NOTE: Although referenced in several areas, photographs are not shown in this document. Future revisions will include appropriate photos and illustrated drawings. Your warranty registration form must be returned promptly to assure receipt of future revisions to this document.

This Class A equipment generates, uses, and can radiate radio frequency energy and if not installed and used in accordance with the instructions manual, may cause interference to radio communications. As temporarily permitted by regulation it has not been tested for compliance with the limits for Class A computing devices pursuant to Subpart I of Part 15 of FCC Rules, which are designed to provide reasonable protection against such interference. Operation of this equipment in a residential area is likely to cause interference in which case the user at his own expense will be required to take whatever measures may be required to correct the interference.
CONGRATULATIONS ON YOUR PURCHASE OF INTERTEC'S COMPUSTAR VIDEO PROCESSING SYSTEM

Your new CompuStar Video Processing System was manufactured at Intertec's 120,000 square foot plant in Columbia, South Carolina under stringent quality control procedures to insure trouble-free operation for many years. If you should encounter difficulties with the use or operation of your terminal, contact the dealer from whom the unit was purchased for instructions regarding the proper servicing techniques. If service cannot be made available through your dealer, contact Intertec's Customer Service Department at (803) 798-9100.

As with all Intertec products, we would appreciate any comments you may have regarding your evaluation and application for this equipment. For your convenience, we have enclosed a customer comment card at the end of this manual. Please address your comments to:

Marketing Services Manager
Intertec Data Systems Corporation
2300 Broad River Road
Columbia, South Carolina 29210

The CompuStar is distributed worldwide through a network of dealer/OEM vendors and through Intertec's own marketing facilities. Contact us at (803) 798-9100 (TWX - 810-666-2115) regarding your requirement for this and other Intertec products.
WILL THE MICROCOMPUTER YOU BUY TODAY STILL BE THE BEST MICROCOMPUTER BUY TOMORROW?

Probably the best test in determining how to spend your microcomputer dollar wisely is to consider the overall versatility of your terminal purchase over the next three to five years. In the fast-paced, ever-changing world of data communications, new features to increase operator and machine efficiency are introduced into the marketplace daily. We at Intertec are acutely aware of this rapid infusion of new ideas into the small systems business. As a result, we have designed the CompuStar in such a manner as to virtually eliminate the possibility of obsolescence.

Many competitive alternatives to the CompuStar available today provide only limited capability for high level programming and system expansion. Indeed, most low-cost microcomputer systems presently available quickly become outdated because of the inability to expand the system. Intertec, however, realizes that increased demands for more efficient utilization of programming makes system expansion capability mandatory. That means a lot. Because the more you use your CompuStar, the more you'll discover its adaptability to virtually any small system requirement. Extensive use of "software-oriented" design concepts instead of conventional "hardware" designs assure you of compatibility with almost any application for which you intend to use the CompuStar.

Once you read our operator's manual and try out some of the features described herein, we are confident that you too will agree with our "top performance--bottom dollar" approach to manufacturing. The CompuStar offers you many more extremely flexible features at a lower cost than any other microcomputer we know of on the market today. The use of newly developed technologies, efficient manufacturing processes and consumer-oriented marketing program enables us to be the first and only major manufacturer to offer such an incredible breakthrough in the microcomputer marketplace.

Browse through our operator's manual and sit down in front of a CompuStar Video Processing Unit for a few hours. Then, let us know what you think about our new system. There is a customer comment card enclosed in the rear section of this manual for your convenience.

Thank you for selecting the CompuStar as your choice for a microcomputer system. We hope you will be selecting it many more times in the future.

SECTION 1.0

1.1 INTRODUCTION

1.2 SYSTEM UNPACKING INSTRUCTIONS

1.3 SYSTEM SETUP INSTRUCTIONS
*** IMPORTANT ***

Do not attempt to write or save programs on your system diskette(s). It has been 'write protected' by placing a small adhesive aluminum strip over the notch on the right hand side of the diskette. Such attempts will result in a 'WRITE' or 'BAD SECTOR' error.

Before using your CompuStar, please copy the System Diskette onto a new blank diskette—an Intertec 1121010 diskette. If you do not have such a diskette, contact your local dealer. He should be able to supply you with one. If you have any questions concerning this procedure, please contact your dealer before proceeding. Failure to do so may result in permanent damage to your System Diskette.

BEFORE APPLYING POWER TO THE MACHINE, INSURE THAT NO DISKETTES ARE INSERTED INTO THE MACHINE. NEVER TURN THE MACHINE ON OR OFF WITH DISKETTES INSERTED IN IT. FAILURE TO OBSERVE THIS PRECAUTION WILL MOST DEFINITELY RESULT IN DAMAGE TO THE DISKETTES.
SECTION 1.0

1.1 INTRODUCTION

WELCOME TO THE WORLD OF COMPUSTAR! We are convinced that you will be impressed with the packaging, operation, reliability, and quality of your new Video Computer System. Your units have received special attention from design to preshipment testing in order to bring you a quality system. To protect this quality, we ask that you carefully follow the unpacking and system setup procedures. These procedures are designed to:

- Reduce the risk of setup damage
- Reduce the time required to make your system operational.

This CompuStar manual contains information covering unpacking, cable connections, and system operation. In addition, comprehensive information is included on specific items of interest to you, the user. Since many CompuStar users are familiar with computer processing, some sections of this manual will not be required reading. However, we strongly recommend that all users read the unpacking, system setup, and system operating instructions contained in Sections 1.0 and 2.0. In addition, all users should become familiar with the system technical information presented in Section 3.0.

Sections 4 through 10 present more detailed information on the use of CP/M and will answer questions you may have concerning the operating system. Sections 11 through 13 present additional information concerning servicing and hardware/software updates.

Thank you for purchasing the INTERTEC COMPUSTAR SYSTEM. We know this system will benefit you greatly in your environment and we are dedicated to insuring the continued success of your system through our

- Optional On-Site Service Program (See Section 11)
- Optional Extended Factory Warranty Service Program (See Section 11)
- Optional Shared Service Program (See Section 11)
SECTION 1.2 - SYSTEM UNPACKING INSTRUCTIONS

1.2.1 Video Processing Unit (VPU) Removal

Step 1: NOTE: Because of the tight-fitting shipping carton, the removal of a VPU from its carton may require two people. One person may be required to hold the box on the floor while the other removes the unit from the carton.

With the arrows on the carton pointing up, stand facing either side of the VPU. Grasp the unit along the top edge of the cover with the fingers of one hand. (Caution: Excessive upward pressure on the cover top will result in damage to the cover.) With the fingers of the other hand, grasp the rear of the unit on the edge directly above the power cord. Lift the unit out of the carton (see Figure 1.2A) place it on the floor and remove the two foam packing inserts. Remove the protective plastic bag from around the terminal. DO NOT DISCARD THE PACKING INSERTS AND CARTON UNTIL YOU HAVE COMPLETELY CHECKED THE OPERATION OF THE VPU.

Using the same lifting points as above, lift the VPU to a table and position the VPU to the front (user looking at keyboard). If the VPU is equipped with disk drives, remove the shipping tape from each disk drive. (See Figure 1.2B) IMPORTANT: THESE DOORS MUST BE TAPED AND ANY DISKETTES REMOVED IF THE UNIT IS EVER RESHIIPPED.

Step 2: Repeat Step 1 for all terminals in the system.

1.2.2 Ten Megabyte Disk Storage System (DSS) Removal (Optional Equipment)

Step 1: Locate the package containing the diskette and remove from carton. Do not bend or otherwise damage the diskette.

Step 2: Grasping the foam inserts, remove the Disk Storage System (DSS) from the container and place on table. Remove the foam packing inserts and protective plastic bag. IMPORTANT: DO NOT CONNECT POWERCORD OF UNIT INTO WALL OUTLET. Turn the DSS on one side and remove the disk locking screw and strap. (See Figure 1.2C) The strap assembly should be saved in the event the unit is reshipped. Position the DSS to the front (user looking at POWER, READY, FAULT, and RESET buttons) and insure that adequate space is available around the unit for good air flow. (CAUTION: During operation do not restrict the flow of air through the bottom or sides of the DSS or put heavy items on top of the unit.)
FIGURE 1.2A  REMOVAL OF VPU FROM CARTON

FIGURE 1.2B  REMOVAL OF SHIPPING TAPE FROM DISK DRIVE DOORS

FIGURE 1.2C  REMOVAL OF DSS LOCKING SCREW AND STRAP
1.2.3 10 Megabyte DSS Cable Removal (Optional Equipment)

Step 1: Remove cable assemblies from their carton. (The number of cables should be one less than the total number of units in the system.)

Example: One DSS and 2 terminals would require 2 cable
One DSS, 2 terminals and 1 printer would require 3 cables.

Place the cables near their respective units for later use.

1.2.4 32 Megabyte DSS Removal (Optional Equipment) (To Be Provided)
1.2.5 32 Megabyte DSS Cable Removal (Optional Equipment) (To Be Provided)
1.2.6 96 Megabyte DSS Removal (Optional Equipment) (To Be Provided)
1.2.7 96 Megabyte DSS Cable Removal (Optional Equipment) (To Be Provided)
1.2.8 Continuation

The unpacking of your system is now complete. Please continue with the system setup instructions, Section 1.3.
1.3.1 Designation of CompuStar VPU Number (Station Number)

**Step 1:** Insure that the powercord on each VPU is disconnected (unplugged).

**Step 2:** If your unit has disk drives, insure that the drive doors are closed. **Caution:** Failure to close these doors could result damage when the cover is removed in Step 6. These doors may be closed by applying a slight pressure on the door pulling it back toward the VPU screen.

**Step 3:** Remove the 5A fuse from the rear panel by pushing in on the fuse holder and rotating it counter-clockwise.

**Step 4:** Position the VPU so that the two cover screws below the front of the keyboard extend slightly beyond the table edge. (See Figure 1.3A) Remove these two screws with a screwdriver.

**Step 5:** Rotate the VPU so that the two rear cover screws above the power cord panel extend slightly beyond the table edge. (See Figure 1.3B) Remove these two screws.

**Step 6:** Carefully remove the cover by lifting straight up after insuring that the disk drives doors are closed (Step 2).

**Step 7:** Locate the VPU designator dipswitches on the rear of the unit (Figure 1.3C). (The switches represent binary counts with the least significant bit on the left when looking at the switch.) The switch has "on" and "off" markings on the side or on the top. Locate these markings. The switches are activated in the "off" position (depressing the "off" half of the switch). They are deactivated in the "on" position (depressing the "on" half of the switch).

Table 1.3A presents the position of each switch for all possible VPU designations (1-255). For a CompuStar network containing less than ten VPUs, choose a unique VPU number between one and ten and set the switches according to Table 1. (NOTE: Other VPU numbers can be used but will require altering your CompuStar system as described in Section 2.1.3.) (For a network containing more than ten VPUs, assign a unique station number between 1 and 255. For these networks, it will be necessary to alter your CompuStar system upon completion of the system setup procedures. See Section 2.1.3.)

**Step 8:** Replace the top cover. Do not accidentally change the switch setting as the cover is being positioned on the unit.

**Step 9:** Replace the two rear cover screws.

</tbody>
</table>
Step 10: Replace the two front cover screws.

Step 11: Replace the fuse by rotating the fuse holder clockwise.

Step 12: Insure that the power switch located at the left rear corner (as you look at rear of VPU) is in the "off" position.

Step 13: Verify that your VPU is wired for a line voltage that is available in your area. The correct line voltage may be determined from the serial tag located on the rear of your VPU. This tag should indicate either 110 or 220 VAC operation. DO NOT ATTEMPT TO CONNECT THE VPU TO YOUR LOCAL POWER OUTLET UNLESS THE VOLTAGE AT YOUR OUTLET IS IDENTICAL TO THE ONE SPECIFIED ON THE SERIAL TAG. Should the voltage differ, contact your dealer at once and do not proceed to connect the CompuStar system to the power outlet. If the voltages are the same, connect the VPU power cord to the wall outlet.

Step 14: Repeat Steps 1 - 13 for each terminal.

Step 15: If your system does not include a Disk Storage System (DSS), continue with Section 2.1. If a DSS is included, continue with 1.3.2, 1.3.3, or 1.3.4.

1.3.2 10 Megabyte Disk Storage System (DSS) Cable Connections and CompuStar System Test

Step 1: Insure that the VPU switch is in the "off" position.

Step 2: Select the cable assembly to be used between the 10 megabyte DSS and an INTERTEC Model 20, 30, or 40 VPU (units which contain floppy disk drives). NOTE: If your system has only Model 10 units, proceed with steps 3 through 9, but substitute Model 10 for Model 20, 30, or 40.

Step 3: Attach one end of the cable assembly to the rear of the DSS. Insure a good connection by tightening the two adaptor holding screws.

Step 4: Attach the other end of the cable assembly to one of the chaining adaptors on the rear of the INTERTEC Model 20, 30 or 40. Either of the chaining adaptor ports may be used. Insure a good connection by tightening the two adaptor holding screws.

Step 5: Verify that your DSS is wired for the line voltage that is available in your area. The serial tag on the right rear of the DSS will indicate that your unit is set for either 110 or 220 VAC operation. DO NOT ATTEMPT TO CONNECT THE DSS TO YOUR LOCAL POWER OUTLET UNLESS THE VOLTAGE AT YOUR OUTLET IS IDENTICAL TO THE ONE SPECIFIED ON THE BACK OF THE DSS. Should the voltages differ, contact your dealer at once and do not connect your DSS to the power outlet. Before connecting the DSS to the wall outlet, be sure that the power switch located on the left
wall outlet, be sure that the power switch located on the left front is OFF (extended out of the front panel the same distance as the "Ready" switch). NOTE: Also make sure the disk locking strap has been removed (see Section 1.2.2, Step 2). Your DSS can be damaged if power is applied with the locking strap attached.

Connect the DSS power plug to the wall outlet. Push the POWER switch on the front of your DSS. At this time, you should hear a faint "whirring" sound coming from the fan inside the DSS. Both the red light on the POWER switch and the green light on the READY switch will be on. The READY FAULT and RESET switch lights will be off. Press the RESET switch at this time.

Step 6: Put the POWER switch located at the left rear corner of the VPU in the "ON" position if the line voltage is the same as the VPU required voltage (Section 1.3.1, Step 13).

Step 7: Refer to Section 2.1.4 for the test procedure to insure your VPU is functioning properly. Upon completion of these tests, return to step 8 below.

Step 8: If another INTERTEC Video Processing Unit (Model 10, 15, 20, 30 or 40) is to be used in the system, attach a cable assembly between the unused chaining adaptor of the tested VPU (setup in Step 4) and the untested VPU. REFER TO FIGURE 1.3D (Typical System Configurations) FOR ADDITIONAL PICTORIAL INFORMATION CONCERNING INTERUNIT CABLE CONNECTIONS. Now repeat steps 6 and 7 for this VPU. Continue to repeat steps 6, 7, and 8 until all units have been connected and tested. Then proceed to step 9.

Step 9: The setup of your system is now complete. Please continue with the System Operating Instructions.

SECTION 2.0

2.1 COMPUSTAR SYSTEM OPERATING INSTRUCTIONS

2.2 PRACTICAL HINTS

2.3 VIDEO DISPLAY FEATURES

2.4 SERIAL INTERFACING

2.5 SUPERBRAIN AND DSS OPERATING INSTRUCTIONS
2.1.0.0 OVERVIEW

Your CompuStar Computer System can consist of as few as one Video Processing Unit (VPU) or as many as 255 VPUs and a Disk Storage System (DSS). This section of the manual will explain how to use your CompuStar system in any or all of these configurations. Each Model 20, Model 30, or Model 40 VPU, as shipped from the factory, is capable of operating as a stand-alone computer, quite similar to our popular SuperBrain Video Computer System. You may choose to operate your VPU in this manner, and later add the DSS and other VPUs. If you purchase a DSS, you should know that these units are configured at the factory, and you may simply attach your VPUs and begin processing. Also, you may change the configuration of the DSS storage layout, allocating more or less disk space to each station. There are portions of this section of the manual devoted to each of these concerns.

It is recommended that you carefully read each of the sections in this part of the manual, as this will familiarize you with the hardware and software of the computer system. If you are going to use your VPU as a stand-alone computer, the section entitled "Using your CompuStar VPU as a Stand-Alone Computer" will describe its operation. The general system of the CompuStar network is described in "Layout of a CompuStar System", and if you ever wish to employ CompuStar's multi-user capabilities, you should carefully study this section. The steps needed to change a DSS allocation scheme can be found in "Altering a CompuStar System". Again, read all sections thoroughly, and reread other sections again as needed.
SECTION 2.1.1.0

2.1.1.0 LAYOUT OF A COMPUSTAR SYSTEM WITH A 10 MEGABYTE DSS

An operating system is a computer program that controls your computer system, properly maintaining its resources, such as the video, memory, peripherals, etc. A Disk Operating System, or DOS, is an operating system that resides on a disk. Using a DOS, files are brought into memory as needed, and therefore, memory usage is lessened. Your CompuStar Computer System uses standard CP/M as its Disk Operating System. A copy of the operating system exists in each user station and makes CompuStar a true computer network. This enables the user at each station to enjoy the benefits of his own computer terminal while allowing users to share the common data and program files located on the computer disk.

A computer disk has a magnetic oxide coating to enable data to be recorded upon it, similar to an audio recording device. The heads in the disk drive read from and write data to the disk. The disk rotates like a phonograph record, and the head positions itself at the proper point on the disk for the desired operation. Unlike a phonograph record, data on a disk is not kept in a spiral fashion, but instead the disk is divided into rings of concentric circles called tracks. The tracks are further divided into sectors. The operating system maintains a directory specifying the sectors which are vacant and the sectors which contain data. By viewing a directory of your disk, you can see a list of all files which exist on that disk.

CP/M gives each disk drive a name. The names are 'A' for the first drive, 'B' for the second, and so on, up to 'P' for the sixteenth disk drive. Each VPU Model (20, 30, or 40) will contain its own floppy disk drives A and B. These are accessible only by the stations themselves. A CompuStar ten megabyte DSS will contain the drives C, D, and E, and there is special significance to this drive scheme. An area will exist for each user on the DSS that will be like drives A and B - accessible only by each individual station. This disk space is called drive C and appears to be just another drive to the station. However, the area called drive D is the shared by all users. Thus, files that need to be common are kept in drive D. Further, drive E will be used by the print spooler (details for the print spooler will be available in the near future).

In a CompuStar Computer System, data files could be kept in the common area, drive D. These files would be available to any station in the network. You could use the local storage in a VPU with A and B disk drives to 'back up' the data on the DSS (this is STRONGLY RECOMMENDED), and thereby preserve a copy of the files in case of erroneous erasure. Data and programs needed only by one station could be placed on that station's drive C, and lightning-fast access to disk files would be available. Refer to Figure 2.1A for a typical CompuStar Computer System configuration.
STORAGE AREAS "A" AND "B" ARE ACCESSABLE ONLY BY STATION 255
STORAGE AREA "C" IS ACCESSABLE ONLY BY ASSIGNED STATIONS (1,2,3...255)
STORAGE AREAS "D" AND "E" ARE ACCESSABLE BY ALL STATIONS

FIGURE 2.1A DISK STORAGE SYSTEM (DSS) ALLOCATIONS
In standard CP/M computer systems, the operating system is loaded from the first two tracks of the first disk drive, which is usually denoted as drive A. This is true for the SuperBrain and CompuStar VPU Models 20, 30, and 40, which each have two disk drives denoted A and B. However, the Model 10 VPU does not have any disk drives. For this model, the operating system is loaded from drive C, which is the first drive for a Model 10. Drive C is located in the DSS and is unique for each station in a CompuStar system. Please note that a copy of the CompuStar operating system exists in each drive C - this enables you to freely swap Model 10 VPU's with other VPU models in your system.

Drive C is the storage area on the Disk Storage System (DSS) that is unique to each station in a CompuStar system. In configuring your network, you may divide the area on the DSS in any fashion you wish until you expend the 8.4 megabytes of formatted disk space on the unit. No station can be attached to the DSS network unless disk space has been allocated for that station. Drive D is the area on the DSS that is common to all stations in the network, and drive E denotes the area devoted to the system print spooler.

As shipped from the factory, a 10 Megabyte Disk Storage System is configured for ten stations, numbered 001 through 010. If you plan to use your CompuStar system in the factory-configuration, you must set the dipswitches in each station in the range of 001 to 010 (refer to section 1.3.1 of the installation instructions for more details). Each station has approximately 250 kilobytes allocated for its drive C. The print spooler area has been allocated 250 kilobytes, and the remaining area is allocated to drive D. This provides common disk storage of approximately 6000 kilobytes, or 6 megabytes. Included with the DSS is a diskette to be used with a Model 20, 30, or 40 VPU for reallocating the DSS storage areas for different configurations. Please note that it is not necessary to have all ten stations in order to use the DSS as shipped. Additional units may be added later. However, if you wish to add more than ten stations, or if you desire other disk allocations, you will have to initialize and configure the DSS yourself. The exact procedure for this is described in the section ALTERING A COMPUSTAR SYSTEM.

If you plan to use any CompuStar VPU with local disk storage (Model 20 VPU, 30 VPU, or 40 VPU) in your CompuStar network, you will have to use a different operating system from the one that is shipped with the unit to enable network communication. A special utility program will install the operating system on your VPU diskette, and is provided on the diskette shipped with the DSS. This program is called MODxxDOS.COM, where xx is either 20, 30, or 40, depending on the VPU type. Please select the correct program for your VPU type, as the wrong one will not work properly. Detailed instructions on the use of this program can be found in the section of this manual called ALTERING A COMPUSTAR SYSTEM.
Operation of the DSS 10 is really quite simple. You should only be concerned with a few aspects. On the front of the unit are four push switches. The leftmost switch is for power. When this switch is depressed the unit should power up, and the switch should light. Also, the READY switch next to the POWER switch should light. After power is applied, press the RESET switch to insure that the unit is operable. If the READY light flickers, this indicates some station in the network has accessed the disk. Otherwise, the light on the READY switch remains on.

NOTICE: If the FAULT light on the ten megabyte DSS comes on, this indicates that the DSS was unable to complete a communication link with one of the stations. When this occurs, you must reset the DSS before further use or it will remain inoperable. To reset the DSS, simply press the switch marked RESET. The unit should then resume normal operation. If the FAULT light remains on or if you are experiencing frequent disk faults, contact your Intertec representative.
SECTION 2.1.2

2.1.2.0 OPERATING A COMPUSTAR VPU AS A STAND-ALONE COMPUTER

As shipped from the factory, your CompuStar Video Processing Unit Model 20, 30, or 40 can be operated as a stand-alone computer. This means that you do not have to have a Disk Storage System to enjoy CompuStar's power and you may begin computing with any VPU that features local disk drives. When used without the DSS, the VPU behaves much like Intertec's popular SuperBrain Computer System. Both the SuperBrain and the CompuStar feature CP/M as their operating system. Before proceeding with operating your CompuStar VPU, it is suggested that you read Section 2.2 of the manual. This section should also be read if you wish to use a VPU Model 20, 30, or 40 in a CompuStar network.

Now that you have removed your CompuStar VPU from the packing carton, you are ready to begin to set up the system. The first step in this procedure is to verify that your CompuStar is wired for the line voltage that is available in your area. This can be ascertained by looking at the serial tag located at the right rear of the terminal. This tag will indicate if your terminal is set up for either 110 or 220 VAC operation. DO NOT ATTEMPT TO CONNECT THE COMPUSTAR VIDEO PROCESSING UNIT TO YOUR LOCAL POWER OUTLET UNLESS THE VOLTAGE AT YOUR OUTLET IS IDENTICAL TO THE ONE SPECIFIED ON THE BACK OF YOUR TERMINAL. Should the voltages differ, contact your dealer at once and do not proceed to connect the CompuStar VPU to the power outlet.

Before connecting the CompuStar VPU to the wall outlet, be sure that the power switch located at the left rear corner is turned OFF. You may now proceed to connect the computer system to the wall outlet. Next, turn the power switch on the rear of your VPU on. At this time, you should hear a faint 'whirring' sound coming from the fan inside the VPU. After approximately 60 seconds the message 'INSERT DISKETTE INTO DRIVE A' will appear on the screen. If this message does not appear after 60 seconds, simultaneously depress both RED keys on either side of the keyboard. These are the master reset keys and should reinitialize the computer system and cause the 'INSERT' message to appear. If, after several attempts at resetting the equipment, you are unable to get this message to appear on the screen, turn the unit off for approximately 3 to 5 minutes and then reapply power. Also, check the brightness adjustment on the rear of the computer's panel, turning the knob clockwise to increase the brightness level. If you are still unable to get the appropriate message on the screen, contact your Intertec representative.
2.1.2.1 SYSTEM DISKETTE

Now that you have applied power to the machine and the 'INSERT DISKETTE' message has been displayed in the upper left corner of the screen, you are ready to proceed with loading the computer's operating system. To do this you will need the 5 1/4" diskette that was packed in this manual. Notice that a small adhesive strip has been placed over the notch on the right side of the diskette. This aluminum strip is used to 'WRITE PROTECT' the diskette. Therefore, you may only load and/or read programs from this diskette. If you wish to write or save programs on the system diskette it will be necessary to remove this strip. This is NOT RECOMMENDED as it will subject your diskette to accidental errors that may be induced by you while you are becoming familiar with the operating system.

You are now ready to proceed with inserting the system diskette into the machine. When facing the front of the machine, notice the disk drives in the upper right corner. The one on the left is drive A, and the one on the right is drive B. It is important to distinguish the two drives, because the operating system will only load from drive A. Now open the disk drive door on drive A. This is done by applying a very slight outward pressure on the small flat door on the center of the opening. Once open, you may now insert the Operating System Diskette. There is a label on the diskette that describes the version of the operating system you have received. For proper insertion, please be sure that (1) the small aluminum 'WRITE PROTECT' strip is oriented toward the top edge of the diskette, and that (2) the label located on the diskette is away from the screen. Refer to Figure 2.1B for further help. It is EXTREMELY important that all diskettes are inserted with the proper orientation since they are inoperable otherwise. Applying gentle pressure on the rear of the diskette, push it all the way into the opening. Now reclose the drive door, pulling it in the opposite direction from which it was opened.

Once the door is closed, you may hear a 'swishing' sound. This is normal and indicates that the VPU is loading the operating system. Some drives are quieter than others and therefore this noise may be inaudible. The following message should appear in the upper left corner of the screen:

64K COMPUSTAR STAND-ALONE DOS VER 1.0 FOR CP/M 2.2
A>

If this message does not appear on the screen, simultaneously depress the two RED keys located on either side of the keyboard. This is how the VPU is reset, and this action should cause the operating system to reload. If, after several seconds, this message does not appear on the screen, try depressing the RED keys several more times. If this proves unsuccessful, then open the disk drive door on drive A and remove the system diskette, making certain that it has been properly inserted. Refer to Figure 2.1A for further help with diskette insertion. Recall that the operating system will not load unless the diskette has been
FIGURE 2.1B  PROPER INSERTION OF DISKETTE
correctly inserted. Once you are certain that the diskette has been correctly placed into disk drive A, close the door and again depress the RED keys simultaneously. If after repeated depressions the indicated message does not appear on the screen, contact your Intertec representative.

2.1.2.2 REVIEWING THE SYSTEM DISKETTE

Now that you have successfully loaded the System Diskette and the Disk Operating System (DOS), your CompuStar VPU is ready to accept your disk operating system commands. Now we shall review several of the commands on the operating system. However, it is recommended that you refer to the appropriate section of this manual for a detailed description of all such commands (Section 4 - Introduction to CP/M features and Facilities). The most used system command is the DIR command. This command instructs your VPU to display the directory of all files on the disk. To enter this command, simply enter 'DIR' on the keyboard and push the RETURN key. The computer should respond by displaying contents similar to this:

A>DIR
A:ED COM : DDT COM : SYSGEN COM : PIP COM
A:ASM COM : STAT COM : LOAD COM : DUMP COM
A:64KTEST COM : CS20BIOS ASM : SUBMIT COM : XSUB COM
A:C520CPM COM

A>

To obtain a better understanding of what this information means, let's take a look at the first entry:

A:ED COM

The first letter on this line is A. This indicates that the information following this letter is on drive A, which is the first drive in CP/M systems. The colon serves as a separator between the drive designator and the other information. The name of this file is "ED", and the file type is "COM". A more detailed treatment of this information can be found in other sections of this manual (Section 4 - An Introduction to CP/M Features and Facilities and Software Addenda).

IMPORTANT NOTE: Some of the system disk programs may have a two digit number suffixed to the file name (i.e., PIP22 instead of just PIP). This suffix is used to indicate the actual revision and/or version level of the program.

2.1.2.3 DUPLICATING THE OPERATING SYSTEM DISKETTE

Now that you have successfully loaded the Disk Operating System into drive A, it is important to duplicate this diskette onto another diskette. You should never remove the small aluminum 'WRITE PROTECT' strip covering the notch on the top edge of the System Diskette, or change or erase any files on this diskette.
You should make a duplicate of this diskette, and then store the original in a safe place. To copy this diskette, you will first need a blank diskette. We recommend an Intertec 1121010 diskette for this purpose. If you do not have any blank diskettes of similar quality, please contact the representative from whom you purchased your equipment. He should be happy to provide you with an ample supply of these diskettes.

Insert the blank diskette into drive B. Follow the procedure outlined in the previous paragraphs regarding the insertion of the operating system diskette. The only difference is that you will be placing the diskette into drive B. Be sure to leave the system diskette installed in drive A. Once installed, three separate steps are necessary to completely duplicate the diskette in drive A. First, the diskette in drive B must be formatted. Secondly, you must copy all of the files to the new diskette. Thirdly, the operating system must be copied to the new diskette. You must use a separate procedure to copy files and operating systems. Each of these steps are described in greater detail in the paragraphs that follow.

Formatting: All new diskettes must be formatted before attempting to read or write upon them. This is necessary because the information stored on these diskettes is in a soft-sectored format. The operating system divides the diskette into sectors. The system program called FORMAT tells the operating system where the sectors are on the diskette and which are in use.

To use the FORMAT program, you must have the program FORMAT.COM on a formatted diskette in drive A. Type FORMAT on the keyboard and then push the RETURN key. You will be asked to select the diskette type next. Respond with 'S' for the single-sided diskettes used on a CompuStar VPU Model 20, 'D' for double-sided diskettes used in a CompuStar VPU Model 30, or 'A' for diskettes used in a CompuStar VPU Model 40. Next type 'F' when ready to begin the format process. You will hear drive B re-set to track 0 and rewrite information to each track (there are 10 sectors per track). The formatting program will display each track as it is formatted.

After the diskette has been formatted, you will be asked whether you wish to reboot the operating system or format another disk. If you wish to continue formatting diskettes, remove the newly formatted diskette from drive B and replace it with an unformatted diskette. Then repeat the above process for each diskette you wish to format. If you do not wish to format any more diskettes, simply push the RETURN key. This will reload the operating system and once again the VPU will be ready to accept your commands.
PIP: Since our original intent was to copy the original System Diskette, we may now proceed with the file transfers. This is done by entering the following command on the keyboard:

\[ \text{PIP B:} = *. *[V] \]

Be sure to push the RETURN key after you have typed out the command.

PIP is actually a file on the diskette that CP/M systems use for file transfer. PIP stands for Peripheral Interchange Program, and more information on PIP can be found in Section 4 of this manual (An Introduction to CP/M Features and Facilities). The PIP command above instructs the computer system to copy each file on drive A onto drive B. As each program is copied, its name will be displayed on the screen. This procedure will take approximately 5 to 10 minutes. After the procedure is complete, the control of the operating system will be returned to the user. If this procedure does not complete, you will see a message indicating the error. Below are listed some possible messages and your response.

<table>
<thead>
<tr>
<th>MESSAGE</th>
<th>ACTION TAKEN</th>
</tr>
</thead>
<tbody>
<tr>
<td>*** disk not ready ***</td>
<td>Make sure the disk drive doors are closed.</td>
</tr>
<tr>
<td>*** disk not ready ***</td>
<td>You are attempting to copy data to an unformatted diskette. Format and repeat.</td>
</tr>
<tr>
<td>Bdos Err on B: Bad Sector</td>
<td>Disk not formatted properly. Reformat and repeat.</td>
</tr>
<tr>
<td>Bdos Err on B: Select</td>
<td>You did not specify the correct disk drive. Make sure you entered 'B'.</td>
</tr>
<tr>
<td>Bdos Err on B: R/O</td>
<td>You probably have a 'WRITE PROTECT' strip over the notch on the top edge of the diskette. Remove and try again.</td>
</tr>
</tbody>
</table>
SYSGEN: Now that you have copied the operating system's programs from drive A to drive B, you are ready to copy the operating system itself. The operating system resides on tracks 0 and 1 of the diskette, and these tracks are inaccessible to other files. To make this transfer, type the following command on the keyboard (followed by the RETURN key):

SYSGEN

The SYSGEN command is used to generate an operating system and place it on the desired diskette. Once you have entered this command you will select the source disk (where to get the operating system) and the destination diskette (where to place the copy). In our case, the source response is 'A' and the destination response is 'B'. SYSGEN will ask you to indicate when the diskettes are loaded, and you press the RETURN key when you have inserted the diskettes in the proper drives. This procedure will inform you when it is finished. As in the FORMAT program, you may repeat this process on another diskette if you desire. To copy another operating system, remove the diskette from drive B and replace it with another diskette. Push the RETURN key to reload the operating system and proceed.

Now you can remove the system diskette from drive A. Remove the diskette in drive B and place it in drive A. Refer to the previous section for proper diskette orientation. Once the newly copied diskette from drive B is in drive A, close the door to the drive. Reset the computer system by simultaneously depressing both RED keys located on either side of the keyboard. This will force the computer to reload the operating system from the diskette - the one you just copied. Use this diskette while becoming familiar with your computer system, and place the system diskette in a safe place in case one copy is destroyed or otherwise damaged (see Section 2.2.2.0 DISKETTE PRECAUTIONS).

IMPORTANT: If you reset the computer with the newly copied diskette and garbled text appears on the screen, an error was made in the use of the 'SYSGEN' program. If this is the case, then remove the diskette from drive A, replace it with the system diskette, and repeat the previously outlined procedure for copying the system diskette. If you continue to encounter difficulties, please read Section 4 of this manual entitled "An Introduction to CP/M Features and Facilities" for a complete review of the system program SYSGEN.

Now that you have successfully copied the system diskette, please read Section 4 of this manual entitled "An Introduction to CP/M Features and Facilities" for a complete description of each of the operating system programs (DDT.COM, PIP.COM, SUBMIT.COM, etc.).

12
2.1.3 ALTERING A COMPUSTAR SYSTEM

If you wish to change your CompuStar disk allocations, you will have to perform some initialization tasks. These procedures include a disk format program and allocation of user, common, and print spooler areas on the Disk Storage System (DSS). Note that all user stations can have exclusive disk storage at the DSS called drive C. Further, the common area or drive D, is available to any user station in the network. The print spooler area (drive E) is also available to any network user.

Before proceeding please be certain the the following has been done:

ALL CABLES TO THE VPU's ARE PROPERLY CONNECTED
ALL DIPSWITCHES FOR STATION NUMBER HAVE BEEN SET
ALL USER STATIONS ARE POWERED OFF
YOU HAVE AT LEAST ONE VPU MODEL 20, MODEL 30, OR MODEL 40
YOU HAVE AN EXTRA FORMATTED DISKETTE

NOTE: You cannot alter your CompuStar DSS configurations until you are familiar with the operation of a stand-alone CompuStar VPU. This section assumes that you understand this kind of operation. Please study the contents of the section of this manual entitled 'OPERATING A COMPUSTAR VPU AS A STAND-ALONE COMPUTER' prior to altering a CompuStar DSS.

First, turn on the power to the station (Model 20, 30, or 40) that you will use to initialize the DSS. This unit must have local disk drives since the initialization procedures are on a diskette. Next, open the door of the left drive of the initialization station - this is drive A. Place the COMPUSTAR INITIALIZATION DISKETTE into it. Refer to Figure 2.1B for correct diskette orientation. Close the door and then simultaneously depress the RED keys at the bottom of the keyboard. The unit will now load the special initialization operating system. The following message should appear at the top left corner of the screen:

64K COMPUSTAR INITIALIZATION DOS VER 0.1 FOR CP/M 2.2 COM

WARNING--THIS PROGRAM WILL ERASE ALL HARD DISK DATA

DO NOT USE THIS DISKETTE UNTIL YOU HAVE READ SECTION 2.1.3 OF YOUR COMPUSTAR MANUAL!

If this does not appear, try depressing the RED keys again. If repeated depressions of the RED keys do not produce the above message, then contact your Intertec dealer. You cannot alter the DSS unless this operating system is loaded in the initialization station. This operating system will work in every Model 20, 30, or 40 VPU.
The initialization and allocation programs will first format the DSS and then obtain from you the amount of disk area you wish to devote to each user station. You may allocate areas for stations to be added later, otherwise you will destroy the DSS's contents if you should decide to repeat this process. Once these areas have been assigned, they cannot be changed or reassigned without destroying the DSS data. Since the initialization uses CP/M's SUBMIT program, aborting the routine will not work properly. (for a review of SUBMIT, see section 4 of this manual). Therefore, it is mandatory to know how you wish to configure the DSS before you start.

Once the special initialization DOS has been properly loaded into the VPU (using the diskette contained in the box with your DSS), and you are sure that the power is off at all other VPUs in the CompuStar network, you may proceed with the initialization process. Type in the following line at the keyboard:

```
SUBMIT22 STARGEN
```

A program on the diskette called STARGEN.SUB contains the names of the system programs needed to initialize the DSS. First, the DSS will be formatted. If you notice, the FAULT light on the DSS will come on during the formatting. This is normal, and indicates that nothing is wrong. Do not reset the DSS until later.

The DSS may have media errors on it. This means that some of the tracks on the disk may not be usable. Supplied with your DSS is a buff-colored card labeled 'SA1004 MEDIA ERROR MAP'. On this card is listed the media defects on your drive. It is necessary for you to enter the tracks and heads listed on the card so that these may be reassigned. As the head positions itself on a defective track, it will then reposition itself to an alternate track area. This makes the defective tracks transparent to the user. After you have entered all defective tracks, enter 'D' for a display of your entries for verification purposes. Then enter 'X' to exit the alternate track assignments and proceed.

There are approximately 8800 kilobytes (8.8 megabytes) of formatted disk area on the DSS. The first area you will be asked to allocate is the common area - drive D. Enter the amount in kilobytes and push the RETURN key. Repeat the process for drive E, the print spooler area. Next enter the allocations for each stations' exclusive area, drive C. Here you will enter a station number (any number from 1 to 255), and again the number of kilobytes you wish to allocate. The station numbers do not have to be in any order and do not have to be contiguous. NOTE: Allocate area for any future stations at this time, because the allocation process destroys the data on the DSS. This routine will display the number of bytes remaining as each entry is made. You may also enter 'D' to review which stations and areas have been allocated in the process at any time. To terminate entry, enter 'E' and push RETURN.
After you have made all of your entries and have entered 'E', the initialization procedure will complete some final tasks and return to the operating system. One more step is now needed to complete the process. You must have a different operating system on the diskette to use a VPU with local disk drives (any Model 20, 30, or 40) in a CompuStar network. The operating system that comes with the unit will not work with a CompuStar network, because its original operating system is designed to treat the VPU as a Stand-Alone computer. You must place a copy of the new operating system on another formatted diskette. A utility program called MODxxDOS should be run (xx is 20 for a VPU Model 20, 30 for a VPU Model 30, or 40 for a VPU Model 40). Notice - you cannot use the CP/M system program SYSGEN to do this because the diskette in drive A contains a special initialization DOS, and you actually need another DOS elsewhere on the diskette. MODxxDOS will insure this transfer. However, once you run the MODxxDOS program, the diskette in drive B will contain the VPU's network operating system in drive B. Subsequent operating system transfers from that diskette should be performed via the SYSGEN command (For a review of SYSGEN and FORMAT, please see section 4 of this manual, AN INTRODUCTION TO CP/M FEATURES AND FACILITIES).
This is a sample session in which a CompuStar DSS is configured for five user stations. The underlined portions in this demonstration are entered by the user, and '(cr)' means that the RETURN key should be pressed here.

2.1.4  VPU SYSTEM TEST

It is necessary to make certain that all VPUs are capable of communicating with the Disk Storage System. To do this, it is suggested that each VPU be attached to your CompuStar network and tested one at a time. This will systematically insure each terminal's operation before others are attached to the network.

If you are testing a VPU that has its own disk drives, it will be necessary to initialize a disk operating system that will permit network communication. Recall that these units are designed to operate in a stand-alone mode as shipped from the factory. Therefore, you only need to copy the network operating system onto another diskette to test the unit. These special operating systems can be generated using the program contained on the diskette that was shipped with your DSS.

To initialize the operating system for your VPU, place the INITIALIZATION diskette into drive A of the VPU (this diskette is the one shipped with your DSS). Be sure to insert the diskette properly with the notch on the upper edge and the labels away from the screen. Depress both RED keys simultaneously and load the initialization operating system. There will be three programs on the diskette that will generate your new operating system, depending on your VPU type. The programs are named MOD20DOS.COM, MOD30DOS.COM, and MOD40DOS.COM. Select the correct program for your VPU type. Type in the name and press the RETURN key. When asked for the source drive name, press the RETURN key. When asked for the destination drive name, type B. Then, when you have properly inserted a formatted diskette into drive B, press the RETURN key to inform the program that you are ready. Don't forget to push the diskette all the way in and lose the drive door. Press the RETURN key again when the function has completed and allow the operating system to reboot.

The operating system contained on the diskette now in drive B will only work with a CompuStar DSS. Remove both diskettes from the VPU and turn the off the power. If any other VPUs are connected to the DSS network, make sure that the power is switched off on each of these.

You are now ready to test the VPU and determine if it is able to communicate with the DSS. Press the POWER switch on the DSS, locking it in the ON position. The red light on the POWER switch and the green light on the READY switch should come on. Next, press the RESET switch in for a few seconds. Now, turn on the power to the VPU being tested. If you have a Model 10 VPU, the operating system should begin to load. If your VPU has its own disk drives, insert the diskette containing the network operating system into drive A. Depress both RED keys. The operating system should load. With all VPU models, the screen should contain the sign-on message in the upper portion of the screen. Also displayed should be the station number and the disk prompt. Reboot the operating system several times and make sure that it loads properly.
If the operating system fails to load, check the cable connections. Make certain that the station number has been correctly set on the dipswitch located on the chaining adaptor board, and that no two stations have the same number setting. If you VPU has its own disk drives (Model 20, 30, or 40), be sure that the operating system was correctly copied. Repeat any steps as necessary. If the unit does not operate properly after you have checked everything, contact your Intertec representative.

Once the VPU passes this step, switch the unit off before attaching any other units. Switch off the power to the DSS. Also, connect the next VPU and test it similarly. Do not test any VPU with the power on any other VPU. This way, you eliminate any potentially defective VPU.
SECTION 2.2

2.2.0.0 PRACTICAL HINTS

By now you should have read the CompuStar manual thoroughly, and you should be familiar with the hardware, operating system, and design scheme of your CompuStar Computer System. Next, we shall discuss some practical hints and little known facts that will help you become even more familiar with your computer system.

2.2.1.0 LOGGING ONTO A DISK

Each time you change a diskette, you must inform the operating system that you have done so. This prevents accidental alteration of disk contents because the operating system's copy of the directory does not agree with the files on the disk. Therefore, for devices with removable media, the directories are checked with each disk access. Each check produces a checksum, which is matched with the disk's last access. If these two sums do not match, then CP/M will not allow you to alter the diskette's contents. The disk is internally flagged READ ONLY, and an attempt to change anything on the diskette will produce the following error message: Bdos Err on d: R/O, where 'd' is the drive in question. So when you change a diskette, you must perform an operating system restart. The easiest way to do this is to hold down the 'control' key (marked CTRL), and then press the 'C' key. This will reload the operating system and will allow you to alter the newly inserted diskette.

2.2.2.0 DISKETTE PRECAUTIONS

Diskettes are a popular method of auxiliary storage for microcomputer systems because of their size, price, and ease of use. There are some rules governing proper diskette care, and you should always be aware of these.

1) Never allow anything to come in contact with the diskette surface. Never attempt to clean a diskette. Although diskette exposure is limited to the access holes in the jacket, you should nevertheless be extremely careful when handling diskettes. Oils on your skin may make the diskette unreadable.

2) Keep diskettes free from smoke or dust. This is best done by leaving diskettes in their protective covers.

3) Keep magnetic objects away from diskettes as this may cause the contents of a diskette to be erased. Remember that tools often become magnetized. Transformers, power cords, and even telephones may emit magnetic radiation.

4) Label your diskettes properly. When labels are attached to the jacket of a diskette, use only a felt-tipped pen to write on them. A pencil or ball-point pen may groove the diskette and
make it unreadable. Place the 'WRITE PROTECT' strip over the notch of any diskette you do not want erased. Each box of Intertec diskettes comes with an ample supply of labels and aluminumized 'WRITE PROTECT' strips.

5) Back up important diskettes by keeping separate copies of them in a safe place. Anticipate diskette failure because mistakes do happen. Place the date on duplicate copies so that you know how current their contents are.

6) Diskettes can become damaged if exposed to temperature extremes. Usually, a safe operating range is 50 to 120 degrees Farenheit. Humidity can also be important - 20 to 80% relative humidity is suggested. Prolonged periods of sunshine can also damage a diskette's contents.

7) Be sure to remove the diskette from the disk drive before the power is turned off the machine and return it to the protective jacket.

8) Never rely upon a diskette that you suspect is damaged. Upon such suspicion, immediately copy its contents onto a newly formatted diskette, and then survey the damage.

9) Remember that the FORMAT system program completely destroys the contents of a diskette. So does the command ERA *.*. The SYSGEN command will only affect the contents on the first two tracks (the operating system) of a diskette.

10) IMPORTANT - The data contained on a diskette are always worth more than the diskette itself. Guard the data carefully. Heed these warnings.
2.2.3.0 CP/M SUMMARY

Detailed operation of all CP/M programs can be found in other sections of this manual. Specifically, refer to Section 4, 'AN INTRODUCTION TO CP/M 2.0 FEATURES AND FACILITIES' for the details on the use of the programs common to all CP/M systems, and see the section 'SOFTWARE ADDENDA' concerning the Intertec computers. Here we shall briefly summarize the system programs supplied on the Operating System Diskette for your CompuStar VPU, and CP/M's built-in functions.

