td>
<td>IBM code page 850 used in European PCs.</td>
</tr>
<tr>
<td>LATIN1</td>
<td>International Standards Organization (ISO) Latin 1 character set.</td>
</tr>
</tbody>
</table>

Set these environment variables to reflect the character set that your keyboard uses.

You can set the variables in AUTOEXEC.BAT if you use a particular character set most of the time. Use this line, for example, to specify code page 437 as the default character set.

```
set charset=437
```

With this variable set, the DOS utilities will interpret the characters in stamped names as ASCII characters. Other character sets and locales are supported, but the ones mentioned here are the only ones relevant to PenPoint 2.0 Japanese.
If you want to specify a character set or locale for just one time, most utilities accept a `-c` or `-l` argument. For example, you can type either of the following commands to display PenPoint directory information, with the PenPoint names interpreted as Shift-JIS characters.

```
pdir -cxjis
pdir -l jpn
```

Notice in the above example that spaces are not required between flags and their values. You can type either `-cXJIS` or `-c XJIS` to specify the character set.

You may specify explicit Unicode characters by embedding `\xhhhh` in your strings, where `hhhh` is up to 4 hexadecimal digits. For example,

```
pstamp MyDir -u -g "Q3 Sales in $\times00A5" -d Q3SALES
```

stamps the directory `MyDir` with the name `Q3 Sales in ¥` because the Unicode value `0x00A5` represents the ¥ symbol.

### PenPoint attribute utilities

PenPoint 2.0 Japanese provides a collection of DOS utilities to stamp directories, applications, services, and documents with PenPoint attributes. This information is stored in a file named `PENPOINT.DIR` in the same DOS directory. Table 31-2 shows the available utilities.

In PenPoint 2.0 Japanese, `PENPOINT.DIR` can contain Unicode strings, although the utilities can still read `PENPOINT.DIR` containing ASCII strings. That means the utilities still work with PenPoint 1.0 files. You must have the `DOS4GW.EXE` file in your DOS PATH to run any of these utilities.

### Attribute utilities

<table>
<thead>
<tr>
<th>Name</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>PSTAMP</td>
<td>Adds special PenPoint information to a DOS file or directory.</td>
</tr>
<tr>
<td>PDEL</td>
<td>Deletes specific directory entries from <code>PENPOINT.DIR</code> files.</td>
</tr>
<tr>
<td>PCOPY</td>
<td>Recursively copies files and directories to other PenPoint directories. Appends the appropriate entries in <code>PENPOINT.DIR</code>.</td>
</tr>
<tr>
<td>PDIR</td>
<td>Lists the PenPoint names and file systems attributes for all the files and directories in a DOS directory. Replaces <code>GDIR</code> from the utilities included with PenPoint 1.0.</td>
</tr>
<tr>
<td>PSYNC</td>
<td>Scans the current directory and removes any entries from <code>PENPOINT.DIR</code> for which there are no corresponding DOS files. Note that this updates the PenPoint directory information from the DOS information; it does not update DOS files from the information in <code>PENPOINT.DIR</code>.</td>
</tr>
</tbody>
</table>
PSTAMP replaces STAMP from PenPoint 1.0. It has changed in the following ways:

- You can stamp Unicode strings by specifying the -u option.
- You can specify a script file of arguments using the -s option to help automate the stamping process. The script file must contain the same arguments you would type in at the command line. These scripts help you avoid the 128-character limit DOS imposes on commands.
- You can now delete an attribute by specifying the -x argument. Previously, the only way to do this was to create a new entry that did not contain the attribute you wanted to delete.
- When manipulating attributes, you can refer to entries one of three ways:
  - By PenPoint name (as it was in the STAMP from 1.0).
  - By DOS name.
  - By the string associated with `tagAppMgrAppFilename` in a resource file (`JPN.RC` or `USA.RC`).
- PSTAMP assumes you want to manipulate the PENPOINT.DIR in the current directory, so you don’t need to specify a PENPOINT.DIR file each time you run PSTAMP. You can still specify PENPOINT.DIR files in other directories if you want.
- You may change the PenPoint name of an entry by specifying the -n flag. You must specify the new PenPoint name and the old DOS name as arguments. If the entry does not exist already, a new one is created. For example, this command changes the name of the Paint sample application from Paint Demo to My Paint Program:

```
PSTAMP -N -D "PAINT.EXE" -G "My Paint Program"
```

- You may specify symbolic names for all system-defined attributes instead of attribute numbers. The symbolic names are the `#define` names of the attributes in the header files. All names that are defined using a function of the form `FSMake*Attr()` are valid.

- Table 31-3 shows some attributes that are commonly stamped onto items you can install in PenPoint (for example, applications and services). Remember that there are three kinds of attributes: strings, variables, and fixed (32-bit or 64-bit). See Chapter 72, Using the File System in the *Architecture Reference* for more information.
## Attributes stamped on installable items

</table>

Sequence number describing the position of an embedded document.

Number of documents embedded within this document.

Document's file system flags (for example, moveable, readOnly).

User-visible name of a document's tab in the notebook.

User-visible author field.

User-visible comments field.

See “Stamping changes” on page 386 for more information about how the standard makefile rules have changed stamping behavior since 1.0.
**PCOPY**

PCOPY allows you to recursively copy files and directories to other PenPoint directories. If the directory you are copying contains a PENPOINT.DIR file, PCOPY updates the target PENPOINT.DIR file to include the new information.

```
PCOPY source [target-dir] [/V] [/L locale | /C charset]
```

The `source` can be a file or a directory. If `source` is a directory, PCOPY copies the contents recursively. You can also use the standard DOS wildcards `*` and `?` to specify multiple files or directories. The `locale` and `charset` specify the locale or character set from which to translate the PenPoint name. PenPoint names, remember, are written as Unicode strings. See “Locales and character sets” on page 403 for a list of valid values.

For example, you might need to copy an application from `\2_0\PENPOINT\SDK\APP`, such as SSHOT, to `\2_0\PENPOINT\APP`. With the tools available in PenPoint 1.0, you had to use XCOPY to copy the SSHOT directory into `\2_0\PENPOINT\APP`, then use PAPPEND to copy SSHOT attributes from its original directory to `\2_0\PENPOINT\APP`.

Now, you can simply type the following to achieve the same result:

```
PCOPY \2_0\PENPOINT\SDK\APP\SSHOT \2_0\PENPOINT\APP
```

PCOPY recursively copies SSHOT to the target and updates the PENPOINT.DIR file in `\2_0\PENPOINT\APP`.

PCOPY cannot copy to already existing subdirectories below the target directory.

For instance, you can't:

```
MD D:\2_0\PENPOINT
PCOPY C:\2_0\PENPOINT\SDK\APP D:\2_0\PENPOINT
PCOPY C:\2_0\PENPOINT\APP D:\2_0\PENPOINT
```

The second PCOPY fails because D:\2_0\PENPOINT\APP already exists.

**PDIR**

PDIR replaces GDIR from PenPoint 1.0. While GDIR allowed you to specify only directories, PDIR allows you to specify files as well. For example:

```
PDIR PENPOINT.BAK
```

displays PenPoint information about the file PENPOINT.BAK.

PDIR also differs from GDIR in the following ways:

- Attributes are only printed when you specify the `-a` argument rather than printing automatically.
- Unicode names that have been stamped using PSTAMP's `-u` option are interpreted as characters from the set specified in CHARSET.

If some of the characters in your Unicode strings display as spaces, there is no equivalent character in the character set you specified. Change your character set or specify the `-u` option to display unprintable Unicode characters as hex numbers.
Resource file utilities

The resource utilities from PenPoint 1.0 have been ported to 2.0 Japanese.

- RC, the resource compiler, compiles .RC files into .RES files. Applications and services actually use .RES files, not .RC files.
- RESAPPEND appends resources from one resource to another. It also compacts the target resource file by removing deleted or duplicated resources.
- RESDUMP allows you to view the contents of a resource file.

RESDEL

A new resource file utility, RESDEL, deletes specific resources from a compiled resource file. The syntax of the command:

RESDEL resource-file-name [ resource-ID-spec ]

The resource-ID-spec identifies a particular resource in a variety of ways. You can find a resource ID by examining the contents of a resource file using RESDUMP.

For example, if you wanted to delete a resource from the USA.RES of Tic-Tac-Toe, first examine the contents of the file by typing:

```
resdump c:\2_0\penpoint\sdk\app\ttt\usa.res > tempfile
```

Open `tempfile` with a text editor and notice that a typical resource looks like the following:

```
Resource 0 is a well-known object resource
resId = [0x0780001A WKN: Scope=Global Admin=13 Tag=15]
Objects class = [0x010002F4 WKN: Scope=Global Admin=378 Ver=1], data length=401
Min sys version = 0
```

You can specify the resource with the hexadecimal number 0x0780001A. To delete it, just type:

```
RESDEL C:\2_0\PENPOINT\SDK\APP\TTT\USA.RES Ox0780001A
```

There are more complex ways of specifying a resource, as shown in Figure 31-1.

Specifying a resource with RESDEL
In the above example, note that the resource if a well-known object resource with global scope, an administered number of 13, and a tag number of 15. Given this information, you can delete the resource by typing:

```
RESDEL C:\2_0\PENPOINT\SDK\APP\TTT\USA.RES 13T15
```

Type RESDEL /H for details on these alternate ways of specifying resources.

### Other DOS utilities

There are a collection of DOS utilities that do not deal with PenPoint attributes or resource files.

#### UCONVERT

A new utility **UCONVERT** allows you to convert entire files from one character set to another. The syntax of the command is as follows:

```
UCONVERT [-d] [-m] source-file dest-file [source CharSet] [dest CharSet]
```

You can specify a character set as either a code page or a locale. Any character set shown in Table 30-1 in Chapter 30, Debugging, is valid. You may also specify UNI to indicate the Unicode character set. Each locale maps to a default character set:

- USA maps to code page 437 (specified as 437).
- JPN maps to Shift-JIS (specified as XJIS).

Table 31-5 shows examples of using the **UCONVERT** utility.

### Using UCONVERT

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>uconvert mytext.doc mytext.unc</td>
<td>Puts a Unicode copy of ASCII document MYTEXT.DOC in the file MYTEXT.UNC. ASCII-to-Unicode is the default conversion.</td>
</tr>
<tr>
<td>uconvert mytext.unc mytext.jis uni xjis</td>
<td>Puts a Shift-JIS version of the Unicode document MYTEXT.UNC in the file MYTEXT.JIS</td>
</tr>
<tr>
<td>uconvert -d myfiles.doc myfiles.jis xjis uni</td>
<td>Puts a Shift-JIS version of the file MYFILES.TXT containing filenames in the file MYFILES.JIS. The -d flag is necessary when the input Shift-JIS file contains filenames.</td>
</tr>
<tr>
<td>uconvert letter.jis letter.unc jpn uni</td>
<td>Puts a Unicode copy of the Shift-JIS file LETTER.JIS in the file LETTER.UNC.</td>
</tr>
<tr>
<td>uconvert -m longfile.437 longfile.unc</td>
<td>Puts a copy of the extended ASCII file LONGFILE.437 in the Unicode file LONGFILE.UNC, converting all CR/LF combinations to the Unicode line separator character (U+2028).</td>
</tr>
</tbody>
</table>

#### RTFTRIM

You can use **RTFTRIM** to convert an RTF document into a form usable by the Help notebook.

RTFTRIM converts the Japanese RTF form \x\x\ yy to uuuu where xx and yy are the first and second bytes of a Shift-JIS character and uuuu is the Unicode equivalent.

RTFTRIM also introduces a new keyword \UNC that allows you to embed Unicode characters in a 7-bit RTF file. Just put \UNC\xxx where xxx is the hex representation of the Unicode character.
This allows you to specify GO gesture glyphs in RTF help files. For example, the literal /UNCF600 represents the Unicode point for the single tap gesture. See the header file \2_\0\PENPOINT\\SDK\\INC\GLYPH.H for a list of Unicode values for the GO gesture glyphs.

**CONTEXT batch file**

The CONTEXT batch file, located in \2_\0\PENPOINT\\SDK\\UTIL\\DOS, helps you set up the DOS environment variables required to run PenPoint and compile PenPoint applications and services.

Because the batch file accepts 1.0 or 2.0 as arguments, it is especially useful if you need to switch between PenPoint 1.0 and 2.0 development.

After reading the argument that represents the development environment, CONTEXT.BAT performs the following actions:

- Sets these environment variables:
  - CONTEXT
  - PENPOINT_PATH, GO_PATH, PATH
  - INCLUDE
  - LIB
- Adds \2_\0\SDK\\UTIL\\DOS to the end of your PATH.
- Creates \PENPOINT and \PENPOINT\BOOT directories in the root of your current volume (if they don't already exist).
- Copies the ENVIRON.INI file from the appropriate \..\\PENPOINT\BOOT directory into \PENPOINT\BOOT in the root.

CONTEXT.BAT assumes C: is the source drive. You can change this by reassigning the SRC_DRV variable.

If you change your path in AUTOEXEC.BAT, reboot your machine. Do not simply run AUTOEXEC.BAT to get the new path because CONTEXT.BAT sets up an environment variable that must be cleared if you change your path.

**GO batch file**

The GO.BAT batch file now takes two optional parameters to specify the locales to boot with:

```
go [system_locale] [user_locale]
```

When you specify a system locale, PenPoint's behavior and user interface are changed to be appropriate to the specified locale (U.S. or Japanese).

When you specify both a system and user locale, the batch file directs PenPoint 2.0 Japanese to change its behavior to match the system locale, but to change its user interface strings to match the user locale.
For example:

- To boot with Japanese behavior and strings, type the following command:
  
  go jpn

- To boot with Japanese behavior and English strings, type the following command:
  
  go jpn usa

When you type GO with no parameters, PenPoint 2.0 Japanese boots in the same state as it was last booted. If you type GO with no parameters and you are in Debug Tablet mode, PenPoint warm boots. See “Warm booting” on page 399 for more information. Because the batch file only controls which resource files PenPoint loads, the stamped application and service names appear in the system locale language.

GO.BAT relies on LOCALE.BAT to do the locale switch. Both GO.BAT and LOCALE.BAT require utilities in the \2_0\PENPOINT\SDK\UTIL\DOS directory to switch locales.

When you specify a locale with GO.BAT (or LOCALE.BAT) the batch file recursively deletes your \PENPOINT\SS directory. This deletes any documents that you had saved in your PenPoint file system. Make sure to save the files to your hard drive if you need them.

Currently, only two locales are supported: JPN and USA.

**LOCALE batch file**

GO.BAT calls LOCALE.BAT to implement the required changes. You can call LOCALE.BAT yourself if you want to change the configuration without booting PenPoint. Its syntax is similar to GO.BAT:

```bash
locale system_locale [user_locale]
```

LOCALE.BAT edits ENVIRON.INI and copies the appropriate MIL.RES file from the appropriate locale-specific boot directory (\2_0\PENPOINT\BOOT\JPN or \2_0\PENPOINT\BOOT\USA) to \2_0\PENPOINT\BOOT. If you want to load any of your applications or services at boot time, remember to specify them in the appropriate APP.INI or SERVICE.INI file. PenPoint 2.0 Japanese uses the initialization files in the directory corresponding to the user locale.

For example, if you are running the system with Japanese behavior and English strings, only the services in \2_0\PENPOINT\BOOT\USA\SERVICE.INI are loaded. The KKC engine is not listed in this SERVICE.INI, so you need to explicitly install this service if you want to test your application with KKC enabled. Use the Settings notebook to install the services.

Do not make the changes that LOCALE.BAT implements unless you are sure your changes are not destabilizing. The way PenPoint 2.0 Japanese handles locales will change in the future, so you should let LOCALE.BAT handle the switch.
**Bitmap editor**

The bitmap editor is in `\2_0\PENPOINT\SDK\APP\BITMAP`.

See “Installing applications from any connected disk” on page 389 for details on how to install the bitmap editor.

Here is the typical procedure for working with bitmaps:

1. Create a bitmap using the bitmap editor. See Chapter 16 of *PenPoint Development Tools* for details on how to use the bitmap editor.
2. If you are creating an icon, define an appropriate hot spot. The hot spot determines the origin of the bitmap. Make sure your hot spot is defined in a way so that the icon is clearly visible when it is drawn on-screen.
3. If you are creating a bitmap other than an application icon, tap on the Custom Resource Id choice under the Options menu. Set the following values:
   - Set the Class number to the administered number for your class.
   - Set the Scope value to match the scope of your class.
   - Set the Id value to the tag value you use to identify your bitmap in your header file.
4. Export the bitmap. If your bitmap is an application icon, select App or Small App from the Resource Id pop-up menu. Otherwise, select Custom. Note that bitmaps are exported as resource object (.RES) files.
5. Create a tag to identify your bitmap with the `MakeTagO` macro. Typically, this is done in a header file. Use the Id value you used in step 3.
6. Create an instance of clsIcon or clsIconToggle.
7. Assign the field that identifies a bitmap to the tag you defined in step 5. For example, set the *win.tag* field of the ICON_NEW structure or the *iconToggle.offTag* of the ICON_TOGGLE_NEW structure to the tag you defined to identify your bitmap. See below for an example.
8. Set the *control.client* field of ICON_NEW to OSThisApp().

The following code comes from the UI Companion, a sample application in `\2_0\PENPOINT\SDK\SAMPLE\UICOMP`. The code shows how the frog icon on the “Lists” page of the UI Companion was created and used.

When the bitmap was created, the following values were assigned in the Custom Resource Id option sheet:

The values used in the option sheets come from the header file UICOMP.H:

```
#define clsUICompApp MakeGlobalWKN (3524, 1)
...
#define tagIconFrog MakeTag (clsUICompApp, 36)
```
The code in LISTS.C uses this tag to identify the bitmap when creating an instance of clslIconToggle:

```
ICON_TOGGLE_NEW       itn;
STATUS                s;
ObjCallWarn(rnsgNewDefaults, clslIconToggle, &itn);

itn.iconToggle.offTag = tagIconProg;
itn.iconToggle.onTag  = tagIconPrince;
itn.icon.pictureSize.w = iconSizeNormal;
itn.icon.pictureSize.h = iconSizeNormal;
itn.control.client    = OSThisApp();
itn.border.style.edge = bsEdgeAll;
ObjCallRet(rnsgNew, clslIconToggle, &itn, s);
```

See the in-line comments in UICOMP.C for more information on using bitmaps.

**Font editor**

The font editor for PenPoint 2.0 Japanese fonts is no longer supported. You should convert your fonts to bitmaps.

If you have fonts created with the font editor that you believe would be valuable to a large community of PenPoint programmers, contact GO to negotiate translating those fonts for use in PenPoint 2.0 Japanese.

Contact GO if you want to see the font specification. With the font specification, you can create your own fonts.

**PenPoint tools**

Aside from the DOS utilities, there are a number of PenPoint 2.0 Japanese applications and accessories to help you create applications and services.

**MiniText**

You can use MiniText as a Shift-JIS and Unicode editor. MiniText supports Japanese handwriting recognition, KKC, and RKC.

See Chapters 4 and 5 of the *Japanese Localization Handbook* for more details on how to use MiniText as a text editor.

**Unicode Browser**

The Unicode Browser allows you to find specific characters and put them into the input stream. It contains all the characters available in the Japanese fonts when those fonts are installed.

The first row of characters in the Unicode Browser consists of Latin characters (the letters a through z, the numbers 0 through 9, mathematical operators, accented characters, Cyrillic characters) and special fonts (gestures and other GO glyphs) installed in PenPoint 2.0 Japanese. The remaining rows of the Unicode Browser contain kanji radicals.
Tap on any character in the top level of the Browser to open a submenu. For non-kanji (the top row), the submenu contains the characters in the set represented. For kanji radicals, the submenu contains all characters that use the displayed radical as their base radical. The size of this submenu varies from radical to radical.

Tap on a character in the submenu to insert the character into the input stream at the current insertion point. Tap outside the submenu to close the submenu without any character being selected. If there is no current insertion point, the submenu closes and nothing happens.

**Japanese virtual keyboard**

The virtual keyboard is another PenPoint 2.0 Japanese accessory that allows users to send characters to the text stream. It offers U.S. and Japanese IBM-A01 keyboard modes. Bring up the keyboard and make the check ✓ gesture over the title bar to switch modes.
Chapter 32 / Miscellaneous

This chapter describes miscellaneous topics including:

- MIL.INI.
- ENVIRON.INI.
- Printing to a spooler.
- Long DOS file names.
- Changes to QuickHelp.
- Corrections to previous documentation.

**MIL.INI**

The MIL may print out some initial errors before PenPoint 2.0 Japanese boots. Because PenPoint isn't running at this time, it hasn't read ENVIRON.INI to determine whether to log to a file. To see these pre-boot errors, either use a second monochrome monitor or use MIL.INI to log to the serial port.

To see low-level output on a second monochrome monitor, set

```
LowLevelDebug=mono
```

in MIL.INI. To direct low-level output to a serial port, connect a serial port to another computer running a telecommunications package and set

```
LowLevelDebug=com1
SerialDebugPort=1
```

in MIL.INI.

**Keyboards**

The MIL.INI file contains a new variable that allows you to specify what kind of keyboard you are using. PenPoint 2.0 Japanese supports the following keyboard types:

- USA 101-key (IBM AT) keyboard.
- IBM A01 Japanese keyboard.
- AX Consortium keyboard.
- Toshiba 3100 desktop keyboards.
- Toshiba 3100 laptop keyboards.

See MIL.INI for valid values for the **Keyboard** variable.

The value of **Keyboard** determines how the keyboard behaves in PenPoint 2.0 Japanese. To change keyboards, you must warm or cold boot. Swap booting does not change keyboard behavior.
MonoDebug

The only reason you need to set the MonoDebug variable is if you have a monochrome card, but you nonetheless want PenPoint to use the VGA screen for debugging output.

The description on page 44 in PenPoint Development Tools may be misleading, because it suggests that you need to set the variable even if you have a VGA card.

ENVIRON.INI

This section describes changes to ENVIRON.INI since PenPoint 1.0.

Locale

You can boot PenPoint 2.0 Japanese with a system locale different than its user locale. For example, you can boot with Japanese behavior and English strings in its user interface. This configuration helps you use PenPoint and test the Japanese version of your product without having to read Japanese.

See “GO batch file” on page 410 for more details on how system and user locales differ and how to switch locales.

A new variable named Locale has been added to ENVIRON.INI to represent the system locale. You should not specify a value for Locale yourself. Instead, use the GO.BAT or LOCALE.BAT batch files to specify locales.

If you specify a user locale while running either GO.BAT or LOCALE.BAT, the batch files create a variable named LocaleUser in your ENVIRON.INI. Do not modify this variable. Instead, call the batch files to specify system and user locales.

PenPoint uses LocaleUser to determine where to search for its initialization files APP.INI, SERVICE.INI, SYSAPP.INI, and SYSCOPY.INI. When Locale is USA, PenPoint uses _0\PENPOINT\BOOT\USA to find the required initialization files. When Locale is JPN, PenPoint uses _0\PENPOINT\BOOT\JPN.

Debugging character set

The DebugCharSet variable in ENVIRON.INI controls the character set of your debugging output. See “DebugCharSet” on page 398 for more information.

Shutdown and standby buttons

You can put shutdown and standby buttons on the Bookshelf at boot time by assigning values to two new variables, ShutDownButton and StandByButton.

The values of the variables indicate the position of the buttons in the Bookshelf.

Versions and trademarks

In PenPoint 1.0, the three variables Version, Trademark, and CommVersion had multiline strings, with text items separated by the vertical bar (|) symbol.
In PenPoint 2.0 Japanese, the version and trademark information is represented with single-part strings. Everything else is stored in a PenPoint resource file.

Version=2.0
Copyright=1992
CommVersion=1991-1992

Note that the Trademark variable has been replaced by the Copyright variable.

If your code depends on the PenPoint 1.0 strings, you must change the code to reflect the new values and variable name. GO discourages you from writing code that depends on these strings.

**Start application**

The variable used to define the default initial application, StartApp, has been removed from the default ENVIRON.INI. If you want to specify your own initial application, add a line to ENVIRON.INI defining the StartApp variable.

Its value should be the complete path and file name of the initial application. The file name must contain only ASCII characters.

**Autozoom**

The Autozoom setting has been removed from ENVIRON.INI. It is now stored in the resource file associated with the Bookshelf application. The resource file contains the name of the document that is to be automatically zoomed.

**BkshelfPath**

The BkShelfPath variable identifies the path to the default contents of the Bookshelf. When PenPoint 2.0 Japanese boots, it copies the contents of this directory into the Bookshelf.

Uncommenting the BkShelfPath line in by default ENVIRON.INI causes PenPoint to load the Help notebook and several sample documents into the main PenPoint notebook.

This description updates the description on pages 36 and 37 of the PenPoint Development Tools.

**Debugging flags**

Some common debugging flags are set in ENVIRON.INI with the DebugSet variable. You can set any debugging flag in DebugSet.

- /D*1 works only if you run the debug version of PenPoint 2.0 Japanese. It directs the heap manager to validate heaps after any heap allocations or deallocations. This validation degrades performance by about 15 percent and dramatically slows screen layout.
- /DD8000 sends a copy of the debugger stream to the file specified in the DebugLog variable in ENVIRON.INI. See “Viewing the debugger stream” on page 397 for details.
• /DB800 causes your PenPoint boot volume (the hard drive from which you booted PenPoint) or RAM (if you specified DebugRAM mode), to appear in the Connections notebook. Set this flag to copy files between your hard drive (or RAM) and the PenPoint file system.

Also, page 34 of PenPoint Development Tools says that you should modify \PENPOINT\BOOT\ENVIRON.INI to enable logging by uncommenting the line

```
#DebugSet =/D*1 /DD8000
```

You should make sure the first DebugSet line is commented out:

```
#DebugSet=/D*1
DebugSet=/DD8000 /DB800 /D*1
```

PenPoint ignores duplicate lines in initialization files.

**BOOT.DLC**

The file BOOT.DLC has moved from \2_0\PENPOINT\BOOT to \2_0\PENPOINT\BOOT\USA and \2_0\PENPOINT\BOOT\jPN.

Do not put comments in any .DLC files, including BOOT.DLC. Comments sometimes cause PenPoint to fail booting.

Where necessary, the version numbers for DLLs have been changed to 2.0. Compared to the 1.0 version, the 2.0 version of BOOT.DLC loads additional DLLs. The exact list of additional DLLs varies between locales.

If you have a .DLC file that refers to a PenPoint DLL, you must update the file to use the DLL's new version number. For example, the Notepaper App sample application uses NOTEPAPR.DLL. In 1.0, NPAPP.DLC contained these lines:

```
GO-NotePaper-V1(0) notepapr.dll
GO-NOTEPAPER_APP-V1(0) npapp.exe
```

In PenPoint 2.0 Japanese, NPAPP.DLC contains:

```
GO-NotePaper-V2(0) notepapr.dll
GO-NOTEPAPER_APP-V2(0) npapp.exe
```

**Interpreting Japanese file names**

Japanese names in the initialization files, such as SERVICE.INI and APP.INI, have English translations in the comments above them.

**Repeated lines**

Make sure you do not try to set a variable twice. PenPoint uses the first assignment if you have two lines trying to assign a value to a variable. For example, if your MIL.INI contains the lines:

```
ScreenType=Std480
ScreenType=SuperScriptII
```

PenPoint uses the Std480 screen parameters.
Printing to a spooler

The PenPoint SDK 2.0 Japanese includes a special printer service called PRSPOOL. Use PRSPOOL to print PenPoint files to a spool file on a DOS disk. You can later copy this spool file to a printer. This procedure lets you print a PenPoint document without a tablet computer and with no printer attached to your PC. Remember that end-user versions do not support printing to a spooler.

1. Make sure you load the Outbox services. Because printers create sections in the Outbox, you cannot create a printer with Outbox support.

2. Install PRSPOOL by uncommenting its line in SERVICE.INI.

3. Install a printer driver by uncommenting the appropriate line in your SERVICE.INI file. Alternatively, install the service by opening the Disk page of the Connections notebook. Select the Services view, and tap on an Install box to install service. HP LaserJet printers use the PCL service.

4. Turn to the Printers page of the Connections notebook. Create a new driver with the caret (\) gesture. Choose a driver in the pop-up list.

5. Enter a name for this virtual printer.

6. Enable the printer by tapping on the Enable box.

7. Turn to the document you want to print.

8. Set any special page layout properties (headers, footers, margins, and so on) by choosing Print Setup in the document menu.

9. Print the document by tapping on the Print command. You should see the Outbox icon change to full, then eventually return to empty.

10. Exit from PenPoint and go to the root of your PenPoint directories. The default root is \2_0 for PenPoint 2.0 Japanese.

11. The documents you printed will be named PROFILE, PROFILE_1, PROFILE_2, and so on in your root PenPoint directory. Print these from DOS by copying them to a port. For example, this line sends the file to the printer attached to LPT1:

   `copy PROFILE LPT1: /b`

   The /B flag tells DOS to use binary mode, which prevents DOS from interpreting print driver control characters as end of file markers.

If you print many documents, your PenPoint directory information may get out of sync. You may want to clean up your directory with a batch file like this:

```
# Delete any spooler files
del \PROFILE*.

# Clean out redundant entries in PENPOINT.DIR
psync /B /D \ /V
```

The arguments to PSYNC direct the utility to creates a backup PENPOINT.BAK file and lets you know what files are being cleaned up.
Long DOS file names

The PenPoint document model creates a directory for each file. Each embedded document is contained in a separate subdirectory within the directory that contains the parent document. This recursive structure could create DOS file names longer than the maximum of 64 characters.

See “Using short DOS path and file names” on page 391 for strategies on creating distribution disks without violating this 64-character limit.

Do not use CHKDSK /F

Do not use the DOS utility CHKDSK with the /F flag if your PenPoint file system contains DOS path names longer than 64 characters.

The DOS utility CHKDSK skips all the files whose path names are longer than 64 characters and marks the clusters used by those as lost. Running CHKDSK with the /F flag will free those erroneously marked clusters, thereby corrupting your file system.

PenPoint returns stsFSVolCorrupt when it tries to read this file system. Even worse, you may lose data before seeing this warning from PenPoint if those incorrectly freed clusters are allocated and used by other files.

You can use CHKDSK without any parameters to check for path names that are too long. To navigate to those files, you need a DOS utility to shorten the path names through renaming.

For example, say you have the following path name on a disk:

```
B:\2_0\PENPOINT\APP\MY_APP\STATNRY\MY_APP_Q\NOTEBOOK\...\DOC.RES
```

Running CHKDSK on B: yields the following output:

```
c:\>chkdsk b:
Errors found, F parameter not specified
Corrections will not be written to disk
1 lost allocation units found in 1 chains.
  512 bytes disk space would be freed
 1457664 bytes total disk space
  4096 bytes in 8 directories
 1453056 bytes available on disk
  512 bytes in each allocation unit
 2847 total allocation units on disk
 2838 available allocation units on disk
 655360 total bytes memory
  473856 bytes free
```

Running CHKDSK /F instead of CHKDSK would have erroneously freed the single allocation unit reported above.
Changes to QuickHelp

In PenPoint 1.0, you specified special characters like the GO gesture glyphs by changing the font to Symbol, and using the /F63 keyword.

In PenPoint 2.0 Japanese, you can specify a Unicode character representing the special character by using the \xhhhh where hhhh is a 4-digit hexadecimal Unicode value. GO has placed its gesture fonts in the Unicode corporate zone from 0xF6600 to 0xF700. The letter gestures share the same code as the corresponding letter, so the codes are scattered between 0x0041 and 0x005A. Look in the header file GLYPH.H for exact code assignments.

The keyword /F63 is no longer recognized in PenPoint 2.0 Japanese.

Working with different locales

You can boot PenPoint with different user and system locales as described in “GO batch file” on page 410.

Only you as a developer can take advantage of this locale switching behavior. GO will never ship an end-user system that supports mixed locales. Consequently, always do your final user testing with the same system and user locales.

Here are a few other things to note when you boot with a USA user locale:

- To enable kana-kanji conversion or romaji-kana conversion, you must install the KKC engine. You can install the engine turning to the Installed Software page of the Settings notebook, and tapping on the Install menu. The KKC engine icon has Japanese characters that say VACS VJE. To load the engine at boot time, add the KKC engine name to \2_0\PENPOINT\BOOT\USA\SERVICE.INI. Copy and paste the name from \2_0\PENPOINT\BOOT\JPN\SERVICE.INI

- To enable Japanese handwriting recognition, you must install the Japanese handwriting recognition engine.