<table>
<thead>
<tr>
<th>PROGRAM NAME</th>
<th>FUNCTION</th>
<th>EXAMPLE</th>
</tr>
</thead>
</table>
| PIP          | Copies files between devices, logical and physical. | PIP B:=A:*.*  
|              |          | PIP CON:=A:FILE.TYP |
| SYSGEN       | Generates a new operating system on diskette. | SYSGEN |
| ED           | Text Editor, allows changes to text files. | ED PROGRAM.BAS |
| ASM          | Assembles an 8080-type assembly language program into a 'HEX' file. | ASM PROG |
| LOAD         | Creates a 'memory image' file from a 'HEX' file that can be executed. | LOAD PROG.HEX |
| DDT          | Allows user to debug and step thru a 'COM' or 'HEX' file's execution. | DDT PROG.COM  
|              |          | DDT PROG.HEX |
| SUBMIT       | Performs successive execution of a list of 'COM' files. | SUBMIT MORNING.SUB |
| XSUB         | Forces data entry into a process under control of SUBMIT. | XSUB |
| DUMP         | Produces a hexadecimal listing of a disk file's contents. | DUMP PROG.COM |
| STAT         | Display or alter file status, device status, or system characteristics. | STAT B:*.*  
|              |          | STAT B:DSK: |
| DIR          | Displays a disk directory. | DIR  
<p>|              |          | DIR B: |
| ERA          | Erases a disk file. | ERA B:PROG.BAK |
| REN          | Renames a disk file. | REN PROG.ASM=PROG( |
| SAVE         | Save memory contents on the disk. | SAVE 10 A.COM |</p>
<table>

</tr>
</tbody>
</table>

The reader should note that a CP/M program usually distributed with CP/M computer systems is not included with Intertec Computer Systems. The program, MOVCPM, allows the user to change the operating system for a number of memory sizes. However, all Intertec computer systems have only one memory size, and MOVCPM is not needed. Intertec furnishes operating system copies for 64K memory size.

For a more complete discussion of these system programs, please refer either to these sections in this manual: AN INTRODUCTION TO CP/M FEATURES AND FACILITIES, CP/M 2.0 USER'S GUIDE FOR CP/M 1.4 OWNERS, and SOFTWARE ADDENDA.
2.2.4.0 AUTOLOAD FEATURE

Perhaps you wish for your computer terminal to perform the same function upon each operating system restart. This is possible with CP/M version 2.2. The command buffer is the area in your computer's memory where the next command to be executed is placed. In normal CP/M systems this buffer is empty, and upon operating system restart the system awaits your command. You may alter this if desired, so that the system will execute any program on the disk upon restart.

In order to facilitate this autoload feature, you have to change the operating system that is stored on the inner two tracks of your diskette. First, make a copy of the program on your distribution diskette that will generate the operating system. In the CompuStar Model 20, this program is called 'CS20DOS.COM'. Using the PIP program, copy as follows:

```plaintext
PIP AUTOLOAD.COM=CS20DOS.COM
```

CS20DOS.COM is similar to the SYSGEN utility, except that no SOURCE DRIVE is specified when using it. After you have made the copy, you will have to alter its command buffer for the autoload capability. The DDT system program will have to be used to do this. It is strongly recommended that you become familiar with the DDT program before attempting to alter the operating system. See Section 7 of this manual, CP/M DYNAMIC DEBUGGING TOOL (DDT) USER'S GUIDE, for assistance.

Next edit the program 'AUTOLOAD.COM' with the use of DDT. The correct command is:

```plaintext
DDT AUTOLOAD.COM
```

DDT will then load into the computer's memory and read in your 'AUTOLOAD' program. After you have decided on the command you want to be executed upon restart, determine its length. This is done by counting the number of characters in the command. If a filename and/or parameters are included in the command, be sure to include their length(s) in the count. Also include any separating spaces. For example, if you wanted the directory display to be your command, the command is 'DIR', and its length is 3. If instead you wanted to see a directory display of disk B, the command is 'DIR B:' and its length is 6.

The CP/M command buffer begins at location 980H. Use the 'S' command to alter the desired memory locations with your new command. Place the hexadecimal value of the command length in this location. The command itself begins at location 981H, and you may use up to location A07H for the buffer. Notice that if you go beyond location 998H, you will overwrite the copyright notice in the operating system. At the end of your command, place the null terminator 00H. When inserting the command itself into the memory locations, please note that you must enter hexadecimal numbers for the ASCII values of the letters in the command. The
ASCII code chart is listed in Section 2.3 of this manual.

When you have finished, use the DDT command 'D' to display the results of your action. Make any necessary corrections, and then exit to the operating system with the GO command. Before you do anything else, you must save the memory contents of the 'AUTOLOAD' program. Using CP/M's 'SAVE' function, enter the following line at the keyboard:

```
SAVE 48 AUTOLOAD.COM
```

Let's review what we have done so far. First, we made a copy of the operating system, and called it 'AUTOLOAD.COM'. (Incidentally, any other name could have been used as long as the file type is '.COM'). Next, we placed a CP/M command into the CP/M command buffer, starting with the command length in hexadecimal. We ended with a null byte terminator. Then we exited to the operating system and saved the revised program in memory on the disk. Now it is time to generate the new operating system.

Please be sure that the command in the command buffer is what you want your computer to do upon each operating restart, because that is exactly what it will do. If sure, then type in the following command at the keyboard:

```
AUTOLOAD
```

From here the operation will be similar to that of the SYSGEN command. First you will be asked to enter a SOURCE DRIVE. Press the RETURN key here, the program itself is carrying the operating system for us. Next you will be asked to enter the DESTINATION DRIVE. Enter your choice, and press the RETURN key when the correct diskette has been inserted in the destination drive. If you are using a new diskette, make certain that it has been formatted with the FORMAT command. When the message 'FUNCTION COMPLETE' is displayed upon the screen, your transfer is done, and you should press the RETURN key to reboot the operating system. If you specified drive A as the destination drive, this reboot will incorporate your new modification. If not, replace the diskette in drive A with your destination diskette, and press both RED keys at the same time. You should now have an operating system with an autoload feature. If not, you probably incorrectly entered the command in the command buffer. Repeat the above procedure if this is the case.

WARNING: If you chose drive A as the destination drive and you made an error in altering the command buffer, this diskette will contain an unusable copy of the operating system. It will probably not operate. You will have to replace its operating system with a valid copy probably using the 'SYSGEN' command. Therefore, it is recommended that you select drive B as your destination drive when altering the command buffer.
Here is a sample session describing the steps needed to alter the command buffer of your operating system. Please carefully read the previous section before attempting to alter the command buffer. Note that all items underlined are to be typed in by you. Otherwise, the displays are generated by the computer. When you encounter ' (cr)', press the RETURN key.

The CompuStar Computer System will employ a unique technique for print spooler operation. The spooler will use drive E in a CompuStar Network to facilitate printer operation. Further details will be released later.
2.2.6.0 SYSTEM FAILURE

Whenever you have a system failure, you should remain calm. Quite often, the results of a system failure are minimal. Failure recovery is important, and you should take all steps to insure that the system is restored as soon as possible. Use the following checklist as a guide and insure that each item is covered. If the system does not work after these items are checked, contact your Intertec representative. Note all failures in a log book so that you know what to suspect with subsequent failures.

Check mechanical conditions:

Is the unit plugged into a proper wall outlet?

Is the power switch 'on'?

Is the brightness knob on the back of the unit turned up?

Are the cables properly connected and fastened tightly?

Is the fuse blown?

Operating System Problems:

Is there a diskette in drive A?

Is a valid copy of the operating system on the diskette in drive A?

Have you incorrectly altered the DSS configuration?

Have you carefully followed the restart instructions?
SECTION 2.3

2.3 VIDEO DISPLAY FEATURES

All CompuStar Video Processing Units (except the Model 15) employ a 'memory-mapped' video scheme. This means that a portion of the central processing unit's memory is devoted to the characters for display on the screen. This memory area is unavailable for program or data use. The CRT Controller performs a direct memory access (DMA) cycle to obtain this data. This relieves the CPU of most screen-related functions. A more complete discussion of the video operation sequence can be found in Section 3.2 of this manual entitled 'THEORY OF OPERATION'.

Memory-mapped video enables the VPU to provide powerful and fast video operation. This technique also permits many screen control features to be performed under software control. When the CRT Controller receives certain special inputs, the display may be affected. There are two main types of screen-directed inputs: 'ESCAPE' sequences and 'CONTROL' sequences. An ESCAPE sequence means the ASCII character ESC (27H) is the first character of the input and is followed by other characters. A CONTROL sequence means that the CTRL key (third row of the keyboard, extreme left) is held down while the other character is depressed. The control key operates similarly to the SHIFT key. The following tables show the ESCAPE and CONTROL sequences and their interpretation by the video system.

ESCAPE SEQUENCES

<table>
<thead>
<tr>
<th>Escape Sequence</th>
<th>Description</th>
</tr>

**CONTROL SEQUENCES**

- **CTL-A**: Home cursor - The cursor is positioned at row 1, column 1.
- **CTL-F**: Cursor forward - The cursor is moved one space to the right.
- **CTL-H**: Cursor back - The cursor is moved one space to the left.
- **CTL-K**: Cursor up - The cursor is positioned up to the previous line.
- **CTL-J**: Cursor down - The cursor is positioned to the next line down.
- **CTL-I**: Tabbing - The cursor is positioned to the next modulo-8 position.
- **CTL-L**: Clear screen - Erases the data on the screen, and the cursor is homed.
- **CTL-G**: Ring bell - The audio indicator is activated.
- **CTL-W**: Page off/on - Video display is disabled/enabled after the 24th line.
SECTION 2.4

2.4.1 SERIAL PORT INTERFACING INFORMATION

In order to use auxiliary devices (sometimes called peripherals) with your CompuStar VPU, it is important to review the interfacing information in this section. Each CompuStar VPU has two serial ports available for peripherals such as printers, modems, optical scanners, etc., and these are located on the back panel of the CompuStar adjacent to the power switch. These are marked MAIN PORT and AUXILIARY PORT.

A port is simply a point of access to the computer system. The ports on a CompuStar VPU allow input or output, provided that the VPU and the peripheral device communicate properly. For proper protocol, simplified RS-232-C serial interface is provided. RS-232-C establishes the pin assignments on the port couplers for transmitted data, received data, handshaking, etc.

Serial transmission refers to the way the data are transferred. Recall that internally the CompuStar manipulates data as bytes. Each byte is composed of eight bits, which may have a value of one or zero (these are numbers that the computer can read). If an entire byte of data were transmitted or received at one time, then the port would be a parallel port. The communication with the DSS is actually parallel. This is faster than serial communication, but requires eight times as many communication lines for transmitting and receiving data as with serial protocol. So the CompuStar internally uses a device called a USART, or a Universal Synchronous/Asynchronous Receiver/Transmitter, which converts a byte of data into eight bits of data. The CPU sends the USART a byte, and the USART sends the coupler eight bits serially. At the other end, the coupler sends the USART eight bits serially, and the USART sends the computer one byte.

Traditionally, in CP/M the printer is attached to the logical port designated as the list device. Logical just means that this is what the operating system calls the port. In the CompuStar, the LST: device is the same as the AUXILIARY PORT. Other devices which accept or transmit serial data can be attached to either port. CP/M refers to the MAIN PORT as the OUT:, PUN:, or RDR: device. You must write or otherwise obtain software needed to operate these devices. For a more complete discussion of CP/M's 'logical devices', please refer to Section 4 of this manual - AN INTRODUCTION TO CP/M 2.0 FEATURES AND FACILITIES.

Each port has two addresses associated with it - status and data. The following gives the port addresses internally for data and status transmission. When ready to accept data for transmission (i.e., out of the computer), the status byte will contain the hexadecimal pattern 01H. When the port has received data for the computer and is ready to send it to the CPU, the status byte will contain 02H. Normally, the CPU will continuously check the
status port until the desired number is present, and then the proper action will be taken accordingly.

The memory address for the auxiliary port status is 41H, and its data address is 40H. For the main port, the status address is 59H, and the data address is 58H. The following assembly language program demonstrates how data might be transmitted out of a port.

```assembly
;********************************************************************************
;*                        2.4.2 SAMPLE OUTPUT DRIVER PROGRAM                          *
;********************************************************************************

PRTOUT: ORG 100H ;base of TPA
PDATA EQU 40H ;address of AUX data
PSTAT EQU 41H ;address of AUX status

LXI H,LINE ;HL <- address of text for output
MVI C,14 ;C <- length of text

LOOP:   LDA PSTAT ;get port status
ANI 01H ;port ready to send?
JNZ LOOP ;no, check again
MOV A,M ;else load next byte of text
OUT PDATA ;send it out the port
INX H ;increment the text pointer
DCR C ;and decrement the count
JNZ LOOP ;continue if text remains
RET ;else quit

LINE DB 'THIS IS A LINE'
END
```

The reader is advised that alternate methods for input and/or output are available using the facilities of the CP/M operating system. Please review Section 9 of this Manual, CP/M 2.0 Interface Guide, for an explanation of such features.
2.4.3 RS-232-C SERIAL INTERFACE

2.4.4 ASYNCHRONOUS/SYNCHRONOUS COMMUNICATIONS

The USART allows the serial data communication link to be either asynchronous or synchronous. With asynchronous operation, a start bit is sent to alert the receiver that a word is being transmitted. After the start bit, 5 to 8 data bits are sent. Subsequent to the data bits, an optional parity (or check) bit (representing an even number or odd number of '1' data bits) can be sent followed by 1, 1-1/2, or 2 stop bits.

The following information for asynchronous communication may be programmed by the user:

- The number of data bits to be sent for each transmitted character (5 to 8)
- Odd or even parity or no parity bit for each transmitted character
- The number of stop bits to be sent for each transmitted character
- The rate at which characters are to be transmitted (1, 16, or 64 times baud rate)

For a synchronous communication link, the transmitted character will consist of 5 to 8 data bits plus an optional parity bit. Preceding the start of a transmitted data stream, the user can program one or two synchronization characters to be sent. These synchronization characters will only be used by the receiver in the internal synchronization mode. If the receiver is in the external synchronization mode, the synchronization characters will be ignored and a synchronization pulse is used. In the synchronous mode, the user may program the following:

- The number of bits per character (5 to 8)
- Optional parity bit (odd, even, or none)
- One or two synchronization characters and bit structure of characters
- External or internal synchronization

Additional information concerning serial port interfacing (asynchronous and synchronous) is presented in sections 12 and 13.
2.5 SUPERBRAIN CHAINING ADAPTOR

Via a special chaining adaptor, a SuperBrain or SuperBrain QD Video Computer Terminal may be connected to a CompuStar DSS. This will provide hard disk storage for a SuperBrain System. This section will instruct you concerning proper installation and configuration of a hard disk system.

The chaining adaptor is shipped with a diskette. This diskette contains the program needed to allocate disk storage however you wish. Also contained on this diskette are the operations systems needed to allow the SuperBrain or SuperBrain QD to use the extra disk device—the standard DOS will not work.

NOTE: Before proceeding, insure that the power cord is removed from the wall outlet.

To attach the chaining adaptor to the SuperBrain, you must first remove the SuperBrain's cover. This is accomplished by removing the four screws holding the cover in place; two are in the front and two are in the rear. Make certain that the diskette drive doors are closed. Next, locate the short cable on the chaining adaptor. This will plug into the 40 pin connector at the top edge of the SuperBrain processor board located just beneath the disk drives. Be sure to align the notch in the connector with the slot on the processor board. Push the cable connector until it is completely seated.

Insert the round end of the four mounting tabs into the four holes on the back of the disk assembly (see Figure 2.5A). Now place the board on the mounting tabs as shown in Figure 2.5B. Be careful that the cable does not come in contact with the fan. Then extend the long cable over the middle of the rear edge of the base. This cable will connect to the disk drive.

Replace the cover on the SuperBrain, binding the long cable between the two cover halves. Replace the hold-down bolts to secure the attachment.

Plug the connector on the end of the long cable into the receptacle at the rear of the DSS. Tighten the connector screws making certain that the pins are in full contact.

Now you may choose to change the disk allocations to other than factory configuration. This is suggested because disk space is lost due to CompuStar allocations for ten user stations. The process is fairly simple. Place the diskette included with the chaining adaptor in drive A of the SuperBrain. Be sure it is properly inserted with the notch on the upper edge and the labels facing away from the screen. Close the door to the diskette, and then simultaneously depress both RED keys. Now type the following line at the keyboard:

SUBMIT22 SBGEN
FIGURE 2.5A  MOUNTING HOLES FOR SUPERBRAIN CHAINING ADAPTOR

FIGURE 2.5B  MOUNTED SUPERBRAIN CHAINING ADAPTOR
A program on the diskette called SBGEN.SUB contains the names of the system programs needed to initialize the DSS. First, the DSS will be formatted. If you notice, the FAULT light on the DSS will come on during the formatting. This is normal, and does not indicate that anything is wrong. Do not reset the DSS until later.

The DSS may have media errors on it. This means that some of the tracks on the disk may not be usable. Supplied with the DSS is a buff-colored card labeled 'SA1004 MEDIA ERROR MAP'. This card lists the media defects on the drive.

It is necessary for you to enter the tracks and heads listed on the card so that these may be reassigned. Then, as the head positions itself at a defective track, it will reposition itself to an alternate track area. This makes the defective tracks transparent to the user. After you have entered all defective tracks, enter 'D' for a display of your entries for verification purposes. Then enter 'X' to exit the alternate track entry and proceed.

There are approximately 8800 kilobytes (or 8.8 megabytes) of formatted disk area on the DSS. Enter allocations for drives C, D, and E. If you make invalid entries, you must reenter your choice. When finished, you are shown a summary of your entries. Don't worry if the numbers are slightly greater than you entered; round-up occurs to insure boundary alignment. If you wish to change your entries, do so now by entering 'N' where asked. Otherwise, enter 'Y'.

After you have made your entries, the initialization will complete a final task and return to the operating system. One more step is needed to complete the process. You must have a different operating system on the diskette to use the DSS. The standard SuperBrain or SuperBrain QD operating system will not work. You must place a copy of the new operating system on another formatted diskette.

These operating systems are on the diskette in drive A. Enter 'SB10MDOS' to copy the operating system for a SuperBrain, or 'QD10MDOS' for the SuperBrain QD. The program will ask you for the source drive. Press return here. Then you will be asked for a destination drive. Here, press the 'B' key. Press the 'RETURN' key when you have placed a formatted diskette into drive B. When the program displays 'FUNCTION COMPLETE', press the 'RETURN' key.

After the new operating system has been placed on the diskette in drive B, you are ready to test it. First, press the RESET button on the DSS, and the FAULT light should go out. Then exchange the two diskettes in drives A and B. Then depress both RED keys simultaneously. This will load in the newly generated operating system. If the screen fills with garbled text, you have improperly copied the operating system, and you should repeat the last step. Otherwise, enjoy your new, powerful computer.
SECTION 3.0
3.1 SYSTEM INFORMATION AND SPECIFICATIONS
3.2 THEORY OF OPERATION
3.3 VIDEO PROCESSING UNIT SPECIFICATIONS
3.4 10 MEGABYTE DISK STORAGE SYSTEM INTERNAL CONSTRUCTION
3.1 SYSTEM INFORMATION

The CompuStar Video Processing System (VPU) represents the latest technological advances in the microprocessor industry. The universal adaptability of its CP/M Disk Operating System satisfies the general purpose requirement for a low cost, high performance microcomputer system.

The price/performance ratio of the CompuStar has rarely been equalled in this industry. By employing innovative design techniques, the system is not only able to offer a competitive price advantage, but boasts many features found only in systems costing three to five times as much. The twin Z80A microprocessors in each CompuStar VPU insure extremely fast program execution even when faced with the most difficult programming tasks. In addition, each unit must pass a grueling 48 hour burn-in before it is shipped to the Customer. By combining advanced microprocessor technology with in-house manufacturing capability and stringent quality control requirements, your CompuStar System should provide unparalleled reliability in any application into which it is passed.

3.1.1 THE COMPUSTAR VPU AND DSS

The CompuStar Multi-User System consists of a network of video display terminals (called video processing units) which employ their own internal microprocessor and dynamic RAM. The terminals are tied together in a network fashion to "share" the resources of a single Winchester or other hard disk device. In this manner, the CompuStar allows true multi-user capability by permitting the sharing of a common data base while at the same time allowing individual users the capability to maintain restricted data bases.

A CompuStar system can be configured using any one of three disk storage devices (called Disk Storage Systems--DSS), all of which are manufactured by Intertec. A DSS consists of a hard disk device, complete with power supply and Intertec's special disk controller and multiplex circuitry to tie users' stations into a common disk. The three DSS models available include a table top ten megabyte Winchester model and Control Data Corporation's 32 or 96 megabyte cartridge module drive models. The CDC drives feature a 16 megabyte removable, top loading platter and either 16 or 80 megabytes fixed disk storage.

A series of 4 types of video processing units (VPU's) can be connected into a disk storage system. The VPU's connect by an 8 bit parallel interface, thus allowing a data transfer rate of 1.6 million WPS between the disk storage system and the terminals. In this manner, the distance over which signals can be transferred (from disk system to terminal station) is significant...up to one mile in total cable length. And since premanufactured cable assemblies (with 37 pin 'D'-type connectors on each end) are offered in a variety of lengths, installation of a CompuStar network is a real snap!
The video processing units are connected in a "daisy chain" fashion; i.e., the first terminal is connected directly into the CompuStar disk storage system, the second terminal is connected into the first, the third into the second, and so on. A total of up to 255 video processing units can be connected into a single network. Each VPU is assigned a variable address via an 8 position dipswitch mounted internally. This allows each terminal access to the common and/or restricted data base on the disk storage system. Plus, each terminal has twin RS-232 Serial Ports for connecting auxiliary printer and/or modem devices.

From the standpoint of human engineering, each CompuStar VPU has been designed to minimize operator fatigue through the use of a typewriter-oriented keyboard and a remarkably clear display. Each video processing unit displays a total of 1,920 characters arranged in 24 lines with 80 characters per line. The video display is unusually crisp and sharp due to Intertec's own specially designed video driver circuitry. And, the high quality, non-glare etched CRT featured on every VPU assures ease of viewing and uniformity of brightness throughout the entire screen.

The CompuStar's unique internal design assures users of exceptional performance for just a fraction of what they would expect to pay for such "big system" capabilities. The CompuStar VPU utilizes a single board "microprocessor" design which combines all processor, RAM, ROM, disk controller, and communications electronics on the same printed circuit board. This type of design engineering enables the CompuStar to deliver superior, competitive performance.

Standard features of the CompuStar Model 20 VPU includes: two double-density, single-sided mini-floppies with a total of over 350,000 bytes formatted disk storage, 64K of dynamic RAM memory, a universally recognized CP/M* Disk Operating System featuring its own text editor, an assembler for assembly language programming, a program debugger and a disk formatter. Also standard are dual universal RS-232 communications ports for serial data transmission between a host computer network via modem or an auxiliary serial printer. A number of transmission rates up to 9600 baud are available and selectable under program control.

The Model 30 VPU incorporates these same features, but boasts nearly 750,000 bytes of disk storage units, twin double-density, double-sided drive mechanism. The Model 40 employs dual double-track drive assemblies to provide the user with nearly 1-1/2 million bytes of local, off-line storage capability.
For reliability, each CompuStar VPU has been designed around modules packaged in an aesthetically pleasing desk-top unit. These major components are: the Keyboard/CPU module, the power supply module, the CRT assembly, the chaining adaptor and the disk drives themselves. Failure of any component within the terminal may be corrected by simply replacing only the defective module. Individual modules are fastened to the chassis in such a manner to facilitate easy removal and reinstallation. Terminal down-time can be greatly minimized by simply "swapping-out" one of the modules and having component level repair performed at one of Intertec's Service Centers. Spare modules may be purchased from an Intertec marketing office to support those customers who maintain their own "in-house" repair facilities.

CompuStar VPU cover assembly is exclusively manufactured "in-house" by Intertec. A high-impact, structural-foam material is covered with a special "felt-like" paint to enhance the overall appearance. Since the cover assembly is injected-molded, there is virtually no possibility of cracks and disfigurations in the cover itself. And, by manufacturing and finishing the cover assembly in-house, Intertec is able to specify only high quality material on the external and internal cover components of your CompuStar to insure unparalleled durability over the years to come.
3.1.2 SOFTWARE AND OPTIONS

A wide variety of programming tools and options are either planned or available for the CompuStar System. Standard software development tools available from Intertec include Basic, Fortran and Cobol programming languages. A wide variety of applications packages (general ledger, accounts receivable, payroll, inventory, word processing, etc.) are available to operate under the CompuStar CP/M Disk Operating System from leading software vendors in the industry.
3.2 THEORY OF OPERATION

The CompuStar contains two Z80 microprocessors. (Reference Figure 3.1) uP1 is the master processor. It communicates with the 64K RAM and the I/O devices (serial port, keyboard encoder, interface controller, and CRT controller). Aside from these devices, it can also access the 2K ROM and DATA BUFFER RAM in the FLOPPY DISK CONTROLLER. uP2 is slaved to uP1 and can only access the 2K ROM, DATA BUFFER, and the DISK INTERFACE. This processor is used exclusively for disk control.

The 64 kilobyte main memory consists of thirty-two 16K x 1 bit dynamic RAMS. These are divided in four banks (0-3) with each bank containing 16 kilobytes of storage. The RAS-CAS timing sequence necessary for memory access is created by the memory timing generator.

There are two devices that can access memory--uP1 and the CRT Controller. uP1 can read and write to memory while the CRT Controller can only perform the read function. Because each device runs at a different speed, two clock frequencies are required for memory timing. The speed is determined by the selection of the control input to the timing generator. The microprocessor functions require the faster clock.

The CRT-VIDEO CONTROLLER contains three main devices—the CRT Controller which generates all the timing signals for data display; the video generator which produces the character font; and the octal 80-bit shift register which stores one row of video data. (80 characters)

The CRT Controller generates all the timing necessary to display 24 rows of characters with 80 characters per row. Thus, the screen can display a total of 1920 characters. These characters are stored in the CRT refresh buffer which is the upper 2048 bytes (2K) of RAM.

Because the CRT buffer is not a separate buffer and the processor must also use the same bus to access memory, this bus must be timeshared between the two. This is accomplished by the CRT controller performing a direct memory access (DMA) cycle which is done at the beginning of each scan row. Each scan row is divided into ten scan lines, therefore during the first scan line time, the controller takes control of the processor bus by generating a bus request. After acquiring the bus, it reads 80 characters from the CRT buffer and loads them into the 80 x 8 shift register. This data is then recirculated in the buffer for the next nine scan lines to produce one row of video characters. Therefore, there are twenty-four DMA cycles performed per vertical frame.

There are also twenty-five interrupts generated--one for each row scan and one extra during vertical blanking. During the first
twenty-four, the processor sets or resets the video blanking depending on whether that row is displayed or not. During the vertical blanking interrupt, the address registers in the CRT controller are initialized to the correct top-of-page address and the cursor register is also updated.

The Interface Controller is basically three 8 bit I/O ports (8255). Through this device, the processor can obtain status bits from other devices and react to the status by setting/resetting individual bits in the 8255.

The Keyboard Encoder scans the keyboard for a key depression, determines its position, and generates the correct ASCII code for the key. The processor is flagged by the 'Data Ready' signal via the Interface Controller. The character is then input by the processor.

The Chaining Adaptor Module provides a high speed interface between each CompuStar VPU and the Disk Storage System (DSS). Its function is to provide a point of access bus for each VPU in the CompuStar Computer Network.

The CompuStar bus is a parallel bi-directional bus with 12 differently driven, TTL signals. The information communicated on the bus includes data and control signals. The bus has been constructed to allow approximately 4000 feet of cable to be used in a single CompuStar System (up to 255 Video Processing Systems).

The remaining I/O device is the RS-232-C Serial Interface Port. Presently, it operates only in the asynchronous mode and adheres to a simplified standard protocol. The baud rate is set to 1200 baud by the operating system. (Refer to the Technical Bulletin enclosed at the end of this manual.)

As previously mentioned, uP1 has the capability of communicating with the RAM and ROM in the FLOPPY DISK CONTROLLER. It does this to obtain the bootloader from ROM on power-up and system reset and also when transferring disk parameters and data to/from the Data Buffer RAM. Because the amount of main memory used is the maximum that the processor addressing can support, different 16K banks of main memory must be switched off line when communicating with the disk RAM or ROM. In these cases, Bank 0 (0000H-3FFH) is switched out when communicating with the ROM, and Bank 2 (8000H-BFFFFH) when communicating with the RAM.

The DISK CONTROLLER performs all disk related I/O functions upon command from the main processor. These commands are:

- Restore to track 0
- Read sector
- Write sector
- Write sector with deleted data mark
- Format
The parameters associated with drive, side, track and sector numbers are loaded, a status word is set at specified location in the disk RAM. When uP2 receives this status, it sets the 'disk busy' status bit and performs the indicated function. Upon completion, it resets the 'busy' bit thus allowing the main processor (uP1) to retrieve data and status from the RAM.

3.3.1  COMPUSTAR VPU INTERNAL CONSTRUCTION

Perhaps the most remarkable feature of the CompuStar VPU is its modular construction using only four major subassemblies which are clearly defined in their respective functions so as to facilitate ease of construction and repair. These four subassemblies are shown in figure 1 and described below.

- Disk Drive Module (not on Model 10)
- CRT Display Module
- Chaining Adaptor
- Main Power Supply I/O Module
- Keyboard/CPU Module
3.3.2 KEYBOARD/CPU MODULE

The control section of the CompuStar VPU is based upon the widely acclaimed Z80A microprocessor. The result is far fewer components and the ability to perform a number of functions not possible with any other approach. The Keyboard/CPU module (figure two) contains the twin Z80 microprocessors. One Z80A (the host processor) performs all processor and screen related functions while the second Z80A can be "downloaded" to execute disk I/O handling routines. The result is extremely fast execution time for even the most sophisticated programs.

In addition to containing the VPU's microprocessor circuitry, the Keyboard/CPU module contains 64K of dynamic RAM (see figure 3). Also found on this module is: the character and keyboard encoder circuitry, the "bootstrap" ROM, the disk controller and all communications electronics. Power is supplied to and signals are transferred from this module via a single 22 pin ribbon cable connected to the main power supply module. Connection of this module to the disk drive subassemblies is via a separate ribbon cable. Figure 4 shows the connectors on the Keyboard/CPU module which are used for interconnecting this module with the disk drive subassemblies, the main power supply and the chaining adaptors.

Figure 2 - CompuStar Keyboard/CPU Module

Figure 3 - Dynamic RAM Section
Every CompuStar is equipped with 64 K dynamic RAM

Figure 4 - Keyboard/CPU Module Connectors
The 40 pin connector on the top edge of the card is for connection to the CompuStar chaining adaptor. The 40 pin connector on the right edge routes signals to and from the disk drive assembly.
3.3.3 CRT DISPLAY MODULE

The CRT Display Module consists of a 12-inch, high resolution, cathode ray tube mounted in a rigid aluminum chassis. The faceplate of the CRT is etched in order to reduce glare on the surface of the screen and provide uniform brightness throughout the entire screen area. The CRT display presentation is arranged in 24 lines of 80 characters per line.

The CRT video driver circuitry is mounted in the base of the CRT chassis to facilitate ease of removal and subsequent repair. In this manner, either the CRT itself or the video circuitry can be easily exchanged without disrupting any of the other major modules within the terminal (see Figure 5).

Figure 5 - CRT Display Module
This module is easily removed for service or replacement. A single edge connector is provided for connection to the VPU's Power Supply Mode.
3.3.4 POWER SUPPLY MODE

The CompuStar power supply is a "solid-state, switching" design and employs switching voltage regulators to provide many years of trouble-free service. This design reduces heat dissipation and allows for efficient cooling of the entire terminal with a specially designed whisper fan to reduce environment noise. The entire power supply can be easily removed by unscrewing the three screws holding it into the base of the terminal. Included on the power supply module are the power off/on switch, the user brightness control, the main and auxiliary RS232 serial ports and the chaining adaptor circuitry (and connectors) which allow multi-users to be connected into a single Disk Storage System. By combining the power supply section and external serial communications connections on the same module, the total module count is able to be kept to a minimum thus greatly facilitating ease of field service repair while at the same time minimizing the number of modules required to be stocked to effect competent field repair (refer to figure six).

Figure 6 - Power Supply Module with Chaining Adapter card installed
3.3.5 DISK DRIVE MODULES FOR MODELS 20, 30 AND 40 VPU's ONLY

Figures 7 and 8 illustrate the left and right views of the specially designed double-density disk drive subassembly. The Model 20, 30 and 40 VPU's contain two of these type drives which are mounted conveniently just to the right of the CRT display module on a rugged aluminum mounting bracket which supports the drives so that they are flush mounted with the front "bezel" of the unit. Power to these drives is derived from the Power Supply Module located just behind the drive assemblies themselves. Data to and from these drives is routed via a single 34 pin ribbon cable connecting the drives to the Keyboard/CPU module.

1. INTRODUCTION.

CP/M is a monitor control program for microcomputer system development which uses IBM-compatible flexible disks for backup storage. Using a computer mainframe based upon Intel's 8080 microcomputer, CP/M provides a general environment for program construction, storage, and editing, along with assembly and program check-out facilities. An important feature of CP/M is that it can be easily altered to execute with any computer configuration which uses an Intel 8080 (or Zilog Z-80) Central Processing Unit, and has at least 16K bytes of main memory with up to four IBM-compatible diskette drives. A detailed discussion of the modifications required for any particular hardware environment is given in the Digital Research document entitled "CP/M System Alteration Guide." Although the standard Digital Research version operates on a single-density Intel MDS 800, several different hardware manufacturers support their own input-output drivers for CP/M.

The CP/M monitor provides rapid access to programs through a comprehensive file management package. The file subsystem supports a named file structure, allowing dynamic allocation of file space as well as sequential and random file access. Using this file system, a large number of distinct programs can be stored in both source and machine executable form.

CP/M also supports a powerful context editor, Intel-compatible assembler, and debugger subsystems. Optional software includes a powerful Intel-compatible macro assembler, symbolic debugger, along with various high-level languages. When coupled with CP/M's Console Command Processor, the resulting facilities equal or excel similar large computer facilities.

CP/M is logically divided into several distinct parts:

- BIOS Basic I/O System (hardware dependent)
- BDOS Basic Disk Operating System
- CCP Console Command Processor
- TPA Transient Program Area

The BIOS provides the primitive operations necessary to access the diskette drives and to interface standard peripherals (teletype, CRT, Paper Tape Reader/Punch, and user-defined peripherals), and can be tailored by the user for any particular hardware environment by "patching" this portion of CP/M. The BDOS provides disk management by controlling one or more disk drives containing independent file directories. The BDOS implements disk allocation strategies which provide fully dynamic file construction while minimizing head movement across the disk during access. Any particular file may contain any number of records, not exceeding the size of any single disk. In a standard CP/M system, each disk can contain up to 64 distinct files. The
BIX-S has entry points which include the following primitive operations which can be programmatically accessed:

- **SEARCH**: Look for a particular disk file by name.
- **OPEN**: Open a file for further operations.
- **CLOSE**: Close a file after processing.
- **RENAME**: Change the name of a particular file.
- **READ**: Read a record from a particular file.
- **WRITE**: Write a record onto the disk.
- **SELECT**: Select a particular disk drive for further operations.

The CCP provides symbolic interface between the user's console and the remainder of the CP/M system. The CCP reads the console device and processes commands which include listing the file directory, printing the contents of files, and controlling the operation of transient programs, such as assemblers, editors, and debuggers. The standard commands which are available in the CCP are listed in a following section.

The last segment of CP/M is the area called the Transient Program Area (TPA). The TPA holds programs which are loaded from the disk under command of the CCP. During program editing, for example, the TPA holds the CP/M text editor machine code and data areas. Similarly, programs created under CP/M can be checked out by loading and executing these programs in the TPA.

It should be mentioned that any or all of the CP/M component subsystems can be "overlayed" by an executing program. That is, once a user's program is loaded into the TPA, the CCP, BDOS, and BIOS areas can be used as the program's data area. A "bootstrap" loader is programmatically accessible whenever the BIOS portion is not overlayed; thus, the user program need only branch to the bootstrap loader at the end of execution, and the complete CP/M monitor is reloaded from disk.

It should be reiterated that the CP/M operating system is partitioned into distinct modules, including the BIOS portion which defines the hardware environment in which CP/M is executing. Thus, the standard system can be easily modified to any non-standard environment by changing the peripheral drivers to handle the custom system.
2. FUNCTIONAL DESCRIPTION OF CP/M.

The user interacts with CP/M primarily through the CCP, which reads and interprets commands entered through the console. In general, the CCP addresses one of several disks which are online (the standard system addresses up to four different disk drives). These disk drives are labelled A, B, C, and D. A disk is "logged in" if the CCP is currently addressing the disk. In order to clearly indicate which disk is the currently logged disk, the CCP always prompts the operator with the disk name followed by the symbol ">" indicating that the CCP is ready for another command. Upon initial start up, the CP/M system is brought in from disk A, and the CCP displays the message

\[ xxK \text{ CP/M VER m.m} \]

where \( xx \) is the memory size (in kilobytes) which this CP/M system manages, and \( m.m \) is the CP/M version number. All CP/M systems are initially set to operate in a 16K memory space, but can be easily reconfigured to fit any memory size on the host system (see the MOVCPM transient command). Following system signon, CP/M automatically logs in disk A, prompts the user with the symbol "A>" (indicating that CP/M is currently addressing disk "A"), and waits for a command. The commands are implemented at two levels: built-in commands and transient commands.

2.1. GENERAL COMMAND STRUCTURE.

Built-in commands are a part of the CCP program itself, while transient commands are loaded into the TPA from disk and executed. The built-in commands are

- **ERA**: Erase specified files.
- **DIR**: List file names in the directory.
- **REN**: Rename the specified file.
- **SAVE**: Save memory contents in a file.
- **TYPE**: Type the contents of a file on the logged disk.

Nearly all of the commands reference a particular file or group of files. The form of a file reference is specified below.

2.2. FILE REFERENCES.

A file reference identifies a particular file or group of files on a particular disk attached to CP/M. These file references can be either "unambiguous" (ufn) or "ambiguous" (afn). An unambiguous file reference uniquely identifies a single file, while an ambiguous file reference may be
satisfied by a number of different files.

File references consist of two parts: the primary name and the secondary name. Although the secondary name is optional, it usually is generic; that is, the secondary name "ASM," for example, is used to denote that the file is an assembly language source file, while the primary name distinguishes each particular source file. The two names are separated by a "." as shown below:

pppppppp.sss

where pppppppp represents the primary name of eight characters or less, and sss is the secondary name of no more than three characters. As mentioned above, the name

pppppppp

is also allowed and is equivalent to a secondary name consisting of three blanks. The characters used in specifying an unambiguous file reference cannot contain any of the special characters

< > . , ; : = ? * [ ]

while all alphanumerics and remaining special characters are allowed.

An ambiguous file reference is used for directory search and pattern matching. The form of an ambiguous file reference is similar to an unambiguous reference, except the symbol "?" may be interspersed throughout the primary and secondary names. In various commands throughout CP/M, the "?" symbol matches any character of a file name in the "?" position. Thus, the ambiguous reference

x?z.com

is satisfied by the unambiguous file names

xyz.com

and

x3z.cam

Note that the ambiguous reference

**

is equivalent to the ambiguous file reference

??????????.

while
and 

`pppppppp.*`

`.sss`

are abbreviations for

`pppppppp.???

and

`????????.sss`

respectively. As an example,

`DIR *.*`

is interpreted by the CCP as a command to list the names of all disk files in the directory, while

`DIR X,Y`

searches only for a file by the name X.Y Similarly, the command

`DIR X?Y,C?M`

causes a search for all (unambiguous) file names on the disk which satisfy this ambiguous reference.

The following file names are valid unambiguous file references:

<table>
<thead>
<tr>
<th>File Name</th>
<th>Drive Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>X</td>
<td></td>
</tr>
<tr>
<td>XYZ</td>
<td></td>
</tr>
<tr>
<td>GAMMA</td>
<td></td>
</tr>
<tr>
<td>X.Y</td>
<td></td>
</tr>
<tr>
<td>XYZ.COM</td>
<td></td>
</tr>
<tr>
<td>GAMMA.l</td>
<td></td>
</tr>
</tbody>
</table>

As an added convenience, the programmer can generally specify the disk drive name along with the file name. In this case, the drive name is given as a letter A through Z followed by a colon (:). The specified drive is then "logged in" before the file operation occurs. Thus, the following are valid file names with disk name prefixes:

<table>
<thead>
<tr>
<th>Drive Name</th>
<th>File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>A:X,Y</td>
<td>B:XYZ</td>
</tr>
<tr>
<td>C:GAMMA</td>
<td></td>
</tr>
<tr>
<td>Z:XYZ.COM</td>
<td>B:X,A?M</td>
</tr>
<tr>
<td>C:*,.ASM</td>
<td></td>
</tr>
</tbody>
</table>

It should also be noted that all alphabetic lower case letters in file and drive names are always translated to upper case when they are processed by the CCP.
3. SWITCHING DISKS.

The operator can switch the currently logged disk by typing the disk drive name (A, B, C, or D) followed by a colon (:) when the CCP is waiting for console input. Thus, the sequence of prompts and commands shown below might occur after the CP/M system is loaded from disk A:

```
16K CP/M VER 1.4
A>DIR
SAMPLE ASM
SAMPLE PRN
A>B:
B>DIR *.ASM
DUMP ASM
FILES ASM
B>A:
```

List all files on disk A.
Switch to disk B.
List all "ASM" files on B.
Switch back to A.
4. THE FORM OF BUILT-IN COMMANDS.

The file and device reference forms described above can now be used to fully specify the structure of the built-in commands. In the description below, assume the following abbreviations:

- **ufn** - unambiguous file reference
- **afn** - ambiguous file reference
- **cr** - carriage return

Further, recall that the CCP always translates lower case characters to upper case characters internally. Thus, lower case alphabets are treated as if they are upper case in command names and file references.

4.1 ERA afn cr

The ERA (erase) command removes files from the currently logged-in disk (i.e., the disk name currently prompted by CP/M preceding the ">"). The files which are erased are those which satisfy the ambiguous file reference afn. The following examples illustrate the use of ERA:

- **ERA X.Y**
  The file named X.Y on the currently logged disk is removed from the disk directory, and the space is returned.

- **ERA X.***
  All files with primary name X are removed from the current disk.

- **ERA *.ASM**
  All files with secondary name ASM are removed from the current disk.

- **ERA X?Y.C?M**
  All files on the current disk which satisfy the ambiguous reference X?Y.C?M are deleted.

- **ERA **
  Erase all files on the current disk (in this case the CCP prompts the console with the message "ALL FILES (Y/N)?" which requires a Y response before files are actually removed).

- **ERA B:* .PRN**
  All files on drive B which satisfy the ambiguous reference ?????????.PRN are deleted, independently of the currently logged disk.
4.2. DIR afn cr

The DIR (directory) command causes the names of all files which satisfy the ambiguous file name afn to be listed at the console device. As a special case, the command

DIR

lists the files on the currently logged disk (the command "DIR" is equivalent to the command "DIR *.*"). Valid DIR commands are shown below.

DIR X,Y
DIR X?Z,C?M
DIR ??,Y

Similar to other CCP commands, the afn can be preceded by a drive name. The following DIR commands cause the selected drive to be addressed before the directory search takes place.

DIR B:
DIR B:X,Y
DIR B:*A?M

If no files can be found on the selected diskette which satisfy the directory request, then the message "NOT FOUND" is typed at the console.

4.3. REN uf1=ufn2 cr

The REN (rename) command allows the user to change the names of files on disk. The file satisfying uf2 is changed to uf1. The currently logged disk is assumed to contain the file to rename (ufnl). The CCP also allows the user to type a left-directed arrow instead of the equal sign, if the user's console supports this graphic character. Examples of the REN command are

REN X,Y=Q.R The file Q.R is changed to X.Y.
REN XYZ.COM=XYZ.XXX The file XYZ.XXX is changed to XYZ.COM.

The operator can precede either uf1 or uf2 (or both) by an optional drive address. Given that uf1 is preceded by a drive name, then uf2 is assumed to exist on the same drive as uf1. Similarly, if uf2 is preceded by a drive name, then uf1 is assumed to reside on that drive as well. If both uf1 and uf2 are preceded by drive names, then the same drive must be
specified in both cases. The following REN commands illustrate this format.

- REN A:X.ASM = Y.ASM  The file Y.ASM is changed to X.ASM on drive A.
- REN B:ZAP.BAS=ZOT.BAS  The file ZOT.BAS is changed to ZAP.BAS on drive B.
- REN B:A.ASM = B:A.BAK  The file A.BAK is renamed to A.ASM on drive B.

If the file ufn1 is already present, the REN command will respond with the error "FILE EXISTS" and not perform the change. If ufn2 does not exist on the specified diskette, then the message "NOT FOUND" is printed at the console.

4.4. SAVE n ufn cr

The SAVE command places n pages (256-byte blocks) onto disk from the TPA and names this file ufn. In the CP/M distribution system, the TPA starts at 100H (hexadecimal), which is the second page of memory. Thus, if the user's program occupies the area from 100H through 2FFH, the SAVE command must specify 2 pages of memory. The machine code file can be subsequently loaded and executed. Examples are:

- SAVE 3 X.COM  Copies 100H through 3FFH to X.COM.
- SAVE 40 Q  Copies 100H through 28FFH to Q (note that 28 is the page count in 28FFH, and that 28H = 2*16+8 = 40 decimal).
- SAVE 4 X.Y  Copies 100H through 4FFH to X.Y.

The SAVE command can also specify a disk drive in the afn portion of the command, as shown below.

- SAVE 10 B:ZOT.COM  Copies 10 pages (100H through 0AFFH) to the file ZOT.COM on drive B.

4.5. TYPE ufn cr

The TYPE command displays the contents of the ASCII source file ufn on the currently logged disk at the console device. Valid TYPE commands are

- TYPE X.Y
TYPE X.PLM

TYPE XXX

The TYPE command expands tabs (ctl-I characters), assuming tab positions are set at every eighth column. The ufn can also reference a drive name as shown below.

TYPE B:X.PRN  The file X.PRN from drive B is displayed.
5. LINE EDITING AND OUTPUT CONTROL.

The CCP allows certain line editing functions while typing command lines.

- **rubout**: Delete and echo the last character typed at the console.
- **ctl-U**: Delete the entire line typed at the console.
- **ctl-X**: (Same as ctl-U)
- **ctl-R**: Retype current command line: types a "clean line" following character deletion with rubouts.
- **ctl-E**: Physical end of line: carriage is returned, but line is not sent until the carriage return key is depressed.
- **ctl-C**: CP/M system reboot (warm start)
- **ctl-Z**: End input from the console (used in PIP and ED).

The control functions ctl-P and ctl-S affect console output as shown below.

- **ctl-P**: Copy all subsequent console output to the currently assigned list device (see the STAT command). Output is sent to both the list device and the console device until the next ctl-P is typed.
- **ctl-S**: Stop the console output temporarily. Program execution and output continue when the next character is typed at the console (e.g., another ctl-S). This feature is used to stop output on high speed consoles, such as CRT's, in order to view a segment of output before continuing.