Part 5 /
PenPoint
Architectural Reference
Supplement
Chapter 33 / Overview

427 About this supplement
   Intended audience
   Document structure
428 PenPoint 2.0 Japanese
   Fundamental changes
   New sample code
   General code and API changes

Chapter 34 / Class Manager

433 What's new
433 Tips and clarifications
   Using keys
   Don't use msgScavenged
   Posting msgDestroy
434 Corrections and errata
   ObjectSend()
   appVersion and minAppVersion
   Change in title
   Typographical errors

Chapter 35 / Application Framework

435 What's new
   Document recovery message
   Initialization DLL
   New and obsolete tags
437 Tips and clarifications
   Unimplemented flag for msgPrintGetProtocol
   Printed document and msgSave
   Class defaults for clsAppMonitor subclasses
   Page sequencing and msgAppMgrCreate
438 Corrections and errata
   msgSave
   Reactivating a document
   Getting attributes for many application directories
   Terminating a Document
   Handling msgAppTerminate
   Typographical errors

Chapter 36 / Windows and Graphics

441 What's new
   PANOSE typeface matching
   Unicode values for gestures and system UI
441 Tips and clarifications
   Filing window resources
   Receiving msgWinVisibilityChanged
   Windows and WKNs
442 Corrections and errata
   The current grafic
   Repaint
   Using a bitmap
   Typographical errors

Chapter 37 / UI Toolkit

445 What's new
   UI components with built-in KKC translation
   Text highlighting and "dirtying"
   Standard strings
   clsKbdFrame
   Acetate Layout and Markup classes
447 Tips and clarifications
   clsBorder tracks on pen down
   Progress bars
   XList handlers must handle msgGWinGesture
   Field change
   Bug in clsLabel
   Bug in clsToggleTable
448 Corrections and errata
   UI Toolkit programming details
   Incorrect table reference
   Providing custom backgrounds
   Typographical errors

Chapter 38 / Input and Handwriting Recognition

451 What's new
   Kana-kanji conversion class
   The character translator classes
   Return of translation alternatives
   Handwriting changes
   Letter practice removed
   Changed and obsolete gesture names
456 Tips and clarifications
   clsAnimSPaper metrics
   Transparent input
456 Corrections and errata
   Adding a filter
   Typographical errors

Chapter 39 / Text

463 What's new
   Gesture targeting
   Font substitution algorithm
   Hankaku/zenkaku implementation
   Unicode import type
   No white space correction in Japanese version
   Taboo and bunsetsu rules
   Using msgTextModify
465 Corrections and errata
   Typographical errors

Chapter 40 / The File System

467 What's new
   Stamped file system attributes
Chapter 41 / System Services

471 What's new
- String composition functions
- Getting the current locale
- Multibyte/Unicode conversion routines

474 Corrections and errata
- Ugetc and Uungetc bugs
- Renaming of 16-bit utility functions
  - cvt and fcvt
- HASH.H
- SYSTEM.H
- OSMemInfo, OSMemUseInfo, OSMemAvailable
- Typographical errors

Chapter 42 / Utility Classes

479 What's New
- Matching hiragana or katakana text
- Adding gestures to Quick Help strings
  - clsNotePaper changes

480 Tips and clarifications
- Cannot intercept export messages
- msgImportQuery can arrive twice
- New stream disconnected status
  - clsTable Bug
- Known bugs in the NotePaper component

Chapter 43 / Connectivity

483 What's new
- Finding, binding to, and opening a modem
  - Initialization
- Establishing a connection (outbound)
- Waiting for a connection (inbound)
- Transmitting and receiving data
- Terminating the modem service
  - clsModem messages

492 Corrections and errata
- Reading and writing with the serial port
- Predefined service managers
- Typographical errors

Chapter 44 / Resources

495 What's new
- Resource file utility routines
- New system preferences
- New resource group
- New and renamed string resource agents

496 Tips and clarifications
  - msgResWriteData does not copy pData
  - Saving bitmap editor resources

Chapter 45 / Installation API

499 What's new
- KKC engine installation

500 Tips and clarifications
- Other installation information

500 Corrections and errata
- Installation clarifications for production PenPoint
  - Erroneous Directory
  - Dynamic Link Libraries

Chapter 46 / Writing PenPoint Services

503 What's new

503 Tips and clarifications
- MIL services and other services
  - theServiceManagers
  - Responding to msgTrackProvideMetrics
  - Deinstalling dependent services and applications

505 Corrections and errata
- The Service Class and class instances
- Handling msgSvcOpenDefaultsRequested
  - In box and Out box changes

Chapter 47 / International Services and Routines

507 International and related header files

508 International routines
- Delimiting and hyphenation routines
- Time conversion routines
- Formatting routines
- Parsing routines
- Collation routines
- String conversion routines
- Character set conversion routines
- String compression routines
- Units conversion routine

512 Character conversion and testing macros
- Character flags
- External tables
Chapter 33 / Overview

This document provides material that supplements the PenPoint Architectural Reference manual published for version 1.0 of the PenPoint Software Developers Kit (SDK). It describes architectural concepts and API definitions and procedures that are new with both PenPoint SDK 1.0 and PenPoint SDK 2.0 Japanese. It also offers programming tips, suggests workarounds for known bugs, clarifies some concepts and procedures, and amends conceptual, procedural, and typographical errors found in the earlier manuals.

About this supplement

Intended audience

This book is intended for PenPoint application developers who are familiar with the two-volume PenPoint Architectural Reference or who have access to it. Ideally, you should read the Supplement with the earlier volumes at hand. This manual makes frequent references to these manuals, particularly when it corrects or clarifies them.

If you do not have copies of the version 1.0 manuals, you can still learn much that is useful and interesting to PenPoint application developers from this document, particularly the material new to PenPoint SDK 2.0 Japanese. But to get the full value of the information presented in the following pages, you should treat the Supplement as a companion document to its predecessors.

Document structure

The structure of Part 4: PenPoint Architectural Reference Supplement is simple. Each chapter after this Overview chapter is mapped to a part of the earlier PenPoint Architectural Reference. Thus Chapter 28 is entitled “The Class Manager,” the same title as Part 1 of the earlier document; Chapter 29 is entitled “The Application Framework,” and so on. The last chapter, “International Routines and Services,” covers functionality entirely new to PenPoint 2.0 so it has no counterpart in the version 1.0 manuals.

Within each chapter there are up to three major sections. The first section, “What’s New,” describes concepts and defines interfaces and functions that are new since the PenPoint 1.0 SDK. “Tips and Clarifications,” the second section, gives some suggestions on programming and clarifies areas that might have caused confusion. The final section, “Corrections and Errata,” catalogs typographical errors and amends sections in the earlier manuals that were inaccurate.
PenPoint 2.0 Japanese

Fundamental changes

The major difference between PenPoint 2.0 Japanese and earlier versions is that PenPoint 2.0 Japanese contains general modifications to support languages other than English and specific modifications to support the Japanese language. This support required three major changes:

- PenPoint expects strings to consist of 16-bit characters.
- Most text strings for display have been moved to resource files.
- Gestures are now Unicode values.

The following sections expand briefly on these changes. For a full description of these changes, please see the Part 2: PenPoint Internationalization Handbook.

PenPoint 2.0 Japanese supports only American English and Japanese. However, the modifications present in PenPoint 2.0 SDK Japanese provide most of the features necessary for supporting other languages in the future.

16-bit characters

Almost all strings in PenPoint 2.0 are represented by 16-bit characters, using the Unicode standard encoding. This global modification implies a number of other changes. For example, the CHAR type is 16 bits wide and all the U...() string functions of the standard C library expect 16-bit characters.

Text strings moved to resource files

Most text strings displayed in PenPoint 2.0 Japanese have been moved to resource files. There are currently two versions of each resource file in the PenPoint operating system; the file USA.RES contains American English strings; the file JPN.RES contains Japanese strings.

The resource files that PenPoint uses are determined by the setting of the Locale and LocaleUser environment variables in ENVIRON.INI. See Part 4: PenPoint Development Tools Supplement for more information on these variables.

While we have worked to ensure that all strings have been moved to resource files and translated to Japanese, a small number of strings might have escaped our notice. If you find one of these strings in the Japanese version, please notify GO Developer Technical Support.
**Gestures are now Unicode values**

Earlier versions of PenPoint encoded gestures as 32-bit IDs. In PenPoint 2.0 Japanese, gestures are encoded as 16-bit Unicode values. Unicode values further separate the character used for a gesture and its meaning.

If you use gestures, you must change the ID for each gesture to the Unicode for that gesture. The Unicode values for gestures and standard User Interface (UI) icons and symbols are in GLYPH.H.

**New sample code**

The PenPoint SDK 2.0 Japanese includes four new sample applications:

- Keisen Table Application (Japanese only), project name KEISEN
- Serial I/O Demo, project name SXDEMO
- Video Player, project name VIDPLAY
- UI Companion, project name UICOMP

Additionally, two samples that were previously released via CompuServe (LBDEMO and SAMPLMON) are now part of the sample code in the PenPoint SDK 2.0 Japanese.

There are also a number of changes to the 1.0 and 1.0.1 SDK samples. Most of them (with the exceptions of EMPTYAPP, HELLO, HELLOTK, BASICSVC and MILSVC) have had their text strings moved to resource files. (All of them have been ported, obviously.) All of the earlier sample code has also been updated to use the Bridging Package; the sample code runs under both the 1.0 and 2.0 Japanese SDKs.

**General code and API changes**

**Library changes**

PenPoint 2.0 Japanese contains a new library, INTL.LIB, which contains many of the functions that you use to store Unicode strings and to get information pertaining to the current locale.

Please see the documents shipped with the WATCOM compiler for changes in the PENPOINT.LIB file.

The library BRIDGE.LIB is empty in the PenPoint SDK 2.0 Japanese but is provided for makefile compatibility when using the Bridging Package. The Bridging Package allows you to compile your applications under both PenPoint 1.0 and PenPoint 2.0 Japanese. See the *PenPoint Bridging Handbook* for details.
New header files

The header files listed in Table 33-1 have been added to PenPoint SDK 2.0 Japanese. Descriptions of these files' contents occur in the appropriate chapter of this document.

New header files

<table>
<thead>
<tr>
<th>File</th>

</table>
**Name changes of data elements**

Table 33-3 presents some of the major name changes of data structures, constants, and variables since version 1.0 of PenPoint. As you can see from scanning the table, many of these name changes reflect the transition to Unicode. This list is not comprehensive; for instance, name changes of enumerated and defined values are not included.

</table>
Chapter 34 / Class Manager

What’s new

The Class Manager contains no new API, functions, or other features.

Tips and clarifications

Using keys

Readers should read Section 2.7 of the *PenPoint Architectural Reference* with the following caveat in mind: you must use unique constants for keys on classes created by distributed DLLs. The keys must be kept private, or others may be able to subvert or delete these classes. Particularly, do not use ObjWknKey as the key.

Many applications use a function pointer or pointer to a method table as a key when creating a class. This will cause a problem if the class is replaced or upgraded; the new key won’t match the old one, so class creation by the new DLL fails. The problem typically surfaces in distributed DLLs, because two versions of one can be running at the same time. It does not cause a problem when upgrading applications, because old and new versions of the application do not co-exist.

Don’t use msgScavenged

msgScavenged is an obsolete message. It is never sent by the Class Manager, and its message number is the same as msgFreeSubtask.

Don’t send or respond to this message. If you see msgScavenged in any debugging output, the actual message sent was probably msgFreeSubtask.

Posting msgDestroy

You can use ObjectPost to deliver messages at a later time, which is usually understood to be when the handling of the current message is complete. If, however, a system modal note is displayed during the execution thread of a message handler, all messages that are currently in the input queue are delivered. Thus a posted message is delivered before the current execution thread is unwound, and this case causes severe problems if the posted message is a destructive message, particularly msgDestroy.

PenPoint guarantees that a posted msgDestroy will not be delivered until the current execution thread has unwound from the current method handler. If you have code or logic that depends on a posted msgDestroy getting through while a system modal note is up, you will need to rethink your logic.

You should also carefully think about any other destructive messages you post which may get delivered before you unwind from the current execution thread.
Corrections and errata

ObjectSend()

Section 2.5.1 in PenPoint Architectural Reference contains the paragraph:

When you send a message with ObjectSend(), your code's task is suspended while waiting for the message handler to return. Your task resumes operation when the message handler returns.

These statements are not quite accurate. When you send a message with ObjectSend(), it is true that the sending task waits for a return status. However, it can still handle incoming messages while it is waiting. After it sends a message, ObjectSend() responds to any one of the following events:

- The return status from the called object, after which the calling task continues to the next line.
- A task-terminated indication, upon which the task continues to the next line.
- Any incoming ObjectSend() messages for objects owned by the tasks, which the waiting ObjectSend() dispatches. Specifically, the task's flow of control jumps to the method that handles the incoming message, returns a status, and resumes waiting for one of the three events.

appVersion and minAppVersion

The fields appVersion in OBJ_RESTORE and minAppVersion in OBJ_SAVE are incorrectly documented in the file CLSMGR.H. These 16-bit fields are no longer used by PenPoint and should not be used by your code.

Change in title

Rename the title of section 4.4.5 of the PenPoint Architectural Reference from "Getting a Class's Class," to "Getting a Class's Ancestor."

Chapter 35 / Application Framework

What's new

Document recovery message

The Application Framework includes a new clsApp message that enables your application to respond appropriately when its resource file is corrupted. The message is msgAppRecover; its pArgs argument points to the handle (DIR_HANDLE) of the resource file and returns STATUS.

When msgAppRestore fails, the application object self-sends msgAppInit. Respond to this message as you would when creating a document (initialize your instance data). clsApp then sends msgAppRecover to its descendants so that they can modify their instance data. It passes in the handle (DIR_HANDLE) to the resource file; if this handle is set to objNull, then the resource-file object was not found or was damaged.

clsApp descendants should respond to msgAppRecover by doing something to handle the error condition:

- They can reset their instance data to a state different than that of a just-created document.
- If they are passed a handle to the resource file, they can salvage as much data as they can. (Make sure that the handle is a valid object, and not objNull.)
- They can determine the cause of the error and display a message that is more informative than the standard PenPoint error message.
- They can simply return stsOK. By doing this, the data is lost, but the document can be re-opened without losing any embedded documents.

If descendents choose not to handle msgAppRecover, PenPoint displays a standard error message and does not recover the document. If this happens, the document cannot be re-opened and all embedded documents are lost.

Initialization DLL

To conserve memory, you can include an initialization DLL in your application's installation procedure. An initialization DLL typically contains code that your application needs to execute only once, such as code that creates UI components.

When installation occurs, the application monitor installs the initialization DLL in the loader database, runs it once and then deinstalls the DLL code before it installs the application code. The objects created by the DLL code are saved to a resource file before the installation of the application.
To use an initialization DLL in your application's installation, complete the procedure outlined here. The examples presented are from the UI Companion sample code (UICOMP):

1. In the application project directory, create a DLL source file named INIT.C. The entry point must be InitMain, not DLLMain. The code should perform some once-only initializations, such as building the application's UI components. In the application's MAKEFILE, you can link the INIT.C file to existing source files (see item 4, below).

2. Create a file called INIT.LBC and in it list all exported functions defined in the initialization DLL. In most cases, the only exported function is InitMain. Each line in the file has the form:
   
   ++entry-point.'company ID-project-major version(minor version)'

   Thus the sole entry in the UICOMP example of INIT.LBC is:
   
   ++InitMain.'GO-UICOMP-V1(0)'

3. Create a file that has the project name and an extension of .DLC (for example, UICOMP.DLC). This file expresses the dependencies between an application's executable file and that application's DLLs. Each line of the file pairs the name for a PenPoint executable or DLL with the DOS path to the corresponding executable or DLL file (relative to the application directory in \PENPOINT\APP). When PenPoint loads an application, it reads the .DLC file to determine which DLL files to load before it installs the application. The UICOMP.DLC file, for example, has these two lines:
   
   GO-UICOMP_DLL-V1(0) uicomp.dll
   GO-UICOMP_EXE-V1(0) uicomp.exe

4. Finally, include several lines in the application's MAKEFILE to specify the linker name, object files and libraries for the initialization DLL. The following example from UICOMP is typical:

   INIT_LNAME = GO-UICOMP_DLL-V1(0)
   INIT_OBJS = init.obj buttons.obj lists.obj menus.obj
   INIT_LIBS = penpoint resfile

   When you build the initialization DLL, the resulting DLL file (such as UICOMP.DLL) is placed in the same location as the application's executable. This is the default initialization DLL file. When installation begins, msgAMLoadInitDll is sent to the application monitor, which then looks in the application directory for the initialization DLL file. If you subclass clsAppMonitor, we recommend that your subclass not respond to msgAMLoadInitDll.

**New and obsolete tags**

New tags defined in APPTAG.H allow application writers to define the following text strings in a resource file:

- **tagAppMgrAppDefaultDocName** The default document name for the application. This appears in the Create menu and the Stationery notebook. If one is not assigned by the application, the **tagAppMgrAppFilename** string is used.
CHAPTER 35 / APPLICATION FRAMEWORK

---

**tagAppMgrAppCompany**  The name of the company creating the application.

**tagAppMgrAppCopyright**  The copyright date information for the application. The Unicode code point \x00A9 can be used for the copyright symbol in the string. (This is defined in GLYPH.H, but must be literally included in the string.)

**tagAppMgrAppName**  The name of the application or service. This appears in the Settings notebook and Installation time of the application. This is also the stamped name of the application when it is built. It is also the name that is entered in the APP.INI file.

**tagAppMgrAppClassName**  The type of executable being created: Application, Service, and so on.

The resource that contains these strings is resAppMgrAppStrings. Two Application Framework tags are now obsolete: tagAppMgrDefaultDocName and tagAppMgrDisplayedAppName.

---

**Tips and clarifications**

**Unimplemented flag for msgPrintGetProtocol**

Do not set the paginationMethod flag to prPaginationScale (PRINT_PROTOCOLS) when you send msgPrintGetProtocol. Pagination scale is not implemented and using it can block printing.

---

**Printed document and msgSave**

Developers should be aware that their documents, when activated by the print wrapper, receive a msgSave before msgAppOpen. This order, of course, is the reverse for a screen document. In summary, a printed document receives msgInit, msgRestore, msgSave and msgAppOpen, in that order.

---

**Class defaults for clsAppMonitor subclasses**

When you create a subclass of clsAppMonitor, set the following CLASS_NEW fields after sending msgNewDefaults to clsClass:

- **new.cls.pMsg**  Assign to this field a pointer to the method table for your subclass.
- **new.cls.size**  Set this to the size of your class instance data. This data is usually defined in some structure such as MY_INST_DATA. In this case, assign SizeOf(MY_INST_DATA) to the size field.
- **new.cls.ancestor**  Set this to the class from which you want your class to inherit its behavior: clsAppMon.
new.cls.newArgsSize  Set this field to the size of the structure that the msgNewDefaults and msgNew messages for class instantiation take as an argument. For some developers who have tried to subclass clsAppMon, this field has caused some confusion. This class has no _NEW_ONLY structure of its own and so no lamination takes place. When this situation occurs, you must provide the size of the ancestor class’s newArgs structure. clsAppMon’s ancestor is clsApp, so you assign sizeof(APP_NEW) to newArgsSize.

For most subclasses that you create, you may recall, you send msgNewDefaults and msgNew to clsClass. But when you create subclasses of clsAppMon and other application classes, send these messages to the application superclass clsAppMgr.

Page sequencing and msgAppMgrCreate

When you create a new document with msgAppMgrCreate, set the sequence field (APP_MSG_CREATE) to a sequential number, with the parent application being 0. Thus, if you want your document to be the first thing in the parent application, set sequence to 1. Page numbers are global sequence numbers and not attributes. PenPoint 2.0 Japanese keeps track of the number of children of a document, and can compute page numbers from that.

By the way, always set the renumber field to TRUE unless you are going to create another document with msgAppMgrCreate immediately afterward.

Corrections and errata

msgSave

Item 2 of the numbered list in section 8.2.5.2 of the PenPoint Architectural Reference, says that “clsApp sends msgResWriteObject to the resource file handle with the document’s main window as the object.” This is incorrect. clsApp sends msgResPutObject to the resource file handle.

Reactivating a document

Item 5 of the numbered list in section 8.2.6 of the PenPoint Architectural Reference (clsApp sending msgResReadObject to the resource file handle) is redundant and should be deleted.

Getting attributes for many application directories

Section 16.6 of the PenPoint Architectural Reference contains a few inaccuracies. First, you should not use msgAppDirGetNextInit in obtaining the attributes of document directories. Instead, use msgAppDirGetNext only.

You cannot specify a starting point in pFirst. PenPoint 2.0 Japanese sets and resets this member (and pNext) internally, regardless of what you assign to them. Instead, assign zero to the handle member and complete attrs, pName, and fsFlags as specified. After the last iteration through an application directory, msgAppDirGetNext returns pNull in pNext. Send the message once before going into the while loop.
because on the first iteration pNext is pNull. When it completes, msgAppDirGetNext returns stsOK if a directory is found and stsNoMatch if none is found.

In addition to the foregoing errors, the section states that "you must send msgAppDirGetNextInit to clsAppDir." Instead, you send msgAppDirGetNextInit and msgAppDirGetNext to an instance of clsAppDir.

Terminating a document

Sections 8.2.5 and 8.2.5.1 of the *PenPoint Architectural Reference* contain a few errors in the actual order of messages that occur when a user closes a document. The Notebook does not terminate a document by sending it msgFree. Also, the first few sentences of 8.2.5.1 give the impression that, after an application frees its objects, it calls its ancestor (clsApp), which sends msgAppSave to save these just-freed objects.

When a user closes a document, the following exchange of messages occur up to the point at which the document (application instance) itself receives msgFree:

1. The Notebook sends msgAppTerminate to the document; the document does not handle this message, but lets it percolate up to clsApp.
2. If msgAppTerminate is sent with pArgs of TRUE, clsApp self-sends msgFreeOK; if the document doesn't respond to this message, stsOK is assumed.
3. If the document responds positively (OK to free), clsApp self-sends msgAppSave. Descendents do not usually handle msgAppSave.
4. clsApp then self-sends msgDestroy.
5. As a result, the document receives msgSave and then msgFree.

The descriptions in section 8.2.5.1 from the third sentence to the end of the section are correct.

Handling msgAppTerminate

Section (13.4.1.2) of the *PenPoint Architectural Reference* can be deleted. msgAppTerminate is no longer sent to application monitors.

Chapter 36 / Windows and Graphics

What's new

PANOSE typeface matching

Clients using the font API (see section 26.12 in the PenPoint Architectural Reference) can now access GO's implementation of the PANOSE™ Typeface Matching System. The PANOSE system defines certain values for typographical attributes in various scripts, or writing systems (GO currently supports only Latin characters and kanji). These attributes include genre (display text, decorative, symbols, and so on), weight, monospace, contrast, ratio, slant, tool type, stroke type, and so on.

Developers of text-processing applications might find the PANOSE API useful. They must specify the required PANOSE values in structure PANOSE_MEM in a nibble format (two values per byte). A set of macros is provided for inserting and extracting these values. Two utility functions, PanoseToXDR and PanoseFromXDR enable the conversion of PANOSE numbers to and from their XDR representations, something you must do before filing away the numbers and reading them back in to your application. (XDR stands for eXternal Data Representation.)

When you have built your PANOSE_MEM structure, insert it into the structure SYSDC_FONT_DESC. Then pass a pointer to SYSDC_FONT_DESC when sending msgDCGetFontDesc and msgDCSetFontDesc. This causes msgDCGetFontDesc to fetch the DC's current font state and msgDCSetFontDesc to set the drawing context's current font state. These messages replace msgDCOpenFont.

The API definitions of the PANOSE structures, functions, macros, and definitions are in PANOSE.H. The API definitions of the drawing-context messages are in SYSGRAF.H. The definition of SYSDC_FONT_DESC is in SYSFONT.H.

Unicode values for gestures and system UI

The file GLYPH.H contains the Unicode values for the standard gestures and for common UI icons, symbols and other graphics.

Tips and clarifications

Filing window resources

If you file a window with msgResPutObject, that window must not have wsFileInline set in its style flags.

This is likely to concern you if you allow windows and components (such as reference buttons) to be embedded in your view and you also file those objects yourself. This is because the view files the objects too, and if wsFileInline is set, then you'll end up with two copies when you restore them.
The solution is that whenever you deal with a embedded window being added (normally in your response to msgWinInsertOK), make sure that the wsFileInline bit is turned off and the wsSendFile bit is set the way you want (usually on).

Receiving msgWinVisibilityChanged

msgWinVisibilityChanged is sent only when a window's wsVisible flag changed. When the window is extracted, msgWinIsVisible will return true, but the flag will not be changed unless you explicitly change it.

The comments for the message in WIN.H are not correct, because they imply that it will be sent on insertion. msgWinExtracted is sent on extraction, and then you can check the wsVisible flag.

Windows and WKNs

Developers should not create window instances with private or process well-known UIDs. The window system maintains a PenPoint-global database of all windows, and it expects each UID to be unique.

You can use private well-known UIDs for classes, not for instances.

Corrections and errata

The current grafic

The third paragraph of section 27.5.2 the PenPoint Architectural Reference states in the:

Note that clsPicSeg allocates the memory for the grafic-dependent data structure from the process heap, but it is up to the client to free it with OSHeapBlockFree().

This statement is not complete. By system default, if pData is pNull, clsPicSeg allocates the memory for the data structure from the local process heap (osProcessHeapId); otherwise, it uses the heap that you pass in. If you want to have the heap shared between your process and another process, assign osProcessSharedHeapId as the default heap when you create your clsPicSeg object (new.object.heap). You must call OSHeapBlockFree() to deallocate both osProcessHeapId and osProcessSharedHeapId.

Repaint

Section 28.2.3 in the PenPoint Architectural Reference begins with two sentences that describe an obsolete message:

A TIFF object repaints when it receives msgPicSegRedraw. Since a TIFF object isn't a window and isn't bound to one, you must pass in a drawing context as the message argument to msgPicSegRedraw.

These descriptions are no longer true. To repaint a TIFF object in its display list, a clsPicSeg object now must send it msgPicSegPaintObject, passing the TIFF object a pointer to PIC_SEG_PAINT_OBJECT. Specify the painting rectangle in logical units
and assign the UID of the drawing context or PicSeg object to the picSeg. Ignore all other fields.

**Using a bitmap**

Replace the second paragraph of section 28.1.1 with in the *PenPoint Architectural Reference* the following text:

Having created a bitmap, you usually want to get it on the screen in some form. One way to display a bitmap is to send an instance of clsBitmap msgBitmapCacheImageDefaults. This message takes a pointer to the SYSDC_IMAGE_CACHE structure used by msgDcCacheImage. clsBitmap fills in the structure with default values. You can send the bitmap msgDcCacheImage, and then send it msgDcCopyImage to have the sampled image stored in the bitmap rendered in the window.

You can also display bitmaps by creating instances of clsIcon or one of its descendants. See *Part 4: PenPoint Development Tools Supplement* for a step-by-step procedure. The UI Companion sample application uses this procedure to create an instance of clsIconToggle to display some bitmaps. The source code and comments are in \2_0\PENPOINT\SDK\INC\SAMPLE\UICOMP\UICOMP.C.

Chapter 37 / UI Toolkit

What's new

UI components with built-in KKC translation

clsField and clsIP objects have built-in support for translation of Japanese characters. If you want to create your own UI client of the kana-kanji conversion (KKC) character translator, see “The character translator classes” on page 453. If you want to subclass clsKCC to make your own interface to a KKC engine, see “Kana-kanji conversion class” on page 451.

Text highlighting and “dirtying”

clsLabel now provides a new flag and message with which you can give text selections one of two highlight styles. One highlight style (strong highlighting) is the standard dark grey rectangle with inverted text. The other highlight style (weak highlighting) encloses the selection in light grey and underlines it.

The new message is msgLabelProvideHighlight. Because clsLabel self-sends this message, you must create a subclassed instance of clsLabel. When you change the LABEL_NEW_ONLY structure defaults for this object, set the label.style.highlight flag to TRUE. (Set only the label.style.stringSelected flag to TRUE if you want only the standard highlighting style.)

During repaint operations (msgWinRepaint or msgBorderPaintForeground), clsLabel self-sends msgLabelProvideHighlight if the getHighlight or stringSelected flags are set. For each area to be highlighted, your subclassed object must specify the span information in a LABEL_SPAN structure and highlight style that clsLabel needs to draw the highlight graphic. (clsLabel ignores this highlight field if the stringSelected flag is set to TRUE.)

Next, put these LABEL_SPAN blocks in the spanBuf array of a LABEL_HIGHLIGHT structure, sorted by increasing index. Set the pSpans field of LABEL_HIGHLIGHT to point to the start of this buffer. When you send msgLabelProvideHighlight to clsLabel, pass it a pointer this LABEL_HIGHLIGHT structure. (clsLabel sets the SYSDC_RGB fields of the structure.)

Another new message, msgLabelDirtySpan, is related to msgLabelProvideHighlight. Send clsLabel this message, passing it a pointer to LABEL_SPAN, to have it dirty the area indicated by the span. The highlight information for the span is ignored.
**Standard strings**

STDSTR.H contains tag definitions for the standard UI Toolkit strings that were moved to resource files (such as “Ok,” “Apply and Close,” and “Contents”).

**clsKbdFrame**

A new class, clsKbdFrame, provides generalized behavior for simulated keyboards. It supports input filtering and the queuing of character events. PenPoint’s virtual keyboard and its Unicode Browser, for example, make use of clsKbdFrame. The immediate ancestor of clsKbdFrame is clsFrame. API definition for clsKbdFrame is in KBDFRAME.H.

**Acetate Layout and Markup classes**

Two classes have been added to PenPoint to increase the markup functionality of clsNotePaper: clsAcetateLayout and clsMarkup. Essentially, clsMarkup implements the transparent, scalable, and rotatable data-drawing layer, and clsAcetateLayout overlays an instance of clsMarkup on top of an application window. You can also use clsAcetateLayout to lay one window over another, thereby enhancing gesture handling.

**Using clsMarkup and clsAcetateLayout together**

When you want to add a markup layer to your application, you can use clsMarkup and clsAcetateLayout in a complementary way. clsAcetateLayout synchronizes the scrolling of a clsMarkup window that is layered over a client application window. It also handles document embedding so that documents are embedded only in the client window.

You can think of clsAcetateLayout as an intermediate layer in the window hierarchy. It mediates between the clsMarkup view and the application’s own view. clsAcetateLayout treats the application window as its client (in this context, a client is a window that is subordinate to the acetate layout in the window hierarchy).

To implement this behavior, insert the instances of clsAcetateLayout and clsMarkup when your application handles msgAppOpen. After creating the application’s scrolling window, instantiate the Acetate Layout, after setting its client field to the scrolling window. The Acetate Layout, in turn, has as its child the application’s view (that is, the Opaque View) and the Markup View, layered so that the Opaque View lies below the Markup View.

**clsAcetateLayout**

When you want to lay a window atop another window, you must typically put up with a lot of drudgery to handle pass-through of gestures and to synchronize the behavior of the two windows. clsAcetateLayout enables an application to implement a markup overlay atop its window without having to implement gesture and event pass-through or graphical markup.
As a subclass of clsCustomLayout, clsAcetateLayout allows an application to place and correctly lay out a client window (usually a markup layer) atop the application window. To synchronize the two windows, it handles the messages described in Table 37-1.

### clsAcetateLayout synchronization messages

### Tips and clarifications

#### clsBorder tracks on pen down

clsBorder doesn’t start tracking until it receives msgPenDown. If your application consumes msgPenDown as part of a press gesture (to create a move icon, for example), it must self-send a new msgPenDown, which tells clsBorder to start tracking.

#### Progress bars

When advancing a progress bar, you must advance it by an amount greater than zero, or your application may page fault.

#### XList handlers must handle msgGWinGesture

If a gesture window has timeout events enabled, and a hold timeout is initiated by the user, the gesture window converts the inputHoldTimeout event directly into a msgGWinGesture, rather than going through the normal protocol of sending out an XList that will get self-converted to a gesture. If your application is processing XLists rather than gestures, you must add a handler for msgGWinGesture.
**Field change**

As a result of better hand printing recognition, there is a change in FIELD.H related to character box memory. \texttt{fstBoxMemoryFour} is replaced with \texttt{fstBoxMemoryTwo}, which uses two characters of box memory. Existing code that uses \texttt{fstBoxMemoryFour} will still compile; however, it will only use two-character box memory.

**Bug in clsLabel**

After you create a label object, \texttt{clsLabel} resets the \texttt{label.style.infoType} field to \texttt{lsInfoString}. This causes problems particularly if you had earlier set \texttt{infoType} to \texttt{lsInfoStringId} so that you could read strings from a resource file; attempts to get new strings for the label object by sending \texttt{msgLabelSetStringId} do not succeed. Until this bug is fixed, work around it by setting the \texttt{label.style.infoType} field to \texttt{lsInfoStringId} before sending \texttt{msgLabelSetStringId}.

**Bug in clsToggleTable**

Instances of \texttt{clsToggleTable} have handlers that override certain \texttt{clsControl} messages. As \texttt{clsControl} defines it, four of these messages (\texttt{msgControlGetDirty, msgControlSetDirty, msgControlGetEnable} and \texttt{msgControlSetEnable}) take as \texttt{P_ARGS} a pointer to a 16-bit \texttt{BOOLEAN} value. But \texttt{clsToggleTable} defines the \texttt{P_ARGS} for these same messages as a pointer to a \texttt{U32} data type, bits of which it reads or toggles before returning the bitmask to the caller. Page faults can occur as a result of this discrepancy, particular with the \texttt{msg...Get...} messages.

As a workaround for \texttt{msgControlGetDirty} and \texttt{msgControlGetEnable}, declare a \texttt{U32} variable for the return value and pass a pointer to it. For \texttt{msgControlSetDirty} and \texttt{msgControlSetEnable}, just be aware of the discrepancy when you send these messages to \texttt{clsToggleTable}.

**Corrections and errata**

**UI Toolkit programming details**

The first paragraph of section 31.5.4 in the \textit{PenPoint Architectural Reference} suggests that you can create your application's UI in a separate INIT.DLL and when the application's `DLLMain` routine is called by the Installer, create the UI.” The entry point for INIT.DLL should be named \texttt{InitMain}, not \texttt{DLLMain}; \texttt{DLLMain} gives INIT.DLL its own process.

For information on creating an initialization DLL for your application, see “Initialization DLL” on page 435 of this document.

**Incorrect table reference**

On the top of page 386 of \textit{PenPoint Architectural Reference} (section 34.4.2) the definition of the \texttt{constraint} field refers to Table 34-2. It should be Table 34-3.
Providing custom backgrounds

The description of the BORDER_BACKGROUND fields in section 33.4.5 in the PenPoint Architectural Reference omits the borderInk field. The value you assign to this field specifies the color of a graphic object’s bordering line. Typical values are color constants such as bsInkGray66 and bsInkBlack (the default).

TABLE 37-2
Chapter 38 / Input and Handwriting Recognition

What's new

Two sections in this chapter present information on two new character-translation components: the kana-kanji conversion class (clsKKC) and the character-translation classes, clsCharTranslator and clsKKCCharTranslator. The information in these sections pertain to developers who:

- Want their application to handle text entry, particularly direct text entry ("The character translator classes").
- Want to write their own classes to support kana-kanji conversion ("Kana-kanji conversion class" and "The character translator class").
- Want to implement their own KKC engine ("Kana-kanji conversion class").

Kana-kanji conversion class

The kana-kanji conversion class (clsKKC) provides default superclass behavior for kana-kanji conversion (KKC) engines. PenPoint's KKC engine, developed for PenPoint 2.0 Japanese, is based on this superclass. clsKKC inherits from clsService; KKC engines are implemented as services. Table 38-1 shows the relationship of clsKKC and the other classes related to translation of Japanese characters.

The API defined in KKC.H is primarily for developers who want to port exiting KKC engines to PenPoint 2.0 Japanese. In PenPoint, all KKC engines inherit from clsKKC. This class provides substantial default behavior for its descendents, thereby simplifying the work of porting.

Developers may also want to be direct clients of a clsKKC service and provide their own user interface to the conversion engine. Although this is possible, the character translator API for KKC (defined in CHARTR.H and KKCC.H) already provides a rich, high-level, international protocol and a sophisticated user interface that is build into objects of clsField and clsIP.

The PenPoint KKC engine has a RKC (romaji-kana) component that converts romaji into hiragana characters as they are typed or written. Then, given the proper gesture or keyboard command, the engine converts the hiragana or katakana characters in the proximate bunsetsu (phrase context) into a list of kanji alternatives for each kana character. It presents these alternative characters to the user in a pop-up window.
Generally, clsKKC and its subclasses operate by processing data contained in an XList. For KKC engines, an XList must contain only two types of elements, xtText and xtKKCSpan. The xtText elements contain unconverted text and xtKKCSpan elements hold text that has already been converted.

A KKC span in an XList contains, in addition to the converted text, information such as conversion alternatives and the decomposition of text into stem and ending. While there can be multiple conversion alternatives associated within a given span, only one of them can be the display choice.

A KKC engine service can always construct a display string from the XList. The display string consists of the ordered concatenation of each xtText element and each xtKKCSpan display choice for that element. The engine operates on the XList by specifying indices into the display string.

The API definition in KKC.H provides many more details about using clsKKC interfaces, both for porting purposes and as a client. For information on writing services, refer to Part 13 of the Penpoint Architectural Reference. For information on using services, see Chapter 94 of Part 10, “Connectivity.” If you are interested in porting KKC engines, you can contact GO Technical Support to obtain a copy of the “KKC Porting Kit.”

</table>

The character translator classes

Character translators assist in the translation of characters from one set to another and in the presentation of translation alternatives to users. Working together with their client UI components, character translators create the user interface for translations of character sets. They also act as intermediaries between their UI clients and the engines that perform the character-set conversions.

PenPoint SDK 2.0 Japanese has two new classes related to character-set translation. The abstract class clsCharTranslator specifies the standard interfaces and implements the standard methods for the translations. It inherits from clsObject.

Because clsCharTranslator is an abstract class, only a subclass of it can realize the latent functionality for a particular character set. PenPoint SDK 2.0 Japanese provides the KKC character translator class for this purpose. clsKKCCharTranslator is a subclass of clsCharTranslator; objects of this class act as clients to kana-kanji conversion engines through interfaces defined in clsKKC.

The sketch to the right depicts the relationship of these classes. The API definition for clsCharTranslator is in CHARTR.H. The API definition for clsKKCCharTranslator is in KKCCCT.H.
Creating a client of KKC character translator

Because a character translator requests gesture information, its clients usually are instances of clsGWin or one of clsGWin’s subclasses (although, strictly speaking, they don’t need to be). Client objects exchange messages with the KKC character translator class, clsKKCCharTranslator (and, by inheritance, with clsCharTranslator). The KKC character translator requests translation services from the KKC conversion-engine class (clsKKC) and receives back translation alternatives, which it forwards to the client.

Developers who want to implement their own UI interface for kana-kanji character conversion in an application must set certain fields in their client object’s _NEW_ONLY structure that derive from clsGWin. Then they must have their client object observe a specific protocol.

During msgInit, every instance of clsGWin (or one of its subclasses) can create a character translator that handles translation requests. You must first indicate that you want a translator created by setting the new.gwin.style.useCharTranslator field TRUE. Then assign to new.gwin.charTranslateLocaleId field the locale identifier (LOCALE_ID) for the translator. If you specify no locale ID (by setting charTranslateLocaleId to zero), clsGWin creates a translator appropriate to the system locale. The default translator for Japan (locJpn) is an instance of clsKKCCharTranslator.

Rather than generalizing the protocol for all possible client objects of clsGWin, we can describe the protocol as a client object of clsIP actually implements it:

1. The user writes a few kana characters in an insertion pad, then requests KKC with the right up -l gesture. When the pad receives the gesture, it self-sends the message msgCharTransGesture.

2. Rather than handling the message itself, clsIP allows clsGWin to handle the message. In turn, clsGWin sends the message to the character translator it created when it responded to msgInit. Again, for PenPoint SDK 2.0 Japanese, the default translator is an instance of clsKKCCharTranslator.

3. When the character translator (an instance of clsKKCCharTranslator) receives the gesture information, it determines whether the gesture is relevant to character translation. Since the right up -l gesture explicitly requests KKC, it sends the message msgCharTransGetClientBuffer to the client (clsIP) requesting a portion of its buffer.

4. The client sends the requested characters in response to msgCharTransGetClientBuffer.

5. The translator communicates with clsKKC, the front-end to the actual service that provides KKC. In this case, a translation is needed, so the translator sends msgCharTransModifyBuffer with the translation to the client.
Using information sent with `msgCharTransModifyBuffer`, the insertion pad updates its internal buffer and user interface to display the translated character. Note that the translated character is highlighted. The `P_ARGS` sent with `msgCharTransModifyBuffer` also contains highlighting information. See Part 6: PenPoint User Interface Design Reference Supplement for details on how character highlighting should behave during KKC.

The user then requests a list of alternatives by tapping on the highlighted character. The insertion pad self-sends `msgCharTransGesture`, again allowing the message to be handled by `clsGWin`.

The translator receives the message from `clsGWin` and queries `clsKKC` for character alternatives. It also asks the client where the character alternatives pop-up box should be placed by sending `msgCharTransProvideListXY`. The insertion pad calculates the coordinates of the upper-left corner of the pop-up box. The pop-up box should appear directly below the original character.

If the user selects an alternative from the pop-up box, the translator sends `msgCharTransModifyBuffer` to the client. The insertion pad should then update its buffer and user interface.

When the user taps `OK` to dismiss the insertion pad, the pad should self-send `msgCharTransGoQuiescent` to synchronize the character counts between the text view and the character translator. This step ensures the correct setting and clearing of the weak and strong character highlights.

The description above does not exhaust the messages involved in the character translation protocol. For example, it did not mention any of the messages that support keyboard input. These are the most important messages involved in the protocol:

The client should self-send the following four messages when appropriate. However, the client should not define a method to handle the message. Rather, the client should allow the message to be passed up to `clsGWin`.

- Self-send `msgCharTransKey` each time the user presses a key.
- Self-send `msgCharTransChar` each time the user edits an existing buffer (for example, when the user inserts or deletes a character). As the user writes new characters, you normally do not send this message until the user makes the translation gesture. However, when the user is typing, you send each character with this message.
- Self-send `msgCharTransGoQuiescent` to cancel the current translation. When the user taps outside an insertion pad, for example, `clsIP` self-sends `msgCharTransGoQuiescent`.
- Self-send `msgCharTransGesture` each time the user makes a gesture on your text.
The client should respond to the following messages sent by the character translator:

- **msgCharTransModifyBuffer**, which contains information on how to translate characters. The client should respond by updating your text buffer and user interface, including updating strong and weak highlighting. The character translator passes you a CHAR_TRANS_MODIFY structure.

- **msgCharTransGetClientBuffer**, which asks your window instance for some text from the client's buffer. Pass the requested text to the character translator as part of a CHAR_TRANS_GET_BUF structure.

- **msgCharTransProvideListXY**, which asks the client where to put the character alternative list. The client should compute the coordinates so that the popup box appears below the original character.

### Highlighting information

When a character translator sends **msgCharTransModifyBuffer** to a client, that client should examine the highlight fields in CHAR_TRAN_HIGHLIGHT. It should begin weak highlighting from **weakStart** and extend it for **weakLen**. Strong highlighting should begin from **strongStart** and extend for **strongLen**. Previous highlighting information is provided in **oldWeakLen**, **oldStrongStart** and **oldStrongLen**.

Some of the length fields can hold 0, indicating that highlighting can be removed. For example, if there is no strong highlighting required, **strongLen** is 0. The client may need to clear any old highlighting that is specified by the **old...** fields. Note that if the character translator just wants to change highlighting information, it will send this message with the **delete** and **insert** lengths of CHAR_TRAN_HIGHLIGHT set to 0, but with the highlight information changed.

### Class Character Translator messages

<table>
<thead>
<tr>
<th>Message</th>
<th>Takes...</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>

<td>P_CHAR_TRANS_NEW</td>
<td>CHAR_TRANS_NEW is passed in with all arguments set to zero (or pNull, as appropriate).</td>
</tr>
<tr>
<td>msgNew</td>
<td>P_CHAR_TRANS_NEW</td>
<td>Creates a character translator. If pArgs-&gt;charTrans.pBindings is pNull, the default bindings (from the system preferences) are used.</td>
</tr>
<tr>
<td>msgCharTransKeyEvent</td>
<td>P_CHAR_TRANS_KEY_EVENT</td>
<td>Clients self-send this message to notify a character translator of a keyboard event. If the character translator does not use the key, it returns an error message. Otherwise, the client should not use the key because it is being used by the translator.</td>
</tr>
</tbody>
</table>
### clsCharTranslator messages

<table>
<thead>
<tr>
<th>Message</th>
<th>Takes...</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>msgCharTransChar</td>
<td>P_CHAR_TRANS_CHAR</td>
<td>The client self-sends this message to notify a character translator of a character about to be changed. The client then receives back msgCharTransModifyBuffer; it should examine the arguments passed it in P_CHAR_TRANS_MODIFY to determine exactly what the character translator wants to have changed.</td>
</tr>
<tr>
<td>msgCharTransSetMark</td>
<td>P_CHAR_TRANS_SET_MARK</td>
<td>The character translator sends this message to the client to notify that it (the translator) is beginning to collect characters at the given position.</td>
</tr>
<tr>
<td>msgCharTransGetClientBuf</td>
<td>P_CHAR_TRANS_GET_BUF</td>
<td>The translator sends this message to the client to request a copy of the characters in the client’s buffer. The client should copy length characters from startPosition into buf. If fewer than length characters are available, the client must end the string that it copies with a null character.</td>
</tr>
<tr>
<td>msgCharTransModifyBuffer</td>
<td>P_CHAR_TRANS_MODIFY</td>
<td>clsCharTranslator (or a subclass of it) sends this message to the client to tell it how to modify its buffer. The client should delete length characters beginning at first and replace them with bufLen characters from buf. The client should also adjust its highlighting according to the values in the highlight structure (CHAR_TRANS_HIGHLIGHT). See “Highlighting information” on page 456.</td>
</tr>
<tr>
<td>msgCharTransProvideListXY</td>
<td>P_CHAR_TRANS_LIST_XY</td>
<td>Sent to the client to request the X-Y coordinates for the top left corner of the pop up menu for the alternatives list. Current UI guidelines dictate that the client should compute the coordinates so that the menu pops up below the character. The coordinates are in relation to the root window.</td>
</tr>
<tr>
<td>msgCharTransListActivate</td>
<td>P_CHAR_TRANS_LIST_XY</td>
<td>Self-sent to subclasses to activate the alternatives list. pArgs-&gt;charPosition has the character position in the client’s buffer and pArgs-&gt;xy has the root window X-Y coordinates for the list.</td>
</tr>
</tbody>
</table>

#### Return of translation alternatives

The text subclasses for handwriting translation, clsXText and clsXWord, include new flags that request the translation object to return information in addition to the best-guess translation. Most other translation flags (hwxFlags) govern which of the various scoring rules the translation object applies when it chooses the best translation. The new translation flags specify which additional data that object is to return:

- **xltReturnAltWords**: Return the highest ranking alternative word translations.
- **xltReturnAltChars**: Return the alternative characters in each position of the best-guess translation.
- **xltReturnStrokeIds**: Return the strokes that belong with each character of the best-guess translation.
You can set one or more of these flags in the _NEW structures for both clsXText and clsXWord (pArgs->xlate.hwxFlags) when you create the translation object. You can also set and clear them with msgXlateSetFlags and msgXlateClearFlags any time before the translation object has received the first stroke from the scribble. To find out the current hwxFlags settings, send msgXlateGetFlags to the translation object.

To get the information on alternatives, send msgXlateData, to the clsXText or clsXWord object as usual; pass it via P_XLATE_DATA an identifier of the heap from which memory is to be allocated for the Xlist elements. The translation object returns the requested information in linked Xlist elements (see Table 38-1).

- **xltReturnAltWords** The translation object returns, along with the best-guess translation for a word (as defined by Locale), a list of alternative word translations, ranked in order of their scores. The Xlist element requested by this flag is of type xtTextAltWords, which points to a WORD_LIST structure that contains the alternative word choices.

- **xltReturnAltChars** The translator returns a list of all alternatives for each of the characters in the best-guess word translation. Each alternative's plausibility is determined by the translator's shape matcher. The Xlist element requested by this flag is of type xtTextAltChars, and it points to a XL_CHAR_LIST structure that holds alternative character information.

- **xltReturnStrokeIds** The translator returns the pen strokes that underlie every best-guess and alternate character in the word translation. The Xlist element requested by this flag is of type xtTextStrokeIdList, and it points to a structure of XL_STROKE_ID_LIST.

If you set the xltReturnStrokeIds flag, you might also want to set xltReturnAltChars. You can use the stroke-count information returned via the xtTextAltChars Xlist element to interpret the stroke IDs returned via the xtTextStrokeIdList Xlist element.

The linked list of Xlist elements returned for each type of alternative information (word, character, and stroke ID) is often extended beyond a single translated word. The translator can link that word's sequence of Xlist elements with the Xlist elements returned for the next translated word.

All hwxFlags are defined in the header file for the abstract superclass, clsXtract/clsXlate (XLATE.H).

**Handwriting changes**

Handwriting customization has been removed as a feature from PenPoint 2.0 Japanese. Because this version of PenPoint does not use the GOWrite engine, there is no implementation of handwriting customization.

The header file HWCUSTOM.H remains, as does the hook to the Customize... button on the Settings notebook's Installed Handwriting page. ISVs who wish to use customization may write their own clsFrame descendants conforming to the HWCUSTOM.H header; customization will proceed as it did in PenPoint 1.0 and...
PenPoint 1.01. But the customization classes that GO provided in PenPoint 1.0 and PenPoint 1.01 are not part of PenPoint 2.0 Japanese.

**Letter practice removed**

The header file HWLETTER.H remains, as does the hook to the Practice... button on the Settings notebook's Installed Handwriting page. ISVs who wish to use letter practice may write their own clsFrame descendants conforming to the HWLETTER.H header; letter practice will proceed as it did in PenPoint 1.0 and 1.01. But the letter practice classes that GO provided in PenPoint 1.0 and 1.01 are not part of PenPoint 2.0.

</table>
Tips and clarifications

clsAnimSPaper metrics

Instances of clsAnimSPaper will crash (divide by zero) if they are redrawn with the delay and interstroke metrics both set to zero. To avoid the problem, ensure that the interstroke is always non-zero whenever the delay is zero.

Transparent input

If you want transparent input (inputTransparent set), you must make sure that inputLRContinue is clear.

Corrections and errata

Adding a filter

Section 53.3.2 in the PenPoint Architectural Reference on InputFilterAdd() shows an incomplete prototype and does not describe two of the function’s arguments (page 571). The actual prototype is:

```c
STATUS EXPORTED InputFilterAdd(
    OBJECT newFilter,
    INPUT_FLAGS inputEventFlags,
    FILTER_FLAGS filterFlags,
    U8 priority
);
```

The arguments are defined as follows:

newFilter  The UID of the filter object to be placed on the filter list.

inputEventFlags  By setting flag bits in this U32 field, you indicate those input events (and related messages) that you want your filter to handle. Examples of input events that you can specify are inputTip, inputEnter, and inputTap. See INPUT.H or Table 53-2 in the PenPoint Architectural Reference for a list of these flags.
**filterFlags**  The flags set in this U32 field control event distribution to your filter. Currently developers can set only one flag, **iflSendMyWindowOnly**. By setting it you instruct the input system to withhold messages from the filter unless the event happened in the filter or in one of that filter's window children or window ancestors.

**priority**  A value from 0 to 255 that indicates the relative priority of the filter. This value specifies the position of the filter in the list.

Chapter 39 / Text

What's new

Gesture targeting

In PenPoint 2.0 Japanese, clsTextView targets gestures differently than in other PenPoint versions. In PenPoint 2.0 Japanese, where a gesture would expand its target to a word (bunsetsu in the Japanese version), the gesture targets the character where the hotpoint of the gesture was. As in PenPoint 1.0x or PenPoint 2.0 running with U.S. behavior, however, if the gesture is over a selection, then the selection is the target.

Table 39-1 lists the gestures that have new (non-bunsetsu) targets in PenPoint 2.0 Japanese. The Like-Type gestures select similar contiguous characters (that is, those characters that are all kana or all kanji) instead of following the standard bunsetsu selection rules.

</tbody>
</table>

1. In PenPoint 2.0 Japanese, these selection gestures have additional behavior. Making a right bracket gesture before a selection is equivalent to a single tap (select character); making a left bracket gesture after a selection is equivalent to a double tap (select word).

In terms of API, a new atom type, atomLikeType, enables the selection of a span that conforms to the international style intlDlmWordStyleWord. (This new atom type is in TXTDATA.H.) In addition, move and copy operations for PenPoint 2.0 Japanese now target to the character instead of to the word.
Font substitution algorithm

When users now type or write in a Latin or non-Latin font, and a certain character is missing, the PenPoint 2.0 Japanese operating system substitutes a character from the closest matching font. This substitution is based on an algorithm that uses the PANOSÉ™ Typeface Matching System.

Each font has a selection of Unicode points that identify its characters, which are mapped to glyphs. If a user-requested glyph is not available in a logical font, the font-substitution algorithm uses the PANOSÉ number of that font to get an ordered list of related fonts, sorted by distance from the original font. It scans the fonts in this list until it finds the glyph, and then substitutes it.

With the Heisei or Mincho fonts selected, PenPoint 2.0 Japanese converts typed or written Latin letters and numbers to the closest matching Latin font, and displays proportionally spaced (hankaku) glyphs. If you don't want this substitution, you can select the appropriate option from the Convert menu or make the right arrow gesture to convert the Latin Unicode points to the Compatibility zone equivalents that display full-width monospaced glyphs. Typing or writing kanji or kana with a Japanese font selected results in no substitution. The full-width (zenkaku) glyphs are used for display.

Hankaku/zenkaku implementation

In clsTextView, all Latin letters including the space character (0x0020) and the Latin punctuation characters (period, question mark, and so on) default to their hankaku form. All other kana, kanji, and Japanese punctuation characters default to their zenkaku form. However, the keyboard driver for the JPN keyboard has mode switches with which you can control the kinds of characters generated. In addition, users can convert characters to all hankaku or all zenkaku via the Gestures or MiniText menus.

Unicode import type

MiniText now supports the Unicode file type (specified in FILETYPE.H). If the import file has the .UNC extension, the code points will be interpreted as Unicode. Other imported files are treated as either 7-bit RTF or Shift-JIS depending on the header. If the file starts with a valid RTF header, it will be read as 7-bit RTF; otherwise it will be treated as a Shift-JIS file. Because there is no standard for exporting 8-bit (that is, Shift-JIS) characters in RTF format, PenPoint no longer exports RTF in the 2.0 Japanese version; it does export text as Unicode and Shift-JIS.

No white space correction in Japanese version

Because Japanese doesn't delimit words with spaces, PenPoint 2.0 Japanese does not correct white space during:

- Move/copy and delete operations.
- While accepting translated text from either an embedded IP or a floating IP.
Taboo and bunsetsu rules

Lines breaks follow taboo processing rules for Japanese text. In addition to the English or European characters that cannot start or end a line, extra Japanese characters have been added that cannot start or end a line. For example, you can't end a line with an open bracket ([) and you can't start a line with a close bracket (]).

Word selection follows the Japanese rules for selecting bunsetsu.

Using msgTextModify

Because text views set the gWin style.useCharTranslator to TRUE, the text view character count must be synchronized with the character translator to ensure the correct setting and clearing of the weak and strong highlights. Always end a KKC session with msgCharTransGoQuiescent before you send a msgTextModify message to a text view. To end the KKC session, send a message similar to the following:

ObjectCallWarn(msgCharTransGoQuiescent, self, pNull);

In this message, self is the text view object. clsGWin handles this message by self-sending messages to clear the weak and strong highlights before the msgTextModify message can change the character counts. Character offsets are thus synchronized between the character translator and the text view object.

The text view itself ends the KKC session in response to gestures that add and delete characters. See CHARTR.H for more information on the character translator.

Tips and clarifications

Open handles on files

When your application has finished with a file or directory, it must free the handle on the node, especially if the node is on a floppy or other removable media. If you don't do this and a user ejects the disk, they will continually get a number of prompts for the disk, which cannot be cancelled.

msgFSSetSize does not reposition file pointer

If you use msgFSSetSize to truncate a file, the file position will not be changed during the call. To write at the end of the file, you must seek to the end of file.

StdioStreamUnbind

If you use StdioStreamBind() and a read, a subsequent StdioStreamUnbind() will change the file pointer. Thus, if you plan to rebind and pick up where you left off, you must get the current file location with an ftell() before unbinding so you can reset the file pointer after rebinding.

Memory mapped file problem

It's not a good idea to implement a memory-mapped file in a document directory. Why? Let's say someone launches a document from an extended bookshelf on a floppy disk. You start writing to the memory map, and then the user ejects the floppy disk. This causes the memory manager to choke with a page fault.

Because all application directories live on theSelectedVolume, memory-mapped files in the global application directory are still okay. This seems to be the standard implementation for memory-mapped files anyway, such as a shared PIM database.

Corrections and errata

Locators

Section 70.6 in the PenPoint Architectural Reference describes implicit and explicit locators, but does not mention flat locators. Flat locators hold an entire locator string in a linear (flat) structure. In PenPoint 2.0 Japanese, flat locators are defined by structure FS_FLAT_LOCATOR and are used by browser objects (clsBrowser). See Chapter 80 for descriptions of how instances of clsBrowser use flat locators.
**Iseek() and msgFSSeek**

The WATCOM C Library Reference for PenPoint states that when calling Iseek(), the requested file position may be beyond the end of the file.

This is not true in PenPoint 2.0 Japanese. When the requested position is beyond the end of file and the file pointer is currently positioned at the end of file, both Iseek() and msgFSSeek return errors. When the requested position is beyond the end of file and the file pointer is not positioned at the end, they move the file pointer to the end and do not return an error status.

The workaround for this problem is to use chsize() or msgFSSetSize to extend the file, then use Iseek() or msgFSSeek.

Chapter 41 / System Services

What's new

String composition functions

PenPoint SDK 2.0 Japanese has added six new routines to its Compose Text package of functions that allow you to compose formatted text strings. The new functions allow the construction of counted strings (as opposed to null-terminated ones) and enable you to compose strings using resource files. These functions are:

- SComposeTextN
- VSComposeTextN
- SComposeTextL
- VSComposeTextL
- SComposeTextNL
- VSComposeTextNL

"Function definitions" on page 473 describes these functions in detail.

These Compose Text functions are similar to standard C stdio functions such as printf() and sprintf(). They use positional format codes to copy a format argument into an output string, after performing the required substitutions for the format codes. Use these functions rather than sprintf() to create strings in your user interface.

The Compose Text functions feature format codes other than those for the usual data-type conversions. One format code and convention enables conditional insertion of singular or plural word forms, such as "is" or "are." Other format codes make it possible to specify text strings and string lists stored as resources.

Although they accomplish the same thing, the Compose Text functions come in several varieties. Some allow you to include the strings for composition as arguments, others require pointers to those strings, and other functions get the strings from resource files. In addition, some functions terminate the composed string with a null character and others do not. The API definitions for these functions are in CMPSTEXT.H. The functions themselves are in SYSTUTIL.LIB.

Format codes

The format string used in string composition contains one or more format codes. Format strings can also contain literal text, though they need not. A format code starts with a caret character (^), has one or more digits in the middle, and concludes with a single letter.
The string arguments (as literal text, pointers or resource file identifiers) follow the format string. The digits of the format code specify which argument to insert in that position and the letter indicates the type of the argument. For instance, format code \^2s directs a function to insert the second argument as a string.

The following example fills buffer with the string “a B b A c”:

SComposeText(&buffer, &size, heap, U_L"a ^2s b ^ls c", "A", "B");

### Compose Text format code types

<table>
<thead>
<tr>
<th>Type Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>s</td>
<td>String. The argument or arguments are pointers to text strings.</td>
</tr>
<tr>
<td>r</td>
<td>Resource ID of a string resource.</td>
</tr>
<tr>
<td>l</td>
<td>Group number and indexed list resource ID for string list. The group number and the list resource ID must be two separate arguments (in that order).</td>
</tr>
<tr>
<td>d</td>
<td>U32 argument printed as a decimal number.</td>
</tr>
<tr>
<td>x</td>
<td>U32 argument printed as a hexadecimal number.</td>
</tr>
<tr>
<td>^</td>
<td>Literal ^ character (^) for putting ^ in a string. There is no number.</td>
</tr>
<tr>
<td>{...}</td>
<td>This delimiter format type permits you to conditionally insert singular or plural word forms into text strings based on the value of an argument. Insert the singular and plural forms of a word, in that order and separated by a</td>
</tr>
</tbody>
</table>

As an example of the {...} format type, the following function call generates “There is 1 apple” if numApples is equal to 1 and “There are 5 apples” if numApples is equal to 5:

```c
{  
  SComposeText(&buffer, &size, heap,
    U_L("There ^{is|are} ^ld ^1{apple|apples}"), numApples);
}
```

### Function arguments and memory management

The first three arguments for all Compose Text functions are identical:

- A handle (type PP_CHAR) to the buffer that will contain the composed string.
- A pointer (type P_U32) to the size of the buffer (In) or to the length of the text string in the buffer (Out).
- An identifier of the heap used to allocate memory for the buffer (OS_HEAP_ID).

All Compose Text functions return the length of the generated string in the length argument. For those functions that compose null-terminated strings, the null is not counted in the length.
The Compose Text functions give you two ways to supply the buffer memory:

- You can supply a buffer handle and buffer length and set the heap ID to null. If this technique is used, and the buffer is too small to hold the results, an error status is returned.
- You can specify a valid heap ID to have the function allocate memory for the buffer from the specified heap. You must free the memory when finished with OSHeapBlockFree(). If you pass null for the buffer length when specifying a heap ID, you do not get the actual length of the string back.

**Function definitions**

SComposeText  Composes a null-terminated text string from a format and arguments.

VSC-composeText  Composes a null-terminated text string from a format and a pointer to an argument list.

SComposeTextL  Composes a null-terminated text string from a resource-file format and arguments. Unlike SComposeText, this function fetches the format string from a string array in a resource file.

VSC-composeTextL  Composes a null-terminated text string from a resource-file format and a pointer to an argument list. This function differs from VSC-composeText in that it fetches the format string from a string array in a resource file.

SComposeTextN  Composes a counted string from a format and arguments. Unlike SComposeText, the generated string is not terminated with a null character.

VSC-composeTextN  Composes a counted string from a format and a pointer to an argument list. Unlike VSC-composeText, the generated string is not terminated with a null character.

SComposeTextNL  Composes a counted string from a resource-file format and arguments. Unlike SComposeTextL, the generated string is not terminated with a null character.

VSC-composeTextNL  Composes a counted string from a resource-file format and a pointer to an argument list. Unlike VSC-composeTextL, the generated string is not terminated with a null character.

**Getting the current locale**

To determine the locale the PenPoint 2.0 Japanese operating system is currently running in, send msgSysGetLocale to the system. The locale ID and a string describing the locale are returned. msgSysGetLocale is defined in SYSTEM.H.
Multibyte/Unicode conversion routines

The international conversion functions IntlMBToUnicode() and IntlUnicodeToMB() replace the PenPoint 2.0 Alpha functions Ustrcpy8to16() and Ustrcpy16to8(), respectively. Note that this is a replacement of functionality, not a renaming of functions. The interfaces for these new, replacement functions are in ISR.H. Chapter 47, International Services and Routines, describes these and similar international conversion functions.

Corrections and errata

Ugetc and Unungetc bugs

Ugetc() and Unungetc() are WATCOM's Unicode implementations of getc() and ungetc(). Ugetc() is supposed to return the next Unicode character from the input stream. Unungetc() is supposed to push that character back onto the stream. There is currently a bug in these routines. Ugetc() loses the upper half of the Unicode character after bufsize (512) bytes have been read. Unungetc() faults when it tries to push this character back just after a new buffer is filled.