Note that the ctl-key sequences shown above are obtained by depressing the control and letter keys simultaneously. Further, CCP command lines can generally be up to 255 characters in length; they are not acted upon until the carriage return key is typed.
6. **TRANSIENT COMMANDS.**

Transient commands are loaded from the currently logged disk and executed in the TPA. The transient commands defined for execution under the CCP are shown below. Additional functions can easily be defined by the user (see the LOAD command definition).

- **STAT**
  
  List the number of bytes of storage remaining on the currently logged disk, provide statistical information about particular files, and display or alter device assignment.

- **ASM**
  
  Load the CP/M assembler and assemble the specified program from disk.

- **LOAD**
  
  Load the file in Intel "hex" machine code format and produce a file in machine executable form which can be loaded into the TPA (this loaded program becomes a new command under the CCP).

- **DDT**
  
  Load the CP/M debugger into TPA and start execution.

- **PIP**
  
  Load the Peripheral Interchange Program for subsequent disk file and peripheral transfer operations.

- **ED**
  
  Load and execute the CP/M text editor program.

- **SYSGEN**
  
  Create a new CP/M system diskette.

- **SUBMIT**
  
  Submit a file of commands for batch processing.

- **DUMP**
  
  Dump the contents of a file in hex.

- **MOVCPM**
  
  Regenerate the CP/M system for a particular memory size.

Transient commands are specified in the same manner as built-in commands, and additional commands can be easily defined by the user. As an added convenience, the transient command can be preceded by a drive name, which causes the transient to be loaded from the specified drive into the TPA for execution. Thus, the command

```
B:STAT
```

causes CP/M to temporarily "log in" drive B for the source of the STAT transient, and then return to the original logged disk for subsequent processing.
The basic transient commands are listed in detail below.

6.1. **STAT cr**

The **STAT** command provides general statistical information about file storage and device assignment. It is initiated by typing one of the following forms:

```
STAT cr
STAT "command line" cr
```

Special forms of the "command line" allow the current device assignment to be examined and altered as well. The various command lines which can be specified are shown below, with an explanation of each form shown to the right.

```
STAT cr

If the user types an empty command line, the **STAT** transient calculates the storage remaining on all active drives, and prints a message

x: R/W, SPACE: nnnK
or
x: R/O, SPACE: nnnK

for each active drive x, where R/W indicates the drive may be read or written, and R/O indicates the drive is read only (a drive becomes R/O by explicitly setting it to read only, as shown below, or by inadvertently changing diskettes without performing a warm start). The space remaining on the diskette in drive x is given in kilobytes by nnn.

STAT x: cr

If a drive name is given, then the drive is selected before the storage is computed. Thus, the command "**STAT B:**" could be issued while logged into drive A, resulting in the message

BYTES REMAINING ON B: nnnK

STAT afn cr

The command line can also specify a set of files to be scanned by **STAT**. The files which satisfy afn are listed in alphabetical order, with storage requirements for each file under the heading

```
RECS BYTS EX D:FILENAME.TYP
rrrr bbbK ee d:ppppppppp.sss
```

where rrrr is the number of 128-byte records
allocated to the file, bbb is the number of kilobytes allocated to the file (\(\text{bbb} = \text{rrrr} \times 128/1024\)), ee is the number of 16K extensions (\(\text{ee} = \text{bbb}/16\)), d is the drive name containing the file (A...Z), pppppppp is the (up to) eight-character primary file name, and sss is the (up to) three-character secondary name. After listing the individual files, the storage usage is summarized.

**STAT x:afn cr**

As a convenience, the drive name can be given ahead of the afn. In this case, the specified drive is first selected, and the form "STAT afn" is executed.

**STAT x:=R/O cr**

This form sets the drive given by x to read-only, which remains in effect until the next warm or cold start takes place. When a disk is read-only, the message

```
BDOS ERR ON x: READ ONLY
```

will appear if there is an attempt to write to the read-only disk x. CP/M waits until a key is depressed before performing an automatic warm start (at which time the disk becomes R/W).

The STAT command also allows control over the physical to logical device assignment (see the IOBYTE function described in the manuals "CP/M Interface Guide" and "CP/M System Alteration Guide"). In general, there are four logical peripheral devices which are, at any particular instant, each assigned to one of several physical peripheral devices. The four logical devices are named:

- **CON**: The system console device (used by CCP for communication with the operator)
- **RDR**: The paper tape reader device
- **PUN**: The paper tape punch device
- **LST**: The output list device

The actual devices attached to any particular computer system are driven by subroutines in the BIOS portion of CP/M. Thus, the logical RDR: device, for example, could actually be a high speed reader, Teletype reader, or cassette tape. In order to allow some flexibility in device naming and assignment, several physical devices are defined, as shown below:
TTY:  Teletype device (slow speed console)
CRT:  Cathode ray tube device (high speed console)
BAT:  Batch processing (console is current RDR:, output goes to current LST: device)
UCl:  User-defined console
PTR:  Paper tape reader (high speed reader)
URL:  User-defined reader #1
UR2:  User-defined reader #2
PTP:  Paper tape punch (high speed punch)
UP1:  User-defined punch #1
UP2:  User-defined punch #2
LPT:  Line printer
ULL:  User-defined list device #1

It must be emphasized that the physical device names may or may not actually correspond to devices which the names imply. That is, the PTP: device may be implemented as a cassette write operation, if the user wishes. The exact correspondence and driving subroutine is defined in the BIOS portion of CP/M. In the standard distribution version of CP/M, these devices correspond to their names on the MDS 800 development system.

The possible logical to physical device assignments can be displayed by typing

```
STAT VAL: cr
```

The STAT prints the possible values which can be taken on for each logical device:

```
CON. = TTY:  CRT:  BAT:  UCl:  
RDR: = TTY:  PTR:  URL:  UR2:  
PUN: = TTY:  PTP:  UP1:  UP2:  
LST: = TTY:  CRT:  LPT:  ULL:  
```

In each case, the logical device shown to the left can take any of the four physical assignments shown to the right on each line. The current logical to physical mapping is displayed by typing the command

```
STAT DEV: cr
```
which produces a listing of each logical device to the left, and the current corresponding physical device to the right. For example, the list might appear as follows:

```
CON: = CRT:
FDR: = URL:
PUN: = PTP:
LST: = TTY:
```

The current logical to physical device assignment can be changed by typing a STAT command of the form

```
STAT ldl = pdl, ld2 = pd2 , ..., ldn = pdn cr
```

where ldl through ldn are logical device names, and pdl through pdn are compatible physical device names (i.e., ldi and pdi appear on the same line in the "VAL:" command shown above). The following are valid STAT commands which change the current logical to physical device assignments:

```
STAT CON:=CRT: cr
STAT PUN: = TTY:,LST:=LPT:, RDR:=TTY: cr
```

6.2. ASM ufn cr

The ASM command loads and executes the CP/M 8080 assembler. The ufn specifies a source file containing assembly language statements where the secondary name is assumed to be ASM, and thus is not specified. The following ASM commands are valid:

```
ASM X
ASM GAMMA
```

The two-pass assembler is automatically executed. If assembly errors occur during the second pass, the errors are printed at the console.

The assembler produces a file

```
x.PRN
```

where x is the primary name specified in the ASM command. The PRN file contains a listing of the source program (with imbedded tab characters if present in the source program), along with the machine code generated for each statement and diagnostic error messages, if any. The PRN file can be listed
at the console using the TYPE command, or sent to a peripheral device using PIP (see the PIP command structure below). Note also that the PRN file contains the original source program, augmented by miscellaneous assembly information in the leftmost 16 columns (program addresses and hexadecimal machine code, for example). Thus, the PRN file can serve as a backup for the original source file: if the source file is accidently removed or destroyed, the PRN file can be edited (see the ED operator's guide) by removing the leftmost 16 characters of each line (this can be done by issuing a single editor "macro" command). The resulting file is identical to the original source file and can be renamed (REN) from PRN to ASM for subsequent editing and assembly. The file

x.HEX

is also produced which contains 8080 machine language in Intel "hex" format suitable for subsequent loading and execution (see the LOAD command). For complete details of CP/M's assembly language program, see the "CP/M Assembler Language (ASM) User's Guide."

Similar to other transient commands, the source file for assembly can be taken from an alternate disk by prefixing the assembly language file name by a disk drive name. Thus, the command

ASM B:ALPHA cr

loads the assembler from the currently logged drive and operates upon the source program ALPHA.ASM on drive B. The HEX and PRN files are also placed on drive B in this case.

6.3. LOAD ufn cr

The LOAD command reads the file ufn, which is assumed to contain "hex" format machine code, and produces a memory image file which can be subsequently executed. The file name ufn is assumed to be of the form

x.HEX

and thus only the name x need be specified in the command. The LOAD command creates a file named

x.COM

which marks it as containing machine executable code. The file is actually loaded into memory and executed when the user types the file name x immediately after the prompting character ">" printed by the CCP.

In general, the CCP reads the name x following the prompting character and looks for a built-in function name. If no function name is found, the CCP searches the system disk directory for a file by the name

17
If found, the machine code is loaded into the TPA, and the program executes. Thus, the user need only LOAD a hex file once; it can be subsequently executed any number of times by simply typing the primary name. In this way, the user can "invent" new commands in the CCP. (Initialized disks contain the transient commands as COM files, which can be deleted at the user's option.) The operation can take place on an alternate drive if the file name is prefixed by a drive name. Thus,

LOAD B:BETA

brings the LOAD program into the TPA from the currently logged disk and operates upon drive B after execution begins.

It must be noted that the BETA.HEX file must contain valid Intel format hexadecimal machine code records (as produced by the ASM program, for example) which begin at 100H, the beginning of the TPA. Further, the addresses in the hex records must be in ascending order; gaps in unfilled memory regions are filled with zeroes by the LOAD command as the hex records are read. Thus, LOAD must be used only for creating CP/M standard "COM" files which operate in the TPA. Programs which occupy regions of memory other than the TPA can be loaded under DDT.

6.4. PIP cr

PIP is the CP/M Peripheral Interchange Program which implements the basic media conversion operations necessary to load, print, punch, copy, and combine disk files. The PIP program is initiated by typing one of the following forms

(1) PIP cr
(2) PIP "command line" cr

In both cases, PIP is loaded into the TPA and executed. In case (1), PIP reads command lines directly from the console, prompted with the "**" character, until an empty command line is typed (i.e., a single carriage return is issued by the operator). Each successive command line causes some media conversion to take place according to the rules shown below. Form (2) of the PIP command is equivalent to the first, except that the single command line given with the PIP command is automatically executed, and PIP terminates immediately with no further prompting of the console for input command lines. The form of each command line is

destination = source#1, source#2, ..., source#n cr

where "destination" is the file or peripheral device to receive the data, and
"source#1, ..., source#n" represents a series of one or more files or devices which are copied from left to right to the destination.

When multiple files are given in the command line (i.e., n > 1), the individual files are assumed to contain ASCII characters, with an assumed CP/M end-of-file character (ctl-Z) at the end of each file (see the O parameter to override this assumption). The equal symbol (=) can be replaced by a left-oriented arrow, if your console supports this ASCII character, to improve readability. Lower case ASCII alphabics are internally translated to upper case to be consistent with CP/M file and device name conventions. Finally, the total command line length cannot exceed 255 characters (ctl-E can be used to force a physical carriage return for lines which exceed the console width).

The destination and source elements can be unambiguous references to CP/M source files, with or without a preceding disk drive name. That is, any file can be referenced with a preceding drive name (A:, B:, C:, or D:) which defines the particular drive where the file may be obtained or stored. When the drive name is not included, the currently logged disk is assumed. Further, the destination file can also appear as one or more of the source files, in which case the source file is not altered until the entire concatenation is complete. If the destination file already exists, it is removed if the command line is properly formed (it is not removed if an error condition arises). The following command lines (with explanations to the right) are valid as input to PIP:

- \texttt{X = Y cr} \quad \text{Copy to file X from file Y, where X and Y are unambiguous file names; Y remains unchanged.}
- \texttt{X = Y,Z cr} \quad \text{Concatenate files Y and Z and copy to file X, with Y and Z unchanged.}
- \texttt{X.ASM=Y.ASM,Z.ASM,FIN.ASM cr} \quad \text{Create the file X.ASM from the concatenation of the Y, Z, and FIN files with type ASM.}
- \texttt{NEW.ZOT = B:OLD.ZAP cr} \quad \text{Move a copy of OLD.ZAP from drive B to the currently logged disk; name the file NEW.ZOT.}
- \texttt{B:A.U = B:B.V,A:C.W,D.X cr} \quad \text{Concatenate file B,V from drive B with C,W from drive A and D,X. from the logged disk; create the file A.U on drive B.}

For more convenient use, PIP allows abbreviated commands for transferring files between disk drives. The abbreviated forms are
The following PIP commands give examples of valid disk-to-disk copy operations:

- **B:*=*.COM cr**
  - Copy all files which have the secondary name "COM" to drive B from the current drive.
- **A:=B:ZAP,* cr**
  - Copy all files which have the primary name "ZAP" to drive A from drive B.
- **ZAP,ASM=B: cr**
  - Equivalent to ZAP,ASM=B:ZAP,ASM
- **B:ZOT,COM=A: cr**
  - Equivalent to B:ZOT,COM=A:ZOT,COM
- **B:=GAMMA,BAS cr**
  - Same as B:GAMMA,BAS=GAMMA,BAS
- **B:=A:GAMMA,BAS cr**
  - Same as B:GAMMA,BAS=A:GAMMA,BAS

PIP also allows reference to physical and logical devices which are attached to the CP/M system. The device names are the same as given under the STAT command, along with a number of specially named devices. The logical devices given in the STAT command are

- **CON:** (console), **RDR:** (reader), **PUN:** (punch), and **LST:** (list)

while the physical devices are
TTY: (console, reader, punch, or list)
Crt: (console, or list), UCl: (console)
FTr: (reader), Ur1: (reader),尿2: (reader)
Ptp: (punch), Up1: (punch), Up2: (punch)
LpT: (list), Ull: (list)

(Note that the "BAT:" physical device is not included, since this assignment is used only to indicate that the RDR: and LST: devices are to be used for console input/output.)

The RDR, LST, PUN, and CON devices are all defined within the BIOS portion of CP/M, and thus are easily altered for any particular I/O system. (The current physical device mapping is defined by IOBYTE; see the "CP/M Interface Guide" for a discussion of this function). The destination device must be capable of receiving data (i.e., data cannot be sent to the punch), and the source devices must be capable of generating data (i.e., the LST: device cannot be read).

The additional device names which can be used in PIP commands are

NUL: Send 40 "nulls" (ASCII 0's) to the device (this can be issued at the end of punched output).

EOF: Send a CP/M end-of-file (ASCII ctrl-Z) to the destination device (sent automatically at the end of all ASCII data transfers through PIP).

INP: Special PIP input source which can be "patched" into the PIP program itself: PIP gets the input data character-by-character by CALLing location 103H, with data returned in location 109H (parity bit must be zero).

OUT: Special PIP output destination which can be patched into the PIP program: PIP CALLs location 106H with data in register C for each character to transmit. Note that locations 109H through 1FFH of the PIP memory image are not used and can be replaced by special purpose drivers using DDT (see the DDT operator's manual).

PRN: Same as LST:; except that tabs are expanded at every eighth character position, lines are numbered, and page ejects are inserted every 60 lines, with an initial eject (same as [t8np]).

File and device names can be interspersed in the PIP commands. In each case, the specific device is read until end-of-file (ctrl-Z for ASCII files, and a real end of file for non-ASCII disk files). Data from each device or file is concatenated from left to right until the last data source has been
read. The destination device or file is written using the data from the source files, and an end-of-file character (ctl-Z) is appended to the result for ASCII files. Note if the destination is a disk file, then a temporary file is created ($$$ secondary name) which is changed to the actual file name only upon successful completion of the copy. Files with the extension "COM" are always assumed to be non-ASCII.

The copy operation can be aborted at any time by depressing any key on the keyboard (a rubollt suffices). PIP will respond with the message "ABORTED" to indicate that the operation was not completed. Note that if any operation is aborted, or if an error occurs during processing, PIP removes any pending commands which were set up while using the SUBMIT command.

It should also be noted that PIP performs a special function if the destination is a disk file with type "HEX" (an Intel hex formatted machine code file), and the source is an external peripheral device, such as a paper tape reader. In this case, the PIP program checks to ensure that the source file contains a properly formed hex file, with legal hexadecimal values and checksum records. When an invalid input record is found, PIP reports an error message at the console and waits for corrective action. It is usually sufficient to open the reader and rerun a section of the tape (pull the tape back about 20 inches). When the tape is ready for the re-read, type a single carriage return at the console, and PIP will attempt another read. If the tape position cannot be properly read, simply continue the read (by typing a return following the error message), and enter the record manually with the ED program after the disk file is constructed. For convenience, PIP allows the end-of-file to be entered from the console if the source file is a RDR device. In this case, the PIP program reads the device and monitors the keyboard. If ctl-Z is typed at the keyboard, then the read operation is terminated normally.

Valid PIP commands are shown below.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PIP LST: = X.PR N cr</td>
<td>Copy X.PR N to the LST device and terminate the PIP program.</td>
</tr>
<tr>
<td>PIP cr</td>
<td>Start PIP for a sequence of commands (PIP prompts with &quot;*&quot;).</td>
</tr>
<tr>
<td>*CON:=X.ASM,Y.ASM,Z.ASM cr</td>
<td>Concatenate three ASM files and copy to the CON device.</td>
</tr>
<tr>
<td>*X.HEX=CON:,Y.HEX,PTR: cr</td>
<td>Create a HEX file by reading the CON (until a ctl-Z is typed), followed by data from Y.HEX, followed by data from PTR until a ctl-Z is encountered.</td>
</tr>
<tr>
<td>*cr</td>
<td>Single carriage return stops PIP.</td>
</tr>
</tbody>
</table>
Send 40 nulls to the punch device; then copy the X.ASM file to the punch, followed by an end-of-file (ctl-Z) and 40 more null characters.

The user can also specify one or more PIP parameters, enclosed in left and right square brackets, separated by zero or more blanks. Each parameter affects the copy operation, and the enclosed list of parameters must immediately follow the affected file or device. Generally, each parameter can be followed by an optional decimal integer value (the S and Q parameters are exceptions). The valid PIP parameters are listed below.

- **B** Block mode transfer: data is buffered by PIP until an ASCII x-off character (ctl-S) is received from the source device. This allows transfer of data to a disk file from a continuous reading device, such as a cassette reader. Upon receipt of the x-off, PIP clears the disk buffers and returns for more input data. The amount of data which can be buffered is dependent upon the memory size of the host system (PIP will issue an error message if the buffers overflow).

- **Dn** Delete characters which extend past column n in the transfer of data to the destination from the character source. This parameter is used most often to truncate long lines which are sent to a (narrow) printer or console device.

- **E** Echo all transfer operations to the console as they are being performed.

- **F** Filter form feeds from the file. All imbedded form feeds are removed. The P parameter can be used simultaneously to insert new form feeds.

- **H** Hex data transfer: all data is checked for proper Intel hex file format. Non-essential characters between hex records are removed during the copy operation. The console will be prompted for corrective action in case errors occur.

- **I** Ignore ":00" records in the transfer of Intel hex format file (the I parameter automatically sets the H parameter).

- **L** Translate upper case alphabetics to lower case.

- **N** Add line numbers to each line transferred to the destination starting at one, and incrementing by 1. Leading zeroes are suppressed, and the number is followed by a colon. If N2 is specified, then leading zeroes are included, and a tab is inserted following the number. The tab is expanded if T is
Object file (non-ASCII) transfer: the normal CP/M end of file is ignored.

Pn Include page ejects at every n lines (with an initial page eject). If n = 1 or is excluded altogether, page ejects occur every 60 lines. If the F parameter is used, form feed suppression takes place before the new page ejects are inserted.

Qs'z Quit copying from the source device or file when the string s (terminated by ctl-Z) is encountered.

Ss'z Start copying from the source device when the string s is encountered (terminated by ctl-Z). The S and Q parameters can be used to "abstract" a particular section of a file (such as a subroutine). The start and quit strings are always included in the copy operation.

NOTE - the strings following the s and q parameters are translated to upper case by the CCP if form (2) of the PIP command is used. Form (1) of the PIP invocation, however, does not perform the automatic upper case translation.

(1) PIP cr
(2) PIP "command line" cr

Tn Expand tabs (ctl-I characters) to every nth column during the transfer of characters to the destination from the source.

U Translate lower case alphabetics to upper case during the copy operation.

V Verify that data has been copied correctly by rereading after the write operation (the destination must be a disk file).

Z Zero the parity bit on input for each ASCII character.

The following are valid PIP commands which specify parameters in the file transfer:

PIP X.ASM=B:[v] cr Copy X_ASM from drive B to the current drive and verify that the data was properly copied.

PIP LPT:=X.ASM[nt8u] cr Copy X_ASM to the LPT: device; number each line, expand tabs to every eighth column, and translate lower case alphabetics to upper case.
PIP PUN:=X.HEX[i],Y.ZOT[h] cr First copy X.HEX to the PUN: device and ignore the trailing ":00" record in X.HEX; then continue the transfer of data by reading Y.ZOT, which contains hex records, including any ":00" records which it contains.

PIP X.LIB = Y.ASM [ sSUBRL::z qJMP L3::z ] cr Copy from the file Y.ASM into the file X.LIB. Start the copy when the string "SUBRL:" has been found, and quit copying after the string "JMP L3" is encountered.

PIP FRN:=X.ASM[p50] Send X.ASM to the LST: device, with line numbers, tabs expanded to every eighth column, and page ejects at every 50th line. Note that ntblp60 is the assumed parameter list for a FRN file; p50 overrides the default value.

6.5. ED ufn cr

The ED program is the CP/M system context editor, which allows creation and alteration of ASCII files in the CP/M environment. Complete details of operation are given the ED user's manual, "ED: a Context Editor for the CP/M Disk System." In general, ED allows the operator to create and operate upon source files which are organized as a sequence of ASCII characters, separated by end-of-line characters (a carriage-return line-feed sequence). There is no practical restriction on line length (no single line can exceed the size of the working memory), which is instead defined by the number of characters typed between cr's. The ED program has a number of commands for character string searching, replacement, and insertion, which are useful in the creation and correction of programs or text files under CP/M. Although the CP/M has a limited memory work space area (approximately 5000 characters in a 16K CP/M system), the file size which can be edited is not limited, since data is easily "paged" through this work area.

Upon initiation, ED creates the specified source file, if it does not exist, and opens the file for access. The programmer then "appends" data from the source file into the work area, if the source file already exists (see the A command), for editing. The appended data can then be displayed, altered, and written from the work area back to the disk (see the W command). Particular points in the program can be automatically paged and located by context (see the N command), allowing easy access to particular portions of a large file.

Given that the operator has typed

ED X.ASM cr
the ED program creates an intermediate work file with the name

\[ X.\$\$ \]

to hold the edited data during the ED run. Upon completion of ED, the \( X.ASM \) file (original file) is renamed to \( X.BAK \), and the edited work file is renamed to \( X.ASM \). Thus, the \( X.BAK \) file contains the original (unedited) file, and the \( X.ASM \) file contains the newly edited file. The operator can always return to the previous version of a file by removing the most recent version, and renaming the previous version. Suppose, for example, that the current \( X.ASM \) file was improperly edited; the sequence of CCP command shown below would reclaim the backup file.

\begin{verbatim}
DIR X.* Check to see that BAK file is available.
ERA X.ASM Erase most recent version.
REN X.ASM=X.BAK Rename the BAK file to ASM.
\end{verbatim}

Note that the operator can abort the edit at any point (reboot, power failure, \( \text{ctl-C} \), or \( \text{Q} \) command) without destroying the original file. In this case, the BAK file is not created, and the original file is always intact.

The ED program also allows the user to "ping-pong" the source and create backup files between two disks. The form of the ED command in this case is

\begin{verbatim}
ED ufn d:
\end{verbatim}

where \( ufn \) is the name of a file to edit on the currently logged disk, and \( d \) is the name of an alternate drive. The ED program reads and processes the source file, and writes the new file to drive \( d \), using the name \( ufn \). Upon completion of processing, the original file becomes the backup file. Thus, if the operator is addressing disk A, the following command is valid:

\begin{verbatim}
ED X.ASM B:
\end{verbatim}

which edits the file \( X.ASM \) on drive \( A \), creating the new file \( X.\$\$ \) on drive \( B \). Upon completion of a successful edit, \( A:X.ASM \) is renamed to \( A:X.BAK \), and \( B:X.\$\$ \) is renamed to \( B:X.ASM \). For user convenience, the currently logged disk becomes drive \( B \) at the end of the edit. Note that if a file by the name \( B:X.ASM \) exists before the editing begins, the message

\begin{verbatim}
FILE EXISTS
\end{verbatim}

is printed at the console as a precaution against accidently destroying a source file. In this case, the operator must first \( \text{ERA} \)se the existing file and then restart the edit operation.
Similar to other transient commands, editing can take place on a drive different from the currently logged disk by preceding the source file name by a drive name. Examples of valid edit requests are shown below.

ED A:X.ASM
Edit the file X.ASM on drive A, with new file and backup on drive A.

ED B:X.ASM A:
Edit the file X.ASM on drive B to the temporary file X.$$ on drive A. On termination of editing, change X.ASM on drive B to X.BAK, and change X.$$ on drive A to X.ASM.

6.6. SYSGEN cr

The SYSGEN transient command allows generation of an initialized diskette containing the CP/M operating system. The SYSGEN program prompts the console for commands, with interaction as shown below.

SYSGEN cr
Initiate the SYSGEN program.

SYSGEN VERSION m.m
SYSGEN sign-on message.

SOURCE DRIVE NAME (OR RETURN TO SKIP)
Respond with the drive name (one of the letters A, B, C, or D) of the disk containing a CP/M system; usually A. If a copy of CP/M already exists in memory, due to a MOVCPM command, type a cr only. Typing a drive name x will cause the response:

SOURCE ON x THEN TYPE RETURN
Place a diskette containing the CP/M operating system on drive x (x is one of A, B, C, or D). Answer with cr when ready.

FUNCTION COMPLETE
System is copied to memory. SYSGEN will then prompt with:

DESTINATION DRIVE NAME (OR RETURN TO REBOOT)
If a diskette is being initialized, place the new disk into a drive and answer with the drive name. Otherwise, type a cr and the system will reboot from drive A. Typing drive name x will cause SYSGEN to prompt
with:

**DESTINATION ON x THEN TYPE RETURN** Place new diskette into drive x; type return when ready.

**FUNCTION COMPLETE** New diskette is initialized in drive x.

The "DESTINATION" prompt will be repeated until a single carriage return is typed at the console, so that more than one disk can be initialized.

Upon completion of a successful system generation, the new diskette contains the operating system, and only the built-in commands are available. A factory-fresh IBM-compatible diskette appears to CP/M as a diskette with an empty directory; therefore, the operator must copy the appropriate COM files from an existing CP/M diskette to the newly constructed diskette using the PIP transient.

The user can copy all files from an existing diskette by typing the PIP command

```
PIP B: = A: *.*[v] cr
```

which copies all files from disk drive A to disk drive B, and verifies that each file has been copied correctly. The name of each file is displayed at the console as the copy operation proceeds.

It should be noted that a SYSGEN does not destroy the files which already exist on a diskette; it results only in construction of a new operating system. Further, if a diskette is being used only on drives B through D, and will never be the source of a bootstrap operation on drive A, the SYSGEN need not take place. In fact, a new diskette needs absolutely no initialization to be used with CP/M.

6.7. **SUBMIT ufn parm#1 ... parm#n cr**

The SUBMIT command allows CP/M commands to be batched together for automatic processing. The ufn given in the SUBMIT command must be the filename of a file which exists on the currently logged disk, with an assumed file type of "SUB." The SUB file contains CP/M prototype commands, with possible parameter substitution. The actual parameters parm#1 ... parm#n are substituted into the prototype commands, and, if no errors occur, the file of substituted commands are processed sequentially by CP/M.
The prototype command file is created using the ED program, with interspersed "$" parameters of the form

\[
$1 \; $2 \; $3 \; \ldots \; $n
\]

corresponding to the number of actual parameters which will be included when the file is submitted for execution. When the SUBMIT transient is executed, the actual parameters parm#1 ... parm#n are paired with the formal parameters $1 ... $n in the prototype commands. If the number of formal and actual parameters does not correspond, then the submit function is aborted with an error message at the console. The SUBMIT function creates a file of substituted commands with the name

$$$.SUB

on the logged disk. When the system reboots (at the termination of the SUBMIT), this command file is read by the CCP as a source of input, rather than the console. If the SUBMIT function is performed on any disk other than drive A, the commands are not processed until the disk is inserted into drive A and the system reboots. Further, the user can abort command processing at any time by typing a rubout when the command is read and echoed. In this case, the $$$.SUB file is removed, and the subsequent commands come from the console. Command processing is also aborted if the CCP detects an error in any of the commands. Programs which execute under CP/M can abort processing of command files when error conditions occur by simply erasing any existing $$$.SUB file.

In order to introduce dollar signs into a SUBMIT file, the user may type a "$$" which reduces to a single "$" within the command file. Further, an up-arrow symbol "↑" may precede an alphabetic character x, which produces a single ctl-x character within the file.

The last command in a SUB file can initiate another SUB file, thus allowing chained batch commands.

Suppose the file ASMBL.SUB exists on disk and contains the prototype commands

\[
\begin{align*}
&\text{ASM }$1 \\
&\text{DIR }$1.* \\
&\text{ERA }*_.BAK \\
&\text{PIP }$2:=$1.PRN \\
&\text{ERA }$1.PRN
\end{align*}
\]

and the command

\[
\text{SUBMIT ASMBL X PRN cr}
\]

is issued by the operator. The SUBMIT program reads the ASMBL.SUB file, substituting "X" for all occurrences of $1 and "PRN" for all occurrences of $2, resulting in a $$$.SUB file containing the commands
ASM X
DIR X, *
ERA *, BAK
PIP PRN: = X, PRN
ERA X, PRN

which are executed in sequence by the CCP.

The SUBMIT function can access a SUB file which is on an alternate drive
by preceding the file name by a drive name. Submitted files are only acted
upon, however, when they appear on drive A. Thus, it is possible to create a
submitted file on drive B which is executed at a later time when it is
inserted in drive A.

6.8. DUMP ufn cr

The DUMP program types the contents of the disk file (ufn) at the console
in hexadecimal form. The file contents are listed sixteen bytes at a time,
with the absolute byte address listed to the left of each line in
hexadecimal. Long typeouts can be aborted by pushing the rubout key during
printout. (The source listing of the DUMP program is given in the "CP/M
Interface Guide" as an example of a program written for the CP/M environment.)

6.9. MOVCPM cr

The MOVCPM program allows the user to reconfigure the CP/M system for any
particular memory size. Two optional parameters may be used to indicate (1)
the desired size of the new system and (2) the disposition of the new system
at program termination. If the first parameter is omitted or a "*" is given,
the MOVCPM program will reconfigure the system to its maximum size, based upon
the kilobytes of contiguous RAM in the host system (starting at 0000H). If
the second parameter is omitted, the system is executed, but not permanently
recorded; if "*" is given, the system is left in memory, ready for a SYSGEN
operation. The MOVCPM program relocates a memory image of CP/M and places
this image in memory in preparation for a system generation operation. The
command forms are:

MOVCPM cr

Relocate and execute CP/M for manage-
ment of the current memory configura-
tion (memory is examined for contigu-
ous RAM, starting at 100H). Upon com-
pletion of the relocation, the new
system is executed but not permanently
recorded on the diskette. The system
which is constructed contains a BIOS
for the Intel MDS 800.
MOVCMP n cr

Create a relocated CP/M system for management of an n kilobyte system (n must be in the range 16 to 64), and execute the system, as described above.

MOVCMP * * cr

Construct a relocated memory image for the current memory configuration, but leave the memory image in memory, in preparation for a SYSGEN operation.

MOVCMP n * cr

Construct a relocated memory image for an n kilobyte memory system, and leave the memory image in preparation for a SYSGEN operation.

The command

MOVCMP * *

for example, constructs a new version of the CP/M system and leaves it in memory, ready for a SYSGEN operation. The message

READY FOR "SYSGEN" OR
"SAVE 32 CP/Mxx.COM"

is printed at the console upon completion, where xx is the current memory size in kilobytes. The operator can then type

SYSGEN cr

Start the system generation.

SOURCE DRIVE NAME (OR RETURN TO SKIP) Respond with a cr to skip the CP/M read operation since the system is already in memory as a result of the previous MOVCMP operation.

DESTINATION DRIVE NAME (OR RETURN TO REBOOT) Respond with B to write new system to the diskette in drive B. SYSGEN will prompt with:

DESTINATION ON B, THEN TYPE RETURN

Ready the fresh diskette on drive B and type a return when ready.

Note that if you respond with "A" rather than "B" above, the system will be written to drive A rather than B. SYSGEN will continue to type the prompt:

DESTINATION DRIVE NAME (OR RETURN TO REBOOT)

until the operator responds with a single carriage return, which stops the
SYSGEN program with a system reboot.

The user can then go through the reboot process with the old or new diskette. Instead of performing the SYSGEN operation, the user could have typed

```
SAVE 32 CPMxx.COM
```

at the completion of the MOVCPM function, which would place the CP/M memory image on the currently logged disk in a form which can be "patched." This is necessary when operating in a non-standard environment where the BIOS must be altered for a particular peripheral device configuration, as described in the "CP/M System Alteration Guide."

Valid MOVCPM commands are given below:

- **MOVCPM 48 cr**  
  Construct a 48K version of CP/M and start execution.

- **MOVCPM 48 * cr**  
  Construct a 48K version of CP/M in preparation for permanent recording; response is READY FOR "SYSGEN" OR "SAVE 32CPM48.COM"

- **MOVCPM * * cr**  
  Construct a maximum memory version of CP/M and start execution.

It is important to note that the newly created system is serialized with the number attached to the original diskette and is subject to the conditions of the Digital Research Software Licensing Agreement.
7. **BDOS ERROR MESSAGES.**

There are three error situations which the Basic Disk Operating System intercepts during file processing. When one of these conditions is detected, the BDOS prints the message:

```
BDOS ERR ON x: error
```

where x is the drive name, and "error" is one of the three error messages:

BAD SECTOR
SELECT
READ ONLY

The "BAD SECTOR" message indicates that the disk controller electronics has detected an error condition in reading or writing the diskette. This condition is generally due to a malfunctioning disk controller, or an extremely worn diskette. If you find that your system reports this error more than once a month, you should check the state of your controller electronics, and the condition of your media. You may also encounter this condition in reading files generated by a controller produced by a different manufacturer. Even though controllers are claimed to be IBM-compatible, one often finds small differences in recording formats. The MDS-800 controller, for example, requires two bytes of one's following the data CRC byte, which is not required in the IBM format. As a result, diskettes generated by the Intel MDS can be read by almost all other IBM-compatible systems, while disk files generated on other manufacturer's equipment will produce the "BAD SECTOR" message when read by the MDS. In any case, recovery from this condition is accomplished by typing a ctl-C to reboot (this is the safest!), or a return, which simply ignores the bad sector in the file operation. Note, however, that typing a return may destroy your diskette integrity if the operation is a directory write, so make sure you have adequate backups in this case.

The "SELECT" error occurs when there is an attempt to address a drive beyond the A through D range. In this case, the value of x in the error message gives the selected drive. The system reboots following any input from the console.

The "READ ONLY" message occurs when there is an attempt to write to a diskette which has been designated as read-only in a STAT command, or has been set to read-only by the BDOS. In general, the operator should reboot CP/M either by using the warm start procedure (ctl-C) or by performing a cold start whenever the diskettes are changed. If a changed diskette is to be read but not written, BDOS allows the diskette to be changed without the warm or cold start, but internally marks the drive as read-only. The status of the drive is subsequently changed to read/write if a warm or cold start occurs. Upon issuing this message, CP/M waits for input from the console. An automatic warm start takes place following any input.
8. OPERATION OF CP/M ON THE MDS.

This section gives operating procedures for using CP/M on the Intel MDS microcomputer development system. A basic knowledge of the MDS hardware and software systems is assumed.

CP/M is initiated in essentially the same manner as Intel's ISIS operating system. The disk drives are labelled 0 through 3 on the MDS, corresponding to CP/M drives A through D, respectively. The CP/M system diskette is inserted into drive 0, and the BOOT and RESET switches are depressed in sequence. The interrupt 2 light should go on at this point. The space bar is then depressed on the device which is to be taken as the system console, and the light should go out (if it does not, then check connections and baud rates). The BOOT switch is then turned off, and the CP/M signon message should appear at the selected console device, followed by the "A>" system prompt. The user can then issue the various resident and transient commands.

The CP/M system can be restarted (warm start) at any time by pushing the INT 0 switch on the front panel. The built-in Intel ROM monitor can be initiated by pushing the INT 7 switch (which generates a RST 7), except when operating under DDT, in which case the DDT program gets control instead.

Diskettes can be removed from the drives at any time, and the system can be shut down during operation without affecting data integrity. Note, however, that the user must not remove a diskette and replace it with another without rebooting the system (cold or warm start), unless the inserted diskette is "read only."

Due to hardware hang-ups or malfunctions, CP/M may type the message

BDOS ERR ON x: BAD SECTOR

where x is the drive which has a permanent error. This error may occur when drive doors are opened and closed randomly, followed by disk operations, or may be due to a diskette, drive, or controller failure. The user can optionally elect to ignore the error by typing a single return at the console. The error may produce a bad data record, requiring re-initialization of up to 128 bytes of data. The operator can reboot the CP/M system and try the operation again.

Termination of a CP/M session requires no special action, except that it is necessary to remove the diskettes before turning the power off, to avoid random transients which often make their way to the drive electronics.

It should be noted that factory-fresh IBM-compatible diskettes should be used rather than diskettes which have previously been used with any ISIS version. In particular, the ISIS "FORMAT" operation produces non-standard sector numbering throughout the diskette. This non-standard numbering seriously degrades the performance of CP/M, and will operate noticeably slower.
than the distribution version. If it becomes necessary to reformat a diskette (which should not be the case for standard diskettes), a program can be written under CP/M which causes the MDS 800 controller to reformat with sequential sector numbering (1-26) on each track.

Note: "MDS 800" and "ISIS" are registered trademarks of Intel Corporation.

1. ED TUTORIAL

1.1. Introduction to ED.

ED is the context editor for CP/M, and is used to create and alter CP/M source files. ED is initiated in CP/M by typing

\[
\text{ED}\{\text{<filename>}} \\
\text{<filename>},\text{<filetype>}
\]

In general, ED reads segments of the source file given by <filename> or <filename> . <filetype> into central memory, where the file is manipulated by the operator, and subsequently written back to disk after alterations. If the source file does not exist before editing, it is created by ED and initialized to empty. The overall operation of ED is shown in Figure 1.

1.2. ED Operation

ED operates upon the source file, denoted in Figure 1 by x.y, and passes all text through a memory buffer where the text can be viewed or altered (the number of lines which can be maintained in the memory buffer varies with the line length, but has a total capacity of about 6000 characters in a 16K CP/M system). Text material which has been edited is written onto a temporary work file under command of the operator. Upon termination of the edit, the memory buffer is written to the temporary file, followed by any remaining (unread) text in the source file. The name of the original file is changed from x.y to x.BAK so that the most recent previously edited source file can be reclaimed if necessary (see the CP/M commands ERASE and RENAME). The temporary file is then changed from x.$$ to x.y which becomes the resulting edited file.

The memory buffer is logically between the source file and working file as shown in Figure 2.

1.3. Text Transfer Functions

Given that n is an integer value in the range 0 through 65535, the following ED commands transfer lines of text from the source file through the memory buffer to the temporary (and eventually final) file:
Figure 1. Overall ED Operation

Note: the ED program accepts both lower and upper case ASCII characters as input from the console. Single letter commands can be typed in either case. The U command can be issued to cause ED to translate lower case alphabets to upper case as characters are filled to the memory buffer from the console. Characters are echoed as typed without translation, however. The -U command causes ED to revert to "no translation" mode. ED starts with an assumed -U in effect.

Figure 3. Logical Organization of Memory Buffer

Memory Buffer

first line  \--------<cr><lf>

\--------<cr><lf>

current line CL  \--------<cr><lf>

last line  \--------<cr><lf>
nA<cr>* - append the next n unprocessed source lines from the source file at SP to the end of the memory buffer at MP. Increment SP and MP by n.

nW<cr> - write the first n lines of the memory buffer to the temporary file free space. Shift the remaining lines n+1 through MP to the top of the memory buffer. Increment TP by n.

E<cr> - end the edit. Copy all buffered text to temporary file, and copy all unprocessed source lines to the temporary file. Rename files as described previously.

H<cr> - move to head of new file by performing automatic E command. Temporary file becomes the new source file, the memory buffer is emptied, and a new temporary file is created (equivalent to issuing an E command, followed by a reinvocation of ED using x.y as the file to edit).

O<cr> - return to original file. The memory buffer is emptied, the temporary file id deleted, and the SP is returned to position 1 of the source file. The effects of the previous editing commands are thus nullified.

Q<cr> - quit edit with no file alterations, return to CP/M.

There are a number of special cases to consider. If the integer n is omitted in any ED command where an integer is allowed, then 1 is assumed. Thus, the commands A and W append one line and write 1 line, respectively. In addition, if a pound sign (#) is given in the place of n, then the integer 65535 is assumed (the largest value for n which is allowed). Since most reasonably sized source files can be contained entirely in the memory buffer, the command #A is often issued at the beginning of the edit to read the entire source file to memory. Similarly, the command #W writes the entire buffer to the temporary file. Two special forms of the A and W

*<cr> represents the carriage-return key
commands are provided as a convenience. The command OA fills the current memory buffer to at least half-full, while OW writes lines until the buffer is at least half empty. It should also be noted that an error is issued if the memory buffer size is exceeded. The operator may then enter any command (such as W) which does not increase memory requirements. The remainder of any partial line read during the overflow will be brought into memory on the next successful append.

1.4. Memory Buffer Organization

The memory buffer can be considered a sequence of source lines brought in with the A command from a source file. The memory buffer has an associated (imaginary) character pointer CP which moves throughout the memory buffer under command of the operator. The memory buffer appears logically as shown in Figure 3 where the dashes represent characters of the source line of indefinite length, terminated by carriage-return (\texttt{<cr>}) and line-feed (\texttt{<lf>}) characters, and \texttt{CP} represents the imaginary character pointer. Note that the CP is always located ahead of the first character of the first line, behind the last character of the last line, or between two characters. The current line CL is the source line which contains the CP.

1.5. Memory Buffer Operation

Upon initiation of ED, the memory buffer is empty (ie, CP is both ahead and behind the first and last character). The operator may either append lines (A command) from the source file, or enter the lines directly from the console with the insert command

\texttt{I<cr>}

ED then accepts any number of input lines, where each line terminates with a \texttt{<cr>} (the \texttt{<lf>} is supplied automatically), until a control-z (denoted by \texttt{^z} is typed by the operator. The CP is positioned after the last character entered. The sequence

\texttt{I<cr>}
\texttt{NOW IS THE<cr>}
\texttt{TIME FOR<cr>}
\texttt{ALL GOOD MEN<cr>}
\texttt{^z}

leaves the memory buffer as shown below
Various commands can then be issued which manipulate the CP or display source text in the vicinity of the CP. The commands shown below with a preceding n indicate that an optional unsigned value can be specified. When preceded by ±, the command can be unsigned, or have an optional preceding plus or minus sign. As before, the pound sign (#) is replaced by 65535. If an integer n is optional, but not supplied, then n=1 is assumed. Finally, if a plus sign is optional, but none is specified, then + is assumed.

±B<cr> - move CP to beginning of memory buffer if +, and to bottom if -.

±nC<cr> - move CP by ±n characters (toward front of buffer if +), counting the <cr><lf> as two distinct characters

±nD<cr> - delete n characters ahead of CP if plus and behind CP if minus.

±nK<cr> - kill (ie remove) ±n lines of source text using CP as the current reference. If CP is not at the beginning of the current line when K is issued, then the characters before CP remain if + is specified, while the characters after CP remain if - is given in the command.

±nL<cr> - if n=0 then move CP to the beginning of the current line (if it is not already there) if n≠0 then first move the CP to the beginning of the current line, and then move it to the beginning of the line which is n lines down (if +) or up (if -). The CP will stop at the top or bottom of the memory buffer if too large a value of n is specified.
±nT<cr> - If n=0 then type the contents of the current line up to CP. If n=1 then type the contents of the current line from CP to the end of the line. If n>1 then type the current line along with n-1 lines which follow, if + is specified. Similarly, if n>1 and - is given, type the previous n lines, up to the CP. The break key can be depressed to abort long type-outs.

±n<cr> - equivalent to ±nLT, which moves up or down and types a single line

1.6. Command Strings

Any number of commands can be typed contiguously (up to the capacity of the CP/M console buffer), and are executed only after the <cr> is typed. Thus, the operator may use the CP/M console command functions to manipulate the input command:

- Rubout remove the last character
- Control-U delete the entire line
- Control-C re-initialize the CP/M System
- Control-E return carriage for long lines without transmitting buffer (max 128 chars)

Suppose the memory buffer contains the characters shown in the previous section, with the CP following the last character of the buffer. The command strings shown below produce the results shown to the right.

<table>
<thead>
<tr>
<th>Command String</th>
<th>Effect</th>
<th>Resulting Memory Buffer</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. B2T&lt;cr&gt;</td>
<td>move to beginning of buffer and type 2 lines: &quot;NOW IS THE TIME FOR&quot;</td>
<td>NOW IS THE&lt;cr&gt;&lt;lf&gt; TIME FOR&lt;cr&gt;&lt;lf&gt; ALL GOOD MEN&lt;cr&gt;&lt;lf&gt;</td>
</tr>
<tr>
<td>2. 5C0T&lt;cr&gt;</td>
<td>move CP 5 characters and type the beginning of the line &quot;NOW I&quot;</td>
<td>NOW I S THE&lt;cr&gt;&lt;lf&gt;</td>
</tr>
</tbody>
</table>
3. 2L-T<cr> move two lines down and type previous line "TIME FOR"
NOW IS THE<cr><lf>
TIME FOR<cr><lf>
ALL GOOD MEN<cr><lf>

4. -L#K<cr> move up one line, delete 65535 lines which follow
NOW IS THE<cr><lf>

5. I<cr> insert two lines of text
TIME TO<cr><lf>
INSERT<cr><lf>
+<cr><lf>

6. -2L#T<cr> move up two lines, and type 65535 lines ahead of CP "NOW IS THE"
NOW IS THE<cr><lf>
TIME TO<cr><lf>
INSERT<cr><lf>

7. <cr> move down one line and type one line "INSERT"
NOW IS THE<cr><lf>
TIME TO<cr><lf>
INSERT<cr><lf>

1.7. Text Search and Alteration

ED also has a command which locates strings within the memory buffer. The command takes the form

\[ nF \ c_1 c_2 \ldots c_k \langle cr \rangle +z \]

where \( c_1 \) through \( c_k \) represent the characters to match followed by either a \(<cr>\) or control -z*. ED starts at the current position of CP and attempts to match all \( k \) characters. The match is attempted \( n \) times, and if successful, the CP is moved directly after the character \( c_k \). If the \( n \) matches are not successful, the CP is not moved from its initial position. Search strings can include \( ^{<cr>}l \) (control-l), which is replaced by the pair of symbols \(<cr><lf>\).

*The control-z is used if additional commands will be typed following the +z.
The following commands illustrate the use of the F command:

<table>
<thead>
<tr>
<th>Command String</th>
<th>Effect</th>
<th>Resulting Memory Buffer</th>
</tr>
</thead>
<tbody>
<tr>
<td>B#T&lt;cr&gt;</td>
<td>move to beginning and type entire buffer</td>
<td>NOW IS THE&lt;cr&gt;&lt;lf&gt; TIME FOR&lt;cr&gt;&lt;lf&gt; ALL GOOD MEN&lt;cr&gt;&lt;lf&gt;</td>
</tr>
<tr>
<td>FS T&lt;cr&gt;</td>
<td>find the end of the string &quot;S T&quot;</td>
<td>NOW IS THE&lt;cr&gt;&lt;lf&gt;</td>
</tr>
<tr>
<td>FItzOTT</td>
<td>find the next &quot;I&quot; and type to the CP then type the remainder of the current line: &quot;TIME FOR&quot;</td>
<td>NOW IS THE&lt;cr&gt;&lt;lf&gt;</td>
</tr>
</tbody>
</table>

An abbreviated form of the insert command is also allowed, which is often used in conjunction with the F command to make simple textual changes. The form is:

\[ I \ c_1c_2\ldots c_n \uparrow z \quad \text{or} \quad I \ c_1c_2\ldots c_n <\cr> \]

where \(c_1\) through \(c_n\) are characters to insert. If the insertion string is terminated by a \(\uparrow z\), the characters \(c_1\) through \(c_n\) are inserted directly following the CP, and the CP is moved directly after character \(c_n\). The action is the same if the command is followed by a \(<\cr>\) except that a \(<\cr><lf>\) is automatically inserted into the text following character \(c_n\). Consider the following command sequences as examples of the F and I commands:

<table>
<thead>
<tr>
<th>Command String</th>
<th>Effect</th>
<th>Resulting Memory Buffer</th>
</tr>
</thead>
<tbody>
<tr>
<td>BITHIS IS (\uparrow z&lt;\cr&gt;)</td>
<td>Insert &quot;THIS IS &quot; at the beginning of the text</td>
<td>THIS IS NOW THE (&lt;\cr&gt;&lt;lf&gt;)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>TIME FOR&lt;cr&gt;&lt;lf&gt;</td>
</tr>
</tbody>
</table>
FTIME+z-4DIPLACE+z<cr>
find "TIME" and delete it; then insert "PLACE"

3FO+z-3D5DICHA NGES<cr>
find third occurrence of "0" (ie the second "0" in GOOD), delete previous 3 characters; then insert "CHANGES"

-8CISOURCE<cr>
move back 8 characters and insert the line "SOURCE<cr><lf>"

ED also provides a single command which combines the F and I commands to perform simple string substitutions. The command takes the form

\[ n \ S \ c_1 c_2 \ldots c_k \uparrow z \ d_1 d_2 \ldots d_m \{ <cr> \} \]

and has exactly the same effect as applying the command string

\[ F \ c_1 c_2 \ldots c_k \uparrow z-k\ D \ d_1 d_2 \ldots d_m \{ <cr> \} \]

a total of n times. That is, ED searches the memory buffer starting at the current position of \( CP \) and successively substitutes the second string for the first string until the end of buffer, or until the substitution has been performed n times.

As a convenience, a command similar to \( F \) is provided by ED which automatically appends and writes lines as the search proceeds. The form is

\[ n \ N \ c_1 c_2 \ldots c_k \{ cr \} \]

which searches the entire source file for the nth occurrence of the string \( c_1 c_2 \ldots c_k \) (recall that \( F \) fails if the string cannot be found in the current buffer). The operation of the
N command is precisely the same as F except in the case that the string cannot be found within the current memory buffer. In this case, the entire memory contents is written (ie, an automatic #W is issued). Input lines are then read until the buffer is at least half full, or the entire source file is exhausted. The search continues in this manner until the string has been found n times, or until the source file has been completely transferred to the temporary file.

A final line editing function, called the juxtaposition command takes the form

$$n \ J \ c_1 c_2 \ldots c_k \ \div \ \ d_1 d_2 \ldots d_m \ \div \ e_1 e_2 \ldots e_q \ {<\text{cr}>} \ {+z}$$

with the following action applied n times to the memory buffer: search from the current CP for the next occurrence of the string $c_1 c_2 \ldots c_k$. If found, insert the string $d_1 d_2 \ldots d_m$, and move CP to follow $d_m$. Then delete all characters following CP up to (but not including) the string $e_1, e_2, \ldots e_q$, leaving CP directly after $d_m$. If $e_1, e_2, \ldots e_q$ cannot be found, then no deletion is made. If the current line is

NOW IS THE TIME<cr><lf>

Then the command

JW +zWHAT+z+t<cr>

Results in

NOW WHAT<cr><lf>

(Recall that +t represents the pair <cr><lf> in search and substitute strings).

It should be noted that the number of characters allowed by ED in the F, S, N, and J commands is limited to 100 symbols.

1.8. Source Libraries

ED also allows the inclusion of source libraries during the editing process with the R command. The form of this command is
where \( f_1 f_2 \ldots f_n \) is the name of a source file on the disk with as assumed filetype of 'LIB'. ED reads the specified file, and places the characters into the memory buffer after CP, in a manner similar to the I command. Thus, if the command

\[ \text{RMACRO<cr>} \]

is issued by the operator, ED reads from the file MACRO.LIB until the end-of-file, and automatically inserts the characters into the memory buffer.

1.9. Repetitive Command Execution

The macro command M allows the ED user to group ED commands together for repeated evaluation. The M command takes the form:

\[ n \text{ M } c_1 c_2 \ldots c_k \{ <\text{cr}> +z \} \]

where \( c_1 c_2 \ldots c_k \) represent a string of ED commands, not including another M command. ED executes the command string \( n \) times if \( n > 1 \). If \( n = 0 \) or 1, the command string is executed repetitively until an error condition is encountered (e.g., the end of the memory buffer is reached with an F command).

As an example, the following macro changes all occurrences of GAMMA to DELTA within the current buffer, and types each line which is changed:

\[ \text{MFGAMMA+z-5DIDELTA+z0TT<cr>} \]

or equivalently

\[ \text{MSGAMMA+zDELTAT+0TT<cr>} \]
2. ED ERROR CONDITIONS

On error conditions, ED prints the last character read before the error, along with an error indicator:

- ? unrecognized command
- > memory buffer full (use one of the commands D,K,N,S, or W to remove characters), F,N, or S strings too long.
- # cannot apply command the number of times specified (e.g., in F command)
- O cannot open LIB file in R command

Cyclic redundancy check (CRC) information is written with each output record under CP/M in order to detect errors on subsequent read operations. If a CRC error is detected, CP/M will type