To work around this bug, include the following code immediately after the #include for STDIO.H:

```c
#define Ugetc(_fp) FixedUgetc((_fp))
static int FixedUgetc(FILE *file)
{
    int tempChar, tempChar2;
    tempChar = getc(file);
    if (tempChar == EOF) return EOF;
    tempChar &= 0x00FF;
    tempChar2 = getc(file);
    if (tempChar2 == EOF) return EOF;
    return (tempChar2 << 8 | tempChar);
}
#define Unungetc(_ch, _fp) \
(CHAR) (ungetc((_ch) >> 8, (_fp)), ungetc((_ch)&0xFF, (_fp)))
```

Renaming of 16-bit utility functions

The following functions have been renamed:

<table>
<thead>
<tr>
<th>Renamed counted string functions</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Version 1.0</strong></td>
</tr>
<tr>
<td>Umemccpy</td>
</tr>
<tr>
<td>Umemchr</td>
</tr>
<tr>
<td>Umemcmp</td>
</tr>
<tr>
<td>Umemcpy</td>
</tr>
<tr>
<td>Umemicmp</td>
</tr>
<tr>
<td>Umemset</td>
</tr>
</tbody>
</table>
Note that Ustrncmp, Ustrncpy and Ustrnicmp, unlike their predecessors, do not copy null as any other character. They treat nulls as early termination, copying the null and then stopping.

These other 16-bit WATCOM functions have also been renamed:

#### cvt and fcvt

These functions are no longer available in PenPoint 2.0 Japanese.

#### HASH.H

The value in hashTableMaxFillPct has changed from 80 to 98. Now it also includes HashFunctionString8() and HashCompareString8() for 8-bit strings.

#### SYSTEM.H

Both sysSysServiceFile (SYSSERV.INI) and sysResFile (PENPOINT.RES) have been removed. These two files are combined in locale.RES (for example, JPN.RES). SYSTEM.H also includes sysLocaleIndependentResFile (ALL.RES), msgSysGetLocale, a SYS_LOCALE structure, an 8-bit sysGoldenMaster_8 and a resource ID for warnings.

#### OSMemInfo, OSMemUseInfo, OSMemAvailable

OSMemInfo() is obsolete and has been replaced by OSMemUseInfo().

OSMemAvailable() returns the amount of swappable memory that can be allocated before the caution zone is reached. This is the point at which the system begins putting up notes warning that memory is getting low.
## Typographical errors

Chapter 42 / Utility Classes

What's New

Matching hiragana or katakana text
In search and replace operations on Japanese text, you can request the SearchManager to match text based on the type—hiragana or katakana—of the specified find string. If the types are different, the target text is passed over, even if the senses are identical.

To effect this search refinement, set the matchHiraKata flag TRUE. This flag is in the SR_FLAGS structure, which is itself part of the SR_METRICS structure. Then call msgSRIInvokeSearch (SR_METRICS is part of the argument structure SR_INVOKE_SEARCH). msgSRRememberMetrics also uses a pointer to SR_METRICS as an argument.

Note the matchHiraKata flag is automatically set TRUE when the user selects the Same Hira/Kata Sense option under Match.

Adding gestures to Quick Help strings
RTF is no longer needed to embed gesture glyphs in Quick Help text strings in your resource files. Because the representation of strings is now Unicode-based, all you must do is type the Unicode code point for a gesture glyph (in hexadecimal) where you want the gesture to appear. (These glyphs are defined in GLYPH.H.) You no longer need to specify \63 to enter a gesture font and \0 to return from it.

You can still use RTF formatting commands in Quick Help text (such as \line), and you can still use the \qh macro to set up an RTF header (although it no longer does any font mapping). However, you must remove all occurrences of {\63 c} (where c is the gesture symbol) and \0 from your Quick Help strings and replace the \63 sequence with the correct Unicode values.

The following code fragment shows a typical use of a Unicode-specified gesture in Quick Help strings:

```
editMenuTag,
U-L("Edit Command\n")
U-L("\qh Tap Edit to display an edit pad \n")
U-L("with the selected text.\line")
U-L("\line")
U-L("You can also put the selected text in an edit")
U-L("pad by drawing a Circle \xE2\x80\x90\x91 gesture")
U-L("on the selection.")")
```

Note that you must type || to separate the title and the body of text, and that you must preface each string with the L (or U_L) macro to provide 16-bit compatibility.
This information on gestures in Quick Help strings replaces sections 84.3.3.1 and 84.3.3.2 in the PenPoint Architectural Reference.

**clsNotePaper changes**

**API changes**

clsNPData includes two new messages, msgGetScribbleClass and msgGetTextClass. When you subclass clsNPTextItem or clsNPScribbleItem, you should also subclass clsNPData and override the handlers for these two messages to have them return the appropriate class. These message handlers are required because clsNotePaper instantiates text and scribble objects on its own, and needs to be told when to use a subclass. For this reason, you should not subclass clsNItem directly; you should only subclass clsNPTextItem and clsNPScribbleItem.

If you want to add different types of graphical objects, you can treat clsScribbleItem in an abstract manner. However, if your implementation is not complete, make sure that it satisfies all requirements of the NPScribbleItem API.

**File format changes**

In addition to API changes, clsNotePaper includes changes in file formats, particularly for file import and export. It now imports Unicode text files. As with MiniText, it requires a file suffix of .UNC for Unicode files. For Shift-JIS it expects files to have suffixes of .SJIS. As before, it expects ASCII files to have .TXT suffixes.

Import of .TXT files depends on locale. In the Japan locale, clsNotePaper imports the file using the Shift-JIS interpretation of the ASCII character set. On the import of files, clsNotePaper also supports the same word or bunsetsu handling (depending on locale) that MiniText performs. It does not perform any taboo processing.

Export can be to Unicode or multibyte text files (Shift-JIS/ASCII). The multibyte format that is used depends on the locale setting of the pen computer (Shift-JIS in Japan, ASCII elsewhere).

**Tips and clarifications**

**Cannot intercept export messages**

Applications that need to modify their document's files on export cannot detect an export operation. If your application modifies the contents of its documents on export, it must provide its own menu button to perform special export operations.

**msgImportQuery can arrive twice**

Under certain race conditions, an application can get msgImportQuery twice. Message handlers should not assume that they will receive msgImportQuery only once.
New stream disconnected status

stsStreamDisconnected has been added to STREAM.H to report disconnected conditions in clsMILasyncSIO.

Typically, SIO clients should not attempt stream calls unless they are connected. However, if the connected state of SIO changes to disconnected while in the middle of an SIO stream call, the stream call will return stsStreamDisconnected instead of stsFailed.

The difference is important. stsFailed return means that a client should or could retry. However a stsStreamDisconnected return means that a client must not retry. For one, there is no reason to retry since the call will continue to return immediately with the same stsStreamDisconnected status, possibly for ever, even if the cable is reconnected. (The connection functionality in PenPoint 2.0 Japanese involves messages so it requires that the message input queue be available.)

SIO clients will need to wait for the connected state to change before attempting any stream call to SIO that can be done in a couple of different ways (they may be observers of theSerialDevices service manager or may poll the service manager for connected state information; see SERVICE.H or SERVMGR.H).

clsTable bug

There is a known bug in clsTable that causes the called table object to return stsOK when it should return an error status. If you set the tblRowPos field of the pArgs structures to Nil(TBL_ROW_POS) when sending msgTBLColGetData or msgTBLRowGetData, stsOK is returned. Nil(TBL_ROW_POS) is undefined for these messages, and should cause the called object to return an error.

Clients must test the tblRowPos field value in their TBL_COL_GET_SET_DATA and TBL_GET_SET_ROW structures to ensure that it is not Nil before sending the messages.

msgTBLColGetData and msgTBLRowGetData are described in the PenPoint Architectural Reference in Table 90-1 (section 90.5, “Using Table Messages”) and section 90.13, “Getting Data.” clsTable interfaces are defined in TS.H.

Known bugs in the NotePaper component

Developers should be aware of the following bugs in MiniNote/NotePaper:

- Setting the paper width to 99999 confuses the horizontal scroll bar.
- Setting the line width to zero confuses MiniNote so that further width changes do not take effect.
- Copying a selection that contains an embedded document from MiniText into MiniNote results in the embedded document being replaced by a check mark.
- The circle tap ⌃ gesture is not targeted, while the circle ◇ gesture is.
Corrections and errata

Getting the current selection
Modify the fourth sentence of section 80.2.2 (in the “Using clsBrowser” chapter in the PenPoint Architectural Reference) so that it reads: “These two messages take a pointer to a FS_FLAT_LOCATOR structure in which the called object returns the path or name of the current selection.” The messages referred to are msgBrowserSelection and msgBrowserSelectionDir.

Classes that respond to search messages
Section 86.3 in the PenPoint Architectural Reference states that “clsText is the only class that responds to the search and replace messages.” You should replace clsText with clsTextView in this sentence.

Reading and writing streams
Sections 79.3 and 79.4 in the PenPoint Architectural Reference are accurate in their descriptions of how to use msgStreamRead and msgStreamReadTimeOut to read communications streams. But some implications raised should be clarified. For a serial communications stream, there is no reliable notion of “end of stream”; conceptually, the byte stream is continuous, with no beginning or end. To read such a stream, you should send msgStreamReadTimeOut only. Moreover, if you want to make a nonblocking read of a serial stream, set the timeOut field (STREAM_READ_WRITE_TIMEOUT) to zero before sending msgStreamReadTimeOut.

Using the PenPoint gesture font
Table 84-2 on pages 188-190 of the PenPoint Architectural Reference lists the tags, symbols, and ASCII values for the PenPoint gesture font. It is no longer accurate. Gesture tags are now associated with glyph tags that represent Unicode values. GLYPH.H contains the current list of glyphs and their associated Unicode values; XGESTURE.H contains the current list of gesture tags and their associated glyphs.
Chapter 43 / Connectivity

What's new

clsModem has been re-implemented as a service. As a result, much of the material covered in Chapter 97 of the PenPoint Architectural Reference, "Data Modem Interface," is no longer valid. This section describes the major conceptual changes and summarizes the new procedure for using a modem service. Except where noted, it replaces Chapter 97. Refer to MODEM.H for complete API definitions.

Finding, binding to, and opening a modem

Since a modem is a service instance, you locate it, bind to it, and open it as you would any other service. In this case, you must send a series of clsServiceMgr messages to the predefined service manager for modems, theModems. (A modem is automatically associated with a serial port, so you no longer need to bind to and open a serial port explicitly, as Chapter 97 describes.)

The following list summarizes the clsServiceMgr messages you must send initially. These messages are described in greater detail in Chapter 94 in the PenPoint Architectural Reference.

1 Find the modem service by sending msgIMFind. You pass theModems service manager the name of the service; in the pArgs structure (IM_FIND), assign a pointer to the service name to the pName field. If the service is found, you get back a handle to that service. If it is not found, the return status is sts-NoMatch.

If your application lets users choose a modem, send msgIMGGetList to theModems to get a list of UIDs for modem services. Then send msgIMGGetName to get the name of each service in the list and display these names in a list. When a user selects one, assign the name to the pName field of IM_FIND and send msgIMFind.

2 Bind to the service instance so that the service manager can add your application to the observer list for the service. Your application should bind to the modem service so that, when the status of the modem changes, theModems will notify your application and all other observers (see Table 43-6, "Client and observer notification messages," on page 491). You bind to the modem service instance by sending msgSIMBind to theModems. In the message argument structure (SM_BIND), set the handle field to the value returned by msgIMFind and set the caller field to self.
Open the service instance by sending msgSMOpen to the modem service manager (theModems). This message takes a pointer to an SM_OPEN_CLOSE structure that contains the handle returned by msgIMFind, the caller (self) and a pointer to an argument structure (pArgs) containing data specific to the modem service.

If msgSMOpen returns stsOK, it also returns the UID of the opened modem service in the service field of SM_OPEN_CLOSE. Assign this UID to a variable of type OBJECT and specify this object in subsequent messages to the modem until you close the modem.

The following code fragment demonstrates the locating, binding and opening procedure:

```c
IM_FIND     imf;
SM_BIND     smb;
SM_OPEN     smo;
OBJECT      myModem;
STATUS      s;
imf.pName = U_L("Hayes2400");
ObjCallRet(msgIMFind, theModems, &imf, s); // find/get the modem handle
smb.handle = imf.handle;
smb.caller = self;
ObjCallRet(msgSMBind, theModems, &smb, s); // bind to modem service
smo.handle = imf.handle;
smo.caller = self;
ObjCallRet(msgSMOpen, theModems, &smo, s); // open modem
myModem = smo.service;
```

Instead of steps 1 to 3 above, you can send msgSMAccess to theModems and get back the UID of the modem service in the service field of a SM_ACCESS structure. When your are finished with the modem service, send msgSMRelease to unbind and close it. See SERVMGR.H for more information about these messages.

### Initialization

The object that opens a modem service (for example, your application) becomes its client. Before it begins sending and receiving data through the modem, the client should initialize the modem firmware and the serial I/O port.

### Applying the default settings

You reset the modem firmware and the I/O port state to the default settings by sending the modem-service instance msgModemReset. This message takes no arguments. After sending this message, you can change the reset defaults selectively. A typical usage, following our previous example, would be:

```c
ObjCallRet(msgModemReset, myModem, Nil(P_ARGS), s);
```

The default modem firmware settings are:

- Auto-answer disabled.
- Busy tone detection enabled, or as current modem option card settings.
- Command termination = carriage return (ASCII 13). 
- Dialing mode from dialing environment.
• Dial tone detection enabled, or as current modem option card settings.
• Enable carrier upon connect.
• Escape code = ASCII 43.
• Local character echo disabled.
• Send command result codes (words).
• Send verbal result codes.
• Speaker control on until carrier detected, or as current modem option card settings.
• Speaker volume medium, or as current modem option card settings.

### Default I/O port state settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>SIO_METRICS Field</th>
<th>Default value</th>
</tr>
</thead>

<td>flowChar.xoffChar</td>
<td>0x13</td>
</tr>
<tr>
<td>flow control</td>
<td>flowType.flowControl</td>
<td>off (sioNoFlowControl)</td>
</tr>
</tbody>
</table>

### Setting I/O port state options

You can change the default I/O port state settings by sending `msgSioSetMetrics` to a modem service. To discover what these settings are, prior to altering them, send `msgSioGetMetrics` to the modem-service object. Other `clsMILAsyncSIODevice` messages that `clsModem` handles are `msSiolnit`, `msgSioBreakSend`, `msgSioControlInStatus`, `msgSioInputBufferStatus`, and `msgSioInputBufferFlush`. Refer to `SIO.H` for descriptions of these messages.

The following code fragment demonstrates a typical use of `msgSioSetMetrics`:

```c
SIO_METRICS smetrics;
/* Initialize serial port to preferences */
ObjCallWarn(msgSioGetMetrics, myModem, &smetrics);
smetrics.baud = (U32)9600;
smetrics.line.dataBits = sioSevenBits;
smetrics.line.stopBits = sioTwoStopBits;
smetrics.flowType.flowControl = sioNoFlowControl;
ObjCallWarn(msgSioSetMetrics, myModem, &smetrics);
```
### Initializing the modem

After the serial I/O port has been initialized, you can send clsModem messages to set the desired features, control flags, and attributes of the modem. You can either make these settings as a group by sending msgSvcSetMetrics. Or you can initialize the modem by sending discrete messages (listed below).

If you elect to use msgSvcSetMetrics, you might first want to send msgSvcGetMetrics to the modem-service object to obtain the current settings.

Both messages take a pointer to the argument structure SVC_GET_SET_METRICS, whose pMetrics field points to a buffer containing MODEM_METRICS. This metrics structure consists of a collection of enumerated types that list mutually exclusive settings for various modem features. These enumerated data types are also used as argument structures in the messages that set individual options in the modem service.

Table 43-2 describes the enumeration fields that make up MODEM_METRICS and that are used by the messages that set discrete options. Table 43-3 lists these discrete initialization messages; note that most of these messages take as pArgs the enumerated value itself (which is 32 bits) and not a pointer to that value.

#### MODEM_METRICS fields

**Response mode**

In your code's modem-initialization section or at any time while a modem service is open, may also want to set the response mode of the modem service. The response mode, set with `msgModemSetResponseBehavior`, affects how the modem-service object responds to its client:

- **Respond via status**  In this mode, the client sends a message to the modem service, which then sends a command to the modem and then blocks, waiting for the response from the modem. If a timeout period (specified in the `pArgs` structure) elapses, `stsTimeout` is returned. Respond via status is the default response mode; the default timeout periods are 2.5 seconds for commands and 30 seconds for the connection.

- **Respond via message notification**  In this mode, the modem service acts as it does in Respond via status mode. But in addition, it sends `msgModemResponse` to the client. This mode is useful when you want to return to handle other work (such as handling certain abort commands) without waiting for a return. The client can post a request (via `ObjectPostAsync`) to the modem, thereby freeing up the execution thread so it can process input events. See Table 43-6, “Client and observer notification messages,” on page 491 for more on `msgModemResponse`. 
Transparent This mode essentially disables the modem service’s response processing. Responses to modem commands remain unaltered in the input data stream. It is the responsibility of the client to read and interpret these responses. They must ensure that the expected sequences of commands are sent (via msgModemSendCommand or through the discrete command messages).

The advantage of transparent mode is that there is less overhead in processing characters received from a remote modem. Aside from better performance, your application is less likely to have character overruns at high baud rates. If decide to operate in transparent mode, you might want to switch to it after initializing the modem and establishing a connection in one of the other modes.

A related message, msgModemGetResponseBehavior, passes back to the client the current modem response mode and timeout values. Refer to MODEM.H for details on msgModemSetResponseBehavior and msgModemSetResponseBehavior.

Establishing a connection (outbound)

If you are initiating an exchange of data, you use clsModem messages to dial and connect with the remote modem.

To dial another modem, send msgModemDial to the modem service. This message takes a pointer to a MODEM_DIAL structure that contains the field dialString, which is of type DIALENV_DIAL_STRING. Assign to this field the phone number (in the form of a text string) of the remote modem.

The phone number usually contains the number to dial. It can also contain a number of dial string modifiers defined by the AT command set (although this is not required). These dial string modifiers are described in the section, "Dial string modifiers", in Chapter 97 of the PenPoint Architectural Reference.

Although this phone-number string would normally be something that a user enters or selects from an address book, the following code fragment shows how dialing would occur with a hard-coded string.

```c
MODEM_DIAL dial;
STATUS s;

dial.dialString = U_L"(415-345-7400");
ObjPostAsync(msgModernDial, myModem, &dial, s);
```

If msgModemDial returns stsOK, a connection is established with the remote modem. You can begin sending and receiving data. You can also send msgGetConnectionInfo to find out the details of the connection. When you are finished, send the modem service msgModemHangUp (it takes no arguments). This message terminates the connection and hangs up the phone.
Waiting for a connection (inbound)

When a remote modem attempts to make a connection with your local modem, you can instruct the modem-service object to automatically answer the phone or you can answer the phone yourself with clsModem messages.

To instruct the modem to answer the phone automatically, set the MODEM_AUTO_ANSWER enumerated type to mdmAutoAnswerEnabled, specify the desired number of rings to wait, and send msgSvcSetMetrics or msgModem-SetAutoAnswer (see "Initializing the modem," on page 486). When another modem dials your modem's number and the phone rings, the modem service takes the phone off-hook and sends the client the notification message msgModemConnected. The client can then send msgModemGetConnectionInfo to get more information about the connection.

To answer the phone yourself, set MODEM_AUTO_ANSWER to mdmAutoAnswerDisabled and send msgSvcSetMetrics or msgModemSet­AutoAnswer. When the phone rings, the modem service notifies the client via msgModemRingDetected. The client answers the phone by sending msgModem­Answer to the modem service (no arguments required). Once connection is estab­lished, the client can send msgModemGetConnectionInfo to get more information about the connection.

Transmitting and receiving data

Once you have established a connection with a remote modem, you can begin reading or writing data. You effect these functions through clsStream messages. Send msgStreamWriteTimeout to transmit data to the modem service (and ulti­mately to the remote modem); send msgStreamReadTimeout to read the stream of data coming into the modem service. See Chapter 79 in the PenPoint Architectural Reference or STREAM.H for more information on these messages.

If the connection between modems is lost, the client receives msgModem­Disconnected.

Terminating the modem service

To end a modem service, first make sure there is no connection established. Then send msgSMClose to theModems to close the service. This message takes a pointer to a SM_BIND structure, which contains:

- handle  Set to the service handle (obtained early in the procedure via msgIMFind).
- caller  Set to the UID of the modem-service client (usually self).

When the message completes successfully, it returns stsOK. Finally, remove your client from the service's observer list by sending msgSMUnbind to the service manager for modems (theModems). If you had opened and bound a modem service through sending msgSMAccess, close and unbind that service by sending msgSMRelease.
clsModem messages

See “Initializing the modem,” on page 486 for a description of msgSvcSetMetrics.
Refer to Table 43-3 for a list of discrete modem initialization messages.

The modem service sends two kinds of notification messages, one to its client and one to its observers. There are several client notification messages, but only one observer notification message, **msgModemActivity**.

In order for the client to receive client notification messages, the response mode must be set to Respond via status (**msgModemSetResponseBehavior**). Observer notification messages are sent to all objects on the modem service’s observer list; they can be objects other than the client of the modem service.

### Client and observer notification messages

Corrections and errata

Reading and writing with the serial port

Section 95.2.4 of the PenPoint Architectural Reference erroneously calls the pointer-to-buffer field of STREAM_READ_WRITE pReadBuffer. It should be called pBuf, and its definition should read:

A pointer to a buffer that receives data read from the stream or that contains data to be written to the stream. On msgStreamRead, the buffer must be big enough to hold at least numBytes of data.

Note that this correction applies also to the definition of the STREAM_READ_WRITE fields in section 79.3 in the PenPoint Architectural Reference.

Predefined service managers

GO defines a number of service managers in UID.H. Table 43-7 defines the service managers only listed in section 94.2.1 in the PenPoint Architectural Reference.

</tr>
<tr>
<td></td>
<td></td>
<td>string list and the index into it. You can allocate memory by specifying</td>
</tr>
<tr>
<td></td>
<td></td>
<td>a heap.</td>
</tr>
</tbody>
</table>

All of these functions are shortcuts to using msgResReadData. They are implemented in RESFILE.LIB.

New system preferences

The system preference file (PREF.H) contains several new preferences and some new functions for accessing and manipulating preferences. These items include:

- New preferences for fully enclosed (Japanese-style) character box height and width.
The function `PrefsIntDateToString()` returns a string containing the Unicode representation of the formatted date based on the current user preference. Use this function instead of `PrefsDateToString()`.

The function `PrefsIntTimeToString()` returns a string containing the Unicode representation of the formatted time based on the current user preference. Use this function instead of `PrefsTimeToString()`.

New tag `tagBSAppAutoZoomDocument`, which identifies the document to be automatically zoomed when PenPoint boots. This replaces the `AutoZoom` string in `ENVIRON.INI`.

**New resource group**

A new resource group in PenPoint SDK 2.0, called `resGrpMisc`, allows developers to read in strings that fall into a miscellaneous category (that is, resources that are not Toolkit or Quick Help strings).

**New and renamed string resource agents**

In PenPoint SDK 2.0, the names `resStringResAgent` and `resStringArrayResAgent` now refer to 16-bit string resources. The two resource agents for strings that in PenPoint 1.0 had these names have been renamed: `resStringResAgent` is now `resString8ResAgent`, while `resStringArrayResAgent` is now `resString8ArrayResAgent`.

**Tips and clarifications**

**msgResWriteData does not copy pData**

You send `msgResWriteData` to file some data in an object file, passing a pointer to the data to be written. If this is inside a `msgSave` handler, `clsResFile` has not been written when `msgResWriteData` returns; `clsResFile` has just queued it for writing in the future.

If `(P_RES_WRITE_DATA)pArgs->pData` points to data on the stack, it will probably be corrupt when `clsResFile` unwinds and writes the data. If `pData` points to allocated memory, there's no easy way to know when it's safe to free it (you could post `msgSelf` to free it).

`clsResFile`'s queued-write behavior is not a complicated multi-threading subtask. Object filing starts when someone tells `clsResFile` to write an object; `clsResFile` tells that object to save. If one object sends a message to write another object or data while it's saving, `clsResFile` queues the write. When `msgSave` returns, control is returned to `clsResFile`, which then processes queued writes. It all takes place by `ObjectCall` within one task. Just remember that `clsResFile` is in the driver's seat.

**Saving bitmap editor resources**

If while using the bitmap editor you save a bitmap to a resource file, make sure the file has a name different from any existing resource files. If you save a bitmap to an existing resource file, the bitmap will be appended to the existing file.

Chapter 45 / Installation API

What's new

KKC engine installation

Several new API enhancements make possible the installation and deinstallation of kana-kanji conversion (KKC) engines. In the user interface, these changes show up in the KKC engines page of the Installed Software section of the Settings notebook. This page lists the installed KKC engines and lets users perform the normal operations for setting the current engine, deleting an engine, and so on. When users tap the Install menu item, or when they select the KKC engines view within the Connections notebook, PenPoint 2.0 Japanese creates a disk viewer that shows all installable KKC engines on the selected volume.

Install Manager class

PenPoint SDK 2.0 has a new class of installation managers, clsKKCInstallMgr, that handles the installation and deinstallation of KKC Engines. This class is a subclass of clsServiceInstallMgr. The new public header file KKCIMGR.H documents the API for implementing clsKKCInstallMgr.

At boot time, the INSTALL.DLL creates clsKKCInstallMgr and a single well-known instance of it, called theInstalledKKCEngines. The clsKKCInstallMgr makes the first KKC Engine installed the current engine.

Before installation, KKC engines are in the same directory as services ($OPENPOINT\SERVICE). Once they are installed, however, KKC engines live in their own subdirectory, $OPENPOINT\KKC. In order for a service to be recognized as a KKC engine, its directory must be stamped differently: appAttrClass must have the value theInstalledKKCEngines (01000416) instead of theInstalledServices (01000240).

KKCCT class

The KKC Character Translator class participates as a client in the protocol defined by clsKKCInstallMgr. This protocol enables clients to open and close engines and provides dynamic notification of engine changes. User interface elements dynamically track the users' preferences for the current engine anywhere that KKC happens in the system. See KKCIMGR.H for definitions of the protocol.

KKC class

clsKKC provides certain default behavior for deinstallation. Specifically, it responds to msgSvcTerminate, msgSvcTerminateOK, and msgSvcClassGetMetrics.
**Installation routing via appAttrClass**

To facilitate the boot-time installation of services and applications, the processing of .INI files has changed. Instead of the INI filename determining the destination installation manager, each installable in an INI file is sent to the installation manager designated by the appAttrClass attribute on the installable.

If the attribute is not a valid installation class, the item is sent to the installation manager designated by the name of the INI file being processed. Although this change implies that APP.INI and SERVICE.INI could be collapsed into a single file, they remain separate.

**Tips and clarifications**

**Other installation information**

There are messages in SYSTEM.H to locate the active area, and messages in AUXNBMGR.H to locate particular auxiliary notebooks on the Bookshelf.

PenPoint 2.0 by default doesn't consider theSelectedVolume something that it displays in a browser, hence the user can't see theSelectedVolume in Connections or any other list of attached volumes. This is why in DebugTablet mode, you can't install software from the hard drive. Setting the B800 debugging flag overrides this.

**Corrections and errata**

**Installation clarifications for production PenPoint**

Chapter 110, “Organization of Distribution Volumes,” in the PenPoint Architectural Reference doesn't mention the \PENPOINT\SYS\LOADER database of code. This is a key concept on a pen computer. There's no \PENPOINT\APP; instead application code is copied to \PENPOINT\SYS\LOADER and renamed after the EXE and DLL lname strings. On a cold boot, PenPoint uses attributes stamped on files in the loader database to determine the order in which to load these .DLL and .EXE files—there's no APP.INI on a pen computer.

The hierarchy descriptions in Chapter 110 are for the PenPoint configuration for the SDK, not the pre-set configuration on pen computer installation disks or the actual configuration of a pen computer running PenPoint.

On a running PenPoint machine, there typically is nothing but \PENPOINT\SYS and \PENPOINT\BOOT\ENVIRON.INI. There's no other .INI files in the BOOT directory and there is no \PENPOINT\APP.

**Erroneous Directory**

Pages 383 and 388 of the PenPoint Architectural Reference, have diagrams showing a \PENPOINT\SYS\DOC directory. The directory is \PENPOINT\SYS\Bookshelf.
Dynamic Link Libraries

Chapter 111 of the PenPoint Architectural Reference on Dynamic Link Libraries (DLLs) requires several corrections and clarifications.

Minor version numbers

Section 111.3 in the PenPoint Architectural Reference claims that the minor version number (the one in parentheses in the dll-id string) is optional and "is ignored by the operating system when it determines whether a DLL is already loaded in the PenPoint computer." Section 111.5 in the PenPoint Architectural Reference says that "the application monitor does not compare minor version numbers." Both statements are wrong. The application monitor does take the minor version number into account if the rest of both dll-ids are identical. If a DLL is being installed and a DLL with the same company name, module name and major version number is already installed, the application monitor installs the new DLL only if it has the higher minor version number.

Deinstallation

Section 111.5 in the PenPoint Architectural Reference states that "when an application is deinstalled, the application monitor again opens the corresponding .DLC file and compares its dll-ids against the currently loaded dll-ids." Not true. Once an application is installed on a running PenPoint system, there might not be any "corresponding .DLC file" to open (for example, the file is on an installation disk). So, when it deinstalls an application, the application monitor gets the application's dll-ids from the attributes stamped in the \PENPOINT\SYS\LOADER database for that application.

What happens next is as described in 111.5. The application monitor matches the to-be-deinstalled dll-id against the application's dll-ids and, if there is a match, decrements the dll-id reference counter. If the reference counter becomes zero, the application monitor deinstalls the DLL.

Naming conventions

Section 111.4 in the PenPoint Architectural Reference is mistaken about the naming conventions for an application directory, an application's .EXE file and its .DLC file. It is not true that "the .DLC file must have the same name as the application directory and the executable file." A simple application might have only an executable file (that is, no DLLs); in this case, the name of the executable file should be the same as that for the application directory. Otherwise, the .DLC file should have the same name as the application directory; the name of the executable file can be any valid DOS filename, as long as it's referenced in the .DLC file.

In light of these changes, the examples cited in section 111.4 need to be updated. An application with the PenPoint name Graph it Right is stored in the directory \PENPOINT\APP\Graph It Right. If the application has no DLL files, the executable file is named Graph It Right.EXE. If the application has DLLs, there is a Graph It Right.DLC file in the application directory; this file lists the dll-ids and DOS pathnames of the application's DLL files and executable file in order of dependency.
Let's say (as in the section 111.4 example) that the executable file in the Graph It Right directory is named GRAPHER.EXE. The application's one DLL file is named FORMS.DLL. Therefore, the application's .DLC file is name Graph It Right.DLC (not grapher, as in the example) and it contains two lines:

```plaintext
GO-forms_dll-V1(2)    FORMS.DLL
GO-Grapher_exe-V1      GRAPHER.EXE
```

### Minimum operating system version

In its last sentence, section 111.8 in the *PenPoint Architectural Reference* says that "an application can specify the minimum operating system version it will run under at installation time." Although an application can no longer specify the minimum operating system version, it can still accomplish the same end.

PenPoint SDK 1.0 has in the *pArgs* structure for msgSave (OBJ_SAVE) the fields `minAppVer` and `minSysVer`. The `minAppVer`, once used to specify the minimum version of PenPoint for an application, is now obsolete. (`minSysVer` is used for a different purpose: it helps to prevent the restoration of a system-synchronized object from a resource file to an older version of PenPoint that may not understand the file format.)

An application, at initialization time, can send the message `msgGetSysVersion` to obtain the current version number of PenPoint. If that version is incompatible with the application, the application can then do something in response, such as displaying a warning message and exiting.
Chapter 46 / Writing PenPoint Services

What's new
PenPoint 2.0 Japanese contains no new features, API, or functions for inclusion in this chapter.

Tips and clarifications

MIL services and other services
Some readers of the PenPoint Architectural Reference thought that section 93.4.2 did not clearly explain the difference between MIL services and other services. One one level, the difference is in function: MIL services generally implement objects that act as device drivers for a type of device. Other services operate at a more abstract level: they are removed from the hardware but have interfaces with MIL services.