```
PERM ERR DISK d
```

where d is the currently selected drive (A,B,...). The operator can choose to ignore the error by typing any character at the console (in this case, the memory buffer data should be examined to see if it was incorrectly read), or the user can reset the system and reclaim the backup file, if it exists. The file can be reclaimed by first typing the contents of the BAK file to ensure that it contains the proper information:

```
TYPE x.BAK<cr>
```

where x is the file being edited. Then remove the primary file:

```
ERA x.y<cr>
```

and rename the BAK file:

```
REN x.y=x.BAK<cr>
```

The file can then be re-edited, starting with the previous version.
3. CONTROL CHARACTERS AND COMMANDS

The following table summarizes the control characters and commands available in ED:

<table>
<thead>
<tr>
<th>Control Character</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>\tc</td>
<td>system reboot</td>
</tr>
<tr>
<td>\te</td>
<td>physical &lt;cr&gt;&lt;lf&gt; (not actually entered in command)</td>
</tr>
<tr>
<td>\ti</td>
<td>logical tab (cols 1, 8, 15,...)</td>
</tr>
<tr>
<td>\tl</td>
<td>logical &lt;cr&gt;&lt;lf&gt; in search and substitute strings</td>
</tr>
<tr>
<td>\tu</td>
<td>line delete</td>
</tr>
<tr>
<td>\tz</td>
<td>string terminator</td>
</tr>
<tr>
<td>rubout</td>
<td>character delete</td>
</tr>
<tr>
<td>break</td>
<td>discontinue command (e.g., stop typing)</td>
</tr>
<tr>
<td>Command</td>
<td>Function</td>
</tr>
<tr>
<td>---------</td>
<td>----------</td>
</tr>
<tr>
<td>±A</td>
<td>append lines</td>
</tr>
<tr>
<td>±B</td>
<td>begin bottom of buffer</td>
</tr>
<tr>
<td>±C</td>
<td>move character positions</td>
</tr>
<tr>
<td>±D</td>
<td>delete characters</td>
</tr>
<tr>
<td>E</td>
<td>end edit and close files (normal end)</td>
</tr>
<tr>

</tr>
<tr>
<td>Q</td>
<td>quit with no file changes</td>
</tr>
<tr>
<td>R</td>
<td>read library file</td>
</tr>
<tr>
<td>±S</td>
<td>substitute strings</td>
</tr>
<tr>
<td>±T</td>
<td>type lines</td>
</tr>
<tr>
<td>±U</td>
<td>translate lower to upper case if U, no translation if -U</td>
</tr>
<tr>
<td>±W</td>
<td>write lines</td>
</tr>
<tr>
<td>±Z</td>
<td>sleep</td>
</tr>
<tr>
<td>±n&lt;cr&gt;</td>
<td>move and type (±nLT)</td>
</tr>
</tbody>
</table>
Appendix A: ED 1.4 Enhancements

The ED context editor contains a number of commands which enhance its usefulness in text editing. The improvements are found in the addition of line numbers, free space interrogation, and improved error reporting.

The context editor issued with CP/M 1.4 produces absolute line number prefixes when the "V" (Verify Line Numbers) command is issued. Following the V command, the line number is displayed ahead of each line in the format:

nnnnn:

where nnnnn is an absolute line number in the range 1 to 65535. If the memory buffer is empty, or if the current line is at the end of the memory buffer, then nnnnn appears as 5 blanks.

The user may reference an absolute line number by preceding any command by a number followed by a colon, in the same format as the line number display. In this case, the ED program moves the current line reference to the absolute line number, if the line exists in the current memory buffer. Thus, the command

345:T

is interpreted as "move to absolute line 345, and type the line." Note that absolute line numbers are produced only during the editing process, and are not recorded with the file. In particular, the line numbers will change following a deleted or expanded section of text.

The user may also reference an absolute line number as a backward or forward distance from the current line by preceding the absolute line number by a colon. Thus, the command

:400T

is interpreted as "type from the current line number through the line whose absolute number is 400." Combining the two line reference forms, the command

345::400T

for example, is interpreted as "move to absolute line 345, then type through absolute line 400." Note that absolute line references of this sort can precede any of the standard ED commands.

A special case of the V command, "0V", prints the memory buffer statistics in the form:

free/total

where "free" is the number of free bytes in the memory buffer (in decimal), and "total" is the size of the memory buffer.
ED 1.4 also includes a "block move" facility implemented through the "X" (Xfer) command. The form

\[ nX \]

transfers the next \( n \) lines from the current line to a temporary file called

\[ X$$$$$$$.LIB \]

which is active only during the editing process. In general, the user can reposition the current line reference to any portion of the source file and transfer lines to the temporary file. The transferred line accumulate one after another in this file, and can be retrieved by simply typing:

\[ R \]

which is the trivial case of the library read command. In this case, the entire transferred set of lines is read into the memory buffer. Note that the X command does not remove the transferred lines from the memory buffer, although a K command can be used directly after the X, and the R command does not empty the transferred line file. That is, given that a set of lines has been transferred with the X command, they can be re-read any number of times back into the source file. The command

\[ \theta X \]

is provided, however, to empty the transferred line file.

Note that upon normal completion of the ED program through Q or E, the temporary LIB file is removed. If ED is aborted through ctl-C, the LIB file will exist if lines have been transferred, but will generally be empty (a subsequent ED invocation will erase the temporary file).

Due to common typographical errors, ED 1.4 requires several potentially disastrous commands to be typed as single letters, rather than in composite commands. The commands

\[ \text{E (end), H (head), O (original), Q (quit)} \]

must be typed as single letter commands.

ED 1.4 also prints error messages in the form

\[ \text{BREAK "x" AT c} \]

where \( x \) is the error character, and \( c \) is the command where the error occurred.

1. AN OVERVIEW OF CP/M 2.0 FACILITIES.

CP/M 2.0 is a high-performance single-console operating system which uses table driven techniques to allow field reconfiguration to match a wide variety of disk capacities. All of the fundamental file restrictions are removed, while maintaining upward compatibility from previous versions of release 1. Features of CP/M 2.0 include field specification of one to sixteen logical drives, each containing up to eight megabytes. Any particular file can reach the full drive size with the capability to expand to thirty-two megabytes in future releases. The directory size can be field configured to contain any reasonable number of entries, and each file is optionally tagged with read/only and system attributes. Users of CP/M 2.0 are physically separated by user numbers, with facilities for file copy operations from one user area to another. Powerful relative-record random access functions are present in CP/M 2.0 which provide direct access to any of the 65536 records of an eight megabyte file.

All disk-dependent portions of CP/M 2.0 are placed into a BIOS-resident "disk parameter block" which is either hand coded or produced automatically using the disk definition macro library provided with CP/M 2.0. The end user need only specify the maximum number of active disks, the starting and ending sector numbers, the data allocation size, the maximum extent of the logical disk, directory size information, and reserved track values. The macros use this information to generate the appropriate tables and table references for use during CP/M 2.0 operation. Deblocking information is also provided which aids in assembly or disassembly of sector sizes which are multiples of the fundamental 128 byte data unit, and the system. alteration manual includes general-purpose subroutines which use the this deblocking information to take advantage of larger sector sizes. Use of these subroutines, together with the table driven data access algorithms, make CP/M 2.0 truly a universal data management system.

File expansion is achieved by providing up to 512 logical file extents, where each logical extent contains 16K bytes of data. CP/M 2.0 is structured, however, so that as much as 128K bytes of data is addressed by a single physical extent (corresponding to a single directory entry), thus maintaining compatibility with previous versions while taking full advantage of directory space.

Random access facilities are present in CP/M 2.0 which allow immediate reference to any record of an eight megabyte file. Using CP/M's unique data organization, data blocks are only allocated when actually required and movement to a record position requires little search time. Sequential file access is upward compatible from earlier versions to the full eight megabytes, while random access compatibility stops at 512K byte files. Due to CP/M 2.0's simpler and faster random access, application programmers are encouraged to alter their programs to take full advantage of the 2.0 facilities.

Several CP/M 2.0 modules and utilities have improvements which correspond to the enhanced file system. STAT and PIP both account for file attributes and user areas, while the CCP provides a "login"

(All Information Contained Herein is Proprietary to Digital Research.)
function to change from one user area to another. The CCP also formats directory displays in a more convenient manner and accounts for both CRT and hard-copy devices in its enhanced line editing functions.

The sections below point out the individual differences between CP/M 1.4 and CP/M 2.0, with the understanding that the reader is either familiar with CP/M 1.4, or has access to the 1.4 manuals. Additional information dealing with CP/M 2.0 I/O system alteration is presented in the Digital Research manual "CP/M 2.0 Alteration Guide."

(All Information Contained Herein is Proprietary to Digital Research.)
2. USER INTERFACE.

Console line processing takes CRT-type devices into account with three new control characters, shown with an asterisk in the list below (the symbol "ctl" below indicates that the control key is simultaneously depressed):

rub/del removes and echoes last character
ctl-C reboot when at beginning of line
ctl-E physical end of line
ctl-H backspace one character position*
ctl-J (line feed) terminates current input*
ctl-M (carriage return) terminates input
ctl-R retype current line after new line
ctl-U remove current line after new line
ctl-X backspace to beginning of current line*

In particular, note that ctl-H produces the proper backspace overwrite function (ctl-H can be changed internally to another character, such as delete, through a simple single byte change). Further, the line editor keeps track of the current prompt column position so that the operator can properly align data input following a ctl-U, ctl-R, or ctl-X command.

(All Information Contained Herein is Proprietary to Digital Research.)
3. CONSOLE COMMAND PROCESSOR (CCP) INTERFACE.

There are four functional differences between CP/M 1.4 and CP/M 2.0 at the console command processor (CCP) level. The CCP now displays directory information across the screen (four elements per line), the USER command is present to allow maintenance of separate files in the same directory, and the actions of the "ERA *.*" and "SAVE" commands have changed. The altered DIR format is self-explanatory, while the USER command takes the form:

```
USER n
```

where n is an integer value in the range 0 to 15. Upon cold start, the operator is automatically "logged" into user area number 0, which is compatible with standard CP/M 1.4 directories. The operator may issue the USER command at any time to move to another logical area within the same directory. Drives which are logged-in while addressing one user number are automatically active when the operator moves to another user number since a user number is simply a prefix which accesses particular directory entries on the active disks.

The active user number is maintained until changed by a subsequent USER command, or until a cold start operation when user 0 is again assumed.

Due to the fact that user numbers now tag individual directory entries, the ERA *.* command has a different effect. In version 1.4, this command can be used to erase a directory which has "garbage" information, perhaps resulting from use of a diskette under another operating system (heaven forbid!). In 2.0, however, the ERA *.* command affects only the current user number. Thus, it is necessary to write a simple utility to erase a nonsense disk (the program simply writes the hexadecimal pattern E5 throughout the disk).

The SAVE command in version 1.4 allows only a single memory save operation, with the potential of destroying the memory image due to directory operations following extent boundary changes. Version 2.0, however, does not perform directory operations in user data areas after disk writes, and thus the SAVE operation can be used any number of times without altering the memory image.

(All Information Contained Herein is Proprietary to Digital Research.)
4. STAT ENHANCEMENTS.

The STAT program has a number of additional functions which allow disk parameter display, user number display, and file indicator manipulation. The command:

```
STAT VAL:
```

produces a summary of the available status commands, resulting in the output:

```
Temp R/O Disk: d:=R/O
Set Indicatar: d:filename.type $R/O $R/W $SYS $DIR
Disk Status : DSK: d:DSK:
User Status : USR:
Iobyte Assign:
(list of possible assignments)
```

which gives an instant summary of the possible STAT commands. The command form:

```
STAT d:filename.type $S
```

where "d:" is an optional drive name, and "filename.type" is an unambiguous or ambiguous file name, produces the output display format:

```
<table>
<thead>
<tr>
<th>Size</th>
<th>Recs</th>
<th>Bytes</th>
<th>Ext</th>
<th>Acc</th>
</tr>
</thead>
<tbody>
<tr>
<td>48</td>
<td>48</td>
<td>6k</td>
<td>1</td>
<td>R/O</td>
</tr>
<tr>
<td>55</td>
<td>55</td>
<td>12k</td>
<td>1</td>
<td>R/O</td>
</tr>
<tr>
<td>65536</td>
<td>128</td>
<td>2k</td>
<td>2</td>
<td>R/W</td>
</tr>
</tbody>
</table>
```

where the $S parameter causes the "Size" field to be displayed (without the $S, the Size field is skipped, but the remaining fields are displayed). The Size field lists the virtual file size in records, while the "Recs" field sums the number of virtual records in each extent. For files constructed sequentially, the Size and Recs fields are identical. The "Bytes" field lists the actual number of bytes allocated to the corresponding file. The minimum allocation unit is determined at configuration time, and thus the number of bytes corresponds to the record count plus the remaining unused space in the last allocated block for sequential files. Random access files are given data areas only when written, so the Bytes field contains the only accurate allocation figure. In the case of random access, the Size field gives the logical end-of-file record position and the Recs field counts the logical records of each extent (each of these extents, however, may contain unallocated "holes" even though they are added into the record count). The "Ext" field counts the number of logical 16K extents allocated to the file. Unlike version 1.4, the Ext count does not necessarily correspond to the number of directory entries given to the file, since there can be up to 128K bytes (8 logical extents) directly addressed by a single directory entry, depending upon allocation size (in a special case, there are actually 256K bytes which can be directly addressed by a physical extent).

The "Acc" field gives the R/O or R/W access mode, which is changed using the commands shown below. Similarly, the parentheses

(All Information Contained Herein is Proprietary to Digital Research.)
shown around the PIP.COM file name indicate that it has the "system" indicator set, so that it will not be listed in DIR commands. The four command forms

```plaintext
STAT d:filename.typ $R/O
STAT d:filename.typ $R/W
STAT d:filename.typ $SYS
STAT d:filename.typ $DIR
```

set or reset various permanent file indicators. The R/O indicator places the file (or set of files) in a read-only status until changed by a subsequent STAT command. The R/O status is recorded in the directory with the file so that it remains R/O through intervening cold start operations. The R/W indicator places the file in a permanent read/write status. The SYS indicator attaches the system indicator to the file, while the DIR command removes the system indicator. The "filename.typ" may be ambiguous or unambiguous, but in either case, the files whose attributes are changed are listed at the console when the change occurs. The drive name denoted by "d:" is optional.

When a file is marked R/O, subsequent attempts to erase or write into the file result in a terminal BDOS message

```plaintext
BDos Err on d: File R/O
```

The BDOS then waits for a console input before performing a subsequent warm start (a "return" is sufficient to continue). The command form

```plaintext
STAT d:DSK:
```

lists the drive characteristics of the disk named by "d:" which is in the range A:, B:, ..., P:. The drive characteristics are listed in the format:

```plaintext
d: Drive Characteristics
65536: 128 Byte record Capacity
8192: Kilobyte Drive Capacity
128: 32 Byte Directory Entries
0: Checked Directory Entries
1024: Records/ Extent
128: Records/ Block
58: Sectors/ Track
2: Reserved Tracks
```

where "d:" is the selected drive, followed by the total record capacity (65536 is an 8 megabyte drive), followed by the total capacity listed in Kilobytes. The directory size is listed next, followed by the "checked" entries. The number of checked entries is usually identical to the directory size for removable media, since this mechanism is used to detect changed media during CP/M operation without an intervening warm start. For fixed media, the number is usually zero, since the media is not changed without at least a cold or warm start. The number of records per extent determines the addressing capacity of each directory entry (1024 times 128 bytes, or

(All Information Contained Herein is Proprietary to Digital Research.)
128K in the example above). The number of records per block shows the basic allocation size (in the example, 128 records/block times 128 bytes per record, or 16K bytes per block). The listing is then followed by the number of physical sectors per track and the number of reserved tracks. For logical drives which share the same physical disk, the number of reserved tracks may be quite large, since this mechanism is used to skip lower-numbered disk areas allocated to other logical disks. The command form

```
STAT DSK:
```

produces a drive characteristics table for all currently active drives. The final STAT command form is

```
STAT USR:
```

which produces a list of the user numbers which have files on the currently addressed disk. The display format is:

```
Active User: 0
Active Files: 0 1 3
```

where the first line lists the currently addressed user number, as set by the last CCP USER command, followed by a list of user numbers scanned from the current directory. In the above case, the active user number is 0 (default at cold start), with three user numbers which have active files on the current disk. The operator can subsequently examine the directories of the other user numbers by logging-in with USER 1, USER 2, or USER 3 commands, followed by a DIR command at the CCP level.

(All Information Contained Herein is Proprietary to Digital Research.)
5. PIP ENHANCEMENTS.

PIP provides three new functions which account for the features of CP/M 2.0. All three functions take the form of file parameters which are enclosed in square brackets following the appropriate file names. The commands are:

- **Gn** Get File from User number n (n in the range 0 - 15)
- **W** Write over R/O files without console interrogation
- **R** Read system files

The G command allows one user area to receive data files from another. Assuming the operator has issued the USER 4 command at the CCP level, the PIP statement

```
PIP X.Y = X.Y[G2]
```

reads file X.Y from user number 2 into user area number 4. The command

```
PIP A:=A:*.*[G2]
```

copies all of the files from the A drive directory for user number 2 into the A drive directory of the currently logged user number. Note that to ensure file security, one cannot copy files into a different area than the one which is currently addressed by the USER command.

Note also that the PIP program itself is initially copied to a user area (so that subsequent files can be copied) using the SAVE command. The sequence of operations shown below effectively moves PIP from one user area to the next.

```
USER 0           login user 0
DDT PIP.COM      load PIP to memory
(note PIP size s)
G0                return to CCP
USER 3           login user 3
SAVE s PIP.COM
```

where s is the integral number of memory "pages" (256 byte segments) occupied by PIP. The number s can be determined when PIP.COM is loaded under DDT, by referring to the value under the "NEXT" display. If for example, the next available address is 1000, then PIP.COM requires 1C hexadecimal pages (or 1 times 16 + 12 = 28 pages), and thus the value of s is 28 in the subsequent save. Once PIP is copied in this manner, it can then be copied to another disk belonging to the same user number through normal pip transfers.

Under normal operation, PIP will not overwrite a file which is set to a permanent R/O status. If attempt is made to overwrite a R/O file, the prompt

(All Information Contained Herein is Proprietary to Digital Research.)
DESTINATION FILE IS R/O, DELETE (Y/N)?

is issued. If the operator responds with the character "y" then the file is overwritten. Otherwise, the response

** NOT DELETED **

is issued, the file transfer is skipped, and PIP continues with the next operation in sequence. In order to avoid the prompt and response in the case of R/O file overwrite, the command line can include the \( W \) parameter, as shown below.

\[
P\text{IP } A:=B:*\text{.COM}[W]
\]

which copies all non-system files to the A drive from the B drive, and overwrites any R/O files in the process. If the operation involves several concatenated files, the \( W \) parameter need only be included with the last file in the list, as shown in the following example.

\[
P\text{IP A.DAT } B.DAT,F:NEW.DAT,G:OLD.DAT[W]
\]

Files with the system attribute can be included in PIP transfers if the \( R \) parameter is included, otherwise system files are not recognized. The command line

\[
P\text{IP ED.COM } B:ED.COM[R]
\]

for example, reads the ED.COM file from the B drive, even if it has been marked as a R/O and system file. The system file attributes are copied, if present.

It should be noted that downward compatibility with previous versions of CP/M is only maintained if the file does not exceed one megabyte, no file attributes are set, and the file is created by user 0. If compatibility is required with non-standard (e.g., "double density") versions of 1.4, it may be necessary to select 1.4 compatibility mode when constructing the internal disk parameter block (see the "CP/M 2.0 Alteration Guide," and refer to Section 10 which describes BIOS differences).

(All Information Contained Herein is Proprietary to Digital Research.)
6. ED ENHANCEMENTS.

The CP/M standard program editor provides several new facilities in the 2.0 release. Experience has shown that most operators use the relative line numbering feature of ED, and thus the editor has the "v" (Verify Line) option set as an initial value. The operator can, of course, disable line numbering by typing the "-v" command. If you are not familiar with the ED line number mode, you may wish to refer to the Appendix in the ED user's guide, where the "v" command is described.

ED also takes file attributes into account. If the operator attempts to edit a read/only file, the message

** FILE IS READ/ONLY **

appears at the console. The file can be loaded and examined, but cannot be altered in any way. Normally, the operator simply ends the edit session, and uses STAT to change the file attribute to R/W. If the edited file has the "system" attribute set, the message

"SYSTEM" FILE NOT ACCESSIBLE

is displayed at the console, and the edit session is aborted. Again, the STAT program can be used to change the system attribute, if desired.

Finally, the insert mode ("i") command allows CRT line editing functions, as described in Section 2, above.
7. THE XSUB FUNCTION.

An additional utility program is supplied with version 2.0 of CP/M, called XSUB, which extends the power of the SUBMIT facility to include line input to programs as well as the console command processor. The XSUB command is included as the first line of your submit file and, when executed, self-relocates directly below the CCP. All subsequent submit command lines are processed by XSUB, so that programs which read buffered console input (BDOS function 10) receive their input directly from the submit file. For example, the file SAVER.SUB could contain the submit lines:

```
XSUB
DDT
I$1.HEX
R
G0
SAVE 1 $2.COM
```

with a subsequent SUBMIT command:

```SUBMIT SAVER X Y```

which substitutes X for $1 and Y for $2 in the command stream. The XSUB program loads, followed by DDT which is sent the command lines "IX.HEX" "R" and "G0" thus returning to the CCP. The final command "SAVE 1 Y.COM" is processed by the CCP.

The XSUB program remains in memory, and prints the message

(xsub active)

on each warm start operation to indicate its presence. Subsequent submit command streams do not require the XSUB, unless an intervening cold start has occurred. Note that XSUB must be loaded after DESPOOL, if both are to run simultaneously.

(All Information Contained Herein is Proprietary to Digital Research.)

11
8. BDOS INTERFACE CONVENTIONS.

CP/M 2.0 system calls take place in exactly the same manner as earlier versions, with a call to location 0005H, function number in register C, and information address in register pair DE. Single byte values are returned in register A, with double byte values returned in HL (for reasons of compatibility, register A = L and register B = H upon return in all cases). A list of CP/M 2.0 calls is given below, with an asterisk following functions which are either new or revised from version 1.4 to 2.0. Note that a zero value is returned for out-of-range function numbers.

</table>

(Functions 28, 29, and 32 should be avoided in application programs to maintain upward compatibility with MP/M.) The new or revised functions are described below.

**Function 6: Direct Console I/O.**

Direct Console I/O is supported under CP/M 2.0 for those applications where it is necessary to avoid the BDOS console I/O operations. Programs which currently perform direct I/O through the BIOS should be changed to use direct I/O under BDOS so that they can be fully supported under future releases of MP/M and CP/M.

Upon entry to function 6, register E either contains hexadecimal FF, denoting a console input request, or register E contains an ASCII character. If the input value is FF, then function 6 returns A = 00 if no character is ready, otherwise A contains the next console input character.

If the input value in E is not FF, then function 6 assumes that E contains a valid ASCII character which is sent to the console.

(All Information Contained Herein is Proprietary to Digital Research.)
Function 10: Read Console Buffer.

The console buffer read operation remains unchanged except that console line editing is supported, as described in Section 2. Note also that certain functions which return the carriage to the leftmost position (e.g., ctl-X) do so only to the column position where the prompt ended (previously, the carriage returned to the extreme left margin). This new convention makes operator data input and line correction more legible.

Function 12: Return Version Number.

Function 12 has been redefined to provide information which allows version-independent programming (this was previously the "lift head" function which returned HL=0000 in version 1.4, but performed no operation). The value returned by function 12 is a two-byte value, with H = 00 for the CP/M release (H = 01 for MP/M), and L = 00 for all releases previous to 2.0. CP/M 2.0 returns a hexadecimal 20 in register L, with subsequent version 2 releases in the hexadecimal range 21, 22, through 2F. Using function 12, for example, you can write application programs which provide both sequential and random access functions, with random access disabled when operating under early releases of CP/M.

In the file operations described below, DE addresses a file control block (FCB). Further, all directory operations take place in a reserved area which does not affect write buffers as was the case in version 1.4, with the exception of Search First and Search Next, where compatibility is required.

The File Control Block (FCB) data area consists of a sequence of 33 bytes for sequential access, and a series of 36 bytes in the case that the file is accessed randomly. The default file control block normally located at 005CH can be used for random access files, since bytes 007DH, 007EH, and 007FH are available for this purpose. For notational purposes, the FCB format is shown with the following fields:

(All Information Contained Herein is Proprietary to Digital Research.)
where

\[ \text{dr} \] drive code \((0 - 16)\)
\[ 0 \Rightarrow \text{use default drive for file} \]
\[ 1 \Rightarrow \text{auto disk select drive A,} \]
\[ 2 \Rightarrow \text{auto disk select drive B,} \]
\[ \ldots \]
\[ 16\Rightarrow \text{auto disk select drive P.} \]

\[ \text{f1...f8} \] contain the file name in ASCII upper case, with high 'bit = 0

\[ t1,t2,t3 \] contain the file type in ASCII upper case, with high bit = 0
\[ t1', t2', \] and \( t3' \) denote the bit of these positions,
\[ t1' = 1 \Rightarrow \text{Read/Only file,} \]
\[ t2' = 1 \Rightarrow \text{SYS file, no DIR list} \]

\[ \text{ex} \] contains the current extent number, normally set to 00 by the user, but in range 0 - 31 during file I/O

\[ s1 \] reserved for internal system use

\[ s2 \] reserved for internal system use, set to zero on call to OPEN, MAKE, SEARCH

\[ \text{rc} \] record count for extent "ex,"
takes on values from 0 - 128

\[ d0...dn \] filled-in by CP/M, reserved for system use

\[ \text{cr} \] current record to read or write in a sequential file operation, normally set to zero by user

\[ r0,r1,r2 \] optional random record number in the range 0-65535, with overflow to r2,
\[ r0,r1 \] constitute a 16-bit value with low byte \( r0 \), and high byte \( r1 \)

Function 15: Open File.

The Open File operation is identical to previous definitions, with the exception that byte \( s2 \) is automatically zeroed. Note that previous versions of CP/M defined this byte as zero, but made no

(All Information Contained Herein is Proprietary to Digital Research.)
checks to assure compliance. Thus, the byte is cleared to ensure upward compatibility with the latest version, where it is required.

Function 17: Search for First.

Search First scans the directory for a match with the file given by the FCB addressed by DE. The value 255 (hexadecimal FF) is returned if the file is not found, otherwise a value of A equal to 0, 1, 2, or 3 is returned indicating the file is present. In the case that the file is found, the current DMA address is filled with the record containing the directory entry, and the relative starting position is \( A \times 32 \) (i.e., rotate the A register left 5 bits, or ADD A five times). Although not normally required for application programs, the directory information can be extracted from the buffer at this position.

An ASCII question mark (63 decimal, 3F hexadecimal) in any position from fl through ex matches the corresponding field of any directory entry on the default or auto-selected disk drive. If the dr field contains an ASCII question mark, then the auto disk select function is disabled, the default disk is searched, with the search function returning any matched entry, allocated or free, belonging to any user number. This latter function is not normally used by application programs, but does allow complete flexibility to scan all current directory values. If the dr field is not a question mark, the s2 byte is automatically zeroed.

Function 18: Search for Next.

The Search Next function is similar to the Search First function, except that the directory scan continues from the last matched entry. Similar to function 17, function 18 returns the decimal value 255 in A when no more directory items match.

Function 19: Delete File.

The Delete File function removes files which match the FCB addressed by DE. The filename and type may contain ambiguous references (i.e., question marks in various positions), but the drive select code cannot be ambiguous, as in the Search and Search Next functions.

Function 19 returns a decimal 255 if the reference file or files could not be found, otherwise a value in the range 0 to 3 is returned.

(All Information Contained Herein is Proprietary to Digital Research.)
Function 22: Make File.

The Make File operation is identical to previous versions of CP/M, except that byte s2 is zeroed upon entry to the BDOS.

Function 23: Rename File.

The actions of the file rename functions are the same as previous releases except that the value 255 is returned if the rename function is unsuccessful (the file to rename could not be found), otherwise a value in the range 0 to 3 is returned.

Function 24: Return Login Vector.

The login vector value returned by CP/M 2.0 is a 16-bit value in HL, where the least significant bit of L corresponds to the first drive A, and the high order bit of H corresponds to the sixteenth drive, labelled P. Note that compatibility is maintained with earlier releases, since registers A and L contain the same values upon return.

Function 28: Write Protect Current Disk.

The disk write protect function provides temporary write protection for the currently selected disk. Any attempt to write to the disk, before the next cold or warm start operation produces the message

Bdos Err on d: R/O

Function 29: Get R/O Vector.

Function 29 returns a bit vector in register pair HL which indicates drives which have the temporary read-only bit set. Similar to function 24, the least significant bit corresponds to drive A, while the most significant bit corresponds to drive P. The R/O bit is set either by an explicit call to function 28, or by the automatic software mechanisms within CP/M which detect changed disks.

Function 30: Set File Attributes.

The Set File Attributes function allows programmatic manipulation of permanent indicators attached to files. In particular, the R/O and System attributes (t1' and t2' above) can be set or reset. The DE pair addresses an unambiguous file name with the appropriate attributes set or reset. Function 30 searches for a

(All Information Contained Herein is Proprietary to Digital Research.)
match, and changes the matched directory entry to contain the selected indicators. Indicators fl' through f4' are not presently used, but may be useful for applications programs, since they are not involved in the matching process during file open and close operations. Indicators f5' through f8' and t3' are reserved for future system expansion.

Function 31: Get Disk Parameter Block Address.

The address of the BIOS resident disk parameter block is returned in HL as a result of this function call. This address can be used for either of two purposes. First, the disk parameter values can be extracted for display and space computation purposes, or transient programs can dynamically change the values of current disk parameters when the disk environment changes, if required. Normally, application programs will not require this facility.

Function 32: Set or Get User Code.

An application program can change or interrogate the currently active user number by calling function 32. If register E = FF hexadecimal, then the value of the current user number is returned in register A, where the value is in the range 0 to 31. If register E is not FF, then the current user number is changed to the value of E (modulo 32).

Function 33: Read Random.

The Read Random function is similar to the sequential file read operation of previous releases, except that the read operation takes place at a particular record number, selected by the 24-bit value constructed from the three byte field following the FCB (byte positions r0 at 33, r1 at 34, and r2 at 35). Note that the sequence of 24 bits is stored with least significant byte first (r0), middle byte next (r1), and high byte last (r2). CP/M release 2.0 does not reference byte r2, except in computing the size of a file (function 35). Byte r2 must be zero, however, since a non-zero value indicates overflow past the end of file.

Thus, in version 2.0, the r0,r1 byte pair is treated as a double-byte, or "word" value, which contains the record to read. This value ranges from 0 to 65535, providing access to any particular record of the 8 megabyte file. In order to process a file using random access, the base extent (extent 0) must first be opened. Although the base extent may or may not contain any allocated data, this ensures that the file is properly recorded in the directory, and is visible in DIR requests. The selected record number is then stored into the random record field (r0,r1), and the BDOS is called to read the record. Upon return from the call, register A either contains an

(All Information Contained Herein is Proprietary to Digital Research.)
error code, as listed below, or the value 00 indicating the operation was successful. In the latter case, the current DMA address contains the randomly accessed record. Note that contrary to the sequential read operation, the record number is not advanced. Thus, subsequent random read operations continue to read the same record.

Upon each random read operation, the logical extent and current record values are automatically set. Thus, the file can be sequentially read or written, starting from the current randomly accessed position. Note, however, that in this case, the last randomly read record will be re-read as you switch from random mode to sequential read, and the last record will be re-written as you switch to a sequential write operation. You can, of course, simply advance the random record position following each random read or write to obtain the effect of a sequential I/O operation.

Error codes returned in register A following a random read are listed below.

01 reading unwritten data
02 (not returned in random mode)
03 cannot close current extent
04 seek to unwritten extent
05 (not returned in read mode)
06 seek past physical end of disk

Error code 01 and 04 occur when a random read operation accesses a data block which has not been previously written, or an extent which has not been created, which are equivalent conditions. Error 3 does not normally occur under proper system operation, but can be cleared by simply re-reading, or re-opening extent zero as long as the disk is not physically write protected. Error code 06 occurs whenever byte r2 is non-zero under the current 2.0 release. Normally, non-zero return codes can be treated as missing data, with zero return codes indicating operation complete.

Function 34: Write Random.

The Write Random operation is initiated similar to the Read Random call, except that data is written to the disk from the current DMA address. Further, if the disk extent or data block which is the target of the write has not yet been allocated, the allocation is performed before the write operation continues. As in the Read Random operation, the random record number is not changed as a result of the write. The logical extent number and current record positions of the file control block are set to correspond to the random record which is being written. Again, sequential read or write operations can commence following a random write, with the notation that the currently addressed record is either read or rewritten again as the sequential operation begins. You can also simply advance the random record position following each write to get the effect of a sequential write operation. Note that in particular, reading or writing the last record of an extent in random mode does not cause an automatic extent

(All Information Contained Herein is Proprietary to Digital Research.)
switch as it does in sequential mode under either CP/M 1.4 or CP/M 2.0.

The error codes returned by a random write are identical to the random read operation with the addition of error code 05, which indicates that a new extent cannot be created due to directory overflow.

Function 35: Compute File Size.

When computing the size of a file, the DE register pair addresses an FCB in random mode format (bytes r0, r1, and r2 are present). The FCB contains an unambiguous file name which is used in the directory scan. Upon return, the random record bytes contain the "virtual" file size which is, in effect, the record address of the record following the end of the file. If, following a call to function 35, the high record byte r2 is 01, then the file contains the maximum record count 65536 in version 2.0. Otherwise, bytes r0 and r1 constitute a 16-bit value (r0 is the least significant byte, as before) which is the file size.

Data can be appended to the end of an existing file by simply calling function 35 to set the random record position to the end of file, then performing a sequence of random writes starting at the preset record address.

The virtual size of a file corresponds to the physical size when the file is written sequentially. If, instead, the file was created in random mode and "holes" exist in the allocation, then the file may in fact contain fewer records than the size indicates. If, for example, only the last record of an eight megabyte file is written in random mode (i.e., record number 65535), then the virtual size is 65536 records, although only one block of data is actually allocated.

Function 36: Set Random Record.

The Set Random Record function causes the BDOS to automatically produce the random record position from a file which has been read or written sequentially to a particular point. The function can be useful in two ways.

First, it is often necessary to initially read and scan a sequential file to extract the positions of various "key" fields. As each key is encountered, function 36 is called to compute the random record position for the data corresponding to this key. If the data unit size is 128 bytes, the resulting record position is placed into a table with the key for later retrieval. After scanning the entire file and tabularizing the keys and their record numbers, you can move instantly to a particular keyed record by performing a random read using the corresponding random record number which was saved earlier. The scheme is easily generalized when variable record lengths are

(All Information Contained Herein is Proprietary to Digital Research.)
involved since the program need only store the buffer-relative byte position along with the key and record number in order to find the exact starting position of the keyed data at a later time.

A second use of function 36 occurs when switching from a sequential read or write over to random read or write. A file is sequentially accessed to a particular point in the file, function 36 is called which sets the record number, and subsequent random read and write operations continue from the selected point in the file.

This section is concluded with a rather extensive, but complete example of random access operation. The program listed below performs the simple function of reading or writing random records upon command from the terminal. Given that the program has been created, assembled, and placed into a file labelled RANDOM.COM, the CCP level command:

```
RANDOM X.DAT
```

starts the test program. The program looks for a file by the name X.DAT (in this particular case) and, if found, proceeds to prompt the console for input. If not found, the file is created before the prompt is given. Each prompt takes the form

```
next command?
```

and is followed by operator input, terminated by a carriage return. The input commands take the form

```
nW   nR   Q
```

where n is an integer value in the range 0 to 65535, and W, R, and Q are simple command characters corresponding to random write, random read, and quit processing, respectively. If the W command is issued, the RANDOM program issues the prompt

```
type data:
```

The operator then responds by typing up to 127 characters, followed by a carriage return. RANDOM then writes the character string into the X.DAT file at record n. If the R command is issued, RANDOM reads record number n and displays the string value at the console. If the Q command is issued, the X.DAT file is closed, and the program returns to the console command processor. In the interest of brevity (ok, so the program's not so brief), the only error message is

```
error, try again
```

The program begins with an initialization section where the input file is opened or created, followed by a continuous loop at the label "ready" where the individual commands are interpreted. The default file control block at 005CH and the default buffer at 0080H are used in all disk operations. The utility subroutines then follow,

(All Information Contained Herein is Proprietary to Digital Research.)
which contain the principal input line processor, called "readc." This particular program shows the elements of random access processing, and can be used as the basis for further program development.

9. CP/M 2.0 MEMORY ORGANIZATION.

Similar to earlier versions, CP/M 2.0 is field-altered to fit various memory sizes, depending upon the host computer memory configuration. Typical base addresses for popular memory sizes are shown in the table below.

The distribution disk contains a CP/M 2.0 system configured for a 20k Intel MDS-800 with standard IBM 8" floppy disk drives. The disk layout is shown below:

In particular, note that the CCP is at the same position on the disk, and occupies the same space as version 1.4. The BDOS portion, however, occupies one more 256-byte page and the BIOS portion extends through the remainder of track 01. Thus, the CCP is 800H (2048 decimal) bytes in length, the BDOS is E00H (3584 decimal) bytes in length, and the BIOS is up to 380H (898 decimal) bytes in length. In version 2.0, the BIOS portion contains the standard subroutines of 1.4, along with some initialized table space, as described in the following section.

(All Information Contained Herein is Proprietary to Digital Research.)
10. BIOS DIFFERENCES.

The CP/M 2.0 Basic I/O System differs only slightly in concept from its predecessors. Two new jump vector entry points are defined, a new sector translation subroutine is included, and a disk characteristics table must be defined. The skeletal form of these changes are found in the program shown below.

```
1:   org 4000h
2:   maciop diskdef
3:   jmp boot
4:   ...
5:   jmp listst ;list status
6:   jmp sectran ;sector translate
7:   disks 4
8:   large capacity drive
9:   bpb equ 16*1024 ;bytes per block
10:  rpbl equ bpb/128 ;records per block
11:  maxb equ 65535/rpob ;max block number
12:  diskdef 0,1,58,3,bpb,maxb+1,128,0,2
13:  diskdef 1,1,58,bpb,maxb+1,128,0,2
14:  diskdef 2,0
15:  diskde 3,1
16:   ...

```

(All Information Contained Herein is Proprietary to Digital Research.)
Referring to the program shown above, lines 3-6 represent the BIOS entry vector of 17 elements (version 1.4 defines only 15 jump vector elements). The last two elements provide access to the "LISTST" (List Status) entry point for DESPOOL. The use of this particular entry point is defined in the DESPOOL documentation, and is no different than the previous 1.4 release. It should be noted that the 1.4 DESPOOL program will not operate under version 2.0, but an update version will be available from Digital Research in the near future.

The "SECTRAN" (Sector Number Translate) entry shown in the jump vector at line 6 provides access to a BIOS-resident sector translation subroutine. This mechanism allows the user to specify the sector skew factor and translation for a particular disk system, and is described below.

A macro library is shown in the listing, called DISKDEF, included on line 2, and referenced in 12-15. Although it is not necessary to use the macro library, it greatly simplifies the disk definition process. You must have access to the MAC macro assembler, of course, to use the DISKDEF facility, while the macro library is included with all CP/M 2.0 distribution disks. (See the CP/M 2.0 Alteration Guide for formulas which you can use to hand-code the tables produced by the DISKDEF library).