But there is a more essential difference. The principle difference between MIL services and other services lies in the use of protected memory. A MIL service comprises two DLLs. One runs as a protected task in Ring 0 (protected) memory. Written in procedural code, this DLL controls and responds to the device itself. Another DLL in Ring 3 memory provides the API for applications and other services. This DLL, written in object-oriented code, mediates between these client objects (applications and regular services) and the Ring 0 code.

Non-MIL services can implement many things. The following is a partial list:

- Connectivity services (for printing, faxing, E-mail, and so on).
- Network protocol stacks (using chain of targeted services).
- Installable file systems.
- Database engines.
- Handwriting engines.

Writing a MIL service is not a trivial matter. If you intend to write a MIL service, refer to the HDK documentation for information on how to proceed.

theServiceManagers
There is a problem with the well-known list theServiceManagers in PenPoint. Its entries are not the UIDs of the currently existing service managers. Rather, the entries are pointers into stack frames that have disappeared. When a service manager is created, it does add an entry to theServiceManagers, but what it adds is a bogus pointer into the stack rather than its own UID.
This situation leads to a couple of effects:

- If your service A targets service B and tries to bind to it before service B’s service manager exists, the delayed bind does not automatically happen (as documented and expected) when B’s service manager gets created. That’s because A is waiting for B’s service manager UID to get added to theServiceManager, and that never happens. If B’s service manager does exist, there’s no problem.

- If (as documented in SERVMGR.H) you observe theServiceManagers you will get notified (via msgListNotifyAddition) when a service manager is created. However, there’s no way of knowing which service manager it is.

If you’re waiting for a particular service manager to be created, first observe theServiceManagers. When you receive msgListNotifyAddition, check pArgs->list to make sure theServiceManagers is sending the notification. Then send msgObjectValid to clsObject, passing in the UID of the service manager that you’re waiting for; the response from clsObject tells you whether this service manager now exists.

**Responding to msgTrackProvideMetrics**

When a service has the autoMsgPass style bit set to TRUE, it forwards all messages that are not clsObject, clsService, or clsOption messages to its target service. One such message can be msgTrackProvideMetrics. For example, if the service is the client of a clsFrame window, it will receive msgTrackProvideMetrics when the window is dragged around on the screen.

Most services do not need to handle msgTrackProvideMetrics. However, if the service’s target is not opened, a stsSvcTargetNotOpen will be returned when clsService attempts to forward the message to the target. This could create a problem if the caller (of msgTrackProvideMetrics) is expecting either stsOK or stsMessageIgnored before proceeding further. In our clsFrame example, msgTrackProvideMetrics is sent to the frame’s client (the service) after clsFrame already provides an adequate track metrics. The idea is to let the frame’s client have a crack at poking the track metrics. If the service returns stsSvcTargetNotOpen instead of stsMessageIgnored, when the user drags the clsFrame window, a black box might appear briefly, but no tracker is created, and thus the window remains where it was.

To fix this problem, simply return stsMessageIgnored in response to msgTrackProvideMetrics. In your method table, you can say:

```{msgTrackProvideMetrics, "StsMessageIgnoredMsgHandler",}
```

See CLSMGR.H for examples of other default message handlers returning stsOK, stsFailed, and so on.
Deinstalling dependent services and applications

PenPoint 2.0 Japanese allows you to bundle applications and services together. For example, you might ship a database user interface application along with the database service. The service, in this case, is referred to as the dependent service. This association is made by putting the database service and the SERVICE.INI file in the application's directory. Deinstallation of the application and service happens when the application is deinstalled.

If you chose not to bundle your application and service together, you need to be very careful about the programmatic dependencies between the two items. You must be especially careful to test deinstallation, because it is possible to write code in such a way that once the application is deinstalled, the service would fail to deinstall, thereby leaving the service permanently installed.

Corrections and errata

The Service Class and class instances

The last paragraph of section 116.4.2 in the PenPoint Architectural Reference says that "the service can also tell its openers the entry points to specific procedural interfaces (if any)." But it neither describes how this is done nor refers to another section containing the general procedure. If you want your service to provide its clients with a function interface, thereby saving the overhead of object calls, it should respond to msgSvcGetFunctions. (This message is merely mentioned in Table 117-1 of the PenPoint Architectural Reference.) To do this, it must be a subclassed instance of clsService (which, by default, returns a null pointer.) Your service should pass back to the opener a pointer to a table of function entry points. The format of this pointer block is up to the service to define. See SERVMISC.H for more information about msgSvcGetFunctions.

Handling msgSvcOpenDefaultsRequested

In section 117.7.2.4 of the PenPoint Architectural Reference, delete the last sentence of the third paragraph. (This sentence is in parentheses and begins "The METHOD.TBL in the TESTSVC directory does not specify an ancestor call for msgSvcOpenDefaultsRequested...") The method table for the TESTSVC sample service does specify objCallAncestorBefore for msgSvcOpenDefaultsRequested.

In box and Out box changes

There is an In box/Out box bug that can affect an existing client of the In box/Out box service. The fix for this bug changes how a client enables or disables an Out box service.

You should use this function-interface approach only if you are having performance problems with your service.
The change adds an explicit message for a client to programmatically enable an Out box service. In 1.0 (and 1.0a), enabling an Out box service means that the service becomes the owner of the target. For example:

```c
ObjCallRet(msgSvcGetTarget, anOutboxService, &getTarget, s);
setOwner.handle = getTarget.targetHandle;
setOwner.owner = anOutboxService;
ObjCallRet(msgSMSetOwner, getTarget.target.manager, &setOwner, s);
```

In PenPoint 1.01 and PenPoint 2.0 Japanese, the above code becomes:

```c
ObjCallRet(msgIOBXSvcEnableService, anOutboxService, (P_ARGS)TRUE, s);
```

And the default behavior of `msgIOBXSvcEnableService` is to do exactly what is done in PenPoint 1.01 and PenPoint 2.0, namely to make `anOutboxService` the owner of its target.
Chapter 47 / International Services and Routines

Falling under the umbrella designation of International Services and Routines are a collection of functions, macros, structures and defined values that help developers internationalize application code. With the international routines, you can write one code base for your application that works naturally in several countries.

Internationalization in PenPoint makes use of both the international routines and resource files. Resource files can hold the Unicode text strings—in multiple languages—that an application requires for its UI and other purposes.

Your application will probably need to use the international routines if it must take into account anything that is culturally dependent, such as time and date formats, hyphenation rules, units of measure, and so on. (Of course, your application must also use Unicode for its strings.)

Part 2: PenPoint Internationalization Handbook, describes all aspects of writing your code for an international market.

### International and related header files

<table>
<thead>
<tr>
<th>Header File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISR.H</td>
<td>Prototypes the functions and defines structures for the PenPoint international routines. Some routines perform text delimiting, hyphenation, data-type conversion and the conversion and parsing of dates and times. Other routines compare, sort and compress strings, and perform conversions involving dialects, character sets, units of measure and other linguistic elements. The routines themselves are in INTL.LIB. See “International routines” on page 508 for descriptions of these routines.</td>
</tr>
<tr>
<td>ISRSTYLE.H</td>
<td>Contains definitions of style values used as parameters in the ISR.H routines. Most international routines allow the client to specify a style for the operation. Styles modify the locale and must be appropriate to the routine. For example, some styles enable the client to specify dates in one of the four (or more) formats possible in each western language.</td>
</tr>
<tr>
<td>GOLOCALE.H</td>
<td>Defines the locale values used as parameters in the ISR.H routines. These values are of type LOCALE_ID, which is itself composed of three values: language, dialect, and country. (See description of INTL.H, below.) Values for weights and measures, currencies, time zones, eras and other international units are also defined. In addition to a list of current locale values, GOLOCALE.H specifies the required resource IDs for the lists containing the text strings, contains some macros that make tags for locale values, and defines some common locales. Note that this header file was named LOCALE.H in earlier versions of PenPoint.</td>
</tr>
</tbody>
</table>
**Header files**

<table>
<thead>
<tr>
<th>Header File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHARTYPE.H</td>
<td>This file defines some classification tables for Unicode characters and provides a set of macros for testing and manipulating characters as specified in those tables. These macros are similar to those defined in CTYPE.H for the conversion and testing of ASCII characters. See “Character conversion and testing macros” on page 512.</td>
</tr>
<tr>
<td>INTL.H</td>
<td>This file defines the LOCALE_ID used as a parameter in the international routines. It also contains the macros that you can use to create, modify and access locale values. LOCALE_ID is an unsigned 32-bit type with three 8-bit fields for the language, dialect and country values defined in GOLOCALE.H. Currently, the other bits are reserved for future use.</td>
</tr>
</tbody>
</table>

The macros in INTL.H are:

```
intLIDMakeLocaleId(l,d,c) // l=language, d=dialect, c=country
intLIDGetLanguage(locale) // (values defined in GOLOCALE)
intLIDGetDialect(locale)
intLIDGetCountry(locale)
intLIDSetAddresslanguage(locale,v) // v = GOLOCALE value
intLIDSetDialect(locale,v)
intLIDSetCountry(locale,v)
```

**International routines**

Most functions require you to supply a locale and a style as arguments. The locale is a 32-bit type (LOCALE_ID) containing three 8-bit values; one identifies the country whose conventions the routine should observe and the remaining two identify the language and dialect that the routine must process. (Currently, no dialect values are defined, but they could easily be added in the future.)

In most cases the international routines require a style value as a parameter. A style value modifies the way a routine processes a locale, because there can be variations of linguistic forms within countries and languages. Styles are 32-bit types containing 16-bit segments; the low-order segment identifies a base style and the high-order segment contains flags that modify the base style.

The locale values are defined in GOLOCALE.H. You can compose LOCALE_ID structures by using the intLIDMakeLocaleId() and related macros in INTL.H. You use bitwise operators and intLIDStyleMask and intLIDStyleFlagsMask to set the base value and one or more of the flags defined in ISRSTYLE.H in an unsigned 32-bit integer.

Those routines that take a locale as argument provide a macro that substitutes intDefaultLocale for the locale. The default locale requests the current system locale. The macro has the same name as the function, but the prefix is Loc instead of Intl. The following example shows a typical macro definition:

```
#define LocDelimitWord(tx,s,st) 
    IntlDelimitWord(tx,s,IntlDefaultLocale,st)
```

Most of the international functions come in nearly identical pairs. The Intl... versions work on null-terminated strings and the IntlN... versions work on counted strings. The IntlN... functions take an extra argument that specifies the length of the passed string. When you read the definitions of international routines in the
following sections, remember that there is a counted-string counterpart to the null-terminating function listed (unless specifically noted otherwise). In other words, the definition for IntlDelimitWord applies equally to IntlNDelimitWord.

Some of the functions that handle null-terminated strings return the required length of an output buffer. Remember that these counts do not include the null character, so if you are using these functions to allocate memory for these buffers, make sure to add one to the count.

**Delimiting and hyphenation routines**

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IntlDelimitWord</td>
<td>Finds a “word” in a string. The style argument controls the internal definition of a word.</td>
</tr>
<tr>
<td>IntlDelimitSentence</td>
<td>Finds a “sentence” in a string. The style argument determines what is considered a sentence.</td>
</tr>
</tbody>
</table>

**Hyphenation routines**

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IntlBreakLine</td>
<td>Given a string of a certain length, this routine calculates a line break that is valid for the locale and returns the hyphenation information in a structure of type INTL_BREAK_LINE. This information includes the position at which to make the line break, the number of characters to delete from each side of the break, and the characters to insert on each side of the break point.</td>
</tr>
</tbody>
</table>

**Time conversion routines**

These routines pass in or receive back time information in an argument of INTL_TIME. This structure is a superset of the standard time structure. In addition to the standard time fields, it includes the time zone as a posix string (pTz) and an era field that can put the year in a context other than anno Domini (AD).

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IntlSecToTimeStruct</td>
<td>Converts the time, in seconds since 0:00 January 1, 1970 UTC (GMT), into an international time structure (INTL_TIME). Use the time() function to get the current time in seconds. For the current release of PenPoint, set the pTimeZone field (the target time zone) to pNull.</td>
</tr>
<tr>
<td>IntlTimeStructToSec</td>
<td>Converts an international time structure (INTL_TIME) to the time in seconds since 0:00 January 1, 1970 UTC (GMT). Currently, this function works only on times in the current time zone.</td>
</tr>
<tr>
<td>IntlOSDateTimeToIntlTime</td>
<td>Converts the time in the PenPoint system format into the international time structure (INTL_TIME). Since the system time is always a modern Gregorian date, the era in INTL_TIME is always set to itcEraAD.</td>
</tr>
<tr>
<td>IntlIntlTimeToOSDateTime</td>
<td>Converts the time specified in the international time structure (INTL_TIME) into the PenPoint system format. Since the system time is always a modern Gregorian date, you must set the era in INTL_TIME to itcEraAD.</td>
</tr>
</tbody>
</table>
Note that these last two functions, IntlOSDateTimeToIntlTime and IntlIntl­TimeToOSDateTime, should be used only by code that is involved in setting the system clock. Other code should use the time() function and then do conversions to and from international time with IntlSecToTimeStruct and IntlTime­StructToSec.

Formatting routines

These functions take an input value and convert it into a string. They return the length of the generated string or, if pString is pNull, they do no formatting but do return the size required for the output buffer.

Calls to IntlFormatS32 and IntlFormatNumber include two extra arguments, one to indicate the minimum number of integer digits and the other to specify the maximum number of fractional digits. For S32 values, the fraction displayed is always zero, unless the intlFmtNumScale flag is set. This allows scaling, particularly for displaying currency.

Calls to IntlFormatDate and IntlFormatTime include as an argument a resource tag for a format string. If this tag is not NIL, the routine fetches the format from theProcessResList with a resource group of resGrpTK. You can use the format with Compose Text functions to generate the output string.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IntlFormatS32</td>
<td>Converts a signed integer to a string.</td>
</tr>
<tr>
<td>IntlFormatNumber</td>
<td>Converts a floating point number to a string.</td>
</tr>
<tr>
<td>IntlFormatDate</td>
<td>Converts a time structure to a date string.</td>
</tr>
<tr>
<td>IntlFormatTime</td>
<td>Converts a time structure to a time string.</td>
</tr>
</tbody>
</table>

Parsing routines

These routines convert an input string into the value of the requested type. They return the length of the parsed string. You can treat the string as a single item or as a set of tokens of known type (see ISR.H for further details). Note that the date and time parsing routines only set values for the date elements that they find in the string; they do not set default date values. For example, “September” results only in IntlParseDate setting the mon field and nothing else. You should therefore initialize the INTL_TIME structure with intlTimeStructInit before making a call, so that you can find out which fields were filled.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IntlParseS32</td>
<td>Converts a string to a signed integer.</td>
</tr>
<tr>
<td>IntlParseNumber</td>
<td>Converts a string to a floating point number.</td>
</tr>
<tr>
<td>IntlParseDate</td>
<td>Converts a string to a date as contained in an international time (INTL_TIME) structure.</td>
</tr>
<tr>
<td>IntlParseTime</td>
<td>Converts a string to a time as contained in an international time (INTL_TIME) structure.</td>
</tr>
</tbody>
</table>
CHAPTER 47 / INTERNATIONAL SERVICES AND Routines

International routines

Collation routines

Sort and compare functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IntlCompare</td>
<td>Compares two strings in a linguistically correct method according to the</td>
</tr>
<tr>
<td></td>
<td>locale. You can use it in searching or in sorting a list (although the IntlSort</td>
</tr>
<tr>
<td></td>
<td>routine does that already).</td>
</tr>
<tr>
<td>IntlSort</td>
<td>Sorts an array of strings in a linguistically correct way, according to the</td>
</tr>
<tr>
<td></td>
<td>locale.</td>
</tr>
</tbody>
</table>

String conversion routines

The IntlStrConvert routine converts Unicode strings from one stylistic or linguistic format to another, such as between upper and lower case, katakana and hiragana and composed characters and floating diacritics. Unlike the character-conversion macros in CHARTYPE.H, these routines handle conversions that affect the lengths of strings, or that depend on locale, on context, or on a dictionary for some characters.

You can use the Unicode string conversion routines in three ways:

- In a single call.
- Writing from a single input buffer.
- Using extended input.

See ISR.H for further details on these methods.

Character set conversion routines

Both functions return the number of target characters that were produced (not counting the null) unless there is an error. If IntlMBToUnicode, for instance, finds an unknown character, it converts it to \(0xFFFD\) unless you specify a flag to override this conversion. (The actual character displayed depends on the character set.) The style parameter specifies the character set to convert from.

The difference in the behavior between the null-terminating and counted-string versions of these functions is significant in this area. If, for example, there is no null character in the string given to IntlMBToUnicode, the output buffer fills up and the string is truncated. IntlNMBToUnicode updates the source length to be the number of characters processed and returns normally. To verify that the string was processed, you can then compare the number of characters passed in with the number returned.

By the way, do not confuse these routines with the IntlStrConvert function, which only does conversions within Unicode.

Character set conversion functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IntlMBToUnicode</td>
<td>Converts a multibyte string to a Unicode string.</td>
</tr>
<tr>
<td>IntlUnicodeToMB</td>
<td>Converts a Unicode string to a multibyte string.</td>
</tr>
</tbody>
</table>
String compression routines

String compression functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IntlCompressUnicode</td>
<td>Converts a Unicode string into a compressed form stored in a counted array of bytes. If successful, it returns the number of bytes of compressed data. The output buffer must be big enough to hold the compressed data, so you can call either routine first with a null pointer for the destination, and the required buffer size is return. (Remember to add 1 for the null character when allocating memory for this buffer.)</td>
</tr>
<tr>
<td>IntlUncompressUnicode</td>
<td>Uncompresses a compressed Unicode string. It returns the number of characters produced, unless there is an error. The output buffer must be big enough to hold the uncompressed data, so you can call either routine first with a null pointer for the destination, and the required buffer size is return. (Remember to add 1 for the null character when allocating memory for this buffer.)</td>
</tr>
</tbody>
</table>

Units conversion routine

The IntlConvertUnits routine converts an input value specified in one unit of measure to a value in another unit of measure. (These unit-of-measure definitions are in GOLOCALE.H.) It does not require locale or style as arguments.

Character conversion and testing macros

These macros are defined in CHARTYPE.H:

CHARTYPE macros

<table>
<thead>
<tr>
<th>Macro</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IntlGetCharType</td>
<td>Returns the 16-bit flags that apply to a character from the set defined in the section &quot;Character flags&quot; on page 514. These flags are intended to be “international,” rather than specific to any particular language.</td>
</tr>
<tr>
<td>IntlCharToUpper</td>
<td>If a character is in lower case, it returns the upper-case equivalent; if the character is not in lower case, it returns the character unchanged. One-to-one single character conversions do not work for all characters.</td>
</tr>
<tr>
<td>IntlCharToLower</td>
<td>If a character is in upper case, it returns the lower-case equivalent; if the character is not in upper case, it returns the character unchanged. One-to-one single character conversions do not work for all characters.</td>
</tr>
<tr>
<td>IntlCharIsUpperCase</td>
<td>Returns TRUE if the character passed is an uppercase character.</td>
</tr>
<tr>
<td>IntlCharIsLowerCase</td>
<td>Returns TRUE if the character passed is a lowercase character.</td>
</tr>
<tr>
<td>IntlCharToFullWidth</td>
<td>If a character is half-width, it returns the full-width equivalent; if the character is not half-width, it returns the character unchanged. This macro maps only the romaji and katakana characters, not the hangul ones.</td>
</tr>
<tr>
<td>IntlCharToHalfWidth</td>
<td>If a character is full-width, it returns the half-width equivalent; if the character is not full-width, it returns the character unchanged. This macro maps only the romaji and katakana characters, not the hangul ones.</td>
</tr>
<tr>
<td>IntlCharIsFullWidth</td>
<td>Returns TRUE if the character passed is a full-width character.</td>
</tr>
<tr>
<td>IntlCharIsHalfWidth</td>
<td>Returns TRUE if the character passed is a half-width character.</td>
</tr>
<tr>
<td>IntlCharIsKatakana</td>
<td>Returns TRUE if the character passed is a katakana character. Includes both hankaku and zenkaku katakana.</td>
</tr>
<tr>
<td>IntlCharIsHiragana</td>
<td>Returns TRUE if the character passed is a hiragana character.</td>
</tr>
</tbody>
</table>
### CHARTYPE macros

<table>
<thead>
<tr>
<th>Macro</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IntlCharIsHan</td>
<td>Returns TRUE if the character passed is a kanji, hanja or hanzi character. XJIS gaiji characters are mapped into the private use area: 0xf300 to 0xf5fc.</td>
</tr>
<tr>
<td>IntlCharIsCompatibilityZone</td>
<td>Returns TRUE if the character passed is in the Compatibility zone.</td>
</tr>
<tr>
<td>IntlCharIsGOCorporate</td>
<td>Returns TRUE if the character passed is in the GO Corporate zone.</td>
</tr>
<tr>
<td>IntlCharIsSpace</td>
<td>Returns TRUE if the character passed is a space character of any kind. This does not include cursor movement control characters such as tab and linefeed.</td>
</tr>
<tr>
<td>IntlCharIsAlphabetic</td>
<td>Returns TRUE if the character passed is a character from an alphabetic script. These include Latin, Greek, Cyrillic, and Latin characters from the Compatibility zone and excludes digits, punctuation, spaces, and so on.</td>
</tr>
<tr>
<td>IntlCharIsAlphanumeric</td>
<td>Returns TRUE if the character passed is a character from an alphabetic script or an international digit (for example, [0-9]). This includes Latin, Greek, Cyrillic, and Latin characters from the Compatibility zone and excludes punctuation, spaces, and so on.</td>
</tr>
<tr>
<td>IntlCharIsFloating</td>
<td>Returns TRUE if the character passed is a floating diacritic. These include bound graphemes such as circumflex, accent acute, and daku ten.</td>
</tr>
<tr>
<td>IntlCharIsComposed</td>
<td>Returns TRUE if the character passed is a composed character. Composed characters can reasonably be represented by a base character and a floating diacritic.</td>
</tr>
<tr>
<td>IntlCharIsPunctuation</td>
<td>Returns TRUE if the character passed is a punctuation character.</td>
</tr>
<tr>
<td>IntlCharIsGraphic</td>
<td>Returns TRUE if the character passed corresponds to a glyph. The character cannot be a control, spacing, or undefined character.</td>
</tr>
<tr>
<td>IntlCharIsPrinting</td>
<td>Returns TRUE if the character passed corresponds to a glyph or space. The character cannot be a control or undefined character.</td>
</tr>
<tr>
<td>IntlCharIsControl</td>
<td>Returns TRUE if the character passed is a control character.</td>
</tr>
<tr>
<td>IntlCharIsDecimalDigit</td>
<td>Returns TRUE if the character passed is an international digit ([0-9]).</td>
</tr>
<tr>
<td>IntlCharIsHexadecimalDigit</td>
<td>Returns TRUE if the character passed is a hex digit ([0-9a-fA-F]).</td>
</tr>
</tbody>
</table>
**Character flags**

The following list defines the flags that can be associated with characters. You can obtain the flags for a character through the `IntlCharGetFlags` macro.

- `IntlCharTypeSentEndFlag0`: Can end a sentence
- `IntlCharTypeLineBrkFlag1`: Breaks a line
- `IntlCharTypeSpaceFlag2`: White Space (not tab, line Brk)
- `IntlCharTypeNumberFlag3`: valid char in a number
- `IntlCharTypeWordFlag4`: valid char in a word
- `IntlCharTypeCantStartLineFlag5`: Can’t start a line
- `IntlCharTypeCantEndLineFlag6`: Can’t end a line
- `IntlCharTypeAlphabeticFlag7`: Latin, Greek, or Cyrillic
- `IntlCharTypeFloatingFlag8`: Floating Diacritic
- `IntlCharTypeComposedFlag9`: Composed Character
- `IntlCharTypePunctuationFlag10`: Punctuation Character
- `IntlCharTypeGraphicFlag11`: Any printing, non-space char
- `IntlCharTypeDecimalDigitFlag12`: Decimal digit

**External tables**

The character conversion and testing macros operate on a set of Unicode tables for each alphabet. These tables are defined in `CHARTYPE.H`.

Chapter 48 / Introduction

This document is intended for software developers who are developing products for PenPoint 2.0 Japanese. It provides a description of the user interface from the end-user’s point of view. However, this document is not intended as a user guide to PenPoint.

The structure of this document is designed to be both useful for finding specific information and for reading large sections at a time. A considerable amount of cross-referencing takes place, allowing information to appear in only one place wherever possible.

Information has been presented in a way that focuses on the “component” level, often to the exclusion of the “big-picture” level that is provided by end-user documentation. Many of these components are used in multiple places throughout PenPoint, and this provides the rationale behind the structure.

The major change between version 1.0 and 2.0 of the PenPoint operating system is support of the Japanese language. Specifically, PenPoint 2.0 Japanese is the Japanese version of PenPoint, as well as the foundation for a future international versions of the operating system. Changes to functional components from PenPoint 1.0 can be found in the sections labelled “Change Notes.”

This document relies heavily on the existing set of PenPoint 1.0 documentation, especially the PenPoint User Interface Design Reference.
Chapter 49 / The Notebook

The Notebook application is the principal user interface to the PenPoint system provided by GO Corporation, the NUl (Notebook User Interface). It serves as the organizing metaphor for the user as well as the underlying component for the Stationery notebook and other system-level applications.

Table of Contents

The Table of Contents (TOC) of the PenPoint 2.0 Japanese notebook is used as the central location for management of documents. The TOC is an application itself that runs inside the Notebook application (clsSectApp).

Operational model

The TOC is the central application in the PenPoint Notebook, appearing on the first page of the Notebook and controlling creation and navigation of the Notebook contents. The user can not delete the TOC page from the Notebook.

The user can only select one item (document or section) at a time in the TOC. The user can re-order pages by moving or copying document icons. To move the document, the user presses the document title and drags it a new location. Similarly, to copy the document, the user taps the document title and drags the marquee to a new location.

When the user creates a new document, the icon appears in one of three places, depending on how the user creates the document:

- At the gesture point if the user uses the caret \ gesture.
- Below the current selection if the user taps Y on the menu item Create.
- After the last page if there is nothing selected when the user taps Y on Create.

The user turns to documents in the Notebook with the tap Y gesture. A double tap Y gesture floats (if float is enabled) the document over the TOC. The user may tap on the page number or the icon or button (depending on the view) to the left of the document name. A tap on the document name selects the text. A double tap on a section name expands the section in the TOC. The circle O gesture is used to edit document names.

Standard elements

The TOC contains a list of the documents and sections currently in the Notebook, along with the pages on which they are found. Section pages contain another TOC for that section. The Layout menu controls the view of the TOC.

Menus

There are five menus in the TOC: Document, Edit, Options, View, and Create.

Document menu

Send Document Submenu of available services. Selected documents are sent via selected service.

About Contents Information sheets on Table of Contents.

Edit menu

Move Places selection into Move mode.
Copy Places selection into Copy mode.
Delete Deletes selection. Confirm note is opened.
Rename Opens Edit Pad with selection name available for editing.

Options menu

Document Only available when a document is selected. Opens Document option sheet.
Section Only available when a section is selected. Opens Section option sheet.
Layout Opens Layout option sheet.
Controls Opens Controls option sheet.

View menu

Expand Opens all sections one level if no selection. Opens selected section one level.
Collapse Collapses all sections if no selection. Collapses selected section.
Turn To Turns to selected document or section.
Bring To Floats selected document or section.
Create menu

Document List  A list of all documents in Stationery notebook that have Menu checked. When the user selects one, PenPoint creates a new document of that type after currently selected document or at end of TOC if no selection.

Section  Creates a new section after current selection or at end of TOC if no selection.

Option sheets

There are 4 option sheets available from the Table of Contents: Document, Section, Layout, and Controls. The Document/Section sheets are only visible when a Document/Section is selected. The main TOC page (as opposed to the Section TOC pages) is the only page in the Notebook that does not have the standard Access and Comments option sheets. The Access Speed for the main TOC is always set to Accelerated.

Document

The Document option sheet provides access to the fixed and variable attributes of a selected document. These include:

Title  The title of the document; not editable here.
Type  The type of document (the application it represents); not editable.
Created  The creation date and time; not editable.
Last Modified  The date and time of the last access (last checkpoint or page-turn away from document); not editable.
Filed Size  The size of the file on disk in kilobytes; not editable.
Author  The author; editable.
Comments  Comments; editable.

Section

The Section option sheet is the same as the Document option sheet described in the preceding section, only the title changes from Document to Section. The option sheet changes its content as the user changes the selection.
**Layout**

The Layout option sheet provides controls for the visual display of the TOC. The Show choice allows the user to select either icons or square buttons or neither as the indicator to the left of the document name. The default is Icons.

The Columns checklist is a multiple choice list that sets up the columns displayed in the TOC as well as the Column Headers. The Document name and Page number always appear, and the user cannot remove them. The default is Column Headers.

The Sort pop-up selects the sort criteria for the TOC. There are five choices: Page, Name, Type, Date, Size. The default is Page. Sort direction is ascending for Page, Name, and Type; descending for Date and Size. Sorting only affects the display in the TOC; it does not re-order the pages of the Notebook.

In PenPoint 2.0 Japanese the sort order is phonetic, with kanji being indexed by the first phonetic of their Chinese reading according to the JIS standard. Non-JIS characters follow in Unicode order.

![Layout Option Sheet](image)

**Controls**

The Controls option sheet is the standard PenPoint Controls sheet with the only choices being: Menu Line, Scroll Margins, and Cork Margin. The default state is Menu Line on, Scroll Margins on, and Cork Margin off.

**Tabs**

**Change notes**

- Tabs do not contain vertical text.
- Contains zenkaku by default.
Chapter 50 / The Bookshelf

Help

Change notes
There are no functional changes to the Help system from 1.0 to 2.0.

Settings

Operational model
The Settings notebook gives the user a single place to go to view and modify settings both for the PenPoint 2.0 Japanese operating system as a whole and for whatever software is currently installed in the system.

While it employs the notebook metaphor, the Settings notebook differs from the normal PenPoint data notebook in two ways:

- It is optimized for quick navigation through a small number of pages with only one level of sections. Instead of local contents pages for each section, each page has a pop-up menu in its title line allowing the user to turn to any other page in that section.
- It is not editable in any way by the user. Neither the pages nor the tabs can be deleted, re-ordered, or renamed, and the table of contents has no menu line and no display options.
- It doesn't have page numbers.
Change notes

- Pen section changed to Pen & Keyboard.
- Writing changed to Writing Style and moved to fifth position from the first position.
- Keyboard choice added to Pen & Keyboard with pop-up: American, Japanese A01.
- Import/Export choice added to Fonts & Layout with pop-up: 1990 JIS, 1978 JIS.
- Kana-Kanji Conversion section added to Software section.
- Practice… button (and facility) removed from Handwriting sheet.
- Date formats changed.
- Time formats changed.

Preferences

The user uses the Preferences section of the Settings notebook for viewing and setting system-wide user preferences. It contains 8 sections.

Pen & Keyboard

There are 5 preferences for pen and keyboard input:

- Tap to Align Pen  User taps in center of square to align pen.
- Pen Cursor  User can turn pen cursor on or off (default = off).
- Primary Input  Determines primary input device, pen or keyboard (default = pen).
- Writing Timeout  Interval system pauses after user lifts pen from screen before translating input (default = 0.6 seconds, range = 0.2 to 1.0 in 0.1 increments, 1.2, 1.5, 2.0 seconds).
- Press Timeout  Interval user must touch the pen to the screen before the press gesture is recognized (default = 0.5 seconds, range = 0.2 to 1.0 seconds in 0.1 increments).

![Preferences & Pen & Keyboard](image-url)
**Fonts & Layout**

**PenPoint Font**  Font used by system and applications for text (not in edit fields) (default = Mincho, choices = Gothic, Roman, Courier, Sans Serif, Mincho).

**Field Font**   Font used by system for translated text (default = Mincho, choices = Gothic, Roman, Courier, Sans Serif, Mincho).

**Font Size**   Font size (in points) used as default for both system text and field text (default = 12 pt., choices = 10, 12, 14, 16, 18, 20, 24 pt.).

**Top Edge**   Determines orientation of screen. Menu has four arrows, one pointing to each edge of computer. The user chooses one arrow to re-orient the display so that the edge is at the top. After the user taps the Apply button, the arrow again points to the top edge.