A BIOS disk definition consists of the following sequence of macro statements:

```
MACLIB DISKDEF

......
DISKS n
DISKDEF 0,...
DISKDEF 1,...
......
DISKDEF n-1
......
ENDEF
```

where the MACLIB statement loads the DISKDEF.LIB file (on the same disk as your BIOS) into MAC's internal tables. The DISKS macro call follows, which specifies the number of drives to be configured with your system, where n is an integer in the range 1 to 16. A series of DISKDEF macro calls then follow which define the characteristics of each logical disk, 0 through n-1 (corresponding to logical drives A through P). Note that the DISKS and DISKDEF macros generate in-line
fixed data tables, and thus must be placed in a non-executable portion of your BIOS, typically directly following the BIOS jump vector.

The remaining portion of your BIOS is defined following the DISKDEF macros, with the ENDEF macro call immediately preceding the END statement. The ENDEF (End of Diskdef) macro generates the necessary uninitialized RAM areas which are located above your BIOS.

The form of the DISKDEF macro call is

\[
\text{DISKDEF } dn, fsc, lsc, [skf], bls, dks, dir, cks, ofs, [0]
\]

where

- \(dn\) is the logical disk number, 0 to n-1
- \(fsc\) is the first physical sector number (0 or 1)
- \(lsc\) is the last sector number
- \(skf\) is the optional sector skew factor
- \(bls\) is the data allocation block size
- \(dir\) is the number of directory entries
- \(cks\) is the number of "checked" directory entries
- \(ofs\) is the track offset to logical track 00
- \([0]\) is an optional 1.4 compatibility flag

The value "dn" is the drive number being defined with this DISKDEF macro invocation. The "fsc" parameter accounts for differing sector numbering systems, and is usually 0 or 1. The "lsc" is the last numbered sector on a track. When present, the "skf" parameter defines the sector skew factor which is used to create a sector translation table according to the skew. If the number of sectors is less than 256, a single-byte table is created, otherwise each translation table element occupies two bytes. No translation table is created if the skf parameter is omitted (or equal to 0). The "bls" parameter specifies the number of bytes allocated to each data block, and takes on the values 1024, 2048, 4096, 8192, or 16384. Generally, performance increases with larger data block sizes since there are fewer directory references and logically connected data records are physically close on the disk. Further, each directory entry addresses more data and the BIOS-residentram space is reduced. The "dks" specifies the total disk size in "bls" units. That is, if the bls = 2048 and dks = 1000, then the total disk capacity is 2,048,000 bytes. If dks is greater than 255, then the block size parameter bls must be greater than 1024. The value of "dir" is the total number of directory entries which may exceed 255, if desired. The "cks" parameter determines the number of directory items to check on each directory scan, and is used internally to detect changed disks during system operation, where an intervening cold or warm start has not occurred (when this situation is detected, CP/M automatically marks the disk read-only so that data is not subsequently destroyed). Normally the value of cks = dir when the media is easily changed, as is the case with a floppy disk subsystem. If the disk is permanently mounted, then the value of cks is typically 0, since the probability of changing disks without a restart is quite low. The "ofs" value determines the number of tracks to skip when this particular drive is addressed, which can be used to reserve additional operating system

(All Information Contained Herein is Proprietary to Digital Research.)
space or to simulate several logical drives on a single large capacity physical drive. Finally, the [0] parameter is included when file compatibility is required with versions of 1.4 which have been modified for higher density disks. This parameter ensures that only 16K is allocated for each directory record, as was the case for previous versions. Normally, this parameter is not included.

For convenience and economy of table space, the special form

\texttt{DISKDEF i,j}

gives disk i the same characteristics as a previously defined drive j. A standard four-drive single density system, which is compatible with version 1.4, is defined using the following macro invocations:

\begin{verbatim}
DISKS 4
DISKDEF 0,1,26,6,1024,243,64,64,2
DISKDEF 1,0
DISKDEF 2,0
DISKDEF 3,0
....
ENDEF
\end{verbatim}

with all disks having the same parameter values of 26 sectors per track (numbered 1 through 26), with 6 sectors skipped between each access, 1024 bytes per data block, 243 data blocks for a total of 243k byte disk capacity, 64 checked directory entries, and two operating system tracks.

The definitions given in the program shown above (lines 12 through 15) provide access to the largest disks addressable by CP/M 2.0. All disks have identical parameters, except that drives 0 and 2 skip three sectors on every data access, while disks 1 and 3 access each sector in sequence as the disk revolves (there may, however, be a transparent hardware skew factor on these drives).

The \texttt{DISKS} macro generates n "disk header blocks," starting at address DPBASE which is a label generated by the macro. Each disk header block contains sixteen bytes, and correspond, in sequence, to each of the defined drives. In the four drive standard system, for example, the \texttt{DISKS} macro generates a table of the form:

\begin{verbatim}
DPBASE EQU $
DPE0: DW XLT0,0000H,0000H,0000H,DIRBUF,DPB0,CSV0,ALV0
DPE1: DW XLT0,0000H,0000H,0000H,DIRBUF,DPB0,CSV1,ALV1
DPE2: DW XLT0,0000H,0000H,0000H,DIRBUF,DPB0,CSV2,ALV2
DPE3: DW XLT0,0000H,0000H,0000H,DIRBUF,DPB0,CSV3,ALV3
\end{verbatim}

where the DPE (disk parameter entry) labels are included for reference purposes to show the beginning table addresses for each drive through 3. The values contained within the disk parameter header are described in detail in the CP/M 2.0 Alteration Guide, but basically address the translation vector for the drive (all reference XLT0, which is the translation vector for drive 0 in the above example),

(All Information Contained Herein is Proprietary to Digital Research.)
followed by three 16-bit "scratch" addresses, followed by the directory buffer address, disk parameter block address, check vector address, and allocation vector address. The check and allocation vector addresses are generated by the ENDEF macro in the ram area following the BIOS code and tables.

The SELDSK function is extended somewhat in version 2.0. In particular, the selected disk number is passed to the BIOS in register C, as before, and the SELDSK subroutine performs the appropriate software or hardware actions to select the disk. Version 2.0, however, also requires the SELDSK subroutine to return the address of the selected disk parameter header (DPE0, DPE1, DPE2, or DPE3, in the above example) in register HL. If SELDSK returns the value HL = 0000H, then the BDOS assumes the disk does not exist, and prints a select error message at the terminal. Program lines 22 through 36 give a sample CP/M 2.0 SELDSK subroutine, showing only the disk parameter header address calculation.

The subroutine SECTRAN is also included in version 2.0 which performs the actual logical to physical sector translation. In earlier versions of CP/M, the sector translation process was a part of the BDOS, and set to skip six sectors between each read. Due differing rotational speeds of various disks, the translation function has become a part of the BIOS in version 2.0. Thus, the BDOS sends sequential sector numbers to SECTRAN, starting at sector number 0. The SECTRAN subroutine uses the sequential sector number to produce a translated sector number which is returned to the BDOS. The BDOS subsequently sends the translated sector number to SELSEC before the actual read or write is performed. Note that many controllers have the capability to record the sector skew on the disk itself, and thus there is no translation necessary. In this case, the "skf" parameter is omitted in the macro call, and SECTRAN simply returns the same value which it receives. The table shown below, for example, is constructed when the standard skew factor skf = 6 is specified in the DISKDEF macro call:

XLT0: DB 1,7,13,19,25,5,11,17,23,3,9,15,21
       DB 2,8,14,20,26,6,12,18,24,4,10,16,22

If SECTRAN is required to translate a sector, then the following process takes place. The sector to translate is received in register pair BC. Only the C register is significant if the sector value does not exceed 255 ($80$ in this case). Register pair DE addresses the sector translate table for this drive, determined by a previous call on SELDSK, corresponding to the first element of a disk parameter header (XLT0 in the case shown above). The SECTRAN subroutine then fetches the translated sector number by adding the input sector number to the base of the translate table, to get the indexed translate table address (see lines 46, 47, and 48 in the above program). The value at this location is then returned in register L. Note that if the number of sectors exceeds 255, the translate table contains 16-bit elements whose value must be returned in HL.

Following the ENDEF macro call, a number of uninitialized data areas are defined. These data areas need not be a part of the BIOS

(All Information Contained Herein is Proprietary to Digital Research.)
which is loaded upon cold start, but must be available between the BIOS and the end of memory. The size of the uninitialized RAM area is determined by EQU statements generated by the ENDEF macro. For a standard four-drive system, the ENDEF macro might produce

```
4C72 = BEGDAT EQU $  (data areas)
4DB0 = ENDDAT EQU $
013C = DATSIZ EQU $-BEGDAT
```

which indicates that uninitialized RAM begins at location 4C72H, ends at 4DB0H-1, and occupies 013CH bytes. You must ensure that these addresses are free for use after the system is loaded.

CP/M 2.0 is also easily adapted to disk subsystems whose sector size is a multiple of 128 bytes. Information is provided by the BDOS on sector write operations which eliminates the need for pre-read operations, thus allowing blocking and deblocking to take place at the BIOS level.

See the "CP/M 2.0 Alteration Guide" for additional details concerning tailoring your CP/M system to your particular hardware.

CP/M Dynamic Debugging Tool (DDT)

User's Guide

I. Introduction.

The DDT program allows dynamic interactive testing and debugging of programs generated in the CP/M environment. The debugger is initiated by typing one of the following commands at the CP/M Console Command level:

```
DDT
DDT filename.HEX
DDT filename.COM
```

where "filename" is the name of the program to be loaded and tested. In both cases, the DDT program is brought into main memory in the place of the Console Command Processor (refer to the CP/M Interface Guide for standard memory organization), and thus resides directly below the Basic Disk Operating System portion of CP/M. The BDO S starting address, which is located in the address field of the JMP instruction at location 5H, is altered to reflect the reduced Transient Program Area size.

The second and third forms of the DDT command shown above perform the same actions as the first, except there is a subsequent automatic load of the specified HEX or COM file. The action is identical to the sequence of commands:

```
DDT
Ifilename.HEX or Ifilename.COM
R
```

where the I and R commands set up and read the specified program to test (see the explanation of the I and R commands below for exact details).

Upon initiation, DDT prints a sign-on message in the format:

```
nnK DDT-s VER m.m
```

where nn is the memory size (which must match the CP/M system being used), s is the hardware system which is assumed, corresponding to the codes:

- D - Digital Research standard version
- M - MDS version
- I - IMSAI standard version
- O - Omron systems
- S - Digital Systems standard version

and m.m is the revision number.
Following the sign on message, DDT prompts the operator with the character "-" and waits for input commands from the console. The operator can type any of several single character commands, terminated by a carriage return to execute the command. Each line of input can be line-edited using the standard CP/M controls.

rubout remove the last character typed
ctl-U remove the entire line, ready for re-typing
ctl-C system reboot

Any command can be up to 32 characters in length (an automatic carriage return is inserted as the 33rd character), where the first character determines the command type.

A enter assembly language mnemonics with operands
D display memory in hexadecimal and ASCII
F fill memory with constant data
G begin execution with optional breakpoints
I set up a standard input file control block
L list memory using assembler mnemonics
M move a memory segment from source to destination
R read program for subsequent testing
S substitute memory values
T trace program execution
U untraced program monitoring
X examine and optionally alter the CPU state

The command character, in some cases, is followed by zero, one, two, or three hexadecimal values which are separated by commas or single blank characters. All DDT numeric output is in hexadecimal form. In all cases, the commands are not executed until the carriage return is typed at the end of the command.

At any point in the debug run, the operator can stop execution of DDT using either a ctl-C or GO (jmp to location 0000H), and save the current memory image using a SAVE command of the form

SAVE n filename.COM

where n is the number of pages (256 byte blocks) to be saved on disk. The number of blocks can be determined by taking the high order byte of the top load address and converting this number to decimal. For example, if the highest address in the Transient Program Area is 1234H then the number of pages is 12H, or 18 in decimal. Thus the operator could type a ctl-C during the debug run, returning to the Console Processor level, followed by

SAVE 18 X.COM

The memory image is saved as X.COM on the diskette, and can be directly executed by simply typing the name X. If further testing is required, the memory image can be recalled by typing
which reloads previously saved program from location 100H through page 18 (12FFH). The machine state is not a part of the COM file, and thus the program must be restarted from the beginning in order to properly test it.

II. DDT COMMANDS.

The individual commands are given below in some detail. In each case, the operator must wait for the prompt character (-) before entering the command. If control is passed to a program under test, and the program has not reached a breakpoint, control can be returned to DDT by executing a RST 7 from the front panel (note that the rubout key should be used instead if the program is executing a T or U command). In the explanation of each command, the command letter is shown in some cases with numbers separated by commas, where the numbers are represented by lower case letters. These numbers are always assumed to be in a hexadecimal radix, and from one to four digits in length (longer numbers will be automatically truncated on the right).

Many of the commands operate upon a "CPU state" which corresponds to the program under test. The CPU state holds the registers of the program being debugged, and initially contains zeroes for all registers and flags except for the program counter (P) and stack pointer (S), which default to 100H. The program counter is subsequently set to the starting address given in the last record of a HEX file if a file of this form is loaded (see the I and R commands).

1. The A (Assemble) Command. DDT allows inline assembly language to be inserted into the current memory image using the A command which takes the form

```
As
```

where s is the hexadecimal starting address for the inline assembly. DDT prompts the console with the address of the next instruction to fill, and reads the console, looking for assembly language mnemonics (see the Intel 8880 Assembly Language Reference Card for a list of mnemonics), followed by register references and operands in absolute hexadecimal form. Each successive load address is printed before reading the console. The A command terminates when the first empty line is input from the console.

Upon completion of assembly language input, the operator can review the memory segment using the DDT disassembler (see the L command).

Note that the assembler/disassembler portion of DDT can be overlayed by the transient program being tested, in which case the DDT program responds with an error condition when the A and L commands are used (refer to Section IV).
2. The D (Display) Command. The D command allows the operator to view the contents of memory in hexadecimal and ASCII formats. The forms are

D
Ds
Ds,f

In the first case, memory is displayed from the current display address (initially 100H), and continues for 16 display lines. Each display line takes the form shown below

aaaa bb bb bb bb bb bb bb bb bb bb bb bb bb bb
cccccccccccccc

where aaaa is the display address in hexadecimal, and bb represents data present in memory starting at aaaa. The ASCII characters starting at aaaa are given to the right (represented by the sequence of c's), where non-graphic characters are printed as a period (.) symbol. Note that both upper and lower case alphabetic are displayed, and thus will appear as upper case symbols on a console device that supports only upper case. Each display line gives the values of 16 bytes of data, except that the first line displayed is truncated so that the next line begins at an address which is a multiple of 16.

The second form of the D command shown above is similar to the first, except that the display address is first set to address s. The third form causes the display to continue from address s through address f. In all cases, the display address is set to the first address not displayed in this command, so that a continuing display can be accomplished by issuing successive D commands with no explicit addresses.

Excessively long displays can be aborted by pushing the rubout key.

3. The F (Fill) Command. The F command takes the form

Fs,f,c

where s is the starting address, f is the final address, and c is a hexadecimal byte constant. The effect is as follows: DDT stores the constant c at address s, increments the value of s and tests against f. If s exceeds f then the operation terminates, otherwise the operation is repeated. Thus, the fill command can be used to set a memory block to a specific constant value.

4. The G (Go) Command. Program execution is started using the G command, with up to two optional breakpoint addresses. The G command takes one of the forms

G
Gs
Gs,b
Gs,b,c
G,b
G,b,c

The first form starts execution of the program under test at the current value of the program counter in the current machine state, with no breakpoints set (the only way to regain control in DDT is through a RST 7 execution). The current program counter can be viewed by typing an X or XP command. The second form is similar to the first except that the program counter in the current machine state is set to address s before execution begins. The third form is the same as the second, except that program execution stops when address b is encountered (b must be in the area of the program under test). The instruction at location b is not executed when the breakpoint is encountered. The fourth form is identical to the third, except that two breakpoints are specified, one at b and the other at c. Encountering either breakpoint causes execution to stop, and both breakpoints are subsequently cleared. The last two forms take the program counter from the current machine state, and set one and two breakpoints, respectively.

Execution continues from the starting address in real-time to the next breakpoint. That is, there is no intervention between the starting address and the break address by DDT. Thus, if the program under test does not reach a breakpoint, control cannot return to DDT without executing a RST 7 instruction. Upon encountering a breakpoint, DDT stops execution and types

*d

where d is the stop address. The machine state can be examined at this point using the X (Examine) command. The operator must specify breakpoints which differ from the program counter address at the beginning of the G command. Thus, if the current program counter is 1234H, then the commands

G,1234
and
G400,400

both produce an immediate breakpoint, without executing any instructions whatsoever.

5. The I (Input) Command. The I command allows the operator to insert a file name into the default file control block at 5CH (the file control block created by CP/M for transient programs is placed at this location; see the CP/M Interface Guide). The default FCB can be used by the program under test as if it had been passed by the CP/M Console Processor. Note that this file name is also used by DDT for reading additional HEX and COM files. The form of the I command is

Ifilename

or
If the second form is used, and the filetype is either HEX or COM, then subsequent R commands can be used to read the pure binary or hex format machine code (see the R command for further details).

6. The L (List) Command. The L command is used to list assembly language mnemonics in a particular program region. The forms are

```
L
Ls
Ls,f
```

The first command lists twelve lines of disassembled machine code from the current list address. The second form sets the list address to s, and then lists twelve lines of code. The last form lists disassembled code from s through address f. In all three cases, the list address is set to the next unlisted location in preparation for a subsequent L command. Upon encountering an execution breakpoint, the list address is set to the current value of the program counter (see the G and T commands). Again, long typeouts can be aborted using the rubout key during the list process.

7. The M (Move) Command. The M command allows block movement of program or data areas from one location to another in memory. The form is

```
Ms,f,d
```

where s is the start address of the move, f is the final address of the move, and d is the destination address. Data is first moved from s to d, and both addresses are incremented. If s exceeds f then the move operation stops, otherwise the move operation is repeated.

8. The R (Read) Command. The R command is used in conjunction with the I command to read COM and HEX files from the diskette into the transient program area in preparation for the debug run. The forms are

```
R
Rb
```

where b is an optional bias address which is added to each program or data address as it is loaded. The load operation must not overwrite any of the system parameters from 000H through 0FFH (i.e., the first page of memory). If b is omitted, then b=0000 is assumed. The R command requires a previous I command, specifying the name of a HEX or COM file. The load address for each record is obtained from each individual HEX record, while an assumed load address of 100H is taken for COM files. Note that any number of R commands can be issued following the I command to re-read the program under test.
assuming the tested program does not destroy the default area at $5CH$. Further, any file specified with the filetype "COM" is assumed to contain machine code in pure binary form (created with the LOAD or SAVE command), and all others are assumed to contain machine code in Intel hex format (produced, for example, with the ASM command).

Recall that the command

```
DDT filename.filetype
```

which initiates the DDT program is equivalent to the commands

```
DDT
-ifilename.filetype
-R
```

Whenever the $R$ command is issued, DDT responds with either the error indicator "?" (file cannot be opened, or a checksum error occurred in a HEX file), or with a load message taking the form

```
NEXT PC
nnnn pppp
```

where $nnnn$ is the next address following the loaded program, and $pppp$ is the assumed program counter ($100H$ for COM files, or taken from the last record if a HEX file is specified).

9. The $S$ (Set) Command. The $S$ command allows memory locations to be examined and optionally altered. The form of the command is

```
Ss
```

where $s$ is the hexadecimal starting address for examination and alteration of memory. DDT responds with a numeric prompt, giving the memory location, along with the data currently held in the memory location. If the operator types a carriage return, then the data is not altered. If a byte value is typed, then the value is stored at the prompted address. In either case, DDT continues to prompt with successive addresses and values until either a period (.) is typed by the operator, or an invalid input value is detected.

10. The $T$ (Trace) Command. The $T$ command allows selective tracing of program execution for 1 to 65535 program steps. The forms are

```
T
Tn
```

In the first case, the CPU state is displayed, and the next program step is executed. The program terminates immediately, with the termination address
displayed as

*hhhh

where hhhh is the next address to execute. The display address (used in the D command) is set to the value of H and L, and the list address (used in the L command) is set to hhhh. The CPU state at program termination can then be examined using the X command.

The second form of the T command is similar to the first, except that execution is traced for n steps (n is a hexadecimal value) before a program breakpoint is occurs. A breakpoint can be forced in the trace mode by typing a rubout character. The CPU state is displayed before each program step is taken in trace mode. The format of the display is the same as described in the X command.

Note that program tracing is discontinued at the interface to CP/M, and resumes after return from CP/M to the program under test. Thus, CP/M functions which access I/O devices, such as the diskette drive, run in real-time, avoiding I/O timing problems. Programs running in trace mode execute approximately 500 times slower than real time since DDT gets control after each user instruction is executed. Interrupt processing routines can be traced, but it must be noted that commands which use the breakpoint facility (G, T, and U) accomplish the break using a RST 7 instruction, which means that the tested program cannot use this interrupt location. Further, the trace mode always runs the tested program with interrupts enabled, which may cause problems if asynchronous interrupts are received during tracing.

Note also that the operator should use the rubout key to get control back to DDT during trace, rather than executing a RST 7, in order to ensure that the trace for the current instruction is completed before interruption.

11. The U (Untrace) Command. The U command is identical to the T command except that intermediate program steps are not displayed. The untrace mode allows from 1 to 65535 (FFFFFH) steps to be executed in monitored mode, and is used principally to retain control of an executing program while it reaches steady state conditions. All conditions of the T command apply to the U command.

12. The X (Examine) Command. The X command allows selective display and alteration of the current CPU state for the program under test. The forms are

X
Xr

where r is one of the 8080 CPU registers

<table>
<thead>
<tr>
<th>r</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>Carry Flag</td>
<td>(0/1)</td>
</tr>
<tr>
<td>Z</td>
<td>Zero Flag</td>
<td>(0/1)</td>
</tr>
</tbody>
</table>
In the first case, the CPU register state is displayed in the format

\[
CfzFMEfIff A=bb \ B=dddd \ D=dddd \ H=dddd \ S=dddd \ P=dddd \ inst
\]

where \( f \) is a 0 or 1 flag value, \( bb \) is a byte value, and \( dddd \) is a double byte quantity corresponding to the register pair. The "inst" field contains the disassembled instruction which occurs at the location addressed by the CPU state's program counter.

The second form allows display and optional alteration of register values, where \( r \) is one of the registers given above (C, Z, M, E, I, A, B, D, H, S, or P). In each case, the flag or register value is first displayed at the console. The DDT program then accepts input from the console. If a carriage return is typed, then the flag or register value is not altered. If a value in the proper range is typed, then the flag or register value is altered. Note that BC, DE, and HL are displayed as register pairs. Thus, the operator types the entire register pair when B, C, or the BC pair is altered.

III. IMPLEMENTATION NOTES.

The organization of DDT allows certain non-essential portions to be overlayed in order to gain a larger transient program area for debugging large programs. The DDT program consists of two parts: the DDT nucleus and the assembler/disassembler module. The DDT nucleus is loaded over the Console Command Processor, and, although loaded with the DDT nucleus, the assembler/disassembler is overlayable unless used to assemble or disassemble.

In particular, the BDOS address at location 6H (address field of the JMP instruction at location 5H) is modified by DDT to address the base location of the DDT nucleus which, in turn, contains a JMP instruction to the BDOS. Thus, programs which use this address field to size memory see the logical end of memory at the base of the DDT nucleus rather than the base of the BDOS.

The assembler/disassembler module resides directly below the DDT nucleus in the transient program area. If the A, L, T, or X commands are used during the debugging process then the DDT program again alters the address field at 6H to include this module, thus further reducing the logical end of memory. If a program loads beyond the beginning of the assembler/disassembler module, the A and L commands are lost (their use produces a "?" in response), and the
trace and display (T and X) commands list the "inst" field of the display in hexadecimal, rather than as a decoded instruction.

IV. AN EXAMPLE.

The following example shows an edit, assemble, and debug for a simple program which reads a set of data values and determines the largest value in the set. The largest value is taken from the vector, and stored into "LARGE" at the termination of the program.

```
ED SCAN.ASM

1. INTRODUCTION.

The CP/M assembler reads assembly language source files from the diskette, and produces 8080 machine language in Intel hex format. The CP/M assembler is initiated by typing

```
ASM filename
```
or

```
ASM filename parms
```

In both cases, the assembler assumes there is a file on the diskette with the name

```
filename.ASM
```

which contains an 8080 assembly language source file. The first and second forms shown above differ only in that the second form allows parameters to be passed to the assembler to control source file access and hex and print file destinations.

In either case, the CP/M assembler loads, and prints the message

```
CP/M ASSEMBLER VER n.n
```

where n.n is the current version number. In the case of the first command, the assembler reads the source file with assumed file type "ASM" and creates two output files

```
filename.HEX
```
and

```
filename.PRN
```

the "HEX" file contains the machine code corresponding to the original program in Intel hex format, and the "PRN" file contains an annotated listing showing generated machine code, error flags, and source lines. If errors occur during translation, they will be listed in the PRN file as well as at the console.

The second command form can be used to redirect input and output files from their defaults. In this case, the "parms" portion of the command is a three letter group which specifies the origin of the source file, the destination of the hex file, and the destination of the print file. The form is

```
filename.plp2p3
```

where pl, p2, and p3 are single letters

```
pl: A,B, ..., Y  designates the disk name which contains
```
Thus, the command

\texttt{ASM X.AAA}

indicates that the source file (X.ASM) is to be taken from disk A, and that the hex (X.HEX) and print (X.PRN) files are to be created also on disk A. This form of the command is implied if the assembler is run from disk A. That is, given that the operator is currently addressing disk A, the above command is equivalent to

\texttt{ASM X}

The command

\texttt{ASM X.ABX}

indicates that the source file is to be taken from disk A, the hex file is placed on disk B, and the listing file is to be sent to the console. The command

\texttt{ASM X.BZZ}

takes the source file from disk B, and skips the generation of the hex and print files (this command is useful for fast execution of the assembler to check program syntax).

The source program format is compatible with both the Intel 8080 assembler (macros are not currently implemented in the CP/M assembler, however), as well as the Processor Technology Software Package #1 assembler. That is, the CP/M assembler accepts source programs written in either format. There are certain extensions in the CP/M assembler which make it somewhat easier to use. These extensions are described below.

2. PROGRAM FORMAT.

An assembly language program acceptable as input to the assembler consists of a sequence of statements of the form

\texttt{line\# label operation operand ;comment}

where any or all of the fields may be present in a particular instance. Each
The assembly language statement is terminated with a carriage return and line feed (the line feed is inserted automatically by the ED program), or with the character "!" which is treated as an end-of-line by the assembler (thus, multiple assembly language statements can be written on the same physical line if separated by exclaim symbols).

The line# is an optional decimal integer value representing the source program line number, which is allowed on any source line to maintain compatibility with the Processor Technology format. In general, these line numbers will be inserted if a line-oriented editor is used to construct the original program, and thus ASM ignores this field if present.

The label field takes the form

```
identifier
```
or

```
identifier:
```

and is optional, except where noted in particular statement types. The identifier is a sequence of alphanumeric characters (alphabetics and numbers), where the first character is alphabetic. Identifiers can be freely used by the programmer to label elements such as program steps and assembler directives, but cannot exceed 16 characters in length. All characters are significant in an identifier, except for the embedded dollar symbol ($) which can be used to improve readability of the name. Further, all lower case alphabetics become are treated as if they were upper case. Note that the "!" following the identifier in a label is optional (to maintain compatibility between Intel and Processor Technology). Thus, the following are all valid instances of labels:

```
x xy long$name
x yx1: longer$named$data:
XLY2 Xlx2 x234$5678$9012$3456:
```

The operation field contains either an assembler directive, or pseudo operation, or an 8080 machine operation code. The pseudo operations and machine operation codes are described below.

The operand field of the statement, in general, contains an expression formed out of constants and labels, along with arithmetic and logical operations on these elements. Again, the complete details of properly formed expressions are given below.

The comment field contains arbitrary characters following the ";" symbol until the next real or logical end-of-line. These characters are read, listed, and otherwise ignored by the assembler. In order to maintain compatibility with the Processor Technology assembler, the CP/M assembler also treat statements which begin with a "*" in column one as comment statements, which are listed and ignored in the assembly process. Note that the Processor
Technology assembler has the side effect in its operation of ignoring the characters after the operand field has been scanned. This causes an ambiguous situation when attempting to be compatible with Intel's language, since arbitrary expressions are allowed in this case. Hence, programs which use this side effect to introduce comments, must be edited to place a ";" before these fields in order to assemble correctly.

The assembly language program is formulated as a sequence of statements of the above form, terminated optionally by an END statement. All statements following the END are ignored by the assembler.

3. FORMING THE OPERAND.

In order to completely describe the operation codes and pseudo operations, it is necessary to first present the form of the operand field, since it is used in nearly all statements. Expressions in the operand field consist of simple operands (labels, constants, and reserved words), combined in properly formed subexpressions by arithmetic and logical operators. The expression computation is carried out by the assembler as the assembly proceeds. Each expression must produce a 16-bit value during the assembly. Further, the number of significant digits in the result must not exceed the intended use. That is, if an expression is to be used in a byte move immediate instruction, then the most significant 8 bits of the expression must be zero. The restrictions on the expression significance is given with the individual instructions.

3.1. Labels.

As discussed above, a label is an identifier which occurs on a particular statement. In general, the label is given a value determined by the type of statement which it precedes. If the label occurs on a statement which generates machine code or reserves memory space (e.g., a MOV instruction, or a DS pseudo operation), then the label is given the value of the program address which it labels. If the label precedes an EQU or SET, then the label is given the value which results from evaluating the operand field. Except for the SET statement, an identifier can label only one statement.

When a label appears in the operand field, its value is substituted by the assembler. This value can then be combined with other operands and operators to form the operand field for a particular instruction.

3.2. Numeric Constants.

A numeric constant is a 16-bit value in one of several bases. The base, called the radix of the constant, is denoted by a trailing radix indicator. The radix indicators are

- B: binary constant (base 2)
- O: octal constant (base 8)
Q octal constant (base 8)
D decimal constant (base 10)
H hexadecimal constant (base 16)

Q is an alternate radix indicator for octal numbers since the letter 0 is easily confused with the digit 0. Any numeric constant which does not terminate with a radix indicator is assumed to be a decimal constant.

A constant is thus composed as a sequence of digits, followed by an optional radix indicator, where the digits are in the appropriate range for the radix. That is binary constants must be composed of 0 and 1 digits, octal constants can contain digits in the range 0 - 7, while decimal constants contain decimal digits. Hexadecimal constants contain decimal digits as well as hexadecimal digits A (10D), B (11D), C (12D), D (13D), E (14D), and F (15D). Note that the leading digit of a hexadecimal constant must be a decimal digit in order to avoid confusing a hexadecimal constant with an identifier (a leading 0 will always suffice). A constant composed in this manner must evaluate to a binary number which can be contained within a 16-bit counter, otherwise it is truncated on the right by the assembler. Similar to identifiers, imbedded "$" are allowed within constants to improve their readability. Finally, the radix indicator is translated to upper case if a lower case letter is encountered. The following are all valid instances of numeric constants

\[
\begin{array}{cccccc}
1234 & 1234D & 1100B & 1111S0000S111S000B \\
1234H & 0FFEH & 33770 & 33S77S22Q \\
3377o & 0fe3h & 1234d & 0ffffh \\
\end{array}
\]

3.3. Reserved Words.

There are several reserved character sequences which have predefined meanings in the operand field of a statement. The names of 8080 registers are given below, which, when encountered, produce the value shown to the right

\[
\begin{array}{ll}
A & 7 \\
B & 0 \\
C & 1 \\
D & 2 \\
E & 3 \\
H & 4 \\
L & 5 \\
M & 6 \\
SP & 6 \\
PSW & 6 \\
\end{array}
\]

(again, lower case names have the same values as their upper case equivalents). Machine instructions can also be used in the operand field, and evaluate to their internal codes. In the case of instructions which require operands, where the specific operand becomes a part of the binary bit pattern
of the instruction (e.g., MOV A,B), the value of the instruction (in this case MOV) is the bit pattern of the instruction with zeroes in the optional fields (e.g., MOV produces 40H).

When the symbol "$" occurs in the operand field (not imbedded within identifiers and numeric constants) its value becomes the address of the next instruction to generate, not including the instruction contained within the current logical line.

3.4. String Constants.

String constants represent sequences of ASCII characters, and are represented by enclosing the characters within apostrophe symbols ('). All strings must be fully contained within the current physical line (thus allowing "$" symbols within strings), and must not exceed 64 characters in length. The apostrophe character itself can be included within a string by representing it as a double apostrophe (the two keystrokes ""), which becomes a single apostrophe when read by the assembler. In most cases, the string length is restricted to either one or two characters (the DB pseudo operation is an exception), in which case the string becomes an 8 or 16 bit value, respectively. Two character strings become a 16-bit constant, with the second character as the low order byte, and the first character as the high order byte.

The value of a character is its corresponding ASCII code. There is no case translation within strings, and thus both upper and lower case characters can be represented. Note however, that only graphic (printing) ASCII characters are allowed within strings. Valid strings are

`'A' 'AB' 'ab' 'C'
'" " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " " &
a AND b  bit-by-bit logical and of a and b
a OR b   bit-by-bit logical or of a and b
a XOR b  bit-by-bit logical exclusive or of a and b
a SHL b  the value which results from shifting a to the left by an amount b, with zero fill
a SHR b  the value which results from shifting a to the right by an amount b, with zero fill

In each case, a and b represent simple operands (labels, numeric constants, reserved words, and one or two character strings), or fully enclosed parenthesized subexpressions such as

10+20  10h+37Q  L1 /3  (L2+4) SHR 3
('a' and 5fh) + '0'  ('B'+B) OR (PSW+M)
(L+(2+c)) shr (A-(B+1))

Note that all computations are performed at assembly time as 16-bit unsigned operations. Thus, -1 is computed as 0-1 which results in the value 0xffffh (i.e., all 1's). The resulting expression must fit the operation code in which it is used. If, for example, the expression is used in a ADI (add immediate) instruction, then the high order eight bits of the expression must be zero. As a result, the operation "ADI -1" produces an error message (-1 becomes 0xffffh which cannot be represented as an 8 bit value), while "ADI (-1) AND 0FFH" is accepted by the assembler since the "AND" operation zeroes the high order bits of the expression.

As a convenience to the programmer, ASM assumes that operators have a relative precedence of application which allows the programmer to write expressions without nested levels of parentheses. The resulting expression has assumed parentheses which are defined by the relative precedence. The order of application of operators in unparenthesized expressions is listed below. Operators listed first have highest precedence (they are applied first in an unparenthesized expression), while operators listed last have lowest precedence. Operators listed on the same line have equal precedence, and are applied from left to right as they are encountered in an expression

*/ MOD SHL SHR
- +
NOT
AND
OR XOR

Thus, the expressions shown to the left below are interpreted by the assembler as the fully parenthesize expressions shown to the right below

a * b + c       (a * b) + c
a + b * c       a + (b * c)
a MOD b * c SHL d     ((a MOD b) * c) SHL d
Balanced parenthesized subexpressions can always be used to override the assumed parentheses, and thus the last expression above could be rewritten to force application of operators in a different order as

\[(a \text{ OR } b) \text{ AND } (\text{NOT } c + d) \text{ SHL } e\]

resulting in the assumed parentheses

\[(a \text{ OR } b) \text{ AND } ((\text{NOT } c) + (d \text{ SHL } e))\]

Note that an unparenthesized expression is well-formed only if the expression which results from inserting the assumed parentheses is well-formed.

4. ASSEMBLER DIRECTIVES.

Assembler directives are used to set labels to specific values during the assembly, perform conditional assembly, define storage areas, and specify starting addresses in the program. Each assembler directive is denoted by a "pseudo operation" which appears in the operation field of the line. The acceptable pseudo operations are

- `ORG`: set the program or data origin
- `END`: end program, optional start address
- `EQU`: numeric "equate"
- `SET`: numeric "set"
- `IF`: begin conditional assembly
- `ENDIF`: end of conditional assembly
- `DB`: define data bytes
- `DW`: define data words
- `DS`: define data storage area

The individual pseudo operations are detailed below

4.1. The `ORG` directive.

The `ORG` statement takes the form

\[\text{label ORG expression}\]

where "label" is an optional program label, and expression is a 16-bit expression, consisting of operands which are defined previous to the `ORG` statement. The assembler begins machine code generation at the location specified in the expression. There can be any number of `ORG` statements within a particular program, and there are no checks to ensure that the programmer is not defining overlapping memory areas. Note that most programs written for the CP/M system begin with an `ORG` statement of the form

\[\text{ORG } \text{100H}\]
which causes machine code generation to begin at the base of the CP/M transient program area. If a label is specified in the ORG statement, then the label is given the value of the expression (this label can then be used in the operand field of other statements to represent this expression).

4.2. The END directive.

The END statement is optional in an assembly language program, but if it is present it must be the last statement (all subsequent statements are ignored in the assembly). The two forms of the END directive are

```
label    END
```
```
label    END expression
```

where the label is again optional. If the first form is used, the assembly process stops, and the default starting address of the program is taken as 0000. Otherwise, the expression is evaluated, and becomes the program starting address (this starting address is included in the last record of the Intel formatted machine code "hex" file which results from the assembly). Thus, most CP/M assembly language programs end with the statement

```
END 100H
```
resulting in the default starting address of 100H (beginning of the transient program area).

4.3. The EQU directive.

The EQU (equivate) statement is used to set up synonyms for particular numeric values. the form is

```
label    EQU expression
```

where the label must be present, and must not label any other statement. The assembler evaluates the expression, and assigns this value to the identifier given in the label field. The identifier is usually a name which describes the value in a more human-oriented manner. Further, this name is used throughout the program to "parameterize" certain functions. Suppose for example, that data received from a Teletype appears on a particular input port, and data is sent to the Teletype through the next output port in sequence. The series of equate statements could be used to define these ports for a particular hardware environment

```
TTYBASE    EQU   10H ;BASE PORT NUMBER FOR TTY
TTYIN      EQU   TTYBASE ;TTY DATA IN
TTYOUT     EQU   TTYBASE+1 ;TTY DATA OUT
```

At a later point in the program, the statements which access the Teletype could appear as
making the program more readable than if the absolute i/o ports had been used. Further, if the hardware environment is redefined to start the Teletype communications ports at 7FH instead of 10H, the first statement need only be changed to

TTYBASE EQU 7FH ;BASE PORT NUMBER FOR TTY

and the program can be reassembled without changing any other statements.

4.4. The SET Directive.

The SET statement is similar to the EQU, taking the form

label SET expression

except that the label can occur on other SET statements within the program. The expression is evaluated and becomes the current value associated with the label. Thus, the EQU statement defines a label with a single value, while the SET statement defines a value which is valid from the current SET statement to the point where the label occurs on the next SET statement. The use of the SET is similar to the EQU statement, but is used most often in controlling conditional assembly.

4.5. The IF and ENDIF directives.

The IF and ENDIF statements define a range of assembly language statements which are to be included or excluded during the assembly process. The form is

IF expression
statement#1
statement#2
•••
statement#n
ENDIF

Upon encountering the IF statement, the assembler evaluates the expression following the IF (all operands in the expression must be defined ahead of the IF statement). If the expression evaluates to a non-zero value, then statement#1 through statement#n are assembled; if the expression evaluates to zero, then the statements are listed but not assembled. Conditional assembly is often used to write a single "generic" program which includes a number of possible run-time environments, with only a few specific portions of the program selected for any particular assembly. The following program segments for example, might be part of a program which communicates with either a Teletype or a CRT console (but not both) by selecting a particular value for TTY before the assembly begins.
TRUE EQU 0FFFFH ;DEFINE VALUE OF TRUE
FALSE EQU NOT TRUE ;DEFINE VALUE OF FALSE

TTY EQU TRUE ;TRUE IF TTY, FALSE IF CRT
TTYBASE EQU 10H ;BASE OF TTY I/O PORTS
CRTBASE EQU 20H ;BASE OF CRT I/O PORTS
IF TTY ;ASSEMBLE RELATIVE TO TTYBASE
CONIN EQU TTYBASE ;CONSOLE INPUT
CONOUT EQU TTYBASE+1 ;CONSOLE OUTPUT
ENDIF

IF NOT TTY ;ASSEMBLE RELATIVE TO CRTBASE
CONIN EQU CRTBASE ;CONSOLE INPUT
CONOUT EQU CRTBASE+1 ;CONSOLE OUTPUT
ENDIF

... IN CONIN ;READ CONSOLE DATA
... OUT CONOUT ;WRITE CONSOLE DATA

In this case, the program would assemble for an environment where a Teletype is connected, based at port 10H. The statement defining TTY could be changed to

TTY EQU FALSE

and, in this case, the program would assemble for a CRT based at port 20H.

The DB directive allows the programmer to define initialize storage areas in single precision (byte) format. The statement form is

label DB e#1, e#2, ..., e#n

where e#1 through e#n are either expressions which evaluate to 8-bit values (the high order eight bits must be zero), or are ASCII strings of length no greater than 64 characters. There is no practical restriction on the number of expressions included on a single source line. The expressions are evaluated and placed sequentially into the machine code file following the last program address generated by the assembler. String characters are similarly placed into memory starting with the first character and ending with the last character. Strings of length greater than two characters cannot be used as operands in more complicated expressions (i.e., they must stand alone between the commas). Note that ASCII characters are always placed in memory with the parity bit reset (0). Further, recall that there is no translation from lower to upper case within strings. The optional label can be used to reference the data area throughout the remainder of the program. Examples of
valid DB statements are

\[
\begin{align*}
\text{data:} & \quad \text{DB} \quad 0,1,2,3,4,5 \\
& \quad \text{DB} \quad \text{data and 0ffh},5,3770,1+2+3+4 \\
\text{signon:} & \quad \text{DB} \quad \text{please type your name}, \text{cr}, \text{lf}, 0 \\
& \quad \text{DB} \quad \text{`AB` SHR 8, `C`, `DE` AND 7FH}
\end{align*}
\]

4.7. The DW Directive.

The DW statement is similar to the DB statement except double precision (two byte) words of storage are initialized. The form is

\[
\begin{align*}
\text{label} \quad \text{DW} \quad e_{1}, e_{2}, \ldots, e_{n}
\end{align*}
\]

where \(e_{1}\) through \(e_{n}\) are expressions which evaluate to 16-bit results. Note that ASCII strings of length one or two characters are allowed, but strings longer than two characters disallowed. In all cases, the data storage is consistent with the 8080 processor: the least significant byte of the expression is stored first in memory, followed by the most significant byte. Examples are

\[
\begin{align*}
\text{doub:} \quad & \text{DW} \quad 0ffeh, \text{doub}+4, \text{signon} -, 255+255 \\
& \quad \text{DW} \quad \text{`a`, 5, `ab`, `CD`, 6 shl 8 or 1lb}
\end{align*}
\]

4.8. The DS Directive.

The DS statement is used to reserve an area of uninitialized memory, and takes the form

\[
\begin{align*}
\text{label} \quad \text{DS} \quad \text{expression}
\end{align*}
\]

where the label is optional. The assembler begins subsequent code generation after the area reserved by the DS. Thus, the DS statement given above has exactly the same effect as the statement

\[
\begin{align*}
\text{label:} \quad \text{EQU} \quad \$ ; \text{LABEL VALUE IS CURRENT CODE LOCATION} \\
& \quad \text{ORG} \quad \$+\text{expression} \quad ; \text{MOVE PAST RESERVED AREA}
\end{align*}
\]

5. OPERATION CODES.

Assembly language operation codes form the principal part of assembly language programs, and form the operation field of the instruction. In general, ASM accepts all the standard mnemonics for the Intel 8080 microcomputer, which are given in detail in the Intel manual "8080 Assembly Language Programming Manual." Labels are optional on each input line and, if included, take the value of the instruction address immediately before the instruction is issued. The individual operators are listed briefly in the
following sections for completeness, although it is understood that the Intel manuals should be referenced for exact operator details. In each case,

\[ e3 \]
represents a 3-bit value in the range 0-7
which can be one of the predefined registers
A, B, C, D, E, H, L, M, SP, or PSW.

\[ e8 \]
represents an 8-bit value in the range 0-255

\[ e16 \]
represents a 16-bit value in the range 0-65535
which can themselves be formed from an arbitrary combination of operands and operators. In some cases, the operands are restricted to particular values within the allowable range, such as the PUSH instruction. These cases will be noted as they are encountered.

In the sections which follow, each operation codes is listed in its most general form, along with a specific example, with a short explanation and special restrictions.

5.1. Jumps, Calls, and Returns.

The Jump, Call, and Return instructions allow several different forms which test the condition flags set in the 8080 microcomputer CPU. The forms are

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>JMP e16</td>
<td>Jump unconditionally to label</td>
</tr>
<tr>
<td>JNZ e16</td>
<td>Jump on non zero condition to label</td>
</tr>
<tr>
<td>JZ e16</td>
<td>Jump on zero condition to label</td>
</tr>
<tr>
<td>JNC e16</td>
<td>Jump no carry to label</td>
</tr>
<tr>
<td>JC e16</td>
<td>Jump on carry to label</td>
</tr>
<tr>
<td>JPO e16</td>
<td>Jump on parity odd to label</td>
</tr>
<tr>
<td>JPE e16</td>
<td>Jump on even parity to label</td>
</tr>
<tr>
<td>JP e16</td>
<td>Jump on positive result to label</td>
</tr>
<tr>
<td>JM e16</td>
<td>Jump on minus to label</td>
</tr>
<tr>
<td>CALL e16</td>
<td>Call subroutine unconditionally</td>
</tr>
<tr>
<td>CNZ e16</td>
<td>Call subroutine if non zero flag</td>
</tr>
<tr>
<td>CZ e16</td>
<td>Call subroutine on zero flag</td>
</tr>
<tr>
<td>CNC e16</td>
<td>Call subroutine if no carry set</td>
</tr>
<tr>
<td>CC e16</td>
<td>Call subroutine if carry set</td>
</tr>
<tr>
<td>CPO e16</td>
<td>Call subroutine if parity odd</td>
</tr>
<tr>
<td>CPE e16</td>
<td>Call subroutine if parity even</td>
</tr>
<tr>
<td>CP e16</td>
<td>Call subroutine if positive result</td>
</tr>
<tr>
<td>CM e16</td>
<td>Call subroutine if minus flag</td>
</tr>
<tr>
<td>RST e3</td>
<td>Programmed &quot;restart&quot;, equivalent to CALL 8*e3, except one byte call</td>
</tr>
</tbody>
</table>

13
5.2. Immediate Operand Instructions.

Several instructions are available which load single or double precision registers, or single precision memory cells, with constant values, along with instructions which perform immediate arithmetic or logical operations on the accumulator (register A).

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MVI e3,e8</td>
<td>Move immediate data to register A, B, C, D, E, H, L, or M (memory)</td>
</tr>
<tr>
<td>ADI e8</td>
<td>Add immediate operand to A without carry</td>
</tr>
<tr>
<td>ACI e8</td>
<td>Add immediate operand to A with carry</td>
</tr>
<tr>
<td>SUI e8</td>
<td>Subtract from A without borrow (carry)</td>
</tr>
<tr>
<td>SBI e8</td>
<td>Subtract from A with borrow (carry)</td>
</tr>
<tr>
<td>ANI e8</td>
<td>Logical &quot;and&quot; A with immediate data</td>
</tr>
<tr>
<td>XRI e8</td>
<td>&quot;Exclusive or&quot; A with immediate data</td>
</tr>
<tr>
<td>ORI e8</td>
<td>Logical &quot;or&quot; A with immediate data</td>
</tr>
<tr>
<td>CPI e8</td>
<td>Compare A with immediate data (same as SUI except register A not changed)</td>
</tr>
<tr>
<td>LXI e3,e16</td>
<td>Load extended immediate to register pair (e3 must be equivalent to B,D,H, or SP)</td>
</tr>
</tbody>
</table>

5.3. Increment and Decrement Instructions.

Instructions are provided in the 8080 repertoire for incrementing or decrementing single and double precision registers. The instructions are

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>INR e3</td>
<td>Single precision increment register (e3 produces one of A, B, C, D, E, H, L, M)</td>
</tr>
<tr>
<td>DCR e3</td>
<td>Single precision decrement register (e3 produces one of A, B, C, D, E, H, L, M)</td>
</tr>
<tr>
<td>INX e3</td>
<td>Double precision increment register pair (e3 must be equivalent to B,D,H, or SP)</td>
</tr>
<tr>
<td>DCX e3</td>
<td>Double precision decrement register pair (e3 must be equivalent to B,D,H, or SP)</td>
</tr>
</tbody>
</table>

5.4. Data Movement Instructions.
Instructions which move data from memory to the CPU and from CPU to memory are given below

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MOV e3,e3</td>
<td>Move data to leftmost element from rightmost element (e3 produces one of A,B,C D,E,H,L, or M). MOV M,M is disallowed</td>
</tr>
<tr>
<td>LDA X e3</td>
<td>Load register A from computed address (e3 must produce either B or D)</td>
</tr>
<tr>
<td>STA e3</td>
<td>Store register A to computed address (e3 must produce either B or D)</td>
</tr>
<tr>
<td>LHL e16</td>
<td>Load HL direct from location e16 (double precision load to H and L)</td>
</tr>
<tr>
<td>SHL e16</td>
<td>Store HL direct to location e16 (double precision store from H and L to memory)</td>
</tr>
<tr>
<td>LDA e16</td>
<td>Load register A from address e16</td>
</tr>
<tr>
<td>STA e16</td>
<td>Store register A into memory at e16</td>
</tr>
<tr>
<td>POP e3</td>
<td>Load register pair from stack, set SP (e3 must produce one of B, D, H, or PSW)</td>
</tr>
<tr>
<td>PUSH e3</td>
<td>Store register pair into stack, set SP (e3 must produce one of B, D, H, or PSW)</td>
</tr>
<tr>
<td>IN e8</td>
<td>Load register A with data from port e8</td>
</tr>
<tr>
<td>OUT e8</td>
<td>Send data from register A to port e8</td>
</tr>
<tr>
<td>XTHL</td>
<td>Exchange data from top of stack with HL</td>
</tr>
<tr>
<td>PCHL</td>
<td>Fill program counter with data from HL</td>
</tr>
<tr>
<td>SPHL</td>
<td>Fill stack pointer with data from HL</td>
</tr>
<tr>
<td>XCHG</td>
<td>Exchange DE pair with HL pair</td>
</tr>
</tbody>
</table>

5.5. Arithmetic Logic Unit Operations.

Instructions which act upon the single precision accumulator to perform arithmetic and logic operations are

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADD e3</td>
<td>Add register given by e3 to accumulator without carry (e3 must produce one of A, B, C, D, E, H, or L)</td>
</tr>
<tr>
<td>ADC e3</td>
<td>Add register to A with carry, e3 as above</td>
</tr>
<tr>
<td>SUB e3</td>
<td>Subtract register e3 from A without carry, e3 defined as above</td>
</tr>
<tr>
<td>SBB e3</td>
<td>Subtract register e3 from A with carry, e3 defined as above</td>
</tr>
<tr>
<td>ANA e3</td>
<td>Logical &quot;and&quot; reg with A, e3 as above</td>
</tr>
<tr>
<td>XRA e3</td>
<td>&quot;Exclusive or&quot; with A, e3 as above</td>
</tr>
<tr>
<td>ORA e3</td>
<td>Logical &quot;or&quot; with A, e3 defined as above</td>
</tr>
<tr>
<td>CMP e3</td>
<td>Compare register with A, e3 as above</td>
</tr>
<tr>
<td>DAA</td>
<td>Decimal adjust register A based upon last arithmetic logic unit operation</td>
</tr>
<tr>
<td>CMA</td>
<td>Complement the bits in register A</td>
</tr>
<tr>
<td>STC</td>
<td>Set the carry flag to 1</td>
</tr>
<tr>
<td>Assembly Instruction</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>CMC</td>
<td>Complement the carry flag</td>
</tr>
<tr>
<td>RLC</td>
<td>Rotate bits left, (re)set carry as a side effect (high order A bit becomes carry)</td>
</tr>
<tr>
<td>RRC</td>
<td>Rotate bits right, (re)set carry as side effect (low order A bit becomes carry)</td>
</tr>
<tr>
<td>RAL</td>
<td>Rotate carry/A register to left (carry is involved in the rotate)</td>
</tr>
<tr>
<td>RAR</td>
<td>Rotate carry/A register to right (carry is involved in the rotate)</td>
</tr>
<tr>
<td>DAD e3 DAD B</td>
<td>Double precision add register pair e3 to HL (e3 must produce B, D, H, or SP)</td>
</tr>
</tbody>
</table>

5.6. Control Instructions.

The four remaining instructions are categorized as control instructions, and are listed below:

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HLT</td>
<td>Halt the 8080 processor</td>
</tr>
<tr>
<td>DI</td>
<td>Disable the interrupt system</td>
</tr>
<tr>
<td>EI</td>
<td>Enable the interrupt system</td>
</tr>
<tr>
<td>NOP</td>
<td>No operation</td>
</tr>
</tbody>
</table>

6. ERROR MESSAGES.

When errors occur within the assembly language program, they are listed as single character flags in the leftmost position of the source listing. The line in error is also echoed at the console so that the source listing need not be examined to determine if errors are present. The error codes are:

- **D**: Data error: element in data statement cannot be placed in the specified data area
- **E**: Expression error: expression is ill-formed and cannot be computed at assembly time
- **L**: Label error: label cannot appear in this context (may be duplicate label)
- **N**: Not implemented: features which will appear in future ASM versions (e.g., macros) are recognized, but flagged in this version
- **O**: Overflow: expression is too complicated (i.e., too many pending operators) to computed, simplify it
- **P**: Phase error: label does not have the same value on two subsequent passes through the program
R Register error: the value specified as a register is not compatible with the operation code

V Value error: operand encountered in expression is improperly formed

Several error message are printed which are due to terminal error conditions

NO SOURCE FILE PRESENT The file specified in the ASM command does not exist on disk

NO DIRECTORY SPACE The disk directory is full, erase files which are not needed, and retry

SOURCE FILE NAME ERROR Improperly formed ASM file name (e.g., it is specified with "?" fields)

SOURCE FILE READ ERROR Source file cannot be read properly by the assembler, execute a TYPE to determine the point of error

OUTPUT FILE WRITE ERROR Output files cannot be written properly, most likely cause is a full disk, erase and retry

CANNOT CLOSE FILE Output file cannot be closed, check to see if disk is write protected

1. INTRODUCTION.

This manual describes CP/M, release 2, system organization including the structure of memory and system entry points. The intention is to provide the necessary information required to write programs which operate under CP/M, and which use the peripheral and disk I/O facilities of the system.

CP/M is logically divided into four parts, called the Basic I/O System (BIOS), the Basic Disk Operating System (BDOS), the Console command processor (CCP), and the Transient Program Area (TPA). The BIOS is a hardware-dependent module which defines the exact low level interface to a particular computer system which is necessary for peripheral device I/O. Although a standard BIOS is supplied by Digital Research, explicit instructions are provided for field reconfiguration of the BIOS to match nearly any hardware environment (see the Digital Research manual entitled "CP/M Alteration Guide"). The BIOS and BDOS are logically combined into a single module with a common entry point, and referred to as the FDOS. The CCP is a distinct program which uses the FDOS to provide a human-oriented interface to the information which is cataloged on the backup storage device. The TPA is an area of memory (i.e., the portion which is not used by the FDOS and CCP) where various non-resident operating system commands and user programs are executed. The lower portion of memory is reserved for system information and is detailed later sections. Memory organization of the CP/M system is shown below:

```
<table>
<thead>
<tr>
<th>high memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>FBASE:</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>
```

The exact memory addresses corresponding to BOOT, TBASE, CBASE, and FBASE vary from version to version, and are described fully in the "CP/M Alteration Guide." All standard CP/M versions, however, assume \( \text{BOOT} = 0000H \), which is the base of random access memory. The machine code found at location BOOT performs a system "warm start" which loads and initializes the programs and variables necessary to return control to the CCP. Thus, transient programs need only jump to location BOOT.

(All Information Contained Herein is Proprietary to Digital Research.)
to return control to CP/M at the command level. Further, the standard versions assume TBASE = BOOT+0100H which is normally location 0100H. The principal entry point to the FDOS is at location BOOT+0005H (normally 0005H) where a jump to FBASE is found. The address field at BOOT+0006H (normally 0006H) contains the value of FBASE and can be used to determine the size of available memory, assuming the CCP is being overlayed by a transient program.

Transient programs are loaded into the TPA and executed as follows. The operator communicates with the CCP by typing command lines following each prompt. Each command line takes one of the forms:

```
command
command file1
command file1 file2
```

where "command" is either a built-in function such as DIR or TYPE, or the name of a transient command or program. If the command is a built-in function of CP/M, it is executed immediately. Otherwise, the CCP searches the currently addressed disk for a file by the name

```
command.COM
```

If the file is found, it is assumed to be a memory image of a program which executes in the TPA, and thus implicitly originates at TBASE in memory. The CCP loads the COM file from the disk into memory starting at TBASE and possibly extending up to CBASE.

If the command is followed by one or two file specifications, the CCP prepares one or two file control block (FCB) names in the system parameter area. These optional FCB's are in the form necessary to access files through the FDOS, and are described in the next section.

The transient program receives control from the CCP and begins execution, perhaps using the I/O facilities of the FDOS. The transient program is "called" from the CCP, and thus can simply return to the CCP upon completion of its processing, or can jump to BOOT to pass control back to CP/M. In the first case, the transient program must not use memory above CBASE, while in the latter case, memory up through FBASE-1 is free.

The transient program may use the CP/M I/O facilities to communicate with the operator's console and peripheral devices, including the disk subsystem. The I/O system is accessed by passing a "function number" and an "information address" to CP/M through the FDOS entry point at BOOT+0005H. In the case of a disk read, for example, the transient program sends the number corresponding to a disk read, along with the address of an FCB to the CP/M FDOS. The FDOS, in turn, performs the operation and returns with either a disk read completion indication or an error number indicating that the disk read was unsuccessful. The function numbers and error indicators are given in below.

(All Information Contained Herein is Proprietary to Digital Research.)
2. OPERATING SYSTEM CALL CONVENTIONS.

The purpose of this section is to provide detailed information for performing direct operating system calls from user programs. Many of the functions listed below, however, are more simply accessed through the I/O macro library provided with the MAC macro assembler, and listed in the Digital Research manual entitled "MAC Macro Assembler: Language Manual and Applications Guide."

CP/M facilities which are available for access by transient programs fall into two general categories: simple device I/O, and disk file I/O. The simple device operations include:

- Read a Console Character
- Write a Console Character
- Read a Sequential Tape Character
- Write a Sequential Tape Character
- Write a List Device Character
- Get or Set I/O Status
- Print Console Buffer
- Read Console Buffer
- Interrogate Console Ready

The FDOS operations which perform disk Input/Output are

- Disk System Reset
- Drive Selection
- File Creation
- File Open
- File Close
- Directory Search
- File Delete
- File Rename
- Random or Sequential Read
- Random or Sequential Write
- Interrogate Available Disks
- Interrogate Selected Disk
- Set DMA Address
- Set/Reset File Indicators

As mentioned above, access to the FDOS functions is accomplished by passing a function number and information address through the primary entry point at location BOOT+0005H. In general, the function number is passed in register C with the information address in the double byte pair DE. Single byte values are returned in register A, with double byte values returned in HL (a zero value is returned when the function number is out of range). For reasons of compatibility, register A = L and register B = H upon return in all cases. Note that the register passing conventions of CP/M agree with those of Intel's PL/M systems programming language. The list of CP/M function numbers is given below.

(All Information Contained Herein is Proprietary to Digital Research.)
0 System Reset 19 Delete File
1 Console Input 20 Read Sequential
2 Console Output 21 Write Sequential
3 Reader Input 22 Make File
4 Punch Output 23 Rename File
5 List Output 24 Return Login Vector
6 Direct Console I/O 25 Return Current Disk
7 Get I/O Byte 26 Set DMA Address
8 Set I/O Byte 27 Get Addr(Alloc)
9 Print String 28 Write Protect Disk
10 Read Console Buffer 29 Get R/O Vector
11 Get Console Status 30 Set File Attributes
12 Return Version Number 31 Get Addr(DiskParms)
13 Reset Disk System 32 Set/Get User Code
14 Select Disk 33 Read Random
15 Open File 34 Write Random
16 Close File 35 Compute File Size
17 Search for First 36 Set Random Record
18 Search for Next

(Functions 28 and 32 should be avoided in application programs to maintain upward compatibility with MP/M.)

Upon entry to a transient program, the CCP leaves the stack pointer set to an eight level stack area with the CCP return address pushed onto the stack, leaving seven levels before overflow occurs. Although this stack is usually not used by a transient program (i.e., most transients return to the CCP though a jump to location 0000H), it is sufficiently large to make CP/M system calls since the FDOS switches to a local stack at system entry. The following assembly language program segment, for example, reads characters continuously until an asterisk is encountered, at which time control returns to the CCP (assuming a standard CP/M system with BOOT = 0000H):

BDOS EQU 0005H ;STANDARD CP/M ENTRY
CONIN EQU 1 ;CONSOLE INPUT FUNCTION
;
ORG 0100H ;BASE OF TPA
NEXTC: MVI C,CONIN ;READ NEXT CHARACTER
CALL BDOS ;RETURN CHARACTER IN <A>
CPI '*' ;END OF PROCESSING?
JNZ NEXTC ;LOOP IF NOT
RET ;RETURN TO CCP
END

CP/M implements a named file structure on each disk, providing a logical organization which allows any particular file to contain any number of records from completely empty, to the full capacity of the drive. Each drive is logically distinct with a disk directory and file data area. The disk file names are in three parts: the drive select code, the file name consisting of one to eight non-blank characters, and the file type consisting of zero to three non-blank characters. The file type names the generic category of a particular file, while the file name distinguishes individual files in each category. The file types listed below name a few generic categories

(All Information Contained Herein is Proprietary to Digital Research.)
Source files are treated as a sequence of ASCII characters, where each "line" of the source file is followed by a carriage-return line-feed sequence (0DH followed by 0AH). Thus one 128 byte CP/M record could contain several lines of source text. The end of an ASCII file is denoted by a control-Z character (1AH) or a real end of file, returned by the CP/M read operation. Control-Z characters embedded within machine code files (e.g., COM files) are ignored, however, and the end of file condition returned by CP/M is used to terminate read operations.

Files in CP/M can be thought of as a sequence of up to 65536 records of 128 bytes each, numbered from 0 through 65535, thus allowing a maximum of 8 megabytes per file. Note, however, that although the records may be considered logically contiguous, they may not be physically contiguous in the disk data area. Internally, all files are broken into 16K byte segments called logical extents, so that counters are easily maintained as 8-bit values. Although the decomposition into extents is discussed in the paragraphs which follow, they are of no particular consequence to the programmer since each extent is automatically accessed in both sequential and random access modes.

In the file operations starting with function number 15, DE usually addresses a file control block (FCB). Transient programs often use the default file control block area reserved by CP/M at location BOOT+005CH (normally 005CH) for simple file operations. The basic unit of file information is a 128 byte record used for all file operations, thus a default location for disk I/O is provided by CP/M at location BOOT+0080H (normally 0080H) which is the initial default DMA address (see function 26). All directory operations take place in a reserved area which does not affect write buffers as was the case in release 1, with the exception of Search First and Search Next, where compatibility is required.

The File Control Block (FCB) data area consists of a sequence of 33 bytes for sequential access and a series of 36 bytes in the case that the file is accessed randomly. The default file control block normally located at 005CH can be used for random access files, since the three bytes starting at BOOT+007DH are available for this purpose. The FCB format is shown with the following fields:
where

- **dr**: drive code (0 - 16)
  - 0 => use default drive for file
  - 1 => auto disk select drive A,
  - 2 => auto disk select drive B,
  - ...
  - 16 => auto disk select drive P.

- **fl...f8**: contain the file name in ASCII upper case, with high bit = 0

- **tl,t2,t3**: contain the file type in ASCII upper case, with high bit = 0
  - tl', t2', and t3' denote the bit of these positions,
  - tl' = 1 => Read/Only file,
  - t2' = 1 => SYS file, no DIR list

- **ex**: contains the current extent number, normally set to 00 by the user, but in range 0 - 31 during file I/O

- **s1**: reserved for internal system use

- **s2**: reserved for internal system use, set to zero on call to OPEN, MAKE, SEARCH

- **rc**: record count for extent "ex," takes on values from 0 - 128

- **d0...dn**: filled-in by CP/M, reserved for system use

- **cr**: current record to read or write in a sequential file operation, normally set to zero by user

- **r0,r1,r2**: optional random record number in the range 0-65535, with overflow to r2,
  - r0,r1 constitute a 16-bit value with low byte r0, and high byte r1

Each file being accessed through CP/M must have a corresponding FCB which provides the name and allocation information for all subsequent file operations. When accessing files, it is the programmer's responsibility to fill the lower sixteen bytes of the FCB and initialize the "cr" field. Normally, bytes 1 through 11 are set to the ASCII character values for the file name and file type, while all other fields are zero.

(All Information Contained Herein is Proprietary to Digital Research.)
FCB's are stored in a directory area of the disk, and are brought into central memory before proceeding with file operations (see the OPEN and MAKE functions). The memory copy of the FCB is updated as file operations take place and later recorded permanently on disk at the termination of the file operation (see the CLOSE command).

The CCP constructs the first sixteen bytes of two optional FCB's for a transient by scanning the remainder of the line following the transient name, denoted by "file1" and "file2" in the prototype command line described above, with unspecified fields set to ASCII blanks. The first FCB is constructed at location BOOT+005CH, and can be used as-is for subsequent file operations. The second FCB occupies the d0 ... dn portion of the first FCB, and must be moved to another area of memory before use. If, for example, the operator types

```
PROGNAME B:X.ZOT Y.ZAP
```

the file PROGNAME.COM is loaded into the TPA, and the default FCB at BOOT+005CH is initialized to drive code 2, file name "X" and file type "ZOT". The second drive code takes the default value 0, which is placed at BOOT+006CH, with the file name "Y" placed into location BOOT+006DH and file type "ZAP" located 8 bytes later at BOOT+0075H. All remaining fields through "cr" are set to zero. Note again that it is the programmer's responsibility to move this second file name and type to another area, usually a separate file control block, before opening the file which begins at BOOT+005CH, due to the fact that the open operation will overwrite the second name and type.

If no file names are specified in the original command, then the fields beginning at BOOT+005DH and BOOT+006DH contain blanks. In all cases, the CCP translates lower case alphabetics to upper case to be consistent with the CP/M file naming conventions.

As an added convenience, the default buffer area at location BOOT+0080H is initialized to the command line tail typed by the operator following the program name. The first position contains the number of characters, with the characters themselves following the character count. Given the above command line, the area beginning at BOOT+0080H is initialized as follows:

```
BOOT+0080H:
+00 +01 +02 +03 +04 +05 +06 +07 +08 +09 +10 +11 +12 +13 +14
14 " " "B" ":" "X" "." "Z" "O" "T" ":" "Y" ":" "Z" "A" "P"
```

where the characters are translated to upper case ASCII with uninitialized memory following the last valid character. Again, it is the responsibility of the programmer to extract the information from this buffer before any file operations are performed, unless the default DMA address is explicitly changed.

The individual functions are described in detail in the pages which follow.

(All Information Contained Herein is Proprietary to Digital Research.)
The system reset function returns control to the CP/M operating system at the CCP level. The CCP re-initializes the disk subsystem by selecting and logging-in disk drive A. This function has exactly the same effect as a jump to location BOOT.

The console input function reads the next console character to register A. Graphic characters, along with carriage return, line feed, and backspace (ctl-H) are echoed to the console. Tab characters (ctl-I) are expanded in columns of eight characters. A check is made for start/stop scroll (ctl-S) and start/stop printer echo (ctl-P). The FDOS does not return to the calling program until a character has been typed, thus suspending execution if a character is not ready.

The ASCII character from register E is sent to the console device. Similar to function 1, tabs are expanded and checks are made for start/stop scroll and printer echo.

(All Information Contained Herein is Proprietary to Digital Research.)
The Reader Input function reads the next character from the logical reader into register A (see the IOBYTE definition in the "CP/M Alteration Guide"). Control does not return until the character has been read.

The Punch Output function sends the character from register E to the logical punch device.

The List Output function sends the ASCII character in register E to the logical listing device.

(All Information Contained Herein is Proprietary to Digital Research.)
FUNCTION 6: DIRECT CONSOLE I/O

Entry Parameters:
- Register C: 06H
- Register E: 0FFH (input) or char (output)

Returned Value:
- Register A: char or status (no value)

Direct console I/O is supported under CP/M for those specialized applications where unadorned console input and output is required. Use of this function should, in general, be avoided since it bypasses all of CP/M's normal control character functions (e.g., control-S and control-P). Programs which perform direct I/O through the BIOS under previous releases of CP/M, however, should be changed to use direct I/O under BDOS so that they can be fully supported under future releases of MP/M and CP/M.

Upon entry to function 6, register E either contains hexadecimal FF, denoting a console input request, or register E contains an ASCII character. If the input value is FF, then function 6 returns A = 00 if no character is ready, otherwise A contains the next console input character.

If the input value in E is not FF, then function 6 assumes that E contains a valid ASCII character which is sent to the console.
* FUNCTION 7: GET I/O BYTE

* Entry Parameters:
  * Register C: 07H
* Returned Value:
  * Register A: I/O Byte Value

The Get I/O Byte function returns the current value of IOBYTE in register A. See the "CP/M Alteration Guide" for IOBYTE definition.

* FUNCTION 8: SET I/O BYTE

* Entry Parameters:
  * Register C: 08H
  * Register E: I/O Byte Value

The Set I/O Byte function changes the system IOBYTE value to that given in register E.

* FUNCTION 9: PRINT STRING

* Entry Parameters:
  * Register C: 09H
  * Registers DE: String Address

The Print String function sends the character string stored in memory at the location given by DE to the console device, until a "$" is encountered in the string. Tabs are expanded as in function 2, and checks are made for start/stop scroll and printer echo.

(All Information Contained Herein is Proprietary to Digital Research.)
The Read Buffer function reads a line of edited console input into a buffer addressed by registers DE. Console input is terminated when either the input buffer overflows. The Read Buffer takes the form:

```
DE: +0 +1 +2 +3 +4 +5 +6 +7 +8 .. .. +n
```

where "mx" is the maximum number of characters which the buffer will hold (1 to 255), "nc" is the number of characters read (set by FDOS upon return), followed by the characters read from the console. if nc < mx, then uninitialized positions follow the last character, denoted by "??" in the above figure. A number of control functions are recognized during line editing:

- **rub/del** removes and echoes the last character
- **ctl-C** reboots when at the beginning of line
- **ctl-E** causes physical end of line
- **ctl-H** backspaces one character position
- **ctl-J** (line feed) terminates input line
- **ctl-M** (return) terminates input line
- **ctl-R** retypes the current line after new line
- **ctl-U** removes current line after new line
- **ctl-X** backspaces to beginning of current line

Note also that certain functions which return the carriage to the leftmost position (e.g., **ctl-X**) do so only to the column position where the prompt ended (in earlier releases, the carriage returned to the extreme left margin). This convention makes operator data input and line correction more legible.
FUNCTION 11: GET CONSOLE STATUS

Entry Parameters:
- Register C: 0BH

Returned Value:
- Register A: Console Status

The Console Status function checks to see if a character has been typed at the console. If a character is ready, the value 0FFH is returned in register A. Otherwise a 00H value is returned.

FUNCTION 12: RETURN VERSION NUMBER

Entry Parameters:
- Register C: 0CH

Returned Value:
- Registers HL: Version Number

Function 12 provides information which allows version independent programming. A two-byte value is returned, with H = 00 designating the CP/M release (H = 01 for MP/M), and L = 00 for all releases previous to 2.0. CP/M 2.0 returns a hexadecimal 20 in register L, with subsequent version 2 releases in the hexadecimal range 21, 22, through 2F. Using function 12, for example, you can write application programs which provide both sequential and random access functions, with random access disabled when operating under early releases of CP/M.

(All Information Contained Herein is Proprietary to Digital Research.)
The Reset Disk Function is used to programmatically restore the file system to a reset state where all disks are set to read/write (see functions 28 and 29), only disk drive A is selected, and the default DMA address is reset to BOOT+0080H. This function can be used, for example, by an application program which requires a disk change without a system reboot.

The Select Disk function designates the disk drive named in register E as the default disk for subsequent file operations, with E = 0 for drive A, 1 for drive B, and so-forth through 15 corresponding to drive P in a full sixteen drive system. The drive is placed in an "on-line" status which, in particular, activates its directory until the next cold start, warm start, or disk system reset operation. If the disk media is changed while it is on-line, the drive automatically goes to a read-only status in a standard CP/M environment (see function 28). FCB's which specify drive code zero (dr = 00H) automatically reference the currently selected default drive. Drive code values between 1 and 16, however, ignore the selected default drive and directly reference drives A through P.
The Open File operation is used to activate a file which currently exists in the disk directory for the currently active user number. The FDOS scans the referenced disk directory for a match in positions 1 through 14 of the FCB referenced by DE (byte s1 is automatically zeroed), where an ASCII question mark (3FH) matches any directory character in any of these positions. Normally, no question marks are included and, further, bytes "ex" and "s2" of the FCB are zero.

If a directory element is matched, the relevant directory information is copied into bytes d0 through dn of the FCB, thus allowing access to the files through subsequent read and write operations. Note that an existing file must not be accessed until a successful open operation is completed. Upon return, the open function returns a "directory code" with the value 0 through 3 if the open was successful, or 0FFH (255 decimal) if the file cannot be found. If question marks occur in the FCB then the first matching FCB is activated. Note that the current record ("cr") must be zeroed by the program if the file is to be accessed sequentially from the first record.
The Close File function performs the inverse of the open file function. Given that the FCB addressed by DE has been previously activated through an open or make function (see functions 15 and 22), the close function permanently records the new FCB in the referenced disk directory. The FCB matching process for the close is identical to the open function. The directory code returned for a successful close operation is 0, 1, 2, or 3, while a 0FFH (255 decimal) is returned if the file name cannot be found in the directory. A file need not be closed if only read operations have taken place. If write operations have occurred, however, the close operation is necessary to permanently record the new directory information.
**FUNCTION 17: SEARCH FOR FIRST**

**Entry Parameters:**
- Register C: 11H
- Registers DE: FCB Address

**Returned Value:**
- Register A: Directory Code

Search First scans the directory for a match with the file given by the FCB addressed by DE. The value 255 (hexadecimal FF) is returned if the file is not found, otherwise 0, 1, 2, or 3 is returned indicating the file is present. In the case that the file is found, the current DMA address is filled with the record containing the directory entry, and the relative starting position is A * 32 (i.e., rotate the A register left 5 bits, or ADD A five times). Although not normally required for application programs, the directory information can be extracted from the buffer at this position.

An ASCII question mark (63 decimal, 3F hexadecimal) in any position from "fl" through "ex" matches the corresponding field of any directory entry on the default or auto-selected disk drive. If the "dr" field contains an ASCII question mark, then the auto disk select function is disabled, the default disk is searched, with the search function returning any matched entry, allocated or free, belonging to any user number. This latter function is not normally used by application programs, but does allow complete flexibility to scan all current directory values. If the "dr" field is not a question mark, the "s2" byte is automatically zeroed.

**FUNCTION 18: SEARCH FOR NEXT**

**Entry Parameters:**
- Register C: 12H

**Returned Value:**
- Register A: Directory Code

The Search Next function is similar to the Search First function, except that the directory scan continues from the last matched entry. Similar to function 17, function 18 returns the decimal value 255 in A when no more directory items match.

(All Information Contained Herein is Proprietary to Digital Research.)
The Delete File function removes files which match the FCB addressed by DE. The filename and type may contain ambiguous references (i.e., question marks in various positions), but the drive select code cannot be ambiguous, as in the Search and Search Next functions.

Function 19 returns a decimal 255 if the referenced file or files cannot be found, otherwise a value in the range 0 to 3 is returned.

Given that the FCB addressed by DE has been activated through an open or make function (numbers 15 and 22), the Read Sequential function reads the next 128 byte record from the file into memory at the current DMA address. The record is read from position "cr" of the extent, and the "cr" field is automatically incremented to the next record position. If the "cr" field overflows then the next logical extent is automatically opened and the "cr" field is reset to zero in preparation for the next read operation. The value 00H is returned in the A register if the read operation was successful, while a non-zero value is returned if no data exists at the next record position (e.g., end of file occurs).
FUNCTION 21: WRITE SEQUENTIAL

Entry Parameters:
- Register C: 15H
- Registers DE: FCB Address

Returned Value:
- Register A: Directory Code

Given that the FCB addressed by DE has been activated through an open or make function (numbers 15 and 22), the Write Sequential function writes the 128 byte data record at the current DMA address to the file named by the FCB. The record is placed at position "cr" of the file, and the "cr" field is automatically incremented to the next record position. If the "cr" field overflows then the next logical extent is automatically opened and the "cr" field is reset to zero in preparation for the next write operation. Write operations can take place into an existing file, in which case newly written records overlay those which already exist in the file. Register A = 00H upon return from a successful write operation, while a non-zero value indicates an unsuccessful write due to a full disk.

FUNCTION 22: MAKE FILE

Entry Parameters:
- Register C: 16H
- Registers DE: FCB Address

Returned Value:
- Register A: Directory Code

The Make File operation is similar to the open file operation except that the FCB must name a file which does not exist in the currently referenced disk directory (i.e., the one named explicitly by a non-zero "dr" code, or the default disk if "dr" is zero). The FDOS creates the file and initializes both the directory and main memory value to an empty file. The programmer must ensure that no duplicate file names occur, and a preceding delete operation is sufficient if there is any possibility of duplication. Upon return, register A = 0, 1, 2, or 3 if the operation was successful and 0FFH (255 decimal) if no more directory space is available. The make function has the side-effect of activating the FCB and thus a subsequent open is not necessary.
**FUNCTION 23: RENAME FILE**

**Entry Parameters:**
- Register C: 17H
- Registers DE: FCB Address

**Returned Value:**
- Register A: Directory Code

The Rename function uses the FCB addressed by DE to change all occurrences of the file named in the first 16 bytes to the file named in the second 16 bytes. The drive code "dr" at position 0 is used to select the drive, while the drive code for the new file name at position 16 of the FCB is assumed to be zero. Upon return, register A is set to a value between 0 and 3 if the rename was successful, and OFFH (255 decimal) if the first file name could not be found in the directory scan.

**FUNCTION 24: RETURN LOGIN VECTOR**

**Entry Parameters:**
- Register C: 18H

**Returned Value:**
- Registers HL: Login Vector

The login vector value returned by CP/M is a 16-bit value in HL, where the least significant bit of L corresponds to the first drive A, and the high order bit of H corresponds to the sixteenth drive, labelled P. A "0" bit indicates that the drive is not on-line, while a "1" bit marks an drive that is actively on-line due to an explicit disk drive selection, or an implicit drive select caused by a file operation which specified a non-zero "dr" field. Note that compatibility is maintained with earlier releases, since registers A and L contain the same values upon return.

(All Information Contained Herein is Proprietary to Digital Research.)
**FUNCTION 25: RETURN CURRENT DISK**

**Entry Parameters:**
- Register C: 19H
- Returned Value:
- Register A: Current Disk

Function 25 returns the currently selected default disk number in register A. The disk numbers range from 0 through 15 corresponding to drives A through P.

**FUNCTION 26: SET DMA ADDRESS**

**Entry Parameters:**
- Register C: 1AH
- Registers DE: DMA Address

"DMA" is an acronym for Direct Memory Address, which is often used in connection with disk controllers which directly access the memory of the mainframe computer to transfer data to and from the disk subsystem. Although many computer systems use non-DMA access (i.e., the data is transferred through programmed I/O operations), the DMA address has, in CP/M, come to mean the address at which the 128 byte data record resides before a disk write and after a disk read. Upon cold start, warm start, or disk system reset, the DMA address is automatically set to BOOT+0080H. The Set DMA function, however, can be used to change this default value to address another area of memory where the data records reside. Thus, the DMA address becomes the value specified by DE until it is changed by a subsequent Set DMA function, cold start, warm start, or disk system reset.

(All Information Contained Herein is Proprietary to Digital Research.)
An "allocation vector" is maintained in main memory for each on-line disk drive. Various system programs use the information provided by the allocation vector to determine the amount of remaining storage (see the STAT program). Function 27 returns the base address of the allocation vector for the currently selected disk drive. The allocation information may, however, be invalid if the selected disk has been marked read/only. Although this function is not normally used by application programs, additional details of the allocation vector are found in the "CP/M Alteration Guide."

The disk write protect function provides temporary write protection for the currently selected disk. Any attempt to write to the disk, before the next cold or warm start operation produces the message

Bdos Err on d: R/O

(All Information Contained Herein is Proprietary to Digital Research.)
FUNCTION 29: GET READ/ONLY VECTOR

* Entry Parameters:
  * Register C: 1DH
* Returned Value:
  * Registers HL: R/O Vector Value

Function 29 returns a bit vector in register pair HL which indicates drives which have the temporary read/only bit set. Similar to function 24, the least significant bit corresponds to drive A, while the most significant bit corresponds to drive P. The R/O bit is set either by an explicit call to function 28, or by the automatic software mechanisms within CP/M which detect changed disks.

FUNCTION 30: SET FILE ATTRIBUTES

* Entry Parameters:
  * Register C: 1EH
  * Registers DE: FCB Address
* Returned Value:
  * Register A: Directory Code

The Set File Attributes function allows programmatic manipulation of permanent indicators attached to files. In particular, the R/O and System attributes (t1' and t2') can be set or reset. The DE pair addresses an unambiguous file name with the appropriate attributes set or reset. Function 30 searches for a match, and changes the matched directory entry to contain the selected indicators. Indicators f1' through f4' are not presently used, but may be useful for applications programs, since they are not involved in the matching process during file open and close operations. Indicators f5' through f8' and t3' are reserved for future system expansion.

(All Information Contained Herein is Proprietary to Digital Research.)
FUNCTION 31: GET ADDR(DISK PARMS)

* Entry Parameters:
  * Register C: 1FH
  * Returned Value:
    * Registers HL: DPB Address

The address of the BIOS resident disk parameter block is returned in HL as a result of this function call. This address can be used for either of two purposes. First, the disk parameter values can be extracted for display and space computation purposes, or transient programs can dynamically change the values of current disk parameters when the disk environment changes, if required. Normally, application programs will not require this facility.

FUNCTION 32: SET/GET USER CODE

* Entry Parameters:
  * Register C: 20H
  * Register E: 0FFH (get) or User Code (set)
  * Returned Value:
    * Register A: Current Code or (no value)

An application program can change or interrogate the currently active user number by calling function 32. If register E = 0FFH, then the value of the current user number is returned in register A, where the value is in the range 0 to 31. If register E is not 0FFH, then the current user number is changed to the value of E (modulo 32).
The Read Random function is similar to the sequential file read operation of previous releases, except that the read operation takes place at a particular record number, selected by the 24-bit value constructed from the three byte field following the FCB (byte positions r0 at 33, r1 at 34, and r2 at 35). Note that the sequence of 24 bits is stored with least significant byte first (r0), middle byte next (r1), and high byte last (r2). CP/M does not reference byte r2, except in computing the size of a file (function 35). Byte r2 must be zero, however, since a non-zero value indicates overflow past the end of file.

Thus, the r0,r1 byte pair is treated as a double-byte, or "word" value, which contains the record to read. This value ranges from 0 to 65535, providing access to any particular record of the 8 megabyte file. In order to process a file using random access, the base extent (extent 0) must first be opened. Although the base extent may or may not contain any allocated data, this ensures that the file is properly recorded in the directory, and is visible in DIR requests. The selected record number is then stored into the random record field (r0,r1), and the BDOS is called to read the record. Upon return from the call, register A either contains an error code, as listed below, or the value 00 indicating the operation was successful. In the latter case, the current DMA address contains the randomly accessed record. Note that contrary to the sequential read operation, the record number is not advanced. Thus, subsequent random read operations continue to read the same record.

Upon each random read operation, the logical extent and current record values are automatically set. Thus, the file can be sequentially read or written, starting from the current randomly accessed position. Note, however, that in this case, the last randomly read record will be re-read as you switch from random mode to sequential read, and the last record will be re-written as you switch to a sequential write operation. You can, of course, simply advance the random record position following each random read or write to obtain the effect of a sequential I/O operation.

Error codes returned in register A following a random read are listed below.
Error code 01 and 04 occur when a random read operation accesses a data block which has not been previously written, or an extent which has not been created, which are equivalent conditions. Error 3 does not normally occur under proper system operation, but can be cleared by simply re-reading, or re-opening extent zero as long as the disk is not physically write protected. Error code 06 occurs whenever byte r2 is non-zero under the current 2.0 release. Normally, non-zero return codes can be treated as missing data, with zero return codes indicating operation complete.
The Write Random operation is initiated similar to the Read Random call, except that data is written to the disk from the current DMA address. Further, if the disk extent or data block which is the target of the write has not yet been allocated, the allocation is performed before the write operation continues. As in the Read Random operation, the random record number is not changed as a result of the write. The logical extent number and current record positions of the file control block are set to correspond to the random record which is being written. Again, sequential read or write operations can commence following a random write, with the notation that the currently addressed record is either read or rewritten again as the sequential operation begins. You can also simply advance the random record position following each write to get the effect of a sequential write operation. Note that in particular, reading or writing the last record of an extent in random mode does not cause an automatic extent switch as it does in sequential mode.

The error codes returned by a random write are identical to the random read operation with the addition of error code 05, which indicates that a new extent cannot be created due to directory overflow.
When computing the size of a file, the DE register pair addresses an FCB in random mode format (bytes r0, r1, and r2 are present). The FCB contains an unambiguous file name which is used in the directory scan. Upon return, the random record bytes contain the "virtual" file size which is, in effect, the record address of the record following the end of the file. If, following a call to function 35, the high record byte r2 is 01, then the file contains the maximum record count 65536. Otherwise, bytes r0 and r1 constitute a 16-bit value (r0 is the least significant byte, as before) which is the file size.

Data can be appended to the end of an existing file by simply calling function 35 to set the random record position to the end of file, then performing a sequence of random writes starting at the preset record address.

The virtual size of a file corresponds to the physical size when the file is written sequentially. If, instead, the file was created in random mode and "holes" exist in the allocation, then the file may in fact contain fewer records than the size indicates. If, for example, only the last record of an eight megabyte file is written in random mode (i.e., record number 65535), then the virtual size is 65536 records, although only one block of data is actually allocated.
The Set Random Record function causes the BDOS to automatically produce the random record position from a file which has been read or written sequentially to a particular point. The function can be useful in two ways.

First, it is often necessary to initially read and scan a sequential file to extract the positions of various "key" fields. As each key is encountered, function 36 is called to compute the random record position for the data corresponding to this key. If the data unit size is 128 bytes, the resulting record position is placed into a table with the key for later retrieval. After scanning the entire file and tabularizing the keys and their record numbers, you can move instantly to a particular keyed record by performing a random read using the corresponding random record number which was saved earlier. The scheme is easily generalized when variable record lengths are involved since the program need only store the buffer-relative byte position along with the key and record number in order to find the exact starting position of the keyed data at a later time.

A second use of function 36 occurs when switching from a sequential read or write over to random read or write. A file is sequentially accessed to a particular point in the file, function 36 is called which sets the record number, and subsequent random read and write operations continue from the selected point in the file.
3. A SAMPLE FILE-TO-FILE COPY PROGRAM.

The program shown below provides a relatively simple example of file operations. The program source file is created as COPY.ASH using the CP/M ED program and then assembled using ASM or MAC, resulting in a "HEX" file. The LOAD program is the used to produce a COPY.COM file which executes directly under the CCP. The program begins by setting the stack pointer to a local area, and then proceeds to move the second name from the default area at 006CH to a 33-byte file control block called DFCB. The DFCB is then prepared for file operations by clearing the current record field. At this point, the source and destination FCB's are ready for processing since the SFCB at 005CH is properly set-up by the CCP upon entry to the COPY program. That is, the first name is placed into the default fcb, with the proper fields zeroed, including the current record field at 007CH. The program continues by opening the source file, deleting any existing destination file, and then creating the destination file. If all this is successful, the program loops at the label COPY until each record has been read from the source file and placed into the destination file. Upon completion of the data transfer, the destination file is closed and the program returns to the CCP command level by jumping to BOOT.

; sample file-to-file copy program
; at the ccp level, the command
; copy a:x.y b:u.v
; copies the file named x.y from drive a to a file named u.v on drive b.

(All Information Contained Herein is Proprietary to Digital Research.)
Note that there are several simplifications in this particular program. First, there are no checks for invalid file names which could, for example, contain ambiguous references. This situation could be detected by scanning the 32 byte default area starting at location 005CH for ASCII question marks. A check should also be made to ensure that the file names have, in fact, been included (check locations 005DH and 006DH for non-blank ASCII characters). Finally, a check should be made to ensure that the source and destination file names are different. A speed improvement could be made by buffering more data on each read operation. One could, for example, determine
the size of memory by fetching FBASE from location 0006H and use the entire remaining portion of memory for a data buffer. In this case, the programmer simply resets the DMA address to the next successive 128 byte area before each read. Upon writing to the destination file, the DMA address is reset to the beginning of the buffer and incremented by 128 bytes to the end as each record is transferred to the destination file.
4. A SAMPLE FILE DUMP UTILITY.

The file dump program shown below is slightly more complex than the simple copy program given in the previous section. The dump program reads an input file, specified in the CCP command line, and displays the content of each record in hexadecimal format at the console. Note that the dump program saves the CCP's stack upon entry, resets the stack to a local area, and restores the CCP's stack before returning directly to the CCP. Thus, the dump program does not perform and warm start at the end of processing.

5. A SAMPLE RANDOM ACCESS PROGRAM.

This manual is concluded with a rather extensive, but complete example of random access operation. The program listed below performs the simple function of reading or writing random records upon command from the terminal. Given that the program has been created, assembled, and placed into a file labelled RANDOM.COM, the CCP level command:

```
RANDOM X.DAT
```

starts the test program. The program looks for a file by the name X.DAT (in this particular case) and, if found, proceeds to prompt the console for input. If not found, the file is created before the prompt is given. Each prompt takes the form

```
next command?
```

and is followed by operator input, terminated by a carriage return. The input commands take the form

```
nW  nR  Q
```

where n is an integer value in the range 0 to 65535, and W, R, and Q are simple command characters corresponding to random write, random read, and quit processing, respectively. If the W command is issued, the RANDCM program issues the prompt

```
type data:
```

The operator then responds by typing up to 127 characters, followed by a carriage return. RANDOM then writes the character string into the X.DAT file at record n. If the R command is issued, RANDOM reads record number n and displays the string value at the console. If the Q command is issued, the X.DAT file is closed, and the program returns to the console command processor. In the interest of brevity, the only error message is

```
error, try again
```

The program begins with an initialization section where the input file is opened or created, followed by a continuous loop at the label "ready" where the individual commands are interpreted. The default file control block at 005CH and the default buffer at 0080H are used in all disk operations. The utility subroutines then follow, which contain the principal input line processor, called "readc." This particular program shows the elements of random access processing, and can be used as the basis for further program development.

(All Information Contained Herein is Proprietary to Digital Research.)
Again, major improvements could be made to this particular program to enhance its operation. In fact, with some work, this program could evolve into a simple data base management system. One could, for example, assume a standard record size of 128 bytes, consisting of arbitrary fields within the record. A program, called GETKEY, could be developed which first reads a sequential file and extracts a specific field defined by the operator. For example, the command

\texttt{GETKEY NAMES.DAT LASTNAME 10 20}

would cause GETKEY to read the data base file \texttt{NAMES.DAT} and extract the "LASTNAME" field from each record, starting at position 10 and ending at character 20. GETKEY builds a table in memory consisting of each particular LASTNAME field, along with its 16-bit record number location within the file. The GETKEY program then sorts this list, and writes a new file, called \texttt{LASTNAME.KEY}, which is an alphabetical list of LASTNAME fields with their corresponding record numbers. (This list is called an "inverted index" in information retrieval parlance.)

Rename the program shown above as QUERY, and massage it a bit so that it reads a sorted key file into memory. The command line might appear as:

\texttt{QUERY NAMES.DAT LASTNAME.KEY}

Instead of reading a number, the QUERY program reads an alphanumeric string which is a particular key to find in the NAMES.DAT data base. Since the LASTNAME.KEY list is sorted, you can find a particular entry quite rapidly by performing a "binary search," similar to looking up a name in the telephone book. That is, starting at both ends of the list, you examine the entry halfway in between and, if not matched, split either the upper half or the lower half for the next search. You'll quickly reach the item you're looking for (in log2(n) steps) where you'll find the corresponding record number. Fetch and display this record at the console, just as we have done in the program shown above.

(All Information Contained Herein is Proprietary to Digital Research.)
At this point you're just getting started. With a little more work, you can allow a fixed grouping size which differs from the 128 byte record shown above. This is accomplished by keeping track of the record number as well as the byte offset within the record. Knowing the group size, you randomly access the record containing the proper group, offset to the beginning of the group within the record read sequentially until the group size has been exhausted.

Finally, you can improve QUERY considerably by allowing boolean expressions which compute the set of records which satisfy several relationships, such as a LASTNAME between HARDY and LAUREL, and an AGE less than 45. Display all the records which fit this description. Finally, if your lists are getting too big to fit into memory, randomly access your key files from the disk as well. One note of consolation after all this work: if you make it through the project, you'll have no more need for this manual!

1. INTRODUCTION

The standard CP/M system assumes operation on an Intel MDS-800 microcomputer development system, but is designed so that the user can alter a specific set of subroutines which define the hardware operating environment. In this way, the user can produce a diskette which operates with any IBM-3741 format compatible drive controller and other peripheral devices.

Although standard CP/M 2.0 is configured for single density floppy disks, field-alteration features allow adaptation to a wide variety of disk subsystems from single drive minidisks through high-capacity "hard disk" systems. In order to simplify the following adaptation process, we assume that CP/M 2.0 will first be configured for single density floppy disks where minimal editing and debugging tools are available. If an earlier version of CP/M is available, the customizing process is eased considerably. In this latter case, you may wish to briefly review the system generation process, and skip to later sections which discuss system alteration for non-standard disk systems.

In order to achieve device independence, CP/M is separated into three distinct modules:

- BIOS - basic I/O system which is environment dependent
- BDOS - basic disk operating system which is not dependent upon the hardware configuration
- CCP - the console command processor which uses the BDOS

Of these modules, only the BIOS is dependent upon the particular hardware. That is, the user can "patch" the distribution version of CP/M to provide a new BIOS which provides a customized interface between the remaining CP/M modules and the user's own hardware system. The purpose of this document is to provide a step-by-step procedure for patching your new BIOS into CP/M.

If CP/M is being tailored to your computer system for the first time, the new BIOS requires some relatively simple software development and testing. The standard BIOS is listed in Appendix B, and can be used as a model for the customized package. A skeletal version of the BIOS is given in Appendix C which can serve as the basis for a modified BIOS. In addition to the BIOS, the user must write a simple memory loader, called GETSYS, which brings the operating system into memory. In order to patch the new BIOS into CP/M, the user must write the reverse of GETSYS, called PUTSYS, which places an altered version of CP/M back onto the diskette. PUTSYS can be derived from GETSYS by changing the disk read commands into disk write commands. Sample skeletal GETSYS and PUTSYS programs are described in Section 3, and listed in Appendix D. In order to make the CP/M system work automatically, the user must also supply a cold start loader, similar to the one provided with CP/M (listed in Appendices A and B). A skeletal form of a cold start loader is given in Appendix E which can serve as a model for your loader.

(All Information Contained Herein is Proprietary to Digital Research.)
2. FIRST LEVEL SYSTEM REGENERATION

The procedure to follow to patch the CP/M system is given below in several steps. Address references in each step are shown with a following "H" which denotes the hexadecimal radix, and are given for a 20K CP/M system. For larger CP/M systems, add a "bias" to each address which is shown with a "+b" following it, where b is equal to the memory size - 20K. Values for b in various standard memory sizes are

- **24K**: \( b = 24K - 20K = 4K = \text{1000H} \)
- **32K**: \( b = 32K - 20K = 12K = \text{3000H} \)
- **40K**: \( b = 40K - 20K = 20K = \text{5000H} \)
- **48K**: \( b = 48K - 20K = 28K = \text{7000H} \)
- **56K**: \( b = 56K - 20K = 36K = \text{9000H} \)
- **62K**: \( b = 62K - 20K = 42K = \text{A800H} \)
- **64K**: \( b = 64K - 20K = 44K = \text{B000H} \)

Note: The standard distribution version of CP/M is set for operation within a 20K memory system. Therefore, you must first bring up the 20K CP/M system, and then configure it for your actual memory size (see Second Level System Generation).

1. Review Section 4 and write a GETSYS program which reads the first two tracks of a diskette into memory. The data from the diskette must begin at location \( \text{3380H} \). Code GETSYS so that it starts at location \( \text{1000H} \) (base of the TPA), as shown in the first part of Appendix D.

2. Test the GETSYS program by reading a blank diskette into memory, and check to see that the data has been read properly, and that the diskette has not been altered in any way by the GETSYS program.

3. Run the GETSYS program using an initialized CP/M diskette to see if GETSYS loads CP/M starting at \( \text{3380H} \) (the operating system actually starts 128 bytes later at \( \text{3400H} \)).

4. Review Section 4 and write the PUTSYS program which writes memory starting at \( \text{3380H} \) back onto the first two tracks of the diskette. The PUTSYS program should be located at \( \text{200H} \), as shown in the second part of Appendix D.

5. Test the PUTSYS program using a blank uninitialized diskette by writing a portion of memory to the first two tracks; clear memory and read it back using GETSYS. Test PUTSYS completely, since this program will be used to alter CP/M on disk.

6. Study Sections 5, 6, and 7, along with the distribution version of the BIOS given in Appendix B, and write a simple version which performs a similar function for the customized environment. Use the program given in Appendix C as a model. Call this new BIOS by the name CBIOS (customized BIOS). Implement only the primitive disk operations on a single drive, and simple console input/output functions in this phase.

(All Information Contained Herein is Proprietary to Digital Research.)
(7) Test CBIOS completely to ensure that it properly performs console character I/O and disk reads and writes. Be especially careful to ensure that no disk write operations occur accidently during read operations, and check that the proper track and sectors are addressed on all reads and writes. Failure to make these checks may cause destruction of the initialized CP/M system after it is patched.

(8) Referring to Figure 1 in Section 5, note that the BIOS is placed between locations 4A00H and 4FFFH. Read the CP/M system using GETSYS and replace the BIOS segment by the new CBIOS developed in step (6) and tested in step (7). This replacement is done in the memory of the machine, and will be placed on the diskette in the next step.

(9) Use PUTSYS to place the patched memory image of CP/M onto the first two tracks of a blank diskette for testing.

(10) Use GETSYS to bring the copied memory image from the test diskette back into memory at 3380H, and check to ensure that it has loaded back properly (clear memory, if possible, before the load). Upon successful load, branch to the cold start code at location 4A00H. The cold start routine will initialize page zero, then jump to the CCP at location 3400H which will call the BOOS, which will call the CBIOS. The CBIOS will be asked by the CCP to read sixteen sectors on track 2, and if successful, CP/M will type "A>" the system prompt.

When you make it this far, you are almost on the air. If you have trouble, use whatever debug facilities you have available to trace and breakpoint your CBIOS.

(11) Upon completion of step (10), CP/M has promoted the console for a command input. Test the disk write operation by typing

```
SAVE 1 X.COM
```

(recall that all commands must be followed by a carriage return). CP/M should respond with another prompt (after several disk accesses):

```
A>
```

If it does not, debug your disk write functions and retry.

(12) Then test the directory command by typing

```
DIR
```

CP/M should respond with

```
A: X COM
```

(13) Test the erase command by typing

```
ERA X.COM
```

(All Information Contained Herein is Proprietary to Digital Research.)
CP/M should respond with the A prompt. When you make it this far, you should have an operational system which will only require a bootstrap loader to function completely.

(14) Write a bootstrap loader which is similar to GETSYS, and place it on track 0, sector 1 using PUTSYS (again using the test diskette, not the distribution diskette). See Sections 5 and 8 for more information on the bootstrap operation.

(15) Retest the new test diskette with the bootstrap loader installed by executing steps (11), (12), and (13). Upon completion of these tests, type a control-C (control and C keys simultaneously). The system should then execute a “warm start” which reboots the system, and types the A prompt.

(16) At this point, you probably have a good version of your customized CP/M system on your test diskette. Use GETSYS to load CP/M from your test diskette. Remove the test diskette, place the distribution diskette (or a legal copy) into the drive, and use PUTSYS to replace the distribution version by your customized version. Do not make this replacement if you are unsure of your patch since this step destroys the system which was sent to you from Digital Research.

(17) Load your modified CP/M system and test it by typing

```
DIR
```

CP/M should respond with a list of files which are provided on the initialized diskette. One such file should be the memory image for the debugger, called DDT.COM.

*NOTE*: from now on, it is important that you always reboot the CP/M system (ctl-C is sufficient) when the diskette is removed and replaced by another diskette, unless the new diskette is to be read only.

(18) Load and test the debugger by typing

```
DDT
```

(see the document "CP/M Dynamic Debugging Tool (DDT)" for operating procedures. You should take the time to become familiar with DDT, it will be your best friend in later steps.

(19) Before making further CBIOS modifications, practice using the editor (see the ED user's guide), and assembler (see the ASM user's guide). Then recode and test the GETSYS, PUTSYS, and CBIOS programs using ED, ASM, and DDT. Code and test a COPY program which does a sector-to-sector copy from one diskette to another to obtain back-up copies of the original diskette *(NOTE: read your CP/M Licensing Agreement; it specifies your legal responsibilities when copying the CP/M system)*.

Copyright (c), 1979
Digital Research

(All Information Contained Herein is Proprietary to Digital Research.)
(20) Modify your CBIOS to include the extra functions for punches, readers, signon messages, and so-forth, and add the facilities for a additional disk drives, if desired. You can make these changes with the GETSYS and PUTSYS programs which you have developed, or you can refer to the following section, which outlines CP/M facilities which will aid you in the regeneration process.

You now have a good copy of the customized CP/M system. Note that although the CBIOS portion of CP/M which you have developed belongs to you, the modified version of CP/M which you have created can be copied for your use only (again, read your Licensing Agreement), and cannot be legally copied for anyone else's use.

It should be noted that your system remains file-compatible with all other CP/M systems, (assuming media compatibility, of course) which allows transfer of non-proprietary software between users of CP/M.

(All Information Contained Herein is Proprietary to Digital Research.)
3. SECOND LEVEL SYSTEM GENERATION

Now that you have the CP/M system running, you will want to configure CP/M for your memory size. In general, you will first get a memory image of CP/M with the "MOVCPM" program (system relocator) and place this memory image into a named disk file. The disk file can then be loaded, examined, patched, and replaced using the debugger, and system generation program. For further details on the operation of these programs, see the "Guide to CP/M Features and Facilities" manual.

Your CBIOS and BOOT can be modified using ED, and assembled using ASM, producing files called CBIOS.HEX and BOOT.HEX, which contain the machine code for CBIOS and BOOT in Intel hex format.

To get the memory image of CP/M into the TPA configured for the desired memory size, give the command:

MOVCPM xx *

where "xx" is the memory size in decimal K bytes (e.g., 32 for 32K). The response will be:

CONSTRUCTING xxK CP/M VERS 2.0
READY FOR "SYSGEN" OR
"SAVE 34 CPMxx.COM"

At this point, an image of a CP/M in the TPA configured for the requested memory size. The memory image is at location 0900H through 227FH. (i.e., The BOOT is at 0900H, the CCP is at 980H, the BDOS starts at 1180H, and the BIOS is at 1F80H.) Note that the memory image has the standard MDS-800 BIOS and BOOT on it. It is now necessary to save the memory image in a file so that you can patch your CBIOS and CBOOT into it:

SAVE 34 CPMxx.COM

The memory image created by the "MOVCPM" program is offset by a negative bias so that it loads into the free area of the TPA, and thus does not interfere with the operation of CP/M in higher memory. This memory image can be subsequently loaded under DDT and examined or changed in preparation for a new generation of the system. DDT is loaded with the memory image by typing:

DDT CPMxx.COM

Load DDT, then read the CP/M image

DDT should respond with

NEXT PC
2300 0100

(The DDT prompt)

You can then use the display and disassembly commands to examine

(All Information Contained Herein is Proprietary to Digital Research.)
portions of the memory image between 900H and 227FH. Note, however, that to find any particular address within the memory image, you must apply the negative bias to the CP/M address to find the actual address. Track 00, sector 01 is loaded to location 900H (you should find the cold start loader at 900H to 97FH), track 00, sector 02 is loaded into 980H (this is the base of the CCP), and so-forth through the entire CP/M system load. In a 20K system, for example, the CCP resides at the CP/M address 3400H, but is placed into memory at 980H by the SYSGEN program. Thus, the negative bias, denoted by n, satisfies

\[ 3400H + n = 980H, \text{ or } n = 980H - 3400H \]

Assuming two's complement arithmetic, \( n = D_{580}H \), which can be checked by

\[ 3400H + D_{580}H = 10980H = 0980H \] (ignoring high-order overflow).

Note that for larger systems, \( n \) satisfies

\[
(3400H+b) + n = 980H, \text{ or }\n\]
\[
n = 980H - (3400H + b), \text{ or } n = D_{580}H - b. \]

The value of \( n \) for common CP/M systems is given below

<table>
<thead>
<tr>
<th>memory size</th>
<th>bias ( b )</th>
<th>negative offset ( n )</th>
</tr>
</thead>
<tbody>
<tr>
<td>20K</td>
<td>0000H</td>
<td>D_{580}H - 0000H = D_{580}H</td>
</tr>
<tr>
<td>24K</td>
<td>1000H</td>
<td>D_{580}H - 1000H = C_{580}H</td>
</tr>
<tr>
<td>32K</td>
<td>3000H</td>
<td>D_{580}H - 3000H = A_{580}H</td>
</tr>
<tr>
<td>40K</td>
<td>5000H</td>
<td>D_{580}H - 5000H = 8_{580}H</td>
</tr>
<tr>
<td>48K</td>
<td>7000H</td>
<td>D_{580}H - 7000H = 6_{580}H</td>
</tr>
<tr>
<td>56K</td>
<td>9000H</td>
<td>D_{580}H - 9000H = 4_{580}H</td>
</tr>
<tr>
<td>62K</td>
<td>A800H</td>
<td>D_{580}H - A800H = 2D_{80}H</td>
</tr>
<tr>
<td>64K</td>
<td>8000H</td>
<td>D_{580}H - 8000H = 25_{80}H</td>
</tr>
</tbody>
</table>

Assume, for example, that you want to locate the address \( x \) within the memory image loaded under DDT in a 20K system. First type

\[ Hx,n \]

Hexadecimal sum and difference

and DDT will respond with the value of \( x+n \) (sum) and \( x-n \) (difference). The first number printed by DDT will be the actual memory address in the image where the data or code will be found. The input

\[ H3400,D_{580} \]

for example, will produce 980H as the sum, which is where the CCP is located in the memory image under DDT.

Use the L command to disassemble portions the BIOS located at \((4A00H+b)-n\) which, when you use the H command, produces an actual address of 1F80H. The disassembly command would thus be

(All Information Contained Herein is Proprietary to Digital Research.)
L1F80

It is now necessary to patch in your CBOOT and CB IOS routines. The
BOOT resides at location 0900H in the memory image. If the actual
load address is "n", then to calculate the bias (m) use the command:

H900,n  Subtract load address from
target address.

The second number typed in response to the command is the desired bias
(m). For example, if your BOOT executes at 0080H, the command:

H900,80

will reply

0980 0880  Sum and difference in hex.

Therefore, the bias "m" would be 0880H. To read-in the BOOT, give the
command:

ICBOOT.HEX  Input file CBOOT.HEX

Then:

Rm  Read CBOOT with a bias of
     m (=900H-n)

You may now examine your CBOOT with:

L900

We are now ready to replace the CB IOS. Examine the area at 1F80H
where the original version of the CB IOS resides. Then type

ICBIOS.HEX  Ready the "hex" file for loading

assume that your CB IOS is being integrated into a 20K CP/M system, and
thus is origined at location 4A00H. In order to properly locate the
CB IOS in the memory image under DDT, we must apply the negative bias n
for a 20K system when loading the hex file. This is accomplished by
typing

RD580  Read the file with bias D580H

Upon completion of the read, re-examine the area where the CB IOS has
been loaded (use an "L1F80" command), to ensure that is was loaded
properly. When you are satisfied that the change has been made,
return from DDT using a control-C or "G0" command.

Now use SYSGEN to replace the patched memory image back onto a
diskette (use a test diskette until you are sure of your patch), as
shown in the following interaction

(All Information Contained Herein is Proprietary to Digital Research.)
Start the SYSGEN program
Sign-on message from SYSGEN
Respond with a carriage return to skip the CP/M read operation since the system is already in memory.
Respond with "B" to write the new system to the diskette in drive B.
Place a scratch diskette in drive B, then type return.
Place the scratch diskette in your drive A, and then perform a coldstart to bring up the new CP/M system you have configured.
Test the new CP/M system, and place the Digital Research copyright notice on the diskette, as specified in your Licensing Agreement:

Copyright (c), 1979
Digital Research
4. SAMPLE GETSYS AND PUTSYS PROGRAMS

The following program provides a framework for the GETSYS and PUTSYS programs referenced in Section 2. The READSEC and WRITESEC subroutines must be inserted by the user to read and write the specific sectors.

; GETSYS PROGRAM - READ TRACKS 0 AND 1 TO MEMORY AT 3380H
; REGISTER USE
; A (SCRATCH REGISTER)
; B TRACK COUNT (0, 1)
; C SECTOR COUNT (1, 2, ..., 26)
; DE (SCRATCH REGISTER PAIR)
; HL LOAD ADDRESS
; SP SET TO STACK ADDRESS

START: LXI SP, 3380H ;SET STACK POINTER TO SCRATCH AREA
LXI H, 3380H ;SET BASE LOAD ADDRESS
MVI B, 0 ;START WITH TRACK 0
RDTRK: MVI C, 1 ;READ NEXT TRACK (INITIALLY 0)
RDSEC: CALL READSEC ;READ NEXT SECTOR
LXI D, 128 ;MOVE LOAD ADDRESS TO NEXT 1/2 PAGE
JAD D ;HL = HL + 128
INR C ;SECTOR = SECTOR + 1
MOV A, C ;CHECK FOR END OF TRACK
CPI 27
JC RDSEC ;CARRY GENERATED IF SECTOR < 27

; ARRIVE HERE AT END OF TRACK, MOVE TO NEXT TRACK
INR B
MOV A, B ;TEST FOR LAST TRACK
CPI 2
JC RDTRK ;CARRY GENERATED IF TRACK < 2

; ARRIVE HERE AT END OF LOAD, HALT FOR NOW
HLT

; USER-SUPPLIED SUBROUTINE TO READ THE DISK
READSEC:
; ENTER WITH TRACK NUMBER IN REGISTER B,
; SECTOR NUMBER IN REGISTER C, AND
; ADDRESS TO FILL IN HL

PUSH B ;SAVE B AND C REGISTERS
PUSH H ;SAVE HL REGISTERS

perform disk read at this point, branch to
label START if an error occurs

PUSH H ;RECOVER HL
POP B ;RECOVER B AND C REGISTERS
RET ;BACK TO MAIN PROGRAM

END START

(All Information Contained Herein is Proprietary to Digital Research.)
Note that this program is assembled and listed in Appendix C for reference purposes, with an assumed origin of 100H. The hexadecimal operation codes which are listed on the left may be useful if the program has to be entered through your machine's front panel switches.

The PUTSYS program can be constructed from GETSYS by changing only a few operations in the GETSYS program given above, as shown in Appendix D. The register pair HL become the dump address (next address to write), and operations upon these registers do not change within the program. The READSEC subroutine is replaced by a WRITESEC subroutine which performs the opposite function: data from address HL is written to the track given by register B and sector given by register C. It is often useful to combine GETSYS and PUTSYS into a single program during the test and development phase, as shown in the Appendix.

(All Information Contained Herein is Proprietary to Digital Research.)
5. DISKETTE ORGANIZATION

The sector allocation for the standard distribution version of CP/M is given here for reference purposes. The first sector (see table on the following page) contains an optional software boot section. Disk controllers are often set up to bring track 0, sector 1 into memory at a specific location (often location 0000H). The program in this sector, called BOOT, has the responsibility of bringing the remaining sectors into memory starting at location 3400H+b. If your controller does not have a built-in sector load, you can ignore the program in track 0, sector 1, and begin the load from track 0 sector 2 to location 3400H+b.

As an example, the Intel MDS-800 hardware cold start loader brings track 0, sector 1 into absolute address 3000H. Upon loading this sector, control transfers to location 3000H, where the bootstrap operation commences by loading the remainder of tracks 0, and all of track 1 into memory, starting at 3400H+b. The user should note that this bootstrap loader is of little use in a non-MDS environment, although it is useful to examine it since some of the boot actions will have to be duplicated in your cold start loader.

(All Information Contained Herein is Proprietary to Digital Research.)

(All Information Contained Herein is Proprietary to Digital Research.)
6. THE BIOS ENTRY POINTS

The entry points into the BIOS from the cold start loader and BDOS are detailed below. Entry to the BIOS is through a "jump vector" located at 4A00H+b, as shown below (see Appendices B and C, as well). The jump vector is a sequence of 17 jump instructions which send program control to the individual BIOS subroutines. The BIOS subroutines may be empty for certain functions (i.e., they may contain a single REP operation) during regeneration of CP/M, but the entries must be present in the jump vector.

The jump vector at 4A00H+b takes the form shown below, where the individual jump addresses are given to the left:

4A00H+b  JMP  BOOT ; ARRIVE HERE FROM COLD START LOAD
4A03H+b  JMP  WBOOT ; ARRIVE HERE FOR WARM START
4A06H+b  JMP  CONST ; CHECK FOR CONSOLE CHAR READY
4A09H+b  JMP  CONIN ; READ CONSOLE CHARACTER IN
4A0CH+b  JMP  CONOUT ; WRITE CONSOLE CHARACTER OUT
4A0FH+b  JMP  LIST ; WRITE LISTING CHARACTER OUT
4A12H+b  JMP  PUNCH ; WRITE CHARACTER TO PUNCH DEVICE
4A15H+b  JMP  READER ; READ READER DEVICE
4A18H+b  JMP  HOME ; MOVE TO TRACK 00 ON SELECTED DISK
4A1BH+b  JMP  SELDSK ; SELECT DISK DRIVE
4A1EH+b  JMP  SETTRK ; SET TRACK NUMBER
4A21H+b  JMP  SETSEC ; SET SECTOR NUMBER
4A24H+b  JMP  SETDMA ; SET DMA ADDRESS
4A27H+b  JMP  READ ; READ SELECTED SECTOR
4A2AH+b  JMP  WRITE ; WRITE SELECTED SECTOR
4A2DH+b  JMP  LISTST ; RETURN LIST STATUS
4A30H+b  JMP  SECTRAN ; SECTOR TRANSLATE SUBROUTINE

Each jump address corresponds to a particular subroutine which performs the specific function, as outlined below. There are three major divisions in the jump table: the system (re)initialization which results from calls on BOOT and WBOOT, simple character I/O performed by calls on CONST, CONIN, CONOUT, LIST, PUNCH, READER, and LISTST, and diskette I/O performed by calls on HOME, SELDSK, SETTRK, SETSEC, SETDMA, READ, WRITE, and SECTRAN.

All simple character I/O operations are assumed to be performed in ASCII, upper and lower case, with high order (parity bit) set to zero. An end-of-file condition for an input device is given by an ASCII control-z (lAH). Peripenral devices are seen by CP/M as "logical" devices, and are assigned to physical devices within the BIOS.

In order to operate, the BDOS needs only the CONST, CONIN, and CONOUT subroutines (LIST, PUNCH, and READER may be used by PIP, but not the BDOS). Further, the LISTST entry is used currently only by DESPOOL, and thus, the initial version of CBIOS may have empty subroutines for the remaining ASCII devices.

(All Information Contained Herein is Proprietary to Digital Research.)
The characteristics of each device are

**CONSOLE**
The principal interactive console which communicates with the operator, accessed through CONST, CONIN, and CONOUT. Typically, the CONSOLE is a device such as a CRT or Teletype.

**LIST**
The principal listing device, if it exists on your system, which is usually a hard-copy device, such as a printer or Teletype.

**PUNCH**
The principal tape punching device, if it exists, which is normally a high-speed paper tape punch or Teletype.

**READER**
The principal tape reading device, such as a simple optical reader or Teletype.

Note that a single peripheral can be assigned as the LIST, PUNCH, and READER device simultaneously. If no peripheral device is assigned as the LIST, PUNCH, or READER device, the CBios created by the user may give an appropriate error message so that the system does not "hang" if the device is accessed by PIP or some other user program. Alternately, the PUNCH and LIST routines can just simply return, and the READER routine can return with a laH (ctl-Z) in reg A to indicate immediate end-of-file.

For added flexibility, the user can optionally implement the "IOBYTE" function which allows reassignment of physical and logical devices. The IOBYTE function creates a mapping of logical to physical devices which can be altered during CP/M processing (see the STAT command). The definition of the IOBYTE function corresponds to the Intel standard as follows: a single location in memory (currently location 0003H) is maintained, called IOBYTE, which defines the logical to physical device mapping which is in effect at a particular time. The mapping is performed by splitting the IOBYTE into four distinct fields of two bits each, called the CONSOLE, READER, PUNCH, and LIST fields, as shown below:

<table>
<thead>
<tr>
<th>most significant</th>
<th>least significant</th>
</tr>
</thead>
<tbody>
<tr>
<td>IOBYTE AT 0003H</td>
<td>LIST</td>
</tr>
<tr>
<td>bits 6,7</td>
<td>bits 4,5</td>
</tr>
</tbody>
</table>

The value in each field can be in the range 0-3, defining the assigned source or destination of each logical device. The values which can be assigned to each field are given below.

(All Information Contained Herein is Proprietary to Digital Research.)
CONSOLE field (bits 0,1)
0 - console is assigned to the console printer device (TTY:)
1 - console is assigned to the CRT device (CRT:)
2 - batch mode: use the READER as the CONSOLE input, and the LIST device as the CONSOLE output (BAT:)
3 - user defined console device (UCl:)

READER field (bits 2,3)
0 - READER is the Teletype device (TTY:)
1 - READER is the high-speed reader device (RDR:)
2 - user defined reader # 1 (URL:)
3 - user defined reader # 2 (UR2:)

PUNCH field (bits 4,5)
0 - PUNCH is the Teletype device (TTY:)
1 - PUNCH is the high-speed punch device (PUN:)
2 - user defined punch # 1 (UP1:)
3 - user defined punch # 2 (UP2:)

LIST field (bits 6,7)
0 - LIST is the Teletype device (TTY:)
1 - LIST is the CRT device (CRT:)
2 - LIST is the line printer device (LPT:)
3 - user defined list device (UPL:)

Note again that the implementation of the IOBYTE is optional, and affects only the organization of your CBIOS. No CP/M systems use the IOBYTE (although they tolerate the existence of the IOBYTE at location $003H), except for PIP which allows access to the physical devices, and STAT which allows logical-physical assignments to be made and/or displayed (for more information, see the "CP/M Features and Facilities Guide"). In any case, the IOBYTE implementation should be omitted until your basic CBIOS is fully implemented and tested; then add the IOBYTE to increase your facilities.

Disk I/O is always performed through a sequence of calls on the various disk access subroutines which set up the disk number to access, the track and sector on a particular disk, and the direct memory access (DMA) address involved in the I/O operation. After all these parameters have been set up, a call is made to the READ or WRITE function to perform the actual I/O operation. Note that there is often a single call to SELDSK to select a disk drive, followed by a number of read or write operations to the selected disk before selecting another drive for subsequent operations. Similarly, there may be a single call to set the DMA address, followed by several calls which read or write from the selected DMA address before the DMA address is changed. The track and sector subroutines are always called before the READ or WRITE operations are performed.

(All Information Contained Herein is Proprietary to Digital Research.)
Note that the READ and WRITE routines should perform several retries (10 is standard) before reporting the error condition to the BDOS. If the error condition is returned to the BDOS, it will report the error to the user. The HOME subroutine may or may not actually perform the track 00 seek, depending upon your controller characteristics; the important point is that track 00 has been selected for the next operation, and is often treated in exactly the same manner as SETTRK with a parameter of 00.

The exact responsibilities of each entry point subroutine are given below:

**BOOT**
The BOOT entry point gets control from the cold start loader and is responsible for basic system initialization, including sending a signon message (which can be omitted in the first version). If the IOBYTE function is implemented, it must be set at this point. The various system parameters which are set by the WBOOT entry point must be initialized, and control is transferred to the CCP at 3400H+b for further processing. Note that reg C must be set to zero to select drive A.

**WBOOT**
The WBOOT entry point gets control when a warm start occurs. A warm start is performed whenever a user program branches to location 0000H, or when the CPU is reset from the front panel. The CP/M system must be loaded from the first two tracks of drive A up to, but not including, the BIOS (or CBIOS, if you have completed your patch). System parameters must be initialized as shown below:

- location 0,1,2 set to JMP WBOOT for warm starts
  (0000H: JMP 4A03H+b)
- location 3 set initial value of IOBYTE, if implemented in your CBIOS
- location 5,6,7 set to JMP BDOS, which is the primary entry point to CP/M for transient programs. (0005H: JMP 3C06H+b)

(See Section 9 for complete details of page zero use.)

Upon completion of the initialization, the WBOOT program must branch to the CCP at 3400H+b to (re)start the system. Upon entry to the CCP, register C is set to the drive to select after system initialization.

**CONST**
Sample the status of the currently assigned console device and return 0FFH in register A if a character is ready to read, and 00H in register A if no console characters are ready.

**CONIN**
Read the next console character into register A, and
set the parity bit (high order bit) to zero. If no console character is ready, wait until a character is typed before returning.

**CONOUT**

Send the character from register C to the console output device. The character is in ASCII, with high order parity bit set to zero. You may want to include a time-out on a line feed or carriage return, if your console device requires some time interval at the end of the line (such as a TI Silent 700 terminal). You can, if you wish, filter out control characters which cause your console device to react in a strange way (a control-z causes the Lear Seigler terminal to clear the screen, for example).

**LIST**

Send the character from register C to the currently assigned listing device. The character is in ASCII with zero parity.

**PUNCH**

Send the character from register C to the currently assigned punch device. The character is in ASCII with zero parity.

**READER**

Read the next character from the currently assigned reader device into register A with zero parity (high order bit must be zero), an end of file condition is reported by returning an ASCII control-z (lAH).

**HOME**

Return the disk head of the currently selected disk (initially disk A) to the track 00 position. If your controller allows access to the track 0 flag from the drive, step the head until the track 0 flag is detected. If your controller does not support this feature, you can translate the HOME call into a call on SETTRK with a parameter of 0.

**SELDSK**

Select the disk drive given by register C for further operations, where register C contains 0 for drive A, 1 for drive B, and so-forth up to 15 for drive P (the standard CP/M distribution version supports four drives). On each disk select, SELDSK must return in HL the base address of a 16-byte area, called the Disk Parameter Header, described in the Section 10. For standard floppy disk drives, the contents of the header and associated tables does not change, and thus the program segment included in the sample CBIOs performs this operation automatically. If there is an attempt to select a non-existent drive, SELDSK returns HL=0000H as an error indicator. Although SELDSK must return the header address on each call, it is advisable to postpone the actual physical disk select operation until an I/O function (seek, read or write) is actually performed, since disk selects often occur without ultimately performing any disk I/O, and many controllers will unload the head of the current disk.
before selecting the new drive. This would cause an excessive amount of noise and disk wear.

**SE'TTRK**
Register BC contains the track number for subsequent disk accesses on the currently selected drive. You can choose to seek the selected track at this time, or delay the seek until the next read or write actually occurs. Register BC can take on values in the range 0-76 corresponding to valid track numbers for standard floppy disk drives, and 0-65535 for non-standard disk subsystems.

**SE'TSEC**
Register BC contains the sector number (1 through 26) for subsequent disk accesses on the currently selected drive. You can choose to send this information to the controller at this point, or instead delay sector selection until a read or write operation occurs.

**SE'TDMA**
Register BC contains the DMA (disk memory access) address for subsequent read or write operations. For example, if \( B = 00H \) and \( C = 80H \) when SETDMA is called, then all subsequent read operations read their data into \( 80H \) through \( 0FFH \), and all subsequent write operations get their data from \( 80H \) through \( 0FFH \), until the next call to SETDMA occurs. The initial DMA address is assumed to be \( 80H \). Note that the controller need not actually support direct memory access. If, for example, all data is received and sent through I/O ports, the CBIOS which you construct will use the 128 byte area starting at the selected DMA address for the memory buffer during the following read or write operations.

**READ**
Assuming the drive has been selected, the track has been set, the sector has been set, and the DMA address has been specified, the READ subroutine attempts to read one sector based upon these parameters, and returns the following error codes in register A:

- 0 no errors occurred
- 1 non-recoverable error condition occurred

Currently, CP/M responds only to a zero or non-zero value as the return code. That is, if the value in register A is 0 then CP/M assumes that the disk operation completed properly. If an error occurs, however, the CBIOS should attempt at least 10 retries to see if the error is recoverable. When an error is reported the BDOS will print the message "BDOS ERR ON x: BAD SECTOR". The operator then has the option of typing <cr> to ignore the error, or ctrl-C to abort.

**WRITE**
Write the data from the currently selected DMA address to the currently selected drive, track, and sector. The data should be marked as "non deleted data" to

(All Information Contained Herein is Proprietary to Digital Research.)
maintain compatibility with other CP/M systems. The error codes given in the READ command are returned in register A, with error recovery attempts as described above.

LISTST
Return the ready status of the list device. Used by the DESPOOL program to improve console response during its operation. The value 00 is returned in A if the list device is not ready to accept a character, and 0FFH if a character can be sent to the printer. Note that a 00 value always suffices.

SECTRAN
Performs sector logical to physical sector translation in order to improve the overall response of CP/M. Standard CP/M systems are shipped with a "skew factor" of 6, where six physical sectors are skipped between each logical read operation. This skew factor allows enough time between sectors for most programs to load their buffers without missing the next sector. In particular computer systems which use fast processors, memory, and disk subsystems, the skew factor may be changed to improve overall response. Note, however, that you should maintain a single density IBM compatible version of CP/M for information transfer into and out of your computer system, using a skew factor of 6. In general, SECTRAN receives a logical sector number in BC, and a translate table address in DE. The sector number is used as an index into the translate table, with the resulting physical sector number in HL. For standard systems, the tables and indexing code is provided in the CBIOS and need not be changed.
7. A SAMPLE BIOS

The program shown in Appendix C can serve as a basis for your first BIOS. The simplest functions are assumed in this BIOS, so that you can enter it through the front panel, if absolutely necessary. Note that the user must alter and insert code into the subroutines for CONST, CONIN, CONOUT, READ, WRITE, and WAITIO subroutines. Storage is reserved for user-supplied code in these regions. The scratch area reserved in page zero (see Section 9) for the BIOS is used in this program, so that it could be implemented in ROM, if desired.

Once operational, this skeletal version can be enhanced to print the initial sign-on message and perform better error recovery. The subroutines for LIST, PUNCH, and READER can be filled-out, and the IOBYTE function can be implemented.

(All Information Contained Herein is Proprietary to Digital Research.)
8. A SAMPLE COLD START LOADER

The program shown in Appendix D can serve as a basis for your cold start loader. The disk read function must be supplied by the user, and the program must be loaded somehow starting at location 0000. Note that space is reserved for your patch so that the total amount of storage required for the cold start loader is 128 bytes. Eventually, you will probably want to get this loader onto the first disk sector (track 0, sector 1), and cause your controller to load it into memory automatically upon system start-up. Alternatively, you may wish to place the cold start loader into ROM, and place it above the CP/M system. In this case, it will be necessary to originate the program at a higher address, and key-in a jump instruction at system start-up which branches to the loader. Subsequent warm starts will not require this key-in operation, since the entry point 'WBOOT' gets control, thus bringing the system in from disk automatically. Note also that the skeletal cold start loader has minimal error recovery, which may be enhanced on later versions.

(All Information Contained Herein is Proprietary to Digital Research.)
9. RESERVED LOCATIONS IN PAGE ZERO

Main memory page zero, between locations 00H and 0FFH, contains several segments of code and data which are used during CP/M processing. The code and data areas are given below for reference purposes.

<table>
<thead>
<tr>
<th>Locations</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000H - 0002H</td>
<td>Contains a jump instruction to the warm start entry point at location 4A03H+b. This allows a simple programmed restart (JMP 0000H) or manual restart from the front panel.</td>
</tr>
<tr>
<td>0003H - 0003H</td>
<td>Contains the Intel standard IOBYTE, which is optionally included in the user's CBIOS, as described in Section 6.</td>
</tr>
<tr>
<td>0004H - 0004H</td>
<td>Current default drive number (0=A,...,15=P).</td>
</tr>
<tr>
<td>0005H - 0007H</td>
<td>Contains a jump instruction to the BDOS, and serves two purposes: JMP 0005H provides the primary entry point to the BDOS, as described in the manual &quot;CP/M Interface Guide,&quot; and LHLD 0006H brings the address field of the instruction to the HL register pair. This value is the lowest address in memory used by CP/M (assuming the CCP is being overlayed). Note that the DDT program will change the address field to reflect the reduced memory size in debug mode.</td>
</tr>
<tr>
<td>0008H - 0027H</td>
<td>(interrupt locations 1 through 5 not used)</td>
</tr>
<tr>
<td>0030H - 0037H</td>
<td>(interrupt location 6, not currently used - reserved)</td>
</tr>
<tr>
<td>0038H - 003AH</td>
<td>Restart 7 - Contains a jump instruction into the DDT or SID program when running in debug mode for programmed breakpoints, but is not otherwise used by CP/M.</td>
</tr>
<tr>
<td>003BH - 003FH</td>
<td>(not currently used - reserved)</td>
</tr>
<tr>
<td>0040H - 004FH</td>
<td>16 byte area reserved for scratch by CBIOS, but is not used for any purpose in the distribution version of CP/M</td>
</tr>
<tr>
<td>0050H - 005BH</td>
<td>(not currently used - reserved)</td>
</tr>
<tr>
<td>005CH - 007CH</td>
<td>default file control block produced for a transient program by the Console Command Processor.</td>
</tr>
<tr>
<td>007DH - 007FH</td>
<td>Optional default random record position</td>
</tr>
</tbody>
</table>

(All Information Contained Herein is Proprietary to Digital Research.)
\text{0000H - 00FFH} \quad \text{default 128 byte disk buffer (also filled with the command line when a transient is loaded under the CCP).}

Note that this information is set-up for normal operation under the CP/M system, but can be overwritten by a transient program if the BDOS facilities are not required by the transient.

If, for example, a particular program performs only simple I/O and must begin execution at location 0, it can be first loaded into the IFA, using normal CP/M facilities, with a small memory move program which gets control when loaded (the memory move program must get control from location \text{0100H}, which is the assumed beginning of all transient programs). The move program can then proceed to move the entire memory image down to location 0, and pass control to the starting address of the memory load. Note that if the BIOS is overwritten, or if location 0 (containing the warm start entry point) is overwritten, then the programmer must bring the CP/M system back into memory with a cold start sequence.
10. DISK PARAMETER TABLES.

Tables are included in the BIOS which describe the particular characteristics of the disk subsystem used with CP/M. These tables can be either hand-coded, as shown in the sample CBIOS in Appendix C, or automatically generated using the DISKDEF macro library, as shown in Appendix B. The purpose here is to describe the elements of these tables.

In general, each disk drive has an associated (16-byte) disk parameter header which both contains information about the disk drive and provides a scratchpad area for certain BDOS operations. The format of the disk parameter header for each drive is shown below.

<table>
<thead>
<tr>
<th>Disk Parameter Header</th>
</tr>
</thead>
<tbody>
<tr>
<td>XLT</td>
</tr>
</tbody>
</table>

where each element is a word (16-bit) value. The meaning of each Disk Parameter Header (DPH) element is:

- **XLT**: Address of the logical to physical translation vector, if used for this particular drive, or the value 0000H if no sector translation takes place (i.e., the physical and logical sector numbers are the same). Disk drives with identical sector skew factors share the same translate tables.
- **0000**: Scratchpad values for use within the BDOS (initial value is unimportant).
- **DIRBUF**: Address of a 128 byte scratchpad area for directory operations within BDOS. All DPH's address the same scratchpad area.
- **DPB**: Address of a disk parameter block for this drive. Drives with identical disk characteristics address the same disk parameter block.
- **CSV**: Address of a scratchpad area used for software check for changed disks. This address is different for each DPH.
- **ALV**: Address of a scratchpad area used by the BDOS to keep disk storage allocation information. This address is different for each DPH.

Given n disk drives, the DPH's are arranged in a table whose first row of 16 bytes corresponds to drive 0, with the last row corresponding to drive n-1. The table thus appears as:

(All Information Contained Herein is Proprietary to Digital Research.)

25
DPBASE:

<table>
<thead>
<tr>
<th>00</th>
<th>XLT 00</th>
<th>0000</th>
<th>0000</th>
<th>0000</th>
<th>DIRBUF</th>
<th>DBP 00</th>
<th>CSV 00</th>
<th>ALV 00</th>
</tr>
</thead>
<tbody>
<tr>
<td>01</td>
<td>XLT 01</td>
<td>0000</td>
<td>0000</td>
<td>0000</td>
<td>DIRBUF</td>
<td>DBP 01</td>
<td>CSV 01</td>
<td>ALV 01</td>
</tr>
<tr>
<td></td>
<td>(and so-forth through)</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>n-1</td>
<td>XLTn-1</td>
<td>0000</td>
<td>0000</td>
<td>0000</td>
<td>DIRBUF</td>
<td>DBPn-1</td>
<td>CSVn-1</td>
<td>ALVn-1</td>
</tr>
</tbody>
</table>

where the label DPBASE defines the base address of the DPH table.

A responsibility of the SELDSK subroutine is to return the base address of the DPH for the selected drive. The following sequence of operations returns the table address, with a 0000H returned if the selected drive does not exist.