**Hand Preference**   Hand Preferences for screen layout. Effects placement of scrollbars (default = Right, choices = Left, Right).

**Scroll Margins**   Allows user to choose either a traditional scroll margin with arrows and a drag box or a simple margin for flicking (default = Arrows & Drag Box, choices = Tap & Flick Area, Arrows & Drag Box).

**Import/Export**   Determines the data exchange format to use (default = New JIS, choices = New JIS, JIS).

---

**Float & Zoom**

**Floating Documents**   Determines if the user can float documents or not (default = Not Allowed, choices = Allowed, Not Allowed).

**Zooming Documents**   Determines if the user can zoom documents or not (default = Not Allowed, choices = Allowed, Not Allowed).
Writing

Writing Style  Determines the type of character input allowed (default = Mixed Case, choices = Upper Case Only, Mixed Case [applies to Roman text only]).

Writing Pad  Determines type of box used in edit pads (default = Boxed, choices = Ruled/Boxed, Ruled, Boxed).

Box Size  Determines size of box in edit pads with boxes (default = Medium, choices = Very Small, Small, Medium, Large, Very Large).

Box Shape  Determines the proportional shape of the box in edit pads (default = Medium, choices = Short, Medium, Tall).

Ruled Height  Determines the height of space above ruled line in edit pads (default = Medium, choices = Very Small, Small, Medium, Large, Very Large).

Unrecognized Character  Determines character used to indicate unrecognized character, default = 8, choices = 8, _).

Time

Current Time  Current time as read from the system clock.

Time Zone  Local time zone, with hours difference from GMT (default = +9 Tokyo).

Format  Determines the time format that the user would like PenPoint and applications to display.

Style  Determines the style of the time display that the user would like PenPoint and applications to display.

Seconds  Determines if the user wants seconds displayed as part of time (default = Not Displayed, choices = Displayed, Not Displayed).

Hour  Write-in field to allow user to set the hour (range = 1 to 12 for 12-hour format, 0 to 23 for 24-hour format).
Minute  Write-in field to allow user to set the minutes (range = 0 to 59).
Second  Write-in field to allow user to set the seconds (range = 0 to 59).
A.M./P.M.  Sets A.M./P.M. for time (available only when format = 12 hours).

**Date**

Current Date  Current date as set in the system clock, displayed in format set below.
Format  Determines default format for display of date.
Month  Determines month of year (choices = January to December).
Day  Write-in field for day of month (range = 1 to number of days in selected month).
Year  Write-in field for last two digits of year, assumes 19 preceding these digits (range = 70 to 99).
Sound

Warning Beep  Determines if warning beep sound is made on error conditions (default = On, choices = On/Off).

Power

If a machine does not have suspend capability, then Manual Standby and Auto Standby choices are not visible.

Manual Standby  Button that puts the processor into suspend mode.

Manual Shutdown  Button that shuts the system down, unless Auto Standby is on, then processor goes into suspend mode.

Auto Standby  Determines if PenPoint automatically suspends the processor whenever there is no input from the user for the specified period (default = No, range = 1 to 99 minutes).

Shutdown from Standby  Determines if PenPoint automatically shuts the processor down whenever the system remains suspended (in Standby) for the specified period (default = No, range = 0.10 and 9.0 hours).

Auto Power-Off Devices  Determines if the computer's main circuitry and peripherals automatically power down when not in use. The manufacturer specifies the period of inactivity after which each device powers down (default = No, choices = Yes, No).

Battery  Gauge of how much power remains in the battery.
**Installed software**

The second section of the Settings notebook is for installed software. The Installed Software section has a page for each category of installable software. From these pages the user can:

- See what's currently installed on the machine.
- Perform housekeeping functions such as deinstalling, saving to disk, restoring from disk.
- Set any options that the installed software provides. For example, an application may provide options that apply to all instances of the application.

There are seven pages (categories) to the Installed Software section of the Settings notebook. All seven have the same two menus: Edit and Options.

**Applications**

The Applications page shows the applications currently installed in the system. The Install... button on the right of the menu line (common to all the pages of the Installed Software section) displays a sheet showing the installable software of the appropriate category. The user taps on the checkbox to install (or deinstall) any of the installable items.

**Services**

The Services page shows the installed services. Services include printer drivers, network connections, and other system-level programs.
**Handwriting**

The Installed Handwriting page shows the installed handwriting profiles. Each profile is associated with a handwriting engine and indicates the Current profile.

**Dictionaries**

The Dictionaries page shows the installed dictionaries. Tapping the Open... button opens the selected dictionary (or current dictionary, if none is selected) into its own pop-up sheet.

**Fonts**

The Fonts page shows the installed fonts for the system.
**User Profiles**

The User Profiles page shows all the profiles established for a machine. A user profile consists of all the preference settings for that user. Tapping the checkbox to make a profile current is equivalent to applying all the user's preferences in a single step.

![User Profiles Table]

**Status**

**Storage Summary**

The Storage Summary page shows the user how much space is currently being used in the machine for storage, and how much remains to create and work with documents. This page is dynamic and updates to reflect changes in usage when it is open.

- **Storage Space** The amount of space available for documents, accessories, and installed software. This is the space available to create new documents, copy existing documents, import files from disk, or install new software.

- **Working Space** The amount of space available for active documents. Active documents include open documents and accessories, and also any documents for which the user has set Access Speed to Accelerated on the Access sheet.
Storage Details

The Storage Details page presents a finer-grained view of the storage space usage than the Storage Summary page.

This page lists:

- Amount of installed RAM (MB).
- Size of internal disk (MB).
- Amount of space on internal disk used by PenPoint operating system.
- Amount of space on internal disk used by other PenPoint files.
- Amount of space on internal disk reserved as working space.
- Amount of space on internal disk used by the installed software (exclusive of PenPoint).
- Amount of space on internal disk used by documents.
- Amount of free space available on internal disk.

PenPoint

This page indicates the version of PenPoint currently running, along with the Copyright notice for the system.
**Accessories**

**Unicode Browser**

The Unicode Browser is an accessory to help the user find specific characters and put them into the input stream. It contains all the characters available in the Japanese fonts when those fonts are installed. (The figure below is not an exact representation.)

The first row of characters in the Unicode Browser are hiragana, katakana, roman alphabet, punctuation, accented upper case roman alphabet, accented lower case roman alphabet, gesture font, GO UI glyph font. The remaining rows of the browser contain the kanji radicals.

Tapping on any character in the top level of the Browser opens a submenu. For non-kanji (the top row), the submenu contains the characters in the set represented. For kanji radicals, the submenu contains all characters that use the top-level radical as their base radical. The size of this submenu varies from radical to radical.

Tapping on a character in the submenu inserts that character into the input stream at the current insertion point. After the user makes a selection, the submenu closes, and the Browser remains open. Tapping outside the submenu closes the submenu without any character being selected. If there is no current insertion point, the submenu closes and nothing happens.

The Unicode Browser only accepts the tap gesture as a valid gesture on the top level and the second-level submenu. The close corner closes the Browser.
Keyboard

The PenPoint™ operating system provides a virtual keyboard. The virtual keyboard enters text directly into the input stream.
Chapter 51 / Overall System Changes

This chapter describes changes that affect aspects of the PenPoint user interface throughout the system.

**Option sheets**

The option sheet model has not changed between PenPoint 1.0 and PenPoint 2.0. You can find additional information about option sheets in this document in:

- “MiniText,” below.
- “MiniNote” on page 539.

**MiniText**

MiniText is a simple text processor provided with PenPoint 2.0 Japanese. It provides multifont capabilities and simple formatting tools. MiniText is implemented as a “wrapper” around the text component of PenPoint. Because it is based on the core text component, it has changed to support Japanese in PenPoint 2.0.

Like most word-processor applications, MiniText uses a blank page into which the user can begin entering text. Input is accomplished in either in-line edit pads, through pop-up edit pads, or with the keyboard. The user selects text and then operates on it for most commands.

MiniText provides text editor and formatting features in a simple interface. The user can format characters and paragraphs, set tabs, as well as embed signatures for letters and other documents.

**Change notes**

These items have changed in MiniText:

- Units are changed from inches to centimeters.
- Case menu is removed.
- Convert menu is added.
- Default font becomes 12 pt. Mincho.
- Convert text gestures (H, Z) added.
- Greater keyboard support provided.
- Proof & Spell functionality only works on English words.
- Text wraps according to Japanese Taboo processing protocols.
- Fully justified text according to Japanese methods.
- Hankaku and zenkaku spaces added to Insert menu.
Option sheets

MiniText provides four option sheets. The user customizes the text and the display of the text with these sheets. All the functionality in these option sheets is part of the PenPoint text component and is available to any application that uses the text component.

Character option sheet

The Character option sheet contains three controls: Font, Size, and Style. The user controls the attributes of the characters in a document with this sheet.

- **Font**: A pop-up list of the fonts currently installed in PenPoint 2.0 Japanese. The default is Mincho.
- **Size**: A pop-up list of the font sizes available for the selected font. The default size is 12 pt.
- **Style**: A multiple checklist of the styles that can be applied to a font. The default is that no additional styles are added to text.

Paragraph option sheet

The Paragraph option sheet contains eight controls. The user sets the attributes of paragraphs in the document with this sheet.

- **Alignment**: The user aligns paragraphs left, right, center, or justified.
- **Line Height**: Height in centimeters.
- **Between Lines**: Space between lines, in centimeters.
- **1st Line Offset**: The user sets the amount of space that the first line is offset.
- **Left margin**: In centimeters.
- **Right Margin**: In centimeters.
- **Space Before**: Space left before a paragraph, in centimeters.
- **Space After**: Space left after a paragraph, in centimeters.

Tab Stops option sheet

The Tab Stops option sheet allows the user to create the tabs for a paragraph. There can be a maximum of 31 tabs. The user adds new tabs with the caret \ gesture on this option sheet and deletes existing tabs with the cross out x gesture. The user specifies tab stops in centimeters.

Display option sheet

The Display option sheet contains two controls that affect the display of the Mini-Text document.

- **Magnify Text on Screen**: Magnification of document display, in text points added to the current point size.
- **Show Special Characters**: Toggles display of tab, line break, and paragraph break characters.
Non-core gestures used in MiniText

<table>
<thead>

</tr>
</tbody>
</table>

1. The selection works only on characters of the same type, for example all hankaku. When there are mixed characters, only characters of the selected type are acted upon.
Menus

The menu structure of MiniText provides the dual command path for the gestures and option sheets.

Edit menu

Most of the Edit menu commands provide the standard functionality described in the PenPoint User Interface Design Reference. Those commands specific to MiniText are:

- Undo: Disabled when keyboard KKC is active.
- Edit: Opens an edit pad with the current selection in it.
- Proof: Opens a proof pad with current word and suggested alternates; only works on English words.
- Spell: Only works on English words.

Options menu

- Character: Opens Character option sheet ("Character option sheet" on page 536).
- Paragraph: Opens Paragraph option sheet ("Paragraph option sheet" on page 536).
- Tab Stops: Opens Tab Stops option sheet ("Tab Stops option sheet" on page 536).
- Display: Opens Display option sheet ("Display option sheet" on page 536).
- Controls: Opens Controls option sheet.
- Comments: Opens Comments option sheet.

View menu

The View menu contains two checklists. Selections immediately update the view of the document.

- Screen Format/Printer Format: Toggles the view of the document between Screen Format, text wraps to the right edge of the current viewing region and Printer Format, text wraps to the right of the currently selected paper size.
- Magnification: Checklist of magnification factors. This is the same as the magnification found in the Display option sheet (see page 536). Magnification only applies when the Screen Format view has been selected, although control is always available.

Insert menu

- Tab: Inserts a tab at the insertion point.
- Hankaku Space: Inserts a hankaku space at the insertion point.
- Zenkaku Space: Inserts a zenkaku space at the insertion point.
Line Break  Inserts a line break after the insertion point.
Paragraph Break  Inserts a new paragraph at the insertion point.
Page Break  Inserts a new page after the insertion point.
Pop-up Pad  Opens a pop-up edit pad; contents go to insertion point.
Embedded Pad  Opens an embedded edit pad at insertion point.
Signature Pad  Places a signature (ink only) pad at insertion point.

군

Convert menu
The Convert menu provides functionality for converting text between hankaku and zenkaku.

To Hankaku  Converts selected text to hankaku.
To Zenkaku  Converts selected text to zenkaku.
To Uppercase  Converts selected text to all uppercase characters (romaji only).
To Lowercase  Converts selected text to all lowercase characters (romaji only).
Initial Caps  Converts selected text to an initial capital letter at the start of each word (romaji only).

MiniNote
MiniNote is an ink processor implemented around PenPoint's ink component (clsNotePaper).

MiniNote has two input modes: ink mode and gesture mode. The default mode is ink mode. In ink mode, pen input is accepted as is and stored as ink, with the following exceptions:

• The double tap  gesture over an ink object selects the object.
• The scratch out  gesture deletes the object.
• The user can make gestures over selected objects.
• The tap press  gesture over white space begins an area select.
• The flick left right  gesture toggles between the two modes.
• The caret tap  gesture for Date/Time menu.

Gesture mode allows the core gestures anywhere on the screen.

The screen is presented as a blank sheet of paper (lined in some predefined stationery) on which the user can begin writing. The menu line contains a mode toggle on the right side. The pen icon indicates ink mode. The check icon indicates gesture mode. The icons are a simple toggle switch that responds to a tap gesture.
**Gesture margin**

MiniNote has a gesture margin that facilitates line-oriented operations. The margin also provides additional mode feedback: it is grey in ink mode and white in gesture mode.

Most of the gestures that are accepted in the body of the document can be made in the gesture margin, where they are interpreted as applying to the entire line. For example, double tap \( \sqrt{ } \) selects the line, circle \( \bigcirc \) edits the line, down left \( \_\_\_ \) tidies the line, and tap press selects the line.

Other useful margin gestures include right down \( \rightarrow \) and right up \( \rightarrow \), to open and close white space by the amount of the vertical leg of the gesture. Left down and left up \( \leftarrow \) are also accepted, and are more easily made if the gesture margin is on the right.

**Option sheets**

MiniNote has two unique Option sheets: Paper and Pen.

**Paper option sheet**

The Paper option sheet allows the user to specify the size and appearance of the paper upon which he or she is writing.

- **Paper Style** Allows the user to specify the ruling of the paper from among the 8 choices available. This is a boxed choice list.
- **Font** Allows the user to select the font for all the translated text in a MiniNote document. The choices are the installed fonts in the system.
- **Line Height** Contains two fixed line heights: College Ruled (18 pts.), and Standard (24 pts.), as well as a text field for entering an arbitrary height in points.
- **Paper Width** Has an overwrite field containing the current paper width and two commands that affect the contents of the field. The overwrite field is scaled in centimeters.
  - **Same as Document** The current width of the viewing region into the overwrite field so that a horizontal scroll margin is not needed.
  - **Same as Print Settings** The current paper width (taken from the Paper Size control on the Print sheet) into the overwrite field.
**Pen option sheet**

The Pen option sheet controls the pen width and color. The choices presented in this sheet are the same as those for the Pen menu.

**MiniNote gestures**

Gestures that work in MiniNote

<table>
<thead>
<tr>
<th>Gestures</th>
<th>Name</th>
<th>Action</th>

**Edit menu**

Delete  Deletes selected objects, closes gap.
Clear  Deletes selected objects, leaves gap.
Insert Line  Inserts a blank line above the selection.
Translate  Translates selection.
Translate & Edit  Translates selection and opens edit pad with translation (Reads Edit for already translated selection).

**Options menu**

Pen  Opens Pen option sheet (“Pen option sheet” on page 541).

**Arrange menu**

Tidy  Moves selected objects to left to even gaps between objects.
Center  Centers the selected objects.
Align Left  Multiple line only. Shifts lines left to begin in same column as left-most line.
Align Right  Multiple line only. Shifts lines right so that they all end in same column as right-most line.
Group  Joins selected objects of like type (scribbles with scribbles, text with text) into a single object.
Ungroup  Breaks a grouped object into constituent scribbles.
Pen menu

See “Pen option sheet” on page 541 for illustrations.

Edit pads

The edit pad (Input Pad) is one of the most universally used controls in PenPoint. It provides the optimized interface for precise and modal handwriting entry. Because of the intimate connection between edit pads and the language being input, edit pads have changed significantly to accommodate Japanese in PenPoint 2.0. This section describes both English language edit pads and Japanese language edit pads. In PenPoint 2.0 Japanese, the language of the text determines the input pad provided by the system. Edit pads are created with clsIP.

Operational model

The circle gesture opens an edit pad. A circle opens an input pad for the object that was the target of the gesture. Edit pads are system modal. PenPoint selects the object being edited so that the user can see what he or she is operating on in context. A caret gesture provides a blank edit pad (often referred to as a writing pad).

Change notes

Japanese edit pads introduced.

English edit pads

The English edit pads are the standard tool for entering and editing English text. In PenPoint 2.0 Japanese, they are used whenever romaji text is edited.

Standard elements

Edit pads come in three styles: boxed, ruled, and ruled/boxed. The boxed style is segmented into character spaces, and the ruled style is not. The ruled/boxed style is ruled when blank, and becomes boxed for all editing. Edit pads have three buttons: OK, Clear, and Cancel.

Input pads in version 2.0 are always in overwrite mode. Additionally, context checking is on during the first translation from ink to text.

The buttons for boxed pads work as follows:

- **OK**: Translates untranslated strokes or closes and accepts completely the translated text. If the pad is empty when the OK button is pressed, the pad is closed and nothing is entered into the text stream. If there are all untranslated strokes in the pad, then OK translates them. Subsequent strokes are translated automatically.
- **Clear**: Clears all text/ink from the writing area.
- **Cancel**: Closes pad without accepting any changes made.
In ruled pads, the OK button both translates the ink and puts the text into the text stream.

In ruled/boxed pads, the OK button presents a boxed pad for editing of the translated text.

**Edit pad gestures**

You can use these gestures in input pads:

### Gestures used in edit pads

<table>
<thead>
<tr>
<th>Gesture</th>
<th>Name</th>
<th>Keyboard</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Pigtail</td>
<td>Delete or Backspace</td>
<td>Deletes single character.</td>
</tr>
<tr>
<td>=</td>
<td>Scratch out</td>
<td></td>
<td>Deletes every character it touches.</td>
</tr>
<tr>
<td>l</td>
<td>Down right</td>
<td>Space</td>
<td>Inserts spaces equal to the length of the right stroke.</td>
</tr>
</tbody>
</table>

This example shows the typical steps you would go through to enter and translate text in an edit pad.

**Translating text in edit pads**

User makes caret gesture, with tip of caret targeted where new text is to be inserted.

Blank ruled pad pops up.

User writes in the pad.

The user taps on OK to translate the text.

The translated text is presented in overwrite boxes for easy correction.
Translating text in edit pads

We designed the Japanese edit pads to make correction of near-miss translations easy and make kana-kanji conversion through both pen and keyboard easier and more accessible.

**Standard elements**

The Japanese input pad supports kana-kanji conversion (KKC) in a seamless and easy-to-use fashion. A new type of highlight, **weak highlight**, has been introduced to help support KKC. Weak highlight occurs after character entry by keyboard:

![Example](image1)

When a phrase (press spacebar once) has been selected, it gets a **strong highlight**:

![Example](image2)

The user can press the spacebar again to get a **choice list** of other phrases to substitute. To select one, use the arrow keys to get to desired choice and use enter key to select:

![Example](image3)

When the entire phrase has been explicitly accepted through a return, the text changes to the no highlight state, ready to accept further keyboard input:

![Example](image4)
If the user enters a new character from the keyboard, a **weak selection** point appears in the text box:

![Character Example]

All forms of text entry devices used with the keyboard (boxed fields, write-in fields, and in-line text views) use these same states—weak highlight, strong highlight, weak selection.

The Japanese input pad is larger than the English input pad to better accommodate the characters and the choice list.

**Character alternative list**

The character alternative list allows the user to select alternatives to the displayed character. This is important because of the occurrence of character “look-a-likes” and homophones among the character set.

![Character Example]

The list contains the known look-a-likes first, in stable order, and always contains a period and katakana middle dot as the last two entries. The choices are laid in an approximately square matrix with the current choice highlighted when the list is opened. The actual character that was written is not necessarily always the first choice in the list. The common endings are removed from the KKC alternatives. The user can access the choices on the list without opening the list through the use of gestures. The last two glyphs in the list are period and katakana middle dot, so that these characters can be accessed in overwrite mode through the list.

![Character Example]

The user can use the arrows key to navigate through this list. The up/down arrow keys will move through the list, wrapping from column to column. The left/right arrow keys will wrap from row to row.
Unicode to character conversion

If the user knows the Unicode equivalent for a character, they may enter the 4-digit code in an input pad and convert it to the character with the right up gesture. If the code is also a valid Shift-JIS or kuten code, the converted characters will appear as alternatives in the choice list.

Part 7 / Sample Code
This chapter lists the source code of the sample applications referred to in the preceding chapters of this book, and describes some of the other applications included with the PenPoint™ SDK. If you have installed the SDK, you'll find the sample code in subdirectories of PENPOINT\SDK\SAMPLE.

The following sample applications are described and their code is listed in this chapter.

551 Empty Application Just about the simplest application you can create.
554 Hello World (toolkit) A simple application that uses the UI Toolkit to display the words “Hello World.”
560 Hello World (custom window) A simple application that uses the ImagePoint™ graphics system to display the words “Hello World.”
568 Counter Application A simple application that saves and restores its data.
578 Tic-Tac-Toe A full-featured PenPoint application.
625 Template Application A template for a full-featured PenPoint application.

The following sample applications are described in this part, but their code is not listed. The sample code is part of the SDK and is in 12-0\PENPOINT\SDK\SAMPLE.

638 Adder A simple pen-centric calculator, limited to addition and subtraction.
639 Calculator A floating, button-operated calculator.
640 Clock A digital alarm clock accessory.
642 Notepaper Application A note-taking application that uses the NotePaper DLL.
643 Paint A simple raster painting program.
644 Toolkit Demo Examples of how to use many of the classes of the UI Toolkit.
646 Input Application An example of pen-based input handling.
647 Writer Application An example of handwriting translation.
648 Keisen Table Application An application that creates a complex layout using clsTkTable.
650 List Box Demo An application that uses clsListBox.
651 Sample Application Monitor An application that implements a reasonably sophisticated application monitor.
652 Serial Transmission Demo An application that uses simple serial I/O from within PenPoint.
653 User Interface Companion An application that implements many of the diagrams in the PenPoint User Interface Design Reference.
655 Basic Service The absolute minimum code required for a service.
656 Test Service A template for services, including message handler stubs for the most common service messages.
657 MIL Service A template for Machine Interface Layer services (device drivers).
Empty Application

Empty Application is the simplest sample application distributed with the PenPoint Software Developer's Kit. It does not have a view or any data. The only behavior it adds to the default PenPoint application is to print out a debugging message when the application is destroyed. To provide this behavior, Empty Application defines clsEmptyApp, which inherits from clsApp. In its handler for msgDestroy, clsEmptyApp prints out a simple debugging message.

clsEmptyApp inherits a rich set of default functionality from clsApp. When using Empty Application, you can create, open, float, zoom, close, rename, embed, and destroy Empty Application documents.

Objectives

Empty Application is used in the PenPoint Application Writing Guide to show how to compile, install, and run applications. This sample application also shows how to:

- Use Debugf() and #ifdef DEBUG and #endif pairs.
- Turn on message tracing for a class.
- Let the PenPoint Application Framework provide default behavior.

Class overview

Empty Application defines one class: clsEmptyApp. It makes use of the following classes:

- clsApp
- clsAppMgr

Files used

The code for Empty Application is in PENPOINT.SDK.SAMPLE.EMPTYAPP. The files are:

- METHODS.TBL  The list of messages that the application class responds to, and the associated message handlers to call.
- EMPTYAPP.C  The application class's code and initialization.
This file contains just about the simplest possible application. It does not have a window. It does not have any state it needs to save. This class does respond to a single message, so it has a separate method table and a method to handle that message. All the method does is print out a debugging string.

If you turn on the "F1" debugging flag (e.g. by putting DEBUGSET=DF0001 in \penpoint\boot\environ.ini), then messages to clsEmptyApp will be traced.

```c
STATUS EXPORTED EmptyApplnit (void);
#define clsEmptyApp wknGDTa

/* utility routines */
#include <methods.h>
#include <string.h>
```

---

Installation

---

```c
STATUS
ClsEmptyApplnit (void)
{
    APP_MGR_NEW new;
    STATUS s;
    // Install the Empty App class as a descendant of clsApp.
    ObjCallWarn(msgNewDefaults, clsAppMgr, &new);
    new.object.uid = clsEmptyApp;
    new.cls.pMsg clsEmptyAppTable;
    new.cls.ancestor clsApp;
    // This class has no instance data, so its size is zero.
    new.cls.size = Nil(SIZEOF);
    // This class has no msgNew arguments of its own.
    new.cls.newArgsSize = SizeOf(APP_NEW);
    new.appMgr.flags.accessory = true;
    Ustrcpy(new.appMgr.company, U_L("GO Corporation"));
    Ustrcpy(new.appMgr.defaultDocName, U_L("Empty App Document"));
    ObjCallJmp(msgNew, clsAppMgr, &new, s, Error);
    // Turn on message tracing if flag is set.
    if (DbgFlagGet('F', OxlL)) {
        Debugf(U_L("Turning on message tracing for clsEmptyApp"));
        (void)ObjCallWarn(msgTrace, clsEmptyApp, (P_ARGS) true);
    }
    return stsOK;
    Error:
    return s;
} */ ClsEmptyApplnit */
```
/***************************************************************
main

Main application entry point (as a PROCESS -- the app's MsgProc
is where messages show up once an instance is running).

{
   Dbg(Debugf(U_L("main: starting emptyapp.exe[\%d]"), processCount);)
   if (processCount == 0) {
      // Create application class.
      ClsEmptyAppInit();
      // Invoke app monitor to install this application.
      AppMonitorMain(clsEmptyApp, objNull);
   } else {
      // Create an application instance and dispatch messages.
      AppMain();
   }
   // Suppress compiler's "unused parameter" warnings
   Unused(argc); Unused(argv);
} /* main */
Hello World (toolkit)

One of the simplest applications in any programming environment is one that prints the string “Hello World.” Because PenPoint provides both an API to the ImagePoint imaging model and a rich collection of classes built on top of ImagePoint, there are two different approaches to building a “Hello World” application. They are:

1. Create a window and draw text in it using ImagePoint calls.
2. Use PenPoint's UI Toolkit classes to create a label object. Each of these approaches is worth demonstrating in a sample application.

The first is a good approach for programs that need to do a lot of their own drawing, such as free-form graphics editors. The second approach shows how easy it is to use the toolkit classes, and serves as an example for programs that need to draw forms or other structured collections of information.

Therefore, there are two “Hello World” sample applications: Hello World (custom window) and Hello World (toolkit). The rest of this document describes Hello World (toolkit).

Hello World (toolkit) uses clsLabel, the UI Toolkit label class, to display the words “Hello World” in a window. The simplest way of doing this is to make a single label, which also serves as the window for the application. The code for doing so is in HELLOTK1.C. Since developers will typically want to display more than one toolkit class in a window, we created a second file, HELLOTK2.C, that shows how to create a layout object (a window with knowledge of how to lay out toolkit objects) and a label which is inserted into the layout object.

To change between these two source code files, simply copy the version you want to HELLOTK.C before compiling the application (see the README.TXT file in PENPOINT\SDK\SAMPLE\HELLOTK for more detailed instructions).

Objectives

This sample application shows how to:

- Use clsLabel.
- Create a custom layout window.

Class overview

Hello World (toolkit) defines one class: clsHelloWorld. It makes use of the following classes:

- clsApp
- clsAppMgr
- clsCustomLayout
- clsLabel

Files used

The code for Hello World (toolkit) is in PENPOINT\SDK\SAMPLE\HELLOTK. The files are:

- METHODS.TBL the method table for clsHelloWorld.
- HELLOTK.C source code (actually a copy of either HELLOTK1.C or HELLOTK2.C) which the makefile compiles.
- HELLOTK1.C source code for making a single label, which also serves as the window for the application.
- HELLOTK2.C source code for making a layout object and inserting a label in it.

$Revision: 1.12 $
$Author: kcatlin $
$Date: 12 Aug 1992 17:49:16 $
This file contains the application class for a "Hello World" application
using toolkit components. This uses the PenPoint UI Toolkit to draw in
its window -- thus it does not create a window class. It creates a label
as its client window in response to msgAppInit. It has dummy message
handlers for msgAppClose and msgAppOpen so it can share the same methods.tbl
with hellotk2.c.
It does not have any state it needs to save.
It does not have any instance data.
Most applications have more than one window in their frame. hellotk2.c
is an alternative version of hellotk.c which creates a label inside a
custom layout window.

DEBUG FLAGS:
If you turn on the "F20" debugging flag (e.g. by putting DEBUGSET=/F020
in \penpoint\boot\environ.ini), then messages to clsHelloWorld will be traced.

$Revision: 1.13 $
$Author: kcatlin $
$Date: 12 Aug 1992 17:49:26 $
This file contains the application class for a "Hello World" application
using toolkit components. This uses the PenPoint UI Toolkit to draw in
its window -- thus it does not create a window class. Instead, it creates
a custom layout window in its frame and inserts a label within the layout
window. (The other version of hellotk.c does not use custom layout or
create more than one toolkit window.)
It does not have any state it needs to save.
It does not have any instance data.
DEBUG FLAGS:
If you turn on the "F20" debugging flag (e.g. by putting DEBUGSET=/F0020
in \penpoint\boot\environ.ini), then messages to clsHelloWorld will be
 traced. If you turn on the "F40" debugging flag then the custom layout window
will be visible (gray background, rounded border).

**Hello World (custom window)**

One of the simplest applications in any programming environment is one that prints the string “Hello World.” Because PenPoint provides both an API to the ImagePoint imaging model and a rich collection of classes built on top of ImagePoint, there are two different approaches to building a “Hello World” application. They are:

1. Create a window and draw text in it using ImagePoint calls.
2. Use PenPoint’s UI Toolkit classes to create a label object.

Each of these approaches is worth demonstrating in a sample application. The first is a good example for programs that need to do a lot of their own drawing, such as free-form graphics editors. The second approach shows how easy it is to use the toolkit classes, and serves as an example for programs that need to draw forms or other structured collections of information.

Therefore, there are two “Hello World” sample applications: Hello World (custom window) and Hello World (toolkit). The rest of this document describes Hello World (custom window).

Hello World (custom window) demonstrates how to draw the string “Hello World” by directly using ImagePoint calls. To do so, it defines a descendant of clsWin. In its msgWinRepaint handler, the window determines the size of the string “Hello World” and then calls msgDcDrawText to actually paint the text. It also paints a large exclamation point after it, using ImagePoint’s ability to draw bezier curves.

For demonstration purposes, this application’s window is compiled as a separate DLL.

**Objectives**

This sample application shows how to:

- Create a window, and a drawing context (DC) to draw on.
- Draw text and bezier curves.
- Separate out part of an application into a re-usable dynamic link library.

**Class overview**

Hello World (custom window) defines two classes: clsHelloWorld and clsHelloWin. It makes use of the following classes:

- clsApp
- clsAppMgr
- clsClass
- clsSysDrwCtx
- clsWin

**Files used**

The code for Hello World (custom window) is in PENPOINT\SDK\SAMPLE\HELLO. The files are:

- HELTBL.TBL the method table for the application class.
- HELWTBL.TBL the method table for the window class.
- DLLINIT.C the routine to initialize the DLL.
- HELLO.C the source code for the application.
- Hellowin.c the source code for the window class.
- Hellowin.h the header file for the window class.

Counter Application

Counter Application displays a number on the screen. Every time you turn to its page, Counter Application increments the number. It also lets you choose the format in which to display the number (decimal, octal, or hexadecimal).

Objectives

Counter Application is the basis for many of the early labs in the PenPoint Programming Workshop. This sample application also shows how to:

- Save and restore application state.
- Memory-map state data.
- Separate text strings from your code and put them in separate resource files so that they can be translated into other languages without requiring recompilation.
- Define tags for strings used as resources.
- Retrieve strings from resource files using ResUtilGetListString().
- Compose “international” strings using SComposeText().
- Use strings contained in a resource file for menu buttons.

Class overview

Counter Application defines two classes: clsCntr and clsCntrApp. It makes use of the following classes:

- clsApp
- clsAppMgr
- clsClass
- clsFileHandle
- clsMenu
- clsMenuButton
- clsObject
- clsLabel

Files used

The code for Counter Application is in PENPOINT\SDK\SAMPLE\CNTRAPP. The files are:

- METHODS.TBL  method tables for Counter Application.
- CNTR.C  clsCntr's code and initialization.
- CNTR.H  header file for clsCntr.
- CNTRAPP.C  clsCntrApp's code and initialization.
- CNTRAPP.H  header file for clsCntrApp.
- JPN.RC  strings for the Japanese version (not listed here for typographical reasons).
- USA.RC  strings for the USA version.

usa.rc is the English language resource file for the Counter Application.
In addition to the standard application resources, the Counter App also
makes use of toolkit resources to store the string values for the
Representation menu and the menu items, and miscellaneous resources to
store the messages that are printed out in the drawing area. The
Counter App does not use Quick Help strings or Standard Message strings.

COUNTER APPLICATION
Tic-Tac-Toe displays a tic-tac-toe board and lets the user enter Xs and Os on it. It is not a true computerized game—the user does not play tic-tac-toe against the computer. Instead, it assumes that there are two users who want to play the game against each other.

Although a tic-tac-toe game is not exactly a typical notebook application, Tic-Tac-Toe has many of the characteristics of a full-blown PenPoint application. It has a graphical interface, handwritten input, keyboard input, gesture support, use of the notebook metaphor, versioning of filed data, selection, move/copy, option cards, undo support, stationery, help text, and so on.

**Objectives**

This sample application shows how to:

- Store data in a separate data object.
- Display data in a view.
- Accept handwritten and keyboard input.
- Implement gesture handling.
- Support most of the standard application menus (move, copy, delete, and undo, for example).
- Add application-specific menus.
- Add application-specific option cards.
- Provide help.
- Provide quick help (using tags in the resource list) for the view, an option card, and the controls in the option card.
- Provide stationery documents.
- Have both large and small application-specific document icons.
- Provide customized undo strings.
- Use ClsSymbolsInit().
- Specify an application version number.

**Class overview**

Tic-Tac-Toe defines three classes: clsTttApp, clsTttView, and clsTttData. It makes use of the following classes:

- clsApp
- clsAppMgr
- clsClass
- clsFileHandle
- clsIntegerField
- clsIP
- clsKey
- clsMenu
- clsNote
- clsObject
- clsOptionTable
- clsPen
- clsScrollWin
- clsSysDrwCtx
- clsView
- clsXferList
- clsXGesture
- clsXText

**Files used**

The code for Tic-Tac-Toe is in PENPOINT\SDK\SAMPLE\TTT. The files are:

- METHODS.TBL the method tables for all of the Tic-Tac-Toe classes.
- TTTAPP.C clsTttApp’s code and initialization.
- TTTAPP.H header file for the application class.
- TTTDATA.C clsTttData’s code and initialization.
- TTTDATA.H header file for the data class.
- TTTDBG.C debugging-related message handlers.
- TTTMBAR.C menu bar-related message handlers.
- TTPRIV.H private include file for Tic-Tac-Toe.

Message Handlers

TttAppInit

Initialize instance data of new object.
Note: clsmgr has already initialized instance data to zeros.

#define DbgTttAppInit(x) \
    TttDbgHelper(U_L("TttAppInit"), tttAppDbgSet, Ox2, x)
MsgHandler(TttAppInit)
{
    P_TTT_APP_INST pInst;
    STATUS s;
    DbgTttAppInit((U_L("")))
    //
    // Initialize for error recovery.
    //
    pinst = pNull;
    //
    // Allocate, initialize, and record instance data.
    //
    StaJmp(OSHeapBlockAlloc(osProcessHeapId, SizeOf(*pInst), &pInst), \
s, Error);
pInst->placeHolder = -1L;
ObjectWrite(self, ctx, &pInst);
DbgTttAppInit((U_L("returns stsOK")))
return stsOK;
MsgHandlerParametersNoWarning;

Error:
if (pInst) {
    OSHepBlockFree(pInst);
}
DbgTttAppInit((U_L("Error; returns 0x%lx"), s))
return s;
} /* TttAppInit */

TttAppFree

Respond to msgFree.
Note: Always return stsOK, even if a problem occurs. This is
(1) because there's nothing useful to do if a problem occurs anyhow
and (2) because the ancestor is called after this function if and
only if stsOK is returned, and it's important that the ancestor
get called.

**********************************************************************

*/ TttUtilStrForSquareValue */

TttUtilSquareValueForChar
TX
TttUtilSquareValueForChar(
    CHAR ch)
{
    return ((T TT SQUARE_VALUE) ch);
} /* TttUtilSquareValueForChar */

TttUtilInsertUnique
Utility routine that inserts and element into an array if
it's not already in the array. Assumes enough space in the array.

#define DbgTttUtilInsertUnique(x) \
    DBG_HELPER(U_L("TttUtilInsertUnique"), tttUtilDbgSet, Ox1, x)

STATIC void PASCAL
TttUtilInsertUnique(
    P_U32 pValues,
    P_U16 pCount, // In: number of elements in pValues
    U32 new)
{
    U16 i;
    DbgTttUtilInsertUnique(U_L("pValues[*pCount]=%ld new=%ld\n old=%ld new\n old"), (U32)(*pCount), \
        (U32)new, (U32)new)
    for (i=0; i<pCount; i++) {
        if (pValues[i] == new) {
            DbgTttUtilInsertUnique(U_L("found it at %ld; returning"), (U32)i))
                return;
        }
    }
    pValues[*pCount] = new;
    *pCount = *pCount + 1;
    DbgTttUtilInsertUnique(U_L("didn’t find it; new\n count=%ld"), (U32)(*pCount)))
} /* TttUtilInsertUnique */

TttUtilCreateScrollWin
This is in a utility routine rather than in the caller because
including win.c brings in too many symbols.
The example of scrolling used here is slightly artificial.
This tells the scroll window that it can expand the Tic-Tac-Toe view
beyond its desired size, but should not contract it. Thus if the
scroll win shrinks, the TttView will be scrollable.
When an application does scrolling, the view should get the
messages. So we set the client window appropriately now.

TttUtilCreateScrollWin(
    OBJECT clientWin,
    P_OBJECT pScrollWin)
{
    SCROLL_WIN_NEW scrollWinNew;
    STATUS s;
    ObjCallApi(msgNewDefaults, clsScrollWin, &scrollWinNew, s, Error);
    scrollWinNew.style.expandChildWidth = clientWin;
    scrollWinNew.style.expandChildHeight = true;
    ObjCallApi(msgNew, clsScrollWin, &scrollWinNew, s, Error);
    *pScrollWin = scrollWinNew.object.uid;
    return stsOK;
}

TttUtilCreateMenu
This is in a utility routine rather than in the caller because
including menu.h brings in too many symbols.

TttUtilCreateMenu(
    OBJECT parent,
    OBJECT client,
    P_UNKNOWN pEntries, // really P_TK_TABLE_ENTRY pEntries
    P_OBJECT pMenu)
{
    MENU_NEW mn;
    STATUS s;
    ObjCallApi(msgNewDefaults, clsMenu, &mn, s, Error);
    mn.win.parent = parent;
    mn.tkTable.client = client;
    mn.tkTable.pEntries = (P_TK_TABLE_ENTRY)pEntries;
    ObjCallApi(msgNew, clsMenu, &mn, s, Error);
    *pMenu = mn.object.uid;
    return stsOK;
}

Error:
    return s;
TttUtilCreateMenu

"Adjusts" the menu by removing the items that this app does not support.

Each menu that has an item removed from it must be laid out and "break adjusted." The latter involves adjusting the border edges and margins for a menu with lines dividing it into sections. But because the Standard Application Menus can change, we don't want to compile in knowledge of which menus these are. (The menu item's containing menu is easy to find -- it's just the menu item's parent window.)

The obvious approach is to simply lay out and break adjust the item's menu after removing the item. Unfortunately this potentially results in laying out and break adjusting the same menu several times, since several of the items could be removed from the same menu.

Our solution is to keep an array of all unique parents seen. The array is known to be no longer than than the array of disableTags, so space allocation is easy. TttUtilUniqueSort is used to do the unique insertion. Finally, we run over the unique array and do the necessary operations on the menus.

#define DbgTttUtilAdjustMenu(x) 
   TttDbgHelper(U_L("TttUtilAdjustMenu"),tttUtilDbgSet,Ox2,x)

II II Tags which correspond to the menu items that this application will not implement.
II II static const TAG disableTags[] = {

TttViewRepaint
Respond to msgRepaint.
This handler demonstrates how to do "smart repainting." It asks the
window manager for the "dirty" rectangle, and then only repaints those
objects that intersect with the rectangle.

Smart repainting should be used by applications that have expensive
repainting procedures. Although Tic-Tac-Toe's repainting is not even
close to being prohibitive, it uses smart repainting for the sake
of demonstrating how to do it.

Instead of using smart repainting, many applications simply redraw
their entire window. For an example of this approach, take a look
at Hello World (Custom Window).

$Revision: 1.7 $
$Author: kcatlin $
$Date: 13 Jul 1992 10:31:36 $

This file contains the API definition for clsTttView. clsTttView inherits from clsView. clsTttView displays a representation of clsTttData as a grid of Xs and Os.

#include <clsmgr.h>
#include <clsmgr.h>
#include <win.h>
/* 
** Private Functions 
** 
** TttViewOptions returns STATUS 
** Called in response to msgSelOptions and the "Check" gesture. 
*/ 
STATUS PASCAL 
TttViewOptions( 
    OBJECT self, 
    PP_TTT_VIEW_INST pData); 

EXPORTED FUNCTIONS 

ClsTttViewInit returns STATUS 
Initializes / installs clsTttView. 
This routine is only called during installation of the class. 
*/ 
STATUS PASCAL 
ClsTttViewInit (void); 

MESSAGES FOR clsTttView 

msgNew takes P_TTT_VIEW_NEW, returns STATUS 
category: class message 
Creates an instance of clsTttView. 
*/ 
#define tttViewNewFields \ 
    viewNewFields \ 
    TTT_VIEW_NEW_ONLY tttView; 
typedef struct TTT_VIEW_NEW { 
    tttViewNewFields 
} TTT_VIEW_NEW, *P_TTT_VIEW_NEW; 

msgNewDefaults takes P_TTT_VIEW_NEW, returns STATUS 
category: class message 
Initializes the TTT_VIEW_NEW structure to default values. 
pArgs->view.createDataObject = true; 
pArgs->tttView.lineThickness = 5L; 
pArgs->tttView.spare1 = 0;
The Option Sheet protocol allows any class of an object to create an option sheet and/or add cards. Therefore this code carefully validates that it only operates on Option Sheets and Cards that it knows about. This could be overkill.

Define the strings for use with the Toolkit resource for clsTttData.

```c
static RC_TAGGED_STRING tttDataTKStrings[] = {
    // Undo menu string to undo a delete
    U_L("Undo Delete"),
    // Undo menu string to undo a move or copy
    U_L("Undo Move/Copy"),
    Nil(TAG)
};
```

Define the quick help resource for TTT.

```c
static RC_TAGGED_STRING tttViewQHelpStrings[] = {
    // Quick help for TTT's option card to change the line thickness.
    tagTttViewCard,
    U_L("Use this option card to change the thickness of the lines ")
    U_L("on the Tic-Tac-Toe board.")
    // Quick help for the line thickness control in TTT's option card.
    U_L("Change the line thickness by writing in a number from 1-9.")
    // Quick Help for the TTT window.
    tagTttView,
    U_L("The Tic-Tac-Toe window lets you to make X's and O's in a Tic-Tac-Toe ")
    U_L("grid. You can write X's and O's and make move, copy ")
    U_L("and pigtail delete gestures. 

    U_L("It does not recognize a completed game, either tied or won. 

    U_L("To clear the game and start again, tap Select All in the Edit menu, ")
    U_L("then tap Delete.")
    Nil(TAG)
};
```

Define the quick help strings.

```c
static RC_INPUT tttViewQHelp = {
    resTttViewQHelp,
    tttViewQHelpStrings,
    0,
    resTaggedStringArrayResAgent
};
```

Define the strings for use with the AppFramework resource for TTT.

```c
static RC_TAGGED_STRING stampStrings[] = {
    // User-visible file name of Stationery already filled in. 32 chars or less
    U_L("Tic-Tac-Toe (filled)")
    // User-visible file name of Stationery with X's. 32 chars or less
    U_L("Tic-Tac-Toe (X's)")
    // User-visible file name of the strategy help file. 32 chars or less
    U_L("Tic-Tac-Toe Strategy")
    // User-visible file name of the rules help file. 32 chars or less
    U_L("Tic-Tac-Toe Rules")
    Nil(TAG)
};
```

List all of the resources so that RC can find them.

```c
static RC_INPUT resInput [] = {
    &app,
    &tttViewQHelp,
    &tttViewTK,
    &tttDataTK,
    &pstamp
};
```

FILED.TXT

xoxoxoxox stationery for tttapp
RULES.TXT

Tic-Tac-Toe is a simple game for two players. The players take turns writing X’s and O’s in the grid. The player that gets three X’s or three O’s in a row (across, down, or diagonally) wins.

STRAT.TXT

The first player should put her X (or O) in the center square. By doing so, she increases the possibility of getting three X’s (or O’s) in a row.

XSONLY.TXT

x x x x x stationery for tttapp
**Template Application**

As its name implies, Template Application is a template, "cookie cutter" application. As such, it does not exhibit much functionality beyond the default actions performed by the Application Framework. However, it does handle many "typical" application messages. This aspect makes Template Application a good starting point for building a real application.

PenPoint applications rely on clsApp to create and display their main window, save state, terminate the application instance, and so on. There are seventy-some messages that clsApp responds to. You will never have to worry about handling most of these, however, every application developer needs to create a descendant of clsApp and have the descendant handle several important messages. Template Application illustrates the messages that most applications will need to be concerned with. You will find a description of these messages and how to handle them in the block comments for each of the methods. In addition, these messages are fully documented in the PenPoint Architectural Reference, and the APP.H header file.

The PenPoint Application Framework defines a number of flags that you can use to explore the classes that it contains and the messages that they respond to. These flags are documented in the header comment for TEMPLTAP.C.

**Objectives**

Template Application serves as a shell of an application and can be used as the starting point for a real application.

This sample application also shows how to:

- File instance data.
- Create the standard menu bar and add application-specific menus.
- Create an icon window as a client window.
- Associate a resource file with your application.
- Use resource files to define the standard application resources.
- Define tags and lists for the strings used as resources.

**Class overview**

Template Application defines two classes: clsTemplateApp and clsFoo. It makes use of the following classes:

- clsApp
- clsAppMgr
- clsClass
- clsIconWin
- clsMenu
- clsObject

**Files used**

The code for Template Application is in PENPOINT\SDK\SAMPLE\TEMPLTAP. The files are:

- METHODS.TBL  the list of messages that the classes respond to, and the associated message handlers to call.
- FOO.C  the source code for clsFoo.
- FOO.H  the header file for clsFoo.
- TEMPLTAP.C  the source code for the application class.
- TEMPLTAP.H  the header file for the application class.
- JPN.RC  strings for the Japanese version (not listed here for typographical reasons).
- USA.RC  strings for the USA version.

**METHODS.TBL**

$Revision: 1.14 $
$Author: aloomis $
$Date: 09 Oct 1992 19:44:22 $

This file contains the templtap application. Template Application serves
as a shell of an application, and can be used as a starting point for a
real application.

PenPoint applications rely on clsApp to create and display their main
window, save state, terminate the application instance, and so on.
There are seventy-some messages that clsApp responds to. You will never
have to worry about handling most of these, however, every application
developer needs to create a descendant of clsApp and have the descendant
handle several important messages. Template App illustrates the messages
that most applications will need to be concerned with. You will find a
description of these messages and how to handle them in the block comments
for each of the methods. In addition, these messages are fully documented
in the Architectural Reference, and the app.h header file.

The PenPoint Application Framework defines a number of flags that you can
use to explore the classes that it contains and the messages that they
t erespond to:

<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
<th>Context</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>AppWin &amp; AppLink debug messages</td>
<td>Traversal</td>
</tr>
<tr>
<td>4</td>
<td>General App Framework debug messages</td>
<td></td>
</tr>
<tr>
<td>8*</td>
<td>move/copy debug messages</td>
<td></td>
</tr>
<tr>
<td>20*</td>
<td>dump filesystem on move/copy/delete</td>
<td>Document Lifecycle</td>
</tr>
<tr>
<td>40</td>
<td>goto button debug messages</td>
<td></td>
</tr>
<tr>
<td>80</td>
<td>traverse debug messages</td>
<td>Traversal</td>
</tr>
<tr>
<td>400</td>
<td>trace document lifecycle</td>
<td></td>
</tr>
<tr>
<td>800</td>
<td>option sheet protocol</td>
<td>Option Sheets</td>
</tr>
<tr>
<td>1000</td>
<td>clsApp performance debug output</td>
<td>Document Lifecycle</td>
</tr>
<tr>
<td>2000</td>
<td>clsAppMgr performance debug output</td>
<td>Document Lifecycle</td>
</tr>
<tr>
<td>10000</td>
<td>Search &amp; Replace</td>
<td>Traversal</td>
</tr>
<tr>
<td>20000</td>
<td>Memory Cop</td>
<td>Memory</td>
</tr>
</tbody>
</table>

(See the Application Writing Guide for information on how to turn on a flag.)

You can try setting the various flag values and exploring the system, or you
can turn on specific flags to isolate a problem that you are having with your
application. The flags that will probably find most useful have been
marked with the asterixes. In particular, you may want to trace the document lifecycle by setting R to 400. Turn a page, and you will see the places where
msgInit, msgAppActivate, msgAppOpen, msgAppClose, msgAppTerminate, msgAppSave,
etc. are received by clsApp and Template App.
/* Defines, Types, Globals, Etc */
typedef struct TEMPLATE_APP_INST {
  TEMPLATE_APP_METRICS metrics;
} TEMPLATE_APP_INST, *P_TEMPLATE_APP_INST;
typedef struct FILED_DATA {
  TEMPLATE_APP_METRICS metrics;
} FILED_DATA, *P_FILED_DATA;

Message Handlers
*
******************************************************************************/

#ifdef DEBUG

******************************************************************************/
*  TemplateAppDump
*
*  Respond to msgDump.
*  
*  msgDump requests an object to format its instance data and send it to
*  the debugger stream. While developing your application, you can send
*  msgDump to any object whose state is questionable. From the PenPoint
*  source debugger, you can use the od command to send msgDump to an
*  object. It is not a good idea to send msgDump in production code.
*  
******************************************************************************/

MsgHandlerArgType (TemplateAppDump, P_ARGS)
{
  Dbg(Debugf(U_L("Template App received: msgDump")));
  return stsOK;
  MsgBoxHandlerParametersNoWarning;
} // TemplateAppDump

#endif // DEBUG

******************************************************************************
*  TemplateAppInit
*
*  Respond to msgInit.
*  
*  msgInit is the first message sent to the activated instance of your
*  application. When your application receives msgInit, it should
*  initialize its instance data and use the function ObjectWrite to save
*  the initialized instance data to protected memory.
*  
*  The method table calls the ancestor before handling msgInit. In
*  response to msgInit, clsApp allocates storage for the application's
*  instance data in protected memory. Included in the instance data are
*  the document's directory handle, resource file list, floating window
*  list, and embedded document list.
*  
******************************************************************************

MsgHandlerArgType (TemplateAppInit, P_APP_NEW)
{
  Dbg(Debugf(U_L("Template App received: msgInit")));
  return stsOK;
  MsgBoxHandlerParametersNoWarning;
} // TemplateAppInit
TemplateAppFree

Respond to msgFree.

When your application receives msgFree, it should destroy any permanent objects that it created and free any allocated memory. (The application receives msgSave before it receives msgFree.)

The method table should call the application's ancestor after it handles msgFree; the application's ancestors will in turn destroy objects and free memory that they allocated.

```
MsgHandlerArgType (TemplateAppFree, P_ARGS)
{
    Dbg(Debugf(U_L("Template App received: msgFree")));
    return stsOK;
    MsgHandlerParametersNoWarning;
} // TemplateAppFree
```

TemplateAppSave

Respond to msgSave.

When your application receives msgSave, it should: (1) Write data that isn't maintained in objects to the resource file. (2) Save any permanent objects. (This will involve sending msgSave to your instance data.)

The method table calls the application's ancestor before handling msgSave. In response, the ancestors save data and objects that they created. clsApp saves your main window, any data objects observed by views, and, optionally, its client window.

```
MsgHandlerWithTypes (TemplateAppSave, P_OBJ_SAVE, P_TEMPLATE_APP_INST)
{
    STREAM_READ_WRITE fsWrite;
    FILED_DATA filed;
    STATUS s;
    Dbg(Debugf(U_L("Template App received: msgSave")));
    memset(&filed, 0, SizeOf(FILED_DATA));
    filed.metrics = pData->metrics;
    // Write filed data to the file.
    fsWrite.numBytes = SizeOf(FILED_DATA);
    fsWrite.pBuf = &filed;
    ObjCallRet(msgStreamWrite, pArgs->file, &fsWrite, s);
    inst.metrics = filed.metrics;
    // Update instance data.
    ObjectWrite(self, ctx, &inst);
    return stsOK;
    MsgHandlerParametersNoWarning;
} // TemplateAppSave
```

TemplateAppRestore

Respond to msgRestore.

In the message handler for msgRestore, you should restore any data that you saved in msgSave.

Your application's method table should call the application's ancestor before handling msgRestore. In response to msgRestore, the ancestors will restore data and objects that they saved earlier. clsApp restores your main window and its client window.

```
MsgHandlerArgType (TemplateAppRestore, P_OBJ_RESTORE)
{
    STREAM_READ_WRITE fsRead;
    TEMPLATE_APP_INST inst;
    FILED_DATA filed;
    STATUS s;
    Dbg(Debugf(U_L("Template App received: msgRestore")));
    memset(&inst, 0, SizeOf(inst));
    // Read instance data from the file.
    fsRead.numBytes = SizeOf(FILED_DATA);
    fsRead.pBuf = &filed;
    ObjCallRet(msgStreamRead, pArgs->file, &fsRead, s);
    inst.metrics = filed.metrics;
    // Update instance data.
    ObjectWrite(self, ctx, &inst);
    return stsOK;
    MsgHandlerParametersNoWarning;
} // TemplateAppRestore
```

TemplateAppAppInit

Respond to msgAppInit.

MsgAppInit is only sent to each instance once during its lifetime. The document receives this message the first time it is activated. (Your document will receive msgAppRestore on all subsequent activations, where it will restore the objects that are created here, and filed when the document is saved.) The ancestor should be called before your message handler for msgAppInit is invoked. In response, clsApp will create your document's main window and object resource file.
In msgAppInit you should handle the one-time initializations of stateful objects that will later be filed. This includes initializing your instance data. Use the function ObjectWrite to save the initialized instance data to protected memory.

Here we create and install the client window in the application’s main window. For a more robust example of handling msgAppInit, see CNTRAPP/cntrapp.c

MsgHandlerArgType (TemplateAppAppInit, DIR_HANDLE)
{
    APP_METRICS am;
    OBJECT win;
    STATUS s;
    Dbg(Debugf(U_L("Template App received: msgAppInit"));
    // Create the client win.
    win = objNull;
    ObjCallRet(msgAppCreateClientWin, self, &win, s);
    // Get the main window.
    ObjCallRet(msgAppGetMetrics, self, &am, s);
    // Set the client win.
    ObjCallRet(msgFrameSetClientWin, am.mainWin, (P_ARGS)win, s);
    return stsOK;
    MsgHandlerParametersNoWarning;
} // TemplateAppAppInit

MsgHandlerArgType (TemplateAppAppInit, DIR_HANDLE)
{
    APP_METRICS am;
    OBJECT win;
    STATUS s;
    Dbg(Debugf(U_L("Template App received: msgAppInit"));
    // Create the client win.
    win = objNull;
    ObjCallRet(msgAppCreateClientWin, self, &win, s);
    // Get the main window.
    ObjCallRet(msgAppGetMetrics, self, &am, s);
    // Set the client win.
    ObjCallRet(msgFrameSetClientWin, am.mainWin, (P_ARGS)win, s);
    return stsOK;
    MsgHandlerParametersNoWarning;
} // TemplateAppAppInit

TemplateAppOpen

In msgAppOpen is where you should create the windows to display data, and any other non-stateful user interface or control objects. You should also fill in childAppParentWin - normally with the document’s client window. The menu bar is also typically created here. Self send msgAppCreateMenuBar to create the menu bar, and then send msgFrameSetMetrics to your main window to insert the menu bar in the window. If you can’t open the document, you should return stsFailed. However, if you have already displayed an error message to the user, then return stsAppOpenFailedSuppressError.

The method table calls the application’s ancestor after the application handles msgAppOpen. In response to msgAppOpen, clsApp then inserts the document’s frame into the main window, which displays the document on screen.

In msgAppClose, you should destroy the windows and control objects that you created in msgAppOpen. If you created the menu bar in your msgAppOpen handler, then you should send msgFrameDestroyMenuBar to your main window.

This message is not an indication to terminate the document; it may be followed by other requests for services such as searching or reopening. However, you will save memory (always desirable for PenPoint applications!) if you destroy the user-interface objects while your application is off screen.

The method table should (and does!) call the application’s ancestor before handling msgAppClose. In response to msgAppClose, clsApp extracts the frame from the main window.

MsgHandlerArgType (TemplateAppClose, P_ARGS)
{
    APP_METRICS am;
    STATUS s;
    Dbg(Debugf(U_L("Template App received: msgAppClose"));
    ObjCallRet(msgAppGetMetrics, self, &am, s);
    ObjCallRet(msgFrameDestroyMenuBar, am.mainWin, (P_ARGS)win, s);
    return stsOK;
} // TemplateAppClose

TemplateAppClose

In msgAppClose, you should destroy the windows and control objects that you created in msgAppOpen. If you created the menu bar in your msgAppOpen handler, then you should send msgFrameDestroyMenuBar to your main window.

This message is not an indication to terminate the document; it may be followed by other requests for services such as searching or reopening. However, you will save memory (always desirable for PenPoint applications!) if you destroy the user-interface objects while your application is off screen.

The method table should (and does!) call the application’s ancestor before handling msgAppClose. In response to msgAppClose, clsApp extracts the frame from the main window.

MsgHandlerArgType (TemplateAppClose, P_ARGS)
{
    APP_METRICS am;
    STATUS s;
    Dbg(Debugf(U_L("Template App received: msgAppClose"));
    ObjCallRet(msgAppGetMetrics, self, &am, s);
    ObjCallRet(msgFrameDestroyMenuBar, am.mainWin, (P_ARGS)null, s);
    return stsOK;
} // TemplateAppClose

TemplateAppClose

In msgAppClose, you should destroy the windows and control objects that you created in msgAppOpen. If you created the menu bar in your msgAppOpen handler, then you should send msgFrameDestroyMenuBar to your main window.

This message is not an indication to terminate the document; it may be followed by other requests for services such as searching or reopening. However, you will save memory (always desirable for PenPoint applications!) if you destroy the user-interface objects while your application is off screen.

The method table should (and does!) call the application’s ancestor before handling msgAppClose. In response to msgAppClose, clsApp extracts the frame from the main window.
Respond to msgAppCreateClientWin.

This is the place to create your application specific client window. The Application Framework does not send this message by default. Instead, you should self send it at the appropriate time (typically during msgAppInit, since the client window is usually stateful). Usually you will not need to call your ancestor.

The document creates a default client window of class clsEmbeddedWin and passes back its uid.

```
ICON_WIN iwn;
Dbg(Debugf(U_L("Template App received: msgAppCreateClientWin"))); // If the client win has already been provided, return.
if (*pArgs != objNull) {
    return stsOK;
}
// Create an iconwin.
ObjectCall(msgNewDefaults, clsIconWin, &iwn);
iwn.iconWin.style.showOptions = true;
iwn.iconWin.style.allowOpenInPlace = true;
iwn.iconWin.style.constrainedLayout = false;
ObjCallWarn(msgNew, clsIconWin, &iwn);
// Return the client win.
*pArgs = iwn.object.uid;
return stsOK;
MsgHandlerParametersNoWarning;
```
* Respond to msgAppSelectAll
*  When the user taps on Select All in the Standard Application Menu, the
document self sends this message.
*  clsApp does not do anything in its message handler for this message.
*  You should handle this message, and select everything in the document.
*  (You tend not to call the ancestor.)
*/
MsgHandler (TemplateAppSelectAll) {
  Dbg(Debugf(U_L("Template App received: msgSelectAll")));  
  return stsOK;
  MsgHandlerParametersNoWarning;
} // TemplateAppSelectAll

$Revision: 1.8 $  
$Author: bldmstr $  
$Date: 19 Aug 1992 22:42:52 $  
usa.rc is the English language resource file for the Template App.
Template App does not actually use any resources besides the standard
application resources, however we have included resource strings for
QuickHelp, standard messages and standard warnings to serve as a template
for your application.

};
**Adder**

Adder is a simple pen-centric calculator, limited to addition and subtraction. The user can write “4 + 5” and Adder will print “4 + 5 = 9” at the top of its window. In addition, Adder can handle slightly more complicated expressions; “42 + -8 + 3 - 2.5” for example.

**Objectives**

This sample application shows how to:

- Create an insertion pad for handwritten input.
- Create a translator and a custom template for the insertion pad.
- Translate the insertion pad ink when the user lifts the pen out of proximity.
- Disable some of the handwriting engine's assumptions to improve arithmetic recognition.
- Create a custom layout window.
- Construct a simple parser.

**Class overview**

Adder defines two classes: `clsAdderApp` and `clsAdderEvaluator`. It makes use of the following classes:

- `clsApp`
- `clsAppMgr`
- `clsClass`
- `clsCustomLayout`
- `clsIP`
- `clsLabel`
- `clsObject`
- `clsXText`

**Files used**

The code for Adder is in `PENPOINT\SDK\SAMPLE\ADDER`. The files are:

- `METHODS.TBL` the method tables for the adder classes.
- `ADDERAPP.C` the source code for the application class.
- `ADDEREVL.C` the source code for the adder evaluator engine class.
- `ADDEREVL.H` the header file for the evaluator class.
- `JPN.RC` strings for the Japanese version.
- `USA.RC` strings for the USA version.
Calculator

The Calculator application implements a typical push-button calculator. This program is split into an application, which handles the user interface, and a calculator engine, which performs the computations.

Objectives

This sample application shows how to:

• Separate out part of an application into a reusable dynamic link library.
• Have an application be an accessory.
• Use ClsSymbolsInit().
• Use table layout and custom layout.
• Use labels.
• Use TK_TABLE_ENTRY struct to create a collection of buttons in a single operation.
• Handle button notification messages.
• Change the default window size.
• File data.
• Use ResUtilGetListString() to load a string from a resource file.
• Reference Unicode characters in a TK_TABLE_ENTRY.

Class overview

Calc defines two classes: clsCalcApp and clsCalcEngine. It makes use of the following classes:

- clsAppMgr
- clsClass
- clsCustomLayout
- clsLabel
- clsObject
- clsTkTable

When clsCalcApp receives msgAppOpen, it creates a set of windows (all of which are standard UI components):

- A table of buttons (clsTkTable) for the calculator's push buttons.
- A label (clsLabel) for the calculator's display.
- A window (clsCustomLayout) to hold the label and the button table.

The application destroys these windows when it receives msgAppClose.

In its msgAppInit handler, the application creates an instance of clsCalcEngine, the calculator engine. This class performs arithmetic operations.

Although clsCalcApp does not file any of its views, it does file the string that is displayed in its label. It also files the calculator engine object by sending it msgResPutObject (in response to msgSave) and msgResGetObject (in response to msgRestore).

Files used

The code for Calc is in PENPOINT\SDKSAMPLE\CALC. The files are:

- CAPPMBT.TBL method table for the application class.
- CENGMETH.TBL method table for the calculator engine.
- CALCAPEC clsCalcApp's code and initialization.
- CALCAPPC header file for the application class.
- CALCEGEC clsCalcEng's code and initialization.
- CALCEGPH header file for the calculator engine.
- S_CALC.C symbol name definitions and call to ClsSymbolsInit() (this file is generated automatically).
- JPN.RC strings for the Japanese version.
- USA.RC strings for the USA version.
**Clock**

Clock is an application that serves two purposes; it is both a digital alarm clock distributed as a part of PenPoint, and a sample application. The end-user can configure the clock's display by changing the placement of the time and date and by specifying things like whether the time should include seconds. The end-user can also set up an alarm. Depending on how the user configures an alarm, it might beep at a certain time on a certain day or display a note every day at the same time.

Clock uses the Bridging Package in order to maintain a single code base for both PenPoint 1.0 and PenPoint 2.0 Japanese.

**Objectives**

This sample application shows how to:
- Observe the system preferences for changes to date and time formats.
- Observe the power switch to refresh on power-up.
- Provide option cards for an application.
- Destroy unneeded controls on a default application option card.
- Disable inappropriate controls on a default application option card.
- Respond to `msgGWinForwardedGesture` (including handling, forwarding, and ignoring gestures).
- Provide quick help.
- Make use of `clsTimer`.
- Use `StdError()` to display application-level error messages.
- Use the international routines for formatting.
- Use the `SystemLocale` to do different behavior for different locales.
- Use the Bridging Package to maintain a single code base under PenPoint 1.0 and PenPoint 2.0 Japanese.

**Class overview**

Clock defines four classes: `clsClockLabel`, `clsClockApp`, `clsClockWin`, and `clsNoteCorkBoardWin`.

It makes use of the following classes:

- `clsApp`
- `clsAppMgr`
- `clsAppWin`
- `clsClass`
- `clsCommandBar`
- `clsDateField`
- `clsGotoButton`
- `clsIconWin`
- `clsIntegerField`
- `clsLabel`
- `clsNote`
- `clsOptionTable`
- `clsPopupChoice`
- `clsPreferences`
- `clsString`
- `clsTableLayout`
- `clsTextField`
- `clsTimer`
- `clsTkTable`
- `clsToggleTable`

Clock uses a table layout of several windows. There can be up to four child windows (time digits, a.m./p.m. indicator, alarm indicator, and the date). All of these are labels. `clsLabel` only repaints the right-most characters that change. So, to minimize flashing as time ticks away, Clock displays the time digits in a separate window from the a.m./p.m. indicator. The text for the clock labels is created using `SComposeText()` and international routines for formatting the date and time (`PrefsIntlDateToString()` and `PrefsIntlTimeToString()`) in `GetDateTimeStr()` rather than assuming English formats. These routines query preferences to find the appropriate date and time formats for a given locale. In addition, clock calls `theSystem` to determine the locale and uses a different default format depending on the locale (time followed by date for USA, and date followed by time for JPN).
The labels can be of varying font sizes. In some cases, because of the way that the clock window grows and shrinks, it is possible for the clock window to be off-screen when it comes time to display. To prevent that, code is added in the CreateClockWindow() routine to ensure that part of the clock window is always on screen.

clsNoteCorkBoardWin appears as a corkboard on the pop-up note that Clock displays when an alarm goes off. The note needs to be dismissed when the user opens one of the icons in the window. To provide this functionality, clsNoteCorkBoardWin observes objects inserted into its window. clsClockApp does not file its labels or client window. It does, however, file most of the settings of the controls in its Display and Alarm option cards. It also files its clsNoteCorkBoardWin corkboard window.

**Files used**

The code for Clock is in PENPOINT\SDK\SAMPLE\CLOCK. The files are:

- METHODS.TBL  The method tables for the four classes.
- CLABEL.C    Source code for clsClockLabel.
- CLABEL.H    Header file for clsClockLabel.
- CLOCKAPP.C  Source for clsClockApp, the application class.
- CLOCKAPP.H  Header file for the application class.
- CWIN.C      Source code for clsClockWin.
- CWIN.H      Header file for clsClockWin.
- NCBWIN.C    Source code for clsNoteCorkBoardWin.
- NCBWIN.H    Header file for clsNoteCorkBoardWin.
- BITMAP.RE    Resource file (compiled) for the clock accessory icon.
- JPN.RC      Strings for the Japanese version.
- USA.RC      Strings for the USA version.
- BRIDGE.RC   Strings that emulate PenPoint 2.0 Japanese functionality in PenPoint 1.0
**Notepaper Application**

Notepaper Application is a simple note-taking application. It relies on the Notepaper DLL for most of its functionality.

**Objectives**

This sample application shows how to use the NotePaper DLL.

**Class overview**

Notepaper Application defines one class: clsNotePaperApp. It makes use of the following classes:

- clsApp
- clsAppMgr
- clsGestureMargin
- clsNotePaper

**Files used**

The code for Notepaper Application is in PENPOINT\SDK\SAMPLE\NPAPP. The files are:

- METHODS.TBL  method table for the notepaper application class.
- BITMAP.RES   resource file for the document bitmap.
- NPAPP.C       source code for the notepaper application.
- JPN.RC        strings for the Japanese version.
- USA.RC        strings for the USA version.
**Paint**

Paint is a simple painting application. The user can choose different nibs (square, circle, or italic) and different paint colors (white, light gray, dark gray, and black) with which to paint. The user can easily clear the window to start painting all over again.

**Objectives**

This sample application shows how to:

- Read and write data and strings to a file.
- Provide a totally application-specific menu bar (no SAMs).
- Place a button on a menu bar.
- Use resources for text in toolkit tables.
- Create a scroll win, and have a gray border displayed around its client window.
- Use pixelmaps, drawing contexts, and image devices.
- Handle pen input events.

While Paint does demonstrate these topics, it is far from being a perfect sample application, for these reasons:

- Pixelmaps are inherently device dependent, so Paint documents are also device dependent.
- When the user changes the screen orientation, Paint does not flush and rebuild its pixelmaps.
- Paint's pixelmaps cannot be printed (which is why the Print menu item and the “P” gesture are not supported).

Within the field of sampled image programming, there are well-understood ways to overcome these problems. However, Paint does not implement them.

**Class overview**

Paint defines three classes: clsPaintApp, clsPaintWin, and clsPixWin. It makes use of the following classes:

- clsApp
- clsAppMgr
- clsChoice
- clsClass
- clsFileHandle
- clsImgDev
- clsMenu
- clsScrollWin
- clsSysDrwCtx
- clsToggleTable
- clsWin

**Files used**

The code for Paint is in PENPOINT\SDK\SAMPLE\PAINT. The files are:

- METHODS.TBL  method table for the paint classes.
- BITMAP.RES  resource file for the document icon.
- CUTIL.C  utility routines for reading and writing data and strings.
- CUTIL.H  header file for reading and writing utility routines.
- PAPP.H  header file for application and its resources.
- PAPP.C  source code for the paint application class.
- PIXELMAP.C  utility routines for using pixel maps.
- PIXELMAP.H  header file for pixel map utility routines.
- PIXWIN.C  source code for the clsPixWin class.
- PIXWIN.H  header file for the clsPixWin class.
- PWIN.C  source code for the clsPaintWin class.
- PWIN.H  header file for the clsPaintWin class.
- JPN.RC  strings for the Japanese version.
- USA.RC  strings for the USA version.
**Toolkit Demo**

Toolkit Demo shows how to use many of the classes in PenPoint’s UI Toolkit. Although it is not exhaustive, it does provide many examples of using the Toolkit’s APIs and setting fields to get different functionality and visual effects.

Toolkit Demo does not show how to use trackers, grab boxes, or progress bars.

**Objectives**

This sample application shows how to:

- Use most of the classes in the PenPoint UI Toolkit.
- Create a table layout.
- Create a custom layout.
- Provide multiple option cards for an application subclass.
- Determine if an option card should be applicable, based on the current selection.
- Provide a bitmap for clsIcon.
- Create a clsScrollWin instance as the application’s frame client window.
- Specify an application version number.
- Implement string literals as resources.

**Class overview**

Toolkit Demo defines one class: clsTkDemo. It makes use of the following classes:

- clsApp
- clsAppMgr
- clsBitmap
- clsBorder
- clsButton
- clsChoice
- clsCustomLayout
- clsDateField
- clsField
- clsFixedField
- clsFontListBox
- clsIcon
- clsIntegerField
- clsLabel
- clsListBox
- clsMenu
- clsMenuButton
- clsNote
- clsOptionTable
- clsPopupChoice
- clsScrollWin
- clsStringListBox
- clsTabBar
- clsTabButton
- clsTableLayout
- clsTextField
- clsTkTable
- clsToggleTable

clsTkDemo creates an instance of clsScrollWin as its frame client window. This lets the demonstration’s windows be larger than the frame. A clsScrollWin window can have many client windows, but it shows only one at a time. So, Toolkit Demo creates several child windows, one for each of the topics it demonstrates. clsTkDemo also creates a tab that corresponds to each window. The tab buttons are set up so that their instance data includes the UID of the associated window. When the user taps on the tab, the tab sends msgTkDemoShowCard to the application. Toolkit Demo then switches to that window by sending msgScrollWinShowClientWin to the clsScrollWin window.

An interesting point is that, to avoid receiving messages while it is creating windows, Toolkit Demo only sets itself as the client of its tab bar after it has created all the windows.

clsTkDemo’s instance data is the tag of the current selection and the UIDs of its option sheets. It files all of this in response to msgSave.
Files used

The code for Toolkit Demo is in PENPOINT\SDK\SAMPLE\TKDEMO. The files are:

- METHODS.TBL  the method table for the Toolkit Demo application.
- BORDERS.C   code for creating different kinds of borders.
- BUTTONS.C    code for creating different kinds of buttons.
- CUSTOMS.C    code for creating clsCustomLayout instances.
- FIELDS.C     code for handwriting fields of clsField and its descendants clsDateField, clsFixedField, clsIntegerField, and clsTextField.
- GOLOGO.INC   include file containing a hand-coded GO logo bitmap.
- ICON.RES     resource file for a smiling face icon, created with PenPoint's bitmap editor.
- ICONS.C      code for creating different kinds of icons.
- LABELS.C     code for creating clsLabel instances with different fonts, rows, columns, and so on.
- LBOXES.C     code for making list boxes (clsListBox, clsStringListBox, and clsFontListBox).
- NOTES.C      creates different kinds of instances of clsNote.
- OPTABLES.C   creates a sample option table.
- OPTIONS.C    demonstrates option cards and their protocol, and also creates an instance of clsPopUpChoice.
- TABLES.C     creates various tables (instances of clsTableLayout).
- TKDEMO.C     code for the overall Toolkit Demo application.
- TKDEMO.H     header file for the application class.
- TKTABLES.C   code for creating several subclasses of clsTkTable, including clsMenu, clsChoice, and clsTabBar.
- USA.RC       strings for USA version.
**Input Application**

Input Application is a simple application that demonstrates pen-based input event handling. As the user drags the pen around, Input Application draws a small square in the window. To provide this functionality, it creates a descendant of clsWin (clsInWin), which looks for pen input events.

Input Application's window tracks the pen by drawing a small box at the X-Y location provided by the event. It also erases the previous box by first setting its DC's raster op to sysDeRopXOR. Then it redraws the box at the previous location, thereby erasing it.

*Note:* If you want your windows to respond to gestures or handwriting, you usually do not look for input events yourself. Instead, you use specialized window classes such as clsGWin and clsIP, which "hide" low-level input event processing from their descendants. These classes send higher-level notifications such as msgGWinGesture and msgIPDataAvailable.

**Objectives**

This sample application shows how to:
- Create a drawing context in a window.
- Set a window's input flags to get pen tip and move events.
- Handle pen events (msgPenUp, msgPenDown, and so on) in a window.
- Use msgBeginPaint and msgEndPaint messages.
- Turn on message tracing for a class.
- Use resource files to associate application-specific strings with the tags provided for standard application resources.

**Class overview**

Input Application defines two classes: clsInputApp and clsInWin. It makes use of the following classes:
- clsApp
- clsAppMgr
- clsClass
- clsSysDrwCtx
- clsWin

The only function of clsInputApp is to create clsInWin as its client window. It does this in its msgAppInit handler.

clsInWin is a descendant of clsWin. Because clsWin does not turn on any window input flags, clsInWin must set window flags to get certain pen events.

Since clsInputApp recreates the input window from scratch and has no other instance data, it does not need to file itself. The input window does not need to save state either. When called upon to restore its state (msgRestore), it simply reinitializes.

**Files used**

The code for Input Application is in PENPOINT\SDK\SAMPLE\INPUTAPP. The files are:
- METHODS.TBL  the method tables for the classes.
- INPUTAPPC  the source code for the Input Application classes.
- USA.RC  strings for the USA version.
**Writer Application**

Writer Application provides a ruled sheet for the user to write on. When the user lifts the pen out of proximity, Writer Application translates what the user has written, and places the translated text on the line below the ink. The user can change the translation algorithm from word-based, to text- or number-based.

**Objectives**

This sample application shows how to:

- Use `clsSPaper` and translation classes.
- Make a translator for words, text, or numbers only.
- Use the `clsXList` instance returned by the translation objects and how to interpret its data.
- Put a choice control in a menu.
- Implement all text strings as resources.

**Class overview**

Writer Application defines two classes: `clsWriter` and `clsWriterApp`. It makes use of the following classes:

- `clsApp`
- `clsAppMgr`
- `clsChoice`
- `clsClass`
- `clsMenu`
- `clsSPaper`
- `clsSysDrwCtx`
- `clsXText`
- `clsXWord`

**Files used**

The code for Writer Application is in `PENPOINT\SDK\SAMPLE\WRITERAP`. The files are:

- `METHODS.TBL` the method table for the classes.
- `WRITERAP.C` the source code for the classes.
- `WRITERAP.H` the header file for the classes.
- `JPN.RC` strings for the Japanese version.
- `USA.RC` strings for the USA version.
Keisen Table Application

Keisen Table Application demonstrates the creation of a complex layout using toolkit tables, instances of clsTkTable. clsTableLayout (hence its subclass clsTkTable) positions items according to a grid, with rows and columns. However, Japanese keisen tables do not have a uniform, global structure. So, the table is broken up into a one column, eight row table representing the horizontal lines across the whole table. These rows are nested horizontal tables, each cell representing a line that divides the row. This nesting continues until the nested table has only clsLabel descendants as its children.

clsTkTable will create a default instance of a class. As this would be very limiting, it also provides style flags in the TK_TABLE_ENTRY structure to provide anticipated style settings, such as bold labels or word wrapping. However, not all circumstances can be meet with these flags, and so this application does not use them. Instead, subclasses which handle msgNewDefaults are created, so their default instance is exactly the style desired.

As well, to prevent having to make a new subclass for every style, msgTkTableInit is handled by some of these subclasses. This message is sent by a toolkit table when it is creating an object from a TK_TABLE_ENTRY. It is sent after all other processing (msgNewDefaults, altering styles, and so on), but before msgNew is sent to the class being created. Subclasses can handle this message by using previously unused fields of the TK_TABLE_ENTRY for their own custom style flags.

The grid around each cell in the table is another special feature. All leaf windows in the window tree—the nested table windows are containers which form nodes in the Keisen Table window tree and the labels and fields are windows which are leaves in the window tree—turn their borders on, and all tables turn their borders off. By growing these leaf windows to the size of their cell, these borders merge to make a grid.

To have the grid lines be a single line unit thick, the gap width is set to be -1 line units. This causes the borders of adjacent cells to overlap, forming a single line instead of one to either side of the cell division.

Objectives

Keisen Table Application demonstrates one way to use existing PenPoint layout facilities (clsTableLayout and its subclass clsTkTable) to build a very complex table.

This sample application also shows how to:

- Create a grid around table cells by overlapping children borders.
- Change default (new) style of a class by subclassing to handle msgNewDefaults.
- Have private style flags in TK_TABLE_ENTRYs for subclasses.
- Nest toolkit tables.
- Have a scroll window as the application frame's client window.
- Create private subclasses.
- Set compiler options to allow for Japanese characters in source code.

Class overview

Keisen Table defines several classes:

- clsBoxedField private subclass of clsField. Handles only msgNewDefaults to set edges to bsEdgeAll.
- clsBoxedKatakanaField private subclass of clsBoxedField. Handles only msgFieldCreateTranslator to disable translation of Hiragana, Kanji, Romaji, and numerals.
- clsBoxedIntegerField private subclass of clsIntegerField. Handles only msgNewDefaults to set edges to bsEdgeAll.
- clsHorizontalTable private subclass of clsTkTable. Sets default styles to be a single row table with children that grow to their cells and overlap by exactly one line unit so their border edges overlap. Handles msgTkTableInit (when being created from a toolkit table) to use arg3 for private style flags.
- clsKeisenTable clsApp subclass. Basically the same as Template Application, except it responds to fewer messages and handles msgAppCreateClientWin differently, creating a table in a scroll window as the client window instead of an icon window.
- clsBoxedLabel private subclass of clsLabel. Handles msgNewDefaults to set edges to bsEdgeAll and center text in both dimensions. Handles msgTkTableInit (when being created from a toolkit table) to use arg2 for private style flags.
- clsVerticalTable private subclass of clsTkTable. Sets default styles to be a single column table with children that grow to their cells and overlap by
exactly one line unit so their border edges overlap. Handles msgTkTableInit (when being created from a toolkit table) to use arg3 for private style flags.

It makes use of the following classes:

- clsApp
- clsAppMgr
- clsClass
- clsField
- clsIntegerField
- clsLabel
- clsScrollWin
- clsTkTable

**Files used**

The code for Keisen Table is in PENPOINT\SDK\SAMPLE\KEISEN. The files are:

- METHODS.TBL the list of messages that the classes respond to, and the associated message handlers to call.
- BFIELD.C the source code for the boxed field class.
- BFIELD.H the header file for the boxed field class.
- BINTFLD.C the source code for the boxed integer field class.
- BINTFLD.H the header file for the boxed integer field class.
- BKFIELD.C the source code for the boxed katakana field class.
- BKFIELD.H the header file for the boxed katakana field class.
- BLABEL.C the source code for the boxed label class.
- BLABEL.H the header file for the boxed label class.
- KEISEN.C the source code for the application class.
- KEISEN.H the header file for the application class.
- TABLES.C the source code for all table subclasses.
- TABLES.H the header file for all table subclasses.
**List Box Demo**

List Box Demo is yet another sample application meant to help developers learn how to use some of the features of PenPoint. This demo does not implement a whole application. Instead, it shows, in an clear way, how to organize and program an application incrementally. In fact, List Box Demo was the starting point for a richer sample application called Video Player.

List Box Demo does not show lots of excess functionality, which makes it hard for developers to reuse and learn from the sample code. This release shows how to set up a window using UI toolkit components. The menu bar supports standard menus. The more interesting code is related to the list box. The list box window supports the copy/move protocol to move (shuffle) and copy rows within itself or any other window that supports the transfer of text. The list box also handles some gestures such as the caret gesture to insert a row and the scratch out or cross gesture to delete a row from the list box.

List Box Demo has the Unicode support required to run under PenPoint 2.0. However, to simplify things, strings are not stored in a resource file.

**Objectives**

This sample application shows how to:

- Embed data in the list box such as list contents and row state.
- Save and restore the list contents (filing).
- Handle gestures in a list box.
- Support the move and copy protocol.
- Deal with the SelectionManager.
- Create a graphical interface with the UI toolkit, including a list box.
- Add application-specific menus to the standard menus.

**Class overview**

List Box Demo defines two classes: clsLBdemo and clsLBList. It makes use of the following classes:

- clsApp
- clsAppMgr
- clsClass
- clsLabel
- clsListBox
- clsMenu
- clsObject
- clsXferList

**Files used**

The code for List Box Demo is in PENPOINT\SDK\SAMPLE\LBDEMO. The files are:

- METHODS.TBL the method tables for the two classes used in List Box Demo.
- LBDEMO.C the List Box Demo application class and the code to build the interface from the UI Toolkit.
- LBDEMO.H header file for the application class.
- LBLIST.C the definition of clsLBList and support methods for gesture processing and list manipulation.
- LBLIST.H header file for clsLBList.
- LBXFER.C code for moving and copying rows.
**Sample Application Monitor**

This sample application shows how to implement a reasonably sophisticated application monitor. The monitor allows for installing and deinstalling optional DLLs, selecting which stationery to load, and saving global options.

This sample looks for a DLL directory in the application directory for the optional DLLs, and looks in the normal STATNRY directory for stationery. It will not create option cards for DLLs or stationery if it doesn't find anything in these directories.

The same global option cards are used in the popup when the application is installed and in the document's option sheet.

This sample's makefile does not create the DLL or STATNRY directories. You can try out the optional DLL and stationery functionality by making these directories in PENPOINT\APP\SAMPLMON, and then putting any DLL or stationery document in the directories.

**Objective**

This sample application shows how to create a descendant of clsAppMon.

**Class overview**

Sample Application Monitor defines two classes: clsSampleApp and clsSampleAppMonitor. It makes use of the following classes:

- clsApp
- clsAppMgr
- clsAppMonitor
- clsButton
- clsDirHandle
- clsFileHandle
- clsOptionTable
- clsToggleTable

**Files used**

The code for Sample Application Monitor is in PENPOINT\SDK\SAMPLE\SAMPLMON. The files are:

- METHODS.TBL: the method tables for the two classes.
- SAMPLMON.C: source for the classes.
- SAMPLMON.H: header file for the classes.
Serial Transmission Demo

Serial Transmission Demo demonstrates the use of simple serial I/O from within PenPoint. Serial input is read by a semaphore-controlled subtask which places the received characters in a text view. The user enters text through an insertion pad; the output is then sent by the main task.

Objectives
This sample application shows how to:

- Query a service manager for available instances.
- Open and close a serial service instance.
- Read from and write to a serial service instance.
- Get and set serial metrics.
- Respond to connection messages from the service manager.
- Handle serial service events.
- Create a subtask.
- Create and use a semaphore.
- Create and use a list.
- Create an option sheet and interpret its values.

Class overview
Serial Transmission Demo defines two classes: clsSX and clsSXView (a subclass of clsTextView). It makes use of the following classes:

- clsApp
- clsAppMgr
- clsButton
- clsChoice
- clsClass
- clsCommandBar
- clsIP
- clsLabel
- clsList
- clsNote
- clsObject
- clsOptionTable
- clsPopupChoice
- clsString
- clsTablelayout

Files used
The code for Serial Transmission Demo is in PENPOINT\SDK\SAMPLE\SXDEMO. The files are:

- METHODS.TBL the method tables for clsSX and clsSXView.
- SXAPPC the source code for the application class.
- SXAPPH header file containing all definitions for Serial Transmission Demo; tags, messages, structures, handlers for clsTextView messages, and so on.
- SXIPC source code for handlers for clsIP messages.
- SXOPT.C source code handlers for clsOption message.s
- SXSER.C source code for all serial I/O handlers.
- SXVIEW.C the source code for the clsTextView subclass.
- USA.RC strings for the USA version.

Note that you need to enable one or more serial ports in MIL.INI to be able to select a serial port. In the SDK, the spooler is available. When Serial Transmission Demo is started for the first time, it opens the first available service instance. If no serial service instance is available, the spooler service will be used. If no service instance is available at all, the application will exit.
User Interface Companion

The User Interface Companion (brings to life many of the diagrams in the PenPoint User Interface Design Reference manual. These diagrams show the various components that you can use to build the user interface for your applications: buttons, lists, menus, pop-up lists, text fields, and other controls. The User Interface Companion sample application focuses specifically on some of the more challenging controls.

The User Interface Companion consists of the application class, clsUICompApp, an initialization DLL, and the class definitions and methods for several classes.

Objectives

The UI Companion demonstrates how to:

- Build a multi-page application within the notebook.
- Create your interface objects ahead of time and file them via an INIT.DLL.
- Use the UI toolkit classes to implement some of the more complicated user interface controls available.
- Subclass a UI toolkit class to get specialized behavior.
- Extend the functionality of existing UI Toolkit classes.

Class overview

The UI Companion creates five classes:

clsUICompApp  the UI Companion application class. The application is derived from Template Application, and handles many typical messages sent by the application framework. In addition, it implements a multi-page application. The UI Companion application creates an option sheet as its main window; this way the user can select different pages from the option sheet's built in title bar. It also creates its own sub-page control, and displays it at the far right of the application menu bar. The user can navigate through different pages in the application using this control. (See UICOMP.C for more information.)

clsUICompPage  defines the behavior for a page in the UI Companion. It is a subclass of clsTableLayout which provides the specialized layout used in the UI Companion application. clsUICompPage is not intended to be a general-purpose class; it has a small set of rigidly defined behaviors and performs the minimum amount of work necessary to accomplish page layout for the UI Companion. It also isolates the layout code from the files which demonstrate how to create the specific toolkit components discussed in the User Interface Design Reference.

clsEdStrListBox  a subclass of clsStringListBox which allows a user to edit the strings displayed in a string list box by making the standard circle gesture to pop up an edit pad. A user can also delete items from the string list box by making the X gesture over an item.

clsOptionCmdBar  is a subclass of clsOption that allows a client to associate a custom, non-standard command bar with each card that is added to the option sheet.

clsScrollPopup  a subclass of clsPopupChoice which implements a scrolling popup choice. The client can specify the maximum number of items to display. If the number of items in the choice is greater than the number of items to display, the items will appear in a scrolling window inside of the popup choice. This results in a substantial savings of screen real estate for choices with many options.

The UI Companion also makes use of the following classes:

clsApp
clsIconChoice
clsOptionTable
clsAppMgr
clsIconTable
clsPopupChoice
clsBorder
clsIconToggle
clsScrollWin
clsButton
clsIntegerField
clsStringListBox
clsChoice
clsIP
**Files used**

The code for the UI Companion is in PENPOINT\SDK\SAMPLE\UICOMP. The files are:

- **METHODS.TBL** the method tables for the UI Companion application and clsUIPage, clsEditStrListBox, clsOpCmdBar and clsScrollPopup.
- **INIT.C** function containing InitMain() entry point, which creates and files the user interface elements before the application is run, so they can be restored quickly at run-time.
- **UICOMP.C** class definition and methods for clsUICompApp, the UI Companion application class.
- **UICOMP.H** global defines, resource lists and tags used in the UI Companion application.
- **EDSTRLB.C** class definition and methods for clsEditStrListBox.
- **EDSTRLB.H** API definition for clsEditStrListBox.
- **OPCMDBAR.C** class definition and methods for clsOptionCmdBar.
- **OPCMDBAR.H** API definition for clsOptionCmdBar.
- **SCRPOPUP.C** class definition and methods for clsScrollPopup.
- **SCRPOPUP.H** API definition for clsScrollPopup.

UIPAGE.C class definition and methods for clsUICompPage.

UIPAGE.H API definition for clsUICompPage.

BUTTONS.C creates tools palette with different styles of buttons, square buttons, command buttons.

LISTS.C creates checklist, boxed lists, toggle switch, editable scrolling list.

MENUS.C creates menu with fill-in fields, multi-column menu, and a menu with a white gap between controls.

POPPUPS.C creates popup with pictures as choices and a scrolling popup list.

TEXT.C creates overwrite field, scrolling field and insertion pad.

ALIGN.RES bitmaps illustrating different alignment options (used in popup choice variations).

ICONS.RES bitmaps for tool icons, and line and fill styles.

MISC.RES frog and prince bitmaps (used in toggle switch).

PATTERNS.RES different fill patterns (used in boxed list).

USA.RC United States English strings for USA version.
**Basic Service**

Basic Service is the absolute minimum code required to implement a service. This is the "Hello World" for service writers. Basic Service handles only one message: msgNewDefaults. Modifying Basic Service will help to get your service up and running in the shortest possible time.

For more complex services, see the Test Service and MIL Service samples.

**Objectives**

This sample service shows how to make a service (the makefile differs from application makefiles).

**Class Overview**

Basic Service defines one class: clsBasicService. It makes use of the following classes:

- clsClass
- clsService

**Files Used**

The code for Basic Service is in PENPOINT\SDK\SAMPLE\BASICSVC. The files are:

- METHOD.TBL method table for clsBasicSvc.
- BASICSVC.C clsBasicSvc's code and initialization.
- BASICSVC.H header file for clsBasicSvc.
Test Service

Test Service is a starter kit for most service writers. It has message handler stubs for the most common service messages.

For other examples of services, see the Basic Service and MIL Service samples.

Objectives

This sample service shows how to:

- Make a service (the makefile differs from application makefiles).
- Define handlers for messages sent to a class.

Class Overview

Test Service defines two classes: clsTestService and clsTestOpenObject. It makes use of the following classes:

- clsButton
- clsClass
- clsFileHandle
- clsOpenServiceObject
- clsOptionTable
- clsService

Files Used

The code for Test Service is in PENPOINT\SDK\SAMPLE\TESTSVC. The files are:

- METHOD.TBL  method table for the classes defined in Test Service.
- OPENOBJ.C    clsTestOpenObject's code and initialization.
- OPENOBJ.H    header file for clsTestOpenObject.
- TESTSVC.C    clsTestService's code and initialization.
- TESTSVC.H    header file for clsTestService.
- USA.RC       strings for USA version.
**MIL Service**

MIL Service is a full implementation of a MIL (Machine Interface Layer) service. This MIL service implementation shows how a client will interface with the MIL service, how to create and use a ring 0 DLL to interface with a MIL device used, and how to perform connection detection. The MIL device used is the parallel printer MIL device. This sample code is a version of the PPORT MIL service code shipped with PenPoint.

For other examples of services, see the Basic Service and Test Service samples.

**Objectives**

This sample service shows how to make a service (the makefile differs from application makefiles).

**Class Overview**

MIL Service defines one class: clsTestMILService. It makes use of the following classes:

- clsClass
- clsMILService
- clsStream

**Files Used**

The code for Test MIL Service is in PENPOINT\SDK\SAMPLE\MILSV. The files are:

- METHOD.TBL method table for clsTestMILService.
- MILSV.C clsTestMILService's ring 3 code and initialization.
- MILSV.H header file for clsTestMILService.
- MILSV.BAT batch file used to build both ring 0 and ring 3 DLLs.
- MILSV0.C clsTestMILService's ring 0 code.
- MILSV0.H private header file for clsTestMILService.
In addition to page references within this book, this index also contains references to files and directories in the sample code (in \PENPOINT\SDK\SAMPLE). These are identified by the directory, or in some cases, the directory and file where you will find the information. The sample code for the While You Were Out (WYWO) application is not shipped with the SDK, but is available on CompuServe. We remind you of this by adding CS: before WYWO.

**PenPoint® Application Writing Guide**

The *PenPoint Application Writing Guide, Expanded Second Edition* teaches you how to write an application for the PenPoint operating system. The information applies equally well to versions 1.0 and 2.0 of the PenPoint operating system. The book begins by introducing the PenPoint operating system and the Application Framework, which is the framework for all PenPoint applications. After discussing how to design an application and GO's coding standards, the book shows you how to build a variety of sample applications—beginning with an extremely simple application and concluding with a comprehensive one that implements most of the features required by a complete PenPoint application.

Two new sections in the book describe how to write applications that can be easily adapted to international markets and how to localize applications to the Japanese market. Three additional new sections supplement the PenPoint SDK documentation for version 2.0.

The PenPoint operating system is a compact, 32-bit, fully object-oriented, multitasking operating system designed expressly for mobile pen computers. GO Corporation designed the PenPoint operating system as a productivity tool for people who may never have used computers before, including salespeople, service technicians, managers and executives, field engineers, insurance agents and adjustors, and government inspectors.

Other volumes in the GO Technical Library are:

- *PenPoint User Interface Design Reference* describes the elements of the PenPoint Notebook User Interface, sets standards for using those elements, and describes how PenPoint uses the elements.
- *PenPoint Development Tools* describes the environment for developing, debugging, and testing PenPoint applications.
- *PenPoint Architectural Reference, Volume I* presents the concepts of the fundamental PenPoint classes.
- *PenPoint Architectural Reference, Volume II* presents the concepts of the supplemental PenPoint classes.
- *PenPoint API Reference, Volume I* provides a complete reference to the fundamental PenPoint classes, messages, and data structures.
- *PenPoint API Reference, Volume II* provides a complete reference to the supplemental PenPoint classes, messages, and data structures.

**GO Corporation** was founded in September 1987 and is a leader in pen computing technology for mobile professionals. The company's mission is to expand the accessibility and utility of computers by establishing its pen-based operating system as a standard.