```
NDISKS EQU 4 ;NUMBER OF DISK DRIVES

SELDSDK:

;SELECT DISK GIVEN BY BC
LXI H,0000H ;ERROR CODE
MOV A,C ;DRIVE OK?
CPI NDISKS ;CY IF SO
RNC ;RET IF ERROR
;NO ERROR, CONTINUE
MOV L,C ;LOW(DISK)
MOV H,B ;HIGH(DISK)
DAD H ;*2
DAD H ;*4
DAD H ;*8
DAD H ;*16
LXI D,DPBASE ;FIRST DPH
DAD D ;DPH(DISK)
RET
```

The translation vectors (XLT 00 through XLTn-1) are located elsewhere in the BIOS, and simply correspond one-for-one with the logical sector numbers zero through the sector count-1. The Disk Parameter Block (DPB) for each drive is more complex. A particular DPB, which is addressed by one or more DPH's, takes the general form

```
<table>
<thead>
<tr>
<th>SPT</th>
<th>BSH</th>
<th>BLM</th>
<th>EXM</th>
<th>DSM</th>
<th>DRM</th>
<th>ALO</th>
<th>AL1</th>
<th>CKS</th>
<th>OFF</th>
</tr>
</thead>
<tbody>
<tr>
<td>16b</td>
<td>8b</td>
<td>8b</td>
<td>8b</td>
<td>16b</td>
<td>16b</td>
<td>8b</td>
<td>8b</td>
<td>16b</td>
<td>16b</td>
</tr>
</tbody>
</table>
```

where each is a byte or word value, as shown by the "8b" or "16b" indicator below the field.

- **SPT** is the total number of sectors per track
- **BSH** is the data allocation block shift factor, determined by the data block allocation size.

(All Information Contained Herein is Proprietary to Digital Research.)
EXM is the extent mask, determined by the data block allocation size and the number of disk blocks.

DSM determines the total storage capacity of the disk drive.

DRM determines the total number of directory entries which can be stored on this drive. AL0, AL1 determine reserved directory blocks.

CKS is the size of the directory check vector.

OFF is the number of reserved tracks at the beginning of the (logical) disk.

The values of BSH and BLM determine (implicitly) the data allocation size BLS, which is not an entry in the disk parameter block. Given that the designer has selected a value for BLS, the values of BSH and BLM are shown in the table below:

<table>
<thead>
<tr>
<th>BLS</th>
<th>BSH</th>
<th>BLM</th>
</tr>
</thead>
<tbody>
<tr>
<td>1,024</td>
<td>3</td>
<td>7</td>
</tr>
<tr>
<td>2,048</td>
<td>4</td>
<td>15</td>
</tr>
<tr>
<td>4,096</td>
<td>5</td>
<td>31</td>
</tr>
<tr>
<td>8,192</td>
<td>6</td>
<td>63</td>
</tr>
<tr>
<td>16,384</td>
<td>7</td>
<td>127</td>
</tr>
</tbody>
</table>

where all values are in decimal. The value of EXM depends upon both the BLS and whether the DSM value is less than 256 or greater than 255, as shown in the following table:

<table>
<thead>
<tr>
<th>BLS</th>
<th>DSM &lt; 256</th>
<th>DSM &gt; 255</th>
</tr>
</thead>
<tbody>
<tr>
<td>1,024</td>
<td>0</td>
<td>N/A</td>
</tr>
<tr>
<td>2,048</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>4,096</td>
<td>3</td>
<td>1</td>
</tr>
<tr>
<td>8,192</td>
<td>7</td>
<td>3</td>
</tr>
<tr>
<td>16,384</td>
<td>15</td>
<td>7</td>
</tr>
</tbody>
</table>

The value of DSM is the maximum data block number supported by this particular drive, measured in BLS units. The product BLS times (DSM+1) is the total number of bytes held by the drive and, of course, must be within the capacity of the physical disk, not counting the reserved operating system tracks.

The DRM entry is the one less than the total number of directory entries, which can take on a 16-bit value. The values of AL0 and AL1, however, are determined by DRM. The two values AL0 and AL1 can together be considered a string of 16-bits, as shown below:

(All Information Contained Herein is Proprietary to Digital Research.)
Where position 00 corresponds to the high order bit of the byte labelled AL0, and 15 corresponds to the low order bit of the byte labelled AL1. Each bit position reserves a data block for number of directory entries, thus allowing a total of 16 data blocks to be assigned for directory entries (bits are assigned starting at 00 and filled to the right until position 15). Each directory entry occupies 32 bytes, resulting in the following table:

<table>
<thead>
<tr>
<th>BLS</th>
<th>Directory Entries</th>
</tr>
</thead>
<tbody>
<tr>
<td>1,024</td>
<td>32 times # bits</td>
</tr>
<tr>
<td>2,048</td>
<td>64 times # bits</td>
</tr>
<tr>
<td>4,096</td>
<td>128 times # bits</td>
</tr>
<tr>
<td>8,192</td>
<td>256 times # bits</td>
</tr>
<tr>
<td>16,384</td>
<td>512 times # bits</td>
</tr>
</tbody>
</table>

Thus, if DRM = 127 (128 directory entries), and BLS = 1024, then there are 32 directory entries per block, requiring 4 reserved blocks. In this case, the 4 high order bits of AL0 are set, resulting in the values AL0 = 0F0H and AL1 = 00H.

The CKS value is determined as follows: if the disk drive media is removable, then CKS = (DRM+1)/4, where DRM is the last directory entry number. If the media is fixed, then set CKS = 0 (no directory records are checked in this case).

Finally, the OFF field determines the number of tracks which are skipped at the beginning of the physical disk. This value is automatically added whenever SETTRK is called, and can be used as a mechanism for skipping reserved operating system tracks, or for partitioning a large disk into smaller segmented sections.

To complete the discussion of the DPB, recall that several DPH's can address the same DPB if their drive characteristics are identical. Further, the DPB can be dynamically changed when a new drive is addressed by simply changing the pointer in the DPH since the BDOS copies the DPB values to a local area whenever the SELDSK function is invoked.

Returning back to the DPH for a particular drive, note that the two address values CSV and ALV remain. Both addresses reference an area of uninitialized memory following the BIOS. The areas must be unique for each drive, and the size of each area is determined by the values in the DPB.

The size of the area addressed by CSV is CKS bytes, which is sufficient to hold the directory check information for this particular drive. If CKS = (DRM+1)/4, then you must reserve (DRM+1)/4 bytes for directory check use. If CKS = 0, then no storage is reserved.

(All Information Contained Herein is Proprietary to Digital Research.)
The size of the area addressed by ALV is determined by the maximum number of data blocks allowed for this particular disk, and is computed as \((DSM/8)+1\).

The CBIOS shown in Appendix C demonstrates an instance of these tables for standard 8" single density drives. It may be useful to examine this program, and compare the tabular values with the definitions given above.

(All Information Contained Herein is Proprietary to Digital Research.)
11. THE DISKDEF MACRO LIBRARY.

A macro library is shown in Appendix F, called DISKDEF, which greatly simplifies the table construction process. You must have access to the MAC macro assembler, of course, to use the DISKDEF facility, while the macro library is included with all CP/M 2.0 distribution disks.

A BIOS disk definition consists of the following sequence of macro statements:

```
MACLIB DISKDEF
......
DISKS n
DISKDEF 0,...
DISKDEF 1,...
......
DISKDEF n-1
......
ENDEF
```

where the MACLIB statement loads the DISKDEF.LIB file (on the same disk as your BIOS) into MAC's internal tables. The DISKS macro call follows, which specifies the number of drives to be configured with your system, where n is an integer in the range 1 to 16. A series of DISKDEF macro calls then follow which define the characteristics of each logical disk, 0 through n-1 (corresponding to logical drives A through P). Note that the DISKS and DISKDEF macros generate the in-line fixed data tables described in the previous section, and thus must be placed in a non-executable portion of your BIOS, typically directly following the BIOS jump vector.

The remaining portion of your BIOS is defined following the DISKDEF macros, with the ENDEF macro call immediately preceding the END statement. The ENDEF (End of Diskdef) macro generates the necessary uninitialized RAM areas which are located in memory above your BIOS.

The form of the DISKDEF macro call is

```
DISKDEF dn,fsc,lsc,[skf],bls,dks,dir,cks,ofs,[0]
```

where

- **dn** is the logical disk number, 0 to n-1
- **fsc** is the first physical sector number (0 or 1)
- **lsc** is the last sector number
- **skf** is the optional sector skew factor
- **bls** is the data allocation block size
- **dir** is the number of directory entries
- **cks** is the number of "checked" directory entries
- **ofs** is the track offset to logical track 00
- **[0]** is an optional 1.4 compatibility flag

The value "dn" is the drive number being defined with this DISKDEF

(All Information Contained Herein is Proprietary to Digital Research.)
macro invocation. The "fsc" parameter accounts for differing sector numbering systems, and is usually 0 or 1. The "lsc" is the last numbered sector on a track. When present, the "skf" parameter defines the sector skew factor which is used to create a sector translation table according to the skew. If the number of sectors is less than 256, a single-byte table is created, otherwise each translation table element occupies two bytes. No translation table is created if the skf parameter is omitted (or equal to 0). The "bls" parameter specifies the number of bytes allocated to each data block, and takes on the values 1024, 2048, 4096, 8192, or 16384. Generally, performance increases with larger data block sizes since there are fewer directory references and logically connected data records are physically close on the disk. Further, each directory entry addresses more data and the BIOS-resident ram space is reduced. The "dks" specifies the total disk size in "bls" units. That is, if the bls = 2048 and dks = 1000, then the total disk capacity is 2,048,000 bytes. If dks is greater than 255, then the block size parameter bls must be greater than 1024. The value of "dir" is the total number of directory entries which may exceed 255, if desired. The "cks" parameter determines the number of directory items to check on each directory scan, and is used internally to detect changed disks during system operation, where an intervening cold or warm start has not occurred (when this situation is detected, CP/M automatically marks the disk read/only so that data is not subsequently destroyed). As stated in the previous section, the value of cks = dir when the media is easily changed, as is the case with a floppy disk subsystem. If the disk is permanently mounted, then the value of cks is typically 0, since the probability of changing disks without a restart is quite low. The "ofs" value determines the number of tracks to skip when this particular drive is addressed, which can be used to reserve additional operating system space or to simulate several logical drives on a single large capacity physical drive. Finally, the [0] parameter is included when file compatibility is required with versions of 1.4 which have been modified for higher density disks. This parameter ensures that only 16K is allocated for each directory record, as was the case for previous versions. Normally, this parameter is not included.

For convenience and economy of table space, the special form

DISKDEF i,j

gives disk i the same characteristics as a previously defined drive j. A standard four-drive single density system, which is compatible with version 1.4, is defined using the following macro invocations:

(All Information Contained Herein is Proprietary to Digital Research.)
with all disks having the same parameter values of 26 sectors per track (numbered 1 through 26), with 6 sectors skipped between each access, 1024 bytes per data block, 243 data blocks for a total of 243k byte disk capacity, 64 checked directory entries, and two operating system tracks.

The DISKS macro generates n Disk Parameter Headers (DPH's), starting at the DPH table address DPBASE generated by the macro. Each disk header block contains sixteen bytes, as described above, and correspond one-for-one to each of the defined drives. In the four drive standard system, for example, the DISKS macro generates a table of the form:

```c
DPBASE EQU $ DPE0: DW XLTO,0000H,0000H,0000H,DIRBUF,DPB0,CSV0,ALV0 DPE1: DW XLTO,0000H,0000H,0000H,DIRBUF,DPB0,CSV1,ALV1 DPE2: DW XLTO,0000H,0000H,0000H,DIRBUF,DPB0,CSV2,ALV2 DPE3: DW XLTO,0000H,0000H,0000H,DIRBUF,DPB0,CSV3,ALV3
```

where the DPH labels are included for reference purposes to show the beginning table addresses for each drive 0 through 3. The values contained within the disk parameter header are described in detail in the previous section. The check and allocation vector addresses are generated by the ENDEF macro in the ram area following the BIOS code and tables.

Note that if the "skf" (skew factor) parameter is omitted (or equal to 0), the translation table is omitted, and a 0000H value is inserted in the XLT position of the disk parameter header for the disk. In a subsequent call to perform the logical to physical translation, SECTRAN receives a translation table address of DE = 0000H, and simply returns the original logical sector from BC in the HL register pair. A translate table is constructed when the skf parameter is present, and the (non-zero) table address is placed into the corresponding DPH's. The table shown below, for example, is constructed when the standard skew factor skf = 6 is specified in the DISKDEF macro call:

```c
XLTO: DB 1,7,13,19,25,5,11,17,23,3,9,15,21 DB 2,8,14,20,26,6,12,18,24,4,10,16,22
```

Following the ENDEF macro call, a number of uninitialized data areas are defined. These data areas need not be a part of the BIOS which is loaded upon cold start, but must be available between the BIOS and the end of memory. The size of the uninitialized RAM area is determined by EQU statements generated by the ENDEF macro. For a standard four-drive system, the ENDEF macro might produce

(All Information Contained Herein is Proprietary to Digital Research.)
which indicates that uninitialized RAM begins at location 4C72H, ends at 4DB0H-1, and occupies 013CH bytes. You must ensure that these addresses are free for use after the system is loaded.

After modification, you can use the STAT program to check your drive characteristics, since STAT uses the disk parameter block to decode the drive information. The STAT command form

```
STAT d:DSK:
```

decodes the disk parameter block for drive d (d=A,...,P) and displays the values shown below:

- r: 128 Byte Record Capacity
- k: Kilobyte Drive Capacity
- d: 32 Byte Directory Entries
- c: Checked Directory Entries
- e: Records/Extent
- b: Records/Block
- s: Sectors/Track
- t: Reserved Tracks

Three examples of DISKDEF macro invocations are shown below with corresponding STAT parameter values (the last produces a full 8-megabyte system).

```
DISKDEF 0,1,58,,2048,256,128,128,2
r=4096, k=512, d=128, c=128, e=256, b=16, s=58, t=2

DISKDEF 0,1,58,,2048,1024,300,0,2
r=16384, k=2048, d=300, c=0, e=128, b=16, s=58, t=2

DISKDEF 0,1,58,,16384,512,128,128,2
r=65536, k=8192, d=128, c=128, e=1024, b=128, s=58, t=2
```

(All Information Contained Herein is Proprietary to Digital Research.)
12. SECTOR BLOCKING AND DEBLOCKING.

Upon each call to the BIOS WRITE entry point, the CP/M BDOS includes information which allows effective sector blocking and deblocking where the host disk subsystem has a sector size which is a multiple of the basic 128-byte unit. The purpose here is to present a general-purpose algorithm which can be included within your BIOS which uses the BDOS information to perform the operations automatically.

Upon each call to WRITE, the BDOS provides the following information in register C:

\[
\begin{align*}
0 & = \text{normal sector write} \\
1 & = \text{write to directory sector} \\
2 & = \text{write to the first sector of a new data block}
\end{align*}
\]

Condition 0 occurs whenever the next write operation is into a previously written area, such as a random mode record update, when the write is to other than the first sector of an unallocated block, or when the write is not into the directory area. Condition 1 occurs when a write into the directory area is performed. Condition 2 occurs when the first record (only) of a newly allocated data block is written. In most cases, application programs read or write multiple 128-byte sectors in sequence, and thus there is little overhead involved in either operation when blocking and deblocking records since pre-read operations can be avoided when writing records.

Appendix G lists the blocking and deblocking algorithms in skeletal form (this file is included on your CP/M disk). Generally, the algorithms map all CP/M sector read operations onto the host disk through an intermediate buffer which is the size of the host disk sector. Throughout the program, values and variables which relate to the CP/M sector involved in a seek operation are prefixed by "sek," while those related to the host disk system are prefixed by "hst." The equate statements beginning on line 29 of Appendix G define the mapping between CP/M and the host system, and must be changed if other than the sample host system is involved.

The entry points BOOT and WBOOT must contain the initialization code starting on line 57, while the SELDSK entry point must be augmented by the code starting on line 65. Note that although the SELDSK entry point computes and returns the Disk Parameter Header address, it does not physically select the host disk at this point (it is selected later at READHST or WRITEHST). Further, SETTRK, SETTRK, and SETDMA simply store the values, but do not take any other action at this point. SECTRAN performs a trivial function of returning the physical sector number.

The principal entry points are READ and WRITE, starting on lines 110 and 125, respectively. These subroutines take the place of your previous READ and WRITE operations.

The actual physical read or write takes place at either WRITEHST or READHST, where all values have been prepared: hstdsk is the host system.

(All Information Contained Herein is Proprietary to Digital Research.)
disk number, hsttrk is the host track number, and hstsec is the host sector number (which may require translation to a physical sector number). You must insert code at this point which performs the full host sector read or write into, or out of, the buffer at hstbuf of length hstsiz. All other mapping functions are performed by the algorithms.

This particular algorithm was tested using an 80 megabyte hard disk unit which was originally configured for 128 byte sectors, producing approximately 35 megabytes of formatted storage. When configured for 512 byte host sectors, usable storage increased to 57 megabytes, with a corresponding 400% improvement in overall response. In this situation, there is no apparent overhead involved in deblocking sectors, with the advantage that user programs still maintain the (less memory consuming) 128-byte sectors. This is primarily due, of course, to the information provided by the BDOS which eliminates the necessity for pre-read operations to take place.

APPENDIX E: A SKELETAL COLD START LOADER

; this is a sample cold start loader which, when modified
; resides on track 00, sector 01 (the first sector on the
; diskette). we assume that the controller has loaded
; this sector into memory upon system start-up (this pro-
; gram can be keyed-in, or can exist in read/only memory
; beyond the address space of the cp/m version you are
; running). the cold start loader brings the cp/m system
; into memory at "loadp" (3400h + "bias"). in a 20k
; memory system, the value of "bias" is 0000h, with large
; values for increased memory sizes (see section 2). afte
; loading the cp/m system, the cold start loader branches
; to the "boot" entry point of the bios, which begins at
; "bios" + "bias." the cold start loader is not used un-
; til the system is powered up again, as long as the bios
; is not overwritten. the origin is assumed at 0000h, an
; must be changed if the controller brings the cold start
; loader into another area, or if a read/only memory area
; is used.

APPENDIX F: CP/M DISK DEFINITION LIBRARY

CP/M 2.0 disk re-definition library

Copyright (c) 1979
Digital Research
Box 579
Pacific Grove, CA
93950

CP/M logical disk drives are defined using the macros given below, where the sequence of calls is:

disks n
diskdef parameter-list-0
diskdef parameter-list-1
... diskdef parameter-list-n
endef

where n is the number of logical disk drives attached to the CP/M system, and parameter-list-i defines the characteristics of the ith drive (i=0,1,...,n-1)

each parameter-list-i takes the form
dn,fsc,lsc,[skf],bls,dks,dir,cks,ofs,[0]

where
dn is the disk number 0,1,...,n-1
fsc is the first sector number (usually 0 or 1)
lsc is the last sector number on a track
skf is optional "skew factor" for sector translate
bls is the data block size (1024, 2048,...,16384)
dks is the disk size in bls increments (word)
dir is the number of directory elements (word)
cks is the number of dir elements to checksum
ofs is the number of tracks to skip (word)
[0] is an optional 0 which forces 16K/directory en

for convenience, the form
dn,dm

defines disk dn as having the same characteristics as a previously defined disk dm.

a standard four drive CP/M system is defined by

disks 4
diskdef 0,1,26,6,1024,243,64,64,2
dsk set 0
rept 3
dsk set dsk+1
diskdef %dsk,0
endm
endef

the value of "begdat" at the end of assembly defines t
beginning of the uninitialized ram area above the bios, while the value of "enddat" defines the next location following the end of the data area, the size of this area is given by the value of "datsiz" at the end of the assembly. note that the allocation vector will be quite large if a large disk size is defined with a small block size.

11.0 SERVICE INFORMATION
11.1 SERVICE PROCEDURES
11.2 LOST OR DAMAGED EQUIPMENT
11.3 ADDITIONAL TECHNICAL DOCUMENTATION
11.4 NON-DISCLOSURE AGREEMENT
11.5 EQUIPMENT MALFUNCTION REPORT
11.6 LIMITED WARRANTY REGISTRATION FORM
11.7 CUSTOMER COMMENT CARD
11.1 SERVICING PROCEDURES

Your CompuStar Video Processing System is warranted to the original purchaser for 90 days from date of shipment. This warranty covers the adjustment or replacement F.O.B. Intertec's plant in Columbia, South Carolina of any part or parts which in Intertec's judgment shall disclose to have been originally defective. A complete statement of your warranty rights is contained on the inside back cover of this manual.

In order to register your warranty, the Warranty Registration form (contained in this section) must be completed in full and returned to Intertec Data Systems within 10 days of receipt of this equipment. Be sure to include the serial number of the specific terminal you are registering. The serial number of your terminal can be found on the rear I/O panel next to the power cord. A Customer Comment Card is also enclosed for your convenience if you desire to make comments regarding the overall operation and/or adaptability of the CompuStar to your particular application. Completion of the Customer Comment Card is optional.

IF SERVICE IS EVER REQUIRED:
If you should encounter difficulties with the use or operation of this equipment, contact the supplier from whom the unit was purchased for instructions regarding the proper servicing techniques. Service procedures differ from dealer to dealer but most Intertec authorized service dealers can provide local, on-site servicing of this equipment on a per-call or maintenance contract basis. Plus, a variety of service programs are available directly from the factory including extended warranty, a module exchange program and on-site contract maintenance from over 50 locations in the U.S.

If you are not covered under one of the three programs described above and service cannot be made available through your local supplier, contact Intertec's Customer Service Department at (803) 798-9100. Be prepared to give the following information when you call:

1. The serial number of the equipment which is defective. If you are returning individual modules to the factory for repair, it will be necessary to have the serial number of the individual modules also. The serial number of the entire terminal may be found on the rear I/O panel just to the right of the power cord. Module serial numbers are listed on white stickers placed in conspicuous locations on each major module or subassembly of the terminal.

NOTE: Individual modules cannot be returned to the factory for repair unless you originally purchased your unit directly from the factory. If your unit was purchased through a Dealer or OEM vendor, and you desire
factory repair, then the entire terminal must be returned.

2. The name and location of the Dealer and/or Agent from which the unit was purchased.

3. A complete description of the alleged failure (including the nature and cause of the failure if readily available.

The Customer Service Department will issue you Return Material Authorization Number (RMA Number) which will be valid for a period of 30 days. This RMA Number will be your official authorization to return equipment to IDSC for repair only. The Customer Service Department will also give you an estimate, if requested, of the time it should take to process and repair your equipment. Turnaround time on repairs varies depending on workloads and availability of parts but normally your equipment will be repaired and returned to you within 10 working days of its receipt. If your repair is urgent, you may authorize a special $50 Emergency Repair fee and have your equipment repaired and returned within no more than 48 hours of its receipt at our Service Center. Ask the Customer Service Department for more information about this program.

IMPORTANT: Any equipment returned to Intertec without an RMA Number will result in the equipment being refused and possible cancellation of your SuperBrain warranty. Also if your RMA Number expires, you must request a new number. Equipment arriving at Intertec bearing expired RMA Number will also be refused.

After securing an RMA Number from the Customer Service Department, return the specified modules and/or complete terminals to Intertec, freight prepaid, at the address below. NOTE: The RMA Number must be plainly marked and visible on your shipping label to prevent the equipment from being refused at Intertec's Receiving Department.

ATTN: FACTORY SERVICE CENTER
Intertec Data Systems Corporation
2300 Broad River Road
Columbia, South Carolina 29210

To aid our technicians in troubleshooting and correcting your reported malfunction, please complete an Intertec Equipment Malfunction Report (contained in this section) and enclose it with the equipment you intend to return to the factory.

Be sure a declared value equal to the price of the unit is shown on the bill of Lading, Express Receipt of Air Freight Bill, whichever is applicable. Risk of loss or damage to equipment during the time it is in transit either to or from Intertec's facilities is your sole responsibility. A declared value must be placed on your Bill of Lading to insure substantiation of your
freight claim if shipping damage or loss is incurred.

All equipment returned to an Intertec Service Center must be freight prepaid. Equipment not prepaid on arrival at Intertec's Receiving Department cannot be accepted. Upon repair of the defective equipment, it will be returned to you, F.O.B. the factory in Columbia, via UPS or equivalent ground transportation unless you specify otherwise.
11.2 INSTRUCTIONS FOR HANDLING LOST OR DAMAGED EQUIPMENT

The goods described on your Packing Slip were delivered to the Transportation Company at Intertec's premises in complete and good condition. If any of the goods called for on this Packing Slip are short or damaged, you must file a claim WITH THE TRANSPORTATION COMPANY FOR THE AMOUNT OF THE DAMAGE AND/OR LOSS.

IF LOSS OR DAMAGE IS EVIDENT AT TIME OF DELIVERY

If any of the goods called for on your Packing Slip are short or damaged at the time of delivery, ACCEPT THEM, but insist that the Freight Agent make a damaged or short notation on your Freight Bill or Express Receipt and sign it.

IF DAMAGE OR LOSS IS CONCEALED AND DISCOVERED AT A LATER DATE

If any concealed loss or damage is discovered, notify your local Freight Agent or Express Agent AT ONCE and request him to make an inspection. This is absolutely necessary. Unless you do this, the Transportation Company will not consider your claim for loss or damage valid. If the agent refuses to make an inspection, you should draw up an affidavit to the effect that you notified him on a certain date and that he failed to make the necessary inspection.

After you have ascertained the extent of the loss or damage, ORDER THE REPLACEMENT PARTS OR COMPLETE NEW UNITS FROM THE FACTORY. We will ship to you and bill you for the cost. This new invoice will then be a part of your claim for reimbursement from the Transportation Company. This together with other papers, will properly support your claim.

IMPORTANT: The claims adjustment procedure for UPS shipments varies somewhat from the procedure listed above for regular motor and air freight shipments. If your equipment was shipped via UPS and sustained either damage or loss, the UPS representative in your area must initiate the claim by inspecting the goods and assigning a freight claim number to the damaged equipment. The representative will attach a "Call Tag" to the outside of the equipment box which will be your authorization to return the merchandise to our factory for claim adjustment. Upon receipt of this damaged equipment, we will perform the necessary repairs, process the appropriate paperwork with UPS and return the equipment to you. Please allow time for processing any type claim. Normal time for proper processing of a UPS claim is 15-30 working days.

Remember, it is extremely important that you do not give the Transportation Company a clear receipt if damage or shortages are evident upon delivery. It is equally important that you call for an inspection if the loss or damage is discovered later. DO NOT, UNDER ANY CIRCUMSTANCES, ORDER THE TRANSPORTATION COMPANY TO RETURN SHIPMENT TO OUR FACTORY OR REFUSE SHIPMENT UNLESS WE HAVE AUTHORIZED SUCH RETURN.
11.3 ADDITIONAL TECHNICAL INFORMATION

Additional Technical documentation (i.e., schematics) describing the operation of the CompuStar System and the electrical interconnection of its various modules is available at a nominal cost directly from Intertec Data System Corporation. However, due to the confidentiality of this technical information, it will be necessary to sign and return the Documentation Non-Disclosure Agreement (appearing on the next page) denoting your concurrence with its terms and conditions.

The handling and processing costs of CompuStar technical documentation is $50. Due to the large amount of requests being processed and the relatively small handling costs involved, we must request that you enclose payment ($50) upon return of your Non-Disclosure Agreement. Normally the documents will be mailed to you within 15 to 30 days after receipt of your payment and a signed copy of the Agreement. (IMPORTANT: The technical documentation will be mailed to the address listed at the top of the Non-Disclosure Agreement.) For prompt processing of your documentation request, please forward your signed agreement and payment to:

Customer Service Department
Intertec Data Systems Corporation
2300 Broad River Road
Columbia, South Carolina 29210

NOTE: Technical documentation for the CompuStar will be sent to you normally within 10-15 days of receipt of your payment and signed Non-Disclosure Agreement.

IMPORTANT: Payment must accompany your Non-Disclosure Agreement. Agreements sent to us without payment will be discarded without notice.
For and in consideration of receiving confidential documentation on the CompuStar™ line of terminals manufactured by INTERTEC DATA SYSTEMS CORPORATION (hereinafter called INTERTEC) at the date hereof, the undersigned hereby agrees with INTERTEC as follows:

(1) The undersigned acknowledges that formulae, programs, manufacturing processes, devices, techniques, plans, methods, drawings, blueprints, reproductions, data, tables, calculations and components were designed and developed by INTERTEC at great expense and over lengthy periods of time, and the same are secret and confidential, are unique and constitute the exclusive property and trade secrets of INTERTEC, and that any use of such property and trade secrets by the undersigned other than for the sole benefit of INTERTEC would be wrongful, tortious and would cause irreparable injury to INTERTEC.

(2) The undersigned shall not at any time, without the express written consent of the Board of Directors of INTERTEC, publish, disclose, use or divulge to any person, firm or corporation, directly or indirectly, or use for his own benefit or the benefit of any person, firm, or use other than to effect repair of INTERTEC manufactured equipment, and property above described, trade secrets or confidential information of INTERTEC, its subsidiaries and its affiliates learned or obtained by him from INTERTEC, including, but not limited to, the information and things set forth in paragraph 1 hereinabove.

(3) This agreement shall be binding upon the undersigned, his personal representatives, successors and assigns, and shall run to the benefit of INTERTEC, its successors and assigns.

(4) Upon termination of the association of the undersigned with INTERTEC or its subsidiaries, the undersigned shall promptly deliver to INTERTEC all drawings, blueprints, reproductions, manuals, letters, notes, notebooks, reports, data, tables, calculations or copies thereof, components, programs, and any and all other secret and confidential property of INTERTEC, its subsidiaries and affiliates, including, but not limited to, all of the property set forth in paragraph 1 hereinabove which are in the possession or under the control of the undersigned.

(5) The undersigned hereby acknowledges and agrees that in the event of any violation hereof, INTERTEC shall be authorized and entitled to obtain from any court of competent jurisdiction preliminary and permanent injunctive relief as well as equitable accounting of all profits or benefits arising out of such violation which rights or remedies shall be cumulative and in addition to any rights or remedies to which INTERTEC may be entitled and that the undersigned shall further be directly liable for any and all reasonable attorney’s fees incurred by INTERTEC to enforce this Agreement against the undersigned in a court of law.

(6) The foregoing understanding shall apply to any subsequent meetings and/or communications between INTERTEC and the above mentioned organization relating to the same subject manner, unless modified in writing as to any such subsequent meetings and/or communications.

We would appreciate your signing and returning to us, prior to the release of INTERTEC product documentation, the original copy of this agreement denoting your concurrence with the foregoing provisions.
Dear Customer:

We are trying to manufacture the most reliable product possible. You would do us a great courtesy by completing this form should you experience any failures. Enclose this form with the equipment you intend to return to the dealer or factory for service. (Additional copies of this form available upon request.)

Thank you for purchasing the CompuStar Video Processing Terminal. If we may be of further assistance to you, please contact our Customer Service Department at the address on the reverse side of this form.
Our past and present customers are directly responsible for the evolution of the CompuStar as you see it presented in this manual. Before Intertec began research and development of the CompuStar, an extensive user survey was conducted to ascertain optimum video computer price/performance ratios to enable us to capture a major portion of the video computer market. In order that we continue with our commitment to excellence in engineering, production and marketing, we would appreciate your comments below regarding your overall opinion of the CompuStar. All comments are given careful consideration in future product design and become the property of Intertec Data Systems Corporation.

(1) What are your comments concerning the overall appearance of the CompuStar? (You may want to comment on color, size and construction.)

12.0 HARDWARE ADDENDA
12.1 SERIAL COMMUNICATION HARDWARE SETUP
12.2 8251A USART OPERATION
12.1 COMPUSTAR SERIAL COMMUNICATIONS DIPSWITCH SETTING PROTOCOL

On all CompuStar Video Processing Units there exists a small 5 position dipswitch located in the upper right hand corner of the keyboard/CPU module. For the normal mode (*asynchronous communication mode) these switches should be set as follows:

1 - OFF, 2 - OFF, 3 - ON, 4 - ON, 5 - OFF

For the synchronous communication mode with another unit providing the transmitter and receiver clock, the switches should be set as follows:

1 - ON, 2 - ON, 3 - OFF, 4 - OFF, 5 - OFF

For the synchronous mode with the user terminal providing both the transmitter and receiver clock, the switches should be set as follows:

1-OFF, 2-OFF, 3-ON, 4-ON, 5-ON

Listed below is a brief description of the function of each of these switches:

1 - External Clock to transmitter section of MAIN USART - Originates from PIN #15 on MAIN RS232 connector at rear of terminal.

2 - External Clock to receiver section of MAIN USART - Originates from Pin #17 on MAIN RS232 connector at rear of terminal.

3 - Internal TX Clock to MAIN USART - When on this switch enables the built-in baud rate generator (Western Digital BR-1941). NOTE: When this switch is in the 'ON' position, switch 1 MUST be in the 'OFF' position.

4 - Internal RX Clock to MAIN USART - When this switch is in the 'ON' position, switch 2 MUST be in the 'OFF' position.

5 - Internal Baud Clock to MAIN Port - This switch enables the transmission of the internal baud rate clock (Western Digital BR-1941) to the main RS232 port - this signal will also appear on Pin #24 of the main port when this switch is in the 'ON' position. If this switch is not used, it should be left in the 'OFF' position to avoid any possible conflict with external RS232 signals.

* NOTE: The switches were set for the asynchronous communication mode before shipping from the factory.
12.2 8251A USART OPERATION

DESCRIPTION OF OPERATION—ASYNCHRONOUS

Transmission —
When a data character is written into the USART, it automatically adds a START bit (low level or "space") and the number of STOP bits (high level or "mark") specified by the Mode Instruction. If Parity has been enabled, an odd or even Parity bit is inserted just before the STOP bit(s), as specified by the Mode Instruction. Then, depending on CTS and TxEN, the character may be transmitted as a serial data stream at the TxD output. Data is shifted out by the falling edge of TxC at a transmission rate of TxC, TxC/16 or TxC/64, as defined by the Mode Instruction.

If no data characters have been loaded into the USART, or if all available characters have been transmitted, the TxD output remains "high" (marking) in preparation for sending the START bit of the next character provided by the processor. TxD may be forced to send a BREAK (continuously low) by setting the correct bit in the Command Instruction.

Receive —
The RxD input line is normally held “high” (marking) by the transmitting device. A falling edge (high to low transition) at RxD signals the possible beginning of a START bit and a new character. The receiver is thus prevented from starting in a "BREAK" state. The START bit is verified by testing for a "low" at its nominal center as specified by the BAUD RATE. If a "low" is detected, it is considered valid, and the bit assembling counter starts counting. The bit counter locates the approximate center of the data, parity (if specified), and STOP bits. The parity error flag (PE) is set, if a parity error occurs. Input bits are sampled at the RxD pin with the rising edge of RxC. If a high is not detected for the STOP bit, which normally signals the end of an input character, a framing error (FE) will be set. After the STOP bit time, the input character is loaded into the parallel Data Bus Buffer of the USART and the RxRDY signal is raised to indicate to the processor that a character is ready to be fetched. If the processor has failed to fetch the previous character, the new character replaces the old and overrun flag (OE) is set. All the error flags can be reset by setting a bit in the Command Instruction. Error flag conditions will not stop subsequent USART operation.

DESCRIPTION OF OPERATION—SYNCHRONOUS

Transmission —
As in Asynchronous transmission, the TxD output remains "high" (marking) until the USART receives the first character (usually a SYNC character) from the processor. After a Command Instruction has set TxEN and after Clear to Send (CTS) goes low, the first character is serially transmitted. Data is shifted out on the falling edge of TxC at the same rate as TxC.

Once transmission has started, Synchronous Data Protocols require that the serial data stream at TxC continue at the TxC rate or SYNC will be lost. If a data character is not provided by the processor before the USART Transmit Buffer becomes empty, the SYNCD character(s) loaded directly following the Mode Instruction will be automatically inserted in the TxD data stream. The SYNC character(s) are inserted to fill the line and maintain synchronization until the new data characters are available for transmission. If the USART becomes empty, and must send the SYNCD character(s), the TxEMPTY output is raised to signal the processor that the Transmitter Buffer is empty and SYNC characters are being transmitted. TxEMPTY is automatically reset by the next character from the processor.

Receive —
In Synchronous receive, character synchronization can be either external or internal. If the internal SYNC mode has been selected, the ENTER HUNT (EH) bit has been set by a Command Instruction, the receiver goes into the HUNT mode.

Incoming data on the RxD input is sampled on the rising edge of RxC, and the contents of the Receive Buffer are compared with the first SYNC character after each bit has been loaded until a match is found. If two SYNC characters have been programmed, the next received character is also compared. When the (two contiguous) SYNC character(s) programmed have been detected, the USART leaves the HUNT mode and is in character synchronization. At this time, the SYNDET (output) is set high. SYNDET is automatically reset by a STATUS READ.

If external SYNC has been specified in the Mode Instruction, a "one" applied to the SYNDET (input) for at least one RxC cycle will synchronize the USART.

Parity and Overrun Errors are treated the same in the Synchronous as in the Asynchronous Mode. If not in HUNT, parity will continue to be checked even if the receiver is not enabled. Framing errors do not apply in the Synchronous format.

The processor may command the receiver to enter the HUNT mode with a Command Instruction which sets Enter HUNT (EH) if synchronization is lost. Under this condition the Rx register will be cleared to all "ones".
OPERATION AND PROGRAMMING

The microprocessor program controlling the COM 8251A performs these tasks:

- Outputs control codes
- Inputs status
- Outputs data to be transmitted
- Inputs data which has been received

Control codes determine the mode in which the COM 8251A will operate and are used to set or reset control signals output by the COM 8251A.

The Status register contents will be read by the program monitoring this device's operation in order to determine error conditions, when and how to read data, write data or output control codes. Program logic may be based on reading status bit levels, or control signals may be used to request interrupts.

INITIALIZING THE COM 8251A

The COM 8251A may be initialized following a system RESET or prior to starting a new serial I/O sequence. The USART must be RESET (external or internal) following power up and subsequently may be reset at any time following completion of one activity and preceding a new set of operations. Following a reset, the COM 8251A enters an idle state in which it can neither transmit nor receive data.

The COM 8251A is initialized with two, three or four control words from the processor. Figure 1 shows the sequence of control words needed to initialize the COM 8251A, for synchronous or for asynchronous operation. Note that in asynchronous operation a mode control is output to the device followed by a command. For synchronous operation, the mode control is followed by one or two SYNC characters, and then a command.

Only a single address is set aside for mode control bytes, command bytes and SYNC character bytes. For this to be possible, logic internal to the chip directs control information to its proper destination based on the sequence in which it is received. Following a RESET (external or internal), the first control code output is interpreted as a mode control. If the mode control specifies synchronous operation, then the next one or two bytes (as determined by the mode byte) output as control codes will be interpreted as SYNC characters. For either asynchronous or synchronous operation, the next byte output as a control code is interpreted as a command. All subsequent bytes output as control codes are interpreted as commands. There are two ways in which control logic may return to anticipating a mode control input; following a RESET input or following an internal reset command. A reset operation (internal via IR or external via RESET) will cause the USART to interpret the next "control write", which should immediately follow the reset, as a Mode Instruction.

After receiving the control words the USART is ready to communicate. TxD is raised to signal the processor that the USART is ready to receive a character for transmission. Concurrently, the USART is ready to receive serial data.

MODE CONTROL CODES

The COM 8251A interprets mode control codes as illustrated in Figures 2 and 3.

Control code bits 0 and 1 determine whether synchronous or asynchronous operation is specified. A non-zero value in bits 0 and 1 specifies asynchronous operation and defines the relationship between data transfer baud rate and receiver or transmitter clock rate. Asynchronous serial data may be received or transmitted on every clock pulse, on every 16th clock pulse, or on every 64th clock pulse, as programmed. A zero in both bits 0 and 1 defines the mode of operation as synchronous.

For synchronous and asynchronous modes, control bits 2 and 3 determine the number of data bits which will be present in each data character. In the case of a programmed character length of less than 8 bits, the least significant DATA BUS unused bits are "don't care" when writing data to the USART and will be "zeros" when reading data. Rx data will be right justified onto D0 and the LSB for Tx data is D0.

For synchronous and asynchronous modes, bits 4 and 5 determine whether there will be a parity bit in each character, and if so, whether odd or even parity will be adopted. Thus in synchronous mode a character will consist of five, six, seven or eight data bits, plus an optional parity bit. In asynchronous mode, the data unit will consist of five, six, seven or eight data bits, an optional parity bit, a preceding start bit, plus 1, 1½ or 2 trailing stop bits. Interpretation of subsequent bits differs for synchronous or asynchronous modes.

Control code bits 6 and 7 in asynchronous mode determine how many stop bits will trail each data unit. 1½ stop bits can only be specified with a 16X or 64X baud rate factor. In these two cases, the half stop bit will be equivalent to 8 or 32 clock pulses, respectively.

In synchronous mode, control bits 6 and 7 determine how character synchronization will be achieved. When SYNDET is an output, internal synchronization is specified; one or two SYNC characters, as specified by control bit 7, must be detected at the head of a data stream in order to establish synchronization.

COMMAND WORDS

Command words are used to initiate specific functions within the COM 8251A such as, "reset all error flags" or "start searching for sync". Consequently, Command Words may be issued by the processor to the COM 8251A at any time during the execution of a program in which specific functions are to be initialized within the communication circuit.

Figure 4 shows the format for the Command Word.

Bit 0 of the Command Word is the Transmit Enable bit (TxEN). Data transmission for the COM 8251A cannot take place unless TxEN is set (assuming CTS = 0) in the command register. The TX Disable command is prevented from halting transmission by the Tx Enable logic until all data previously written has been transmitted. Figure 5 defines the way in which TxEN, TXE and TxRDY combine to control transmitter operations.

Bit 1 is the Data Terminal Ready (DTR) bit. When the DTR command bit is set, the DTR output connection is active (low). DTR is used to advise a modem that the data terminal is prepared to accept or transmit data.

Bit 2 is the Receiver Enable Command bit (RxE). RxE is used to enable the RxRDY output signal. RxE, when zero, prevents the RxRDY signal from being generated to notify the processor that a complete character is framed in the Receive Character Buffer. It does not inhibit the assembly of data characters at the input, however. Consequently, if communication circuits are active, characters will be assembled by the receiver and transferred to the Receiver Buffer. If RxE is disabled, the overrun error (OE) will probably be set; to insure proper operation, the overrun error is usually reset with the same command that enables RxE.

</tbody>
</table>

Bit 3 is the Send Break Command bit (SBRK). When SBRK is set, the transmitter output (TxD) is interrupted and a continuous binary “0” level, (spacing) is applied to the TxD output signal. The break will continue until a subsequent Command Word is sent to the COM 8251A to remove SBRK.

Bit 4 is the Error Reset bit (ER). When a Command Word is transferred with the ER bit set, all three error flags (PE, OE, FE) in the Status Register are reset. Error Reset occurs when the Command Word is loaded into the COM 8251A. No latch is provided in the Command Register to save the ER command bit.

Bit 5, the Request To Send Command bit (RTS), sets a latch to reflect the RTS signal level. The output of this latch is created independently of other signals in the COM 8251A. As a result, data transfers may be made by the processor to the Transmit Register, and data may be actively transmitted to the communication line through TxD regardless of the status of RTS.

Bit 6, the Internal Reset (IR), causes the COM 8251A to return to the Idle mode. All functions within the COM 8251A cease and no new operation can be resumed until the circuit is reinitialized. If the operating mode is to be altered during the execution of a processor program, the COM 8251A must first be reset. Either the RESET input can be activated, or the Internal Reset Command can be sent to the COM 8251A. Internal Reset is a momentary function performed only when the command is issued.

Bit 7 is the Enter Hunt command bit (EH). The Enter Hunt mode command is only effective for the COM 8251A when it is operating in the Synchronous mode. EH causes the receiver to stop assembling characters at the RxD input, clear the Rx register to all "ones", and start searching for the prescribed sync pattern. Once the "Enter Hunt" mode has been initiated, the search for the sync pattern will continue indefinitely until EH is reset when a subsequent Command Word is sent, when the IR command is sent to the COM 8251A, or when SYNC characters are recognized. Parity is not checked in the EH mode.

STATUS REGISTER

The Status Register maintains information about the current operational status of the COM 8251A. Status can be read at any time, however, the status update will be inhibited during status read. Figure 6 shows the format of the Status Register.

TxRDY signals the processor that the Transmit Character Buffer is empty and that the COM 8251A can accept a new character for transmission. The TxRDY status bit is not totally equivalent to the TxRDY output pin, the relationship is as follows:

\[ \text{TxRDY (status bit)} = \text{Tx Character Buffer Empty} \times \text{TxRDY (pin 15)} = \text{Tx Character Buffer Empty} \times \text{CTS} \times \text{TxEN} \]

RxDY signals the processor that a completed character is holding in the Receive Character Buffer Register for transfer to the processor.
Figure 6. The COM 8251A Status Register

- **TxRDY**
- **RxRDY**
- **TxE**
- **PE** Parity error
- **OE** Overrun error
- **FE** Framing error
- **SYNDET/BRKDET**
- **DSR**

**Note:**

1. While operating the receiver it is important to realize that the RxE bit of the Command Instruction only inhibits the assertion of RxRDY; it does not inhibit the actual reception of characters. As the receiver is constantly running, it is possible for it to contain extraneous data when it is enabled. To avoid problems this data should be read from the USART and discarded. This read should be done immediately following the setting of the RxE bit in the asynchronous mode, and following the setting of EH in the synchronous mode. It is not necessary to wait for RxRDY before executing the dummy read.

2. ER should be performed whenever RxE of EH are programmed. ER resets all error flags, even if RxE = 0.

3. The USART may provide faulty RxRDY for the first read after power-on or for the first read after the receiver is re-enabled by a command instruction (RxE). A dummy read is recommended to clear faulty RxRDY. This is not the case for the first read after hardware or software reset after the device operation has been established.

4. Internal Sync Detect is disabled when External Sync Detect is programmed. An External Sync Detect Status is provided through an internal flip-flop which clears itself, assuming the External Sync Detect assertion has removed, upon a status read. As long as External Sync Detect is asserted, External Sync Detect Status will remain high.

13.1 CONFIGUR.COM

This program enables the user to select various operating parameters for the CompuStar. This feature allows flexibility in your CompuStar's use. The parameters affect the MAIN and AUXILIARY ports, the AC line frequency, and disk verification. By allowing the user to change these parameters, a variety of peripheral devices can be used with your CompuStar VPU.

The CONFIGUR program is menu-driven; the user selects the parameter to change, and then follows the instructions listed. To initiate the CONFIGUR command, type 'CONFIGUR (cr)' at the keyboard. CONFIGUR will then accept your commands for parameter changes. After you are finished, press the return key (you may change several of the parameters if you wish); the screen will clear, and you will be instructed to press both RED keys on the keyboard. This action will force an operating system reload containing your new parameters, and these parameters will be reloaded each time you reset the operating system.

Note that the CONFIGUR program will change the copy of the operating system located on the diskette in drive A. Even if your copy of CONFIGUR.COM is located on drive B, drive A will be affected. A summary of parameter selections is included for reference.

Before diskettes can be used by an Intertec computer, they must first be formatted. This process will erase the diskette of all data and write certain sector-header information on the diskette so that the operating system is able to properly locate data on the diskette. FORMAT.COM is a versatile program that will allow the user to format diskettes for both SuperBrain and CompuStar computers.

To load the format program from diskette, type 'FORMAT (cr)' at the keyboard. After loading, you should select the type of diskette you wish to format. You may select single-sided (for SuperBrain and CompuStar Model 20 computers), double-sided (for SuperBrain QD and CompuStar Model 30 computers), or double-sided/double-tracked (for CompuStar Model 40 diskettes). Once your selection has been entered, you will be asked to place an unformatted diskette into drive B and type the 'F' key to begin formatting. When the formatting is completed, you may continue formatting by placing another diskette into drive B and pressing the 'F' key. You may repeat this process until all of your diskettes have been formatted. Press the 'RETURN' key to end the formatting session.

The diskette that you format does not have to be a blank diskette. You may format on old diskette if you wish, but you should remember that 'FORMAT' will destroy all data on a diskette. However, if the data on a diskette becomes damaged (or if you suspect that the data is damaged), copy the diskette onto another diskette and reformat the original. This way, you save some (or all) of the original data and you don't lose any diskettes.
This program performs an extensive test on main memory by writing and reading all possible binary patterns to all locations in the random access memory (RAM). The process takes between eight and ten minutes to complete.

The test procedure begins by typing '64KTEST (cr)' at the keyboard. After the program is loaded into memory, you will be asked to remove all diskettes from their drives. If you have a CompuStar Disk Storage System (DSS) connected to the terminal to be tested, either power down the DSS or disconnect the DSS from the terminal by removing the interconnecting cable.

Once you have pressed the 'G' key to start the test, the screen should fill with random text. The patterns on the screen should move around. This is because the memory for the screen is also undergoing the test. After the test is completed, the screen will display 'RAM OK', indicating that the test was successful. The test is an endless loop, and will repeat until the RED keys are depressed simultaneously. Therefore, you can test the RAM as long as you desire.

If an error is detected by the test, the test will stop and the audible tone will sound continuously. Should this occur, retry the test. If the tone occurs frequently, please contact the Intertec Service Department.
The TX utility is written in standard CP/M assembly language. TX is designed to communicate via the computer's Main Port with the program RX running in the destination machine. Therefore, TX is considered the "Master" program, and RX is the "Slave" program. RX receives commands from TX such as "Open file", "Read incoming data block", "Write block to file", and so on. For this reason, the user should only be concerned with console operations for the machine in which TX is running. RX receives all directions from the communications link.

Unlike data transfer operations initiated with PIP, the TX/RX pair perform block checksum verification, retransmission in the event of error, and are insensitive to the type of data being transferred. TX/RX may be used to send any type of CP/M file without modification, including .COM files.

TX is initiated by typing the command: 'TX (cr)'. The TX program will then "sign-on" with an identifying message and version number and then give the user an option to proceed or abort. The actual console dialogue appears as:

```
A>TX
INTERTEC File Transfer Utility Vers 1.6
HIT CR WHEN RECEIVE MACHINE READY OR Q TO ABORT
```

At this point, start up RX in the destination machine (See RX.COM in Section 13.5)

When a carriage return is entered to TX, it will attempt to establish a linkage to the destination RX machine over the computer's Main Port. Given that a link can be established, TX will display the message:

```
LINK TO SLAVE MACHINE ESTABLISHED
```

or, if many attempts to link fail:

```
UNABLE TO ESTABLISH/MAINTAIN DATA LINK
```

(This probably indicates that some aspect of the connection with the destination machine is not correct, i.e. inconsistent baud rates, improper cabling, or excessive line noise.)

The TX program then prompts the user to enter both the source file name and the destination file name. These names must be fully qualified, non-ambiguous file references. This includes disk specifiers.

If the specified file already exists on the receiving machine, TX will display:
FILE ALREADY EXISTS ON RECEIVING MACHINE

and the link is terminated.

As an expediency, send the file again, but with a temporary destination file name.

As a file is being transmitted under TX/RX, both TX and RX will display a record count. This serves to indicate that the data is being transferred correctly. It is normal to see a difference of one record between the two counts upon completion of a file transfer.

If TX detects a failure in the data link, it will output the message:

   UNABLE TO ESTABLISH/MAINTAIN DATA LINK

When a file has been transmitted, TX displays the message:

   FUNCTION COMPLETE
   TYPE R TO REPEAT, CR TO EXIT

If another file is to be transferred, enter the letter "R" and TX will request another pair of file names. Entry of a carriage return will cause TX to command RX to shutdown and both will terminate.

There are two other messages that could be output by TX.

As each data block is sent, a checksum is calculated and transmitted. If RX detects a discrepancy between the received checksum and that which has been calculated for the received data, it will request that TX re-send the block in question. If the block cannot be received correctly after several re-transmissions, the message:

   HARD DATA TRANSMISSION ERROR

will be rendered. The most likely cause of this failure is bad hardware.

If the diskette on which RX attempts to place the incoming data file is write protected, or if there is not enough space to contain the incoming file, TX will display:

   RECEIVE CANNOT CLOSE FILE
13.5 RX.COM

RX is an assembly language program designed to receive data files transmitted by TX from the computer's Main Port. It operates as a slave to the TX program, receiving commands from TX to perform operations on the destination machine.

RX is initiated by typing the command 'RX (cr)'. Upon initiation, RX displays a "sign-on" message of the form:

   INTERTEC File Transfer Utility Vers 1.3

From this point on, unless an error condition occurs, no further operator action is required.

As each data block is received, RX outputs a running count of the data blocks received. At the end of each received file, RX displays the message:

   END-OF-FILE RECEIVED

When all files have been received, TX will command RX to terminate and RX will display:

   LINK TERMINATED

If the data link cannot be established or maintained (indicated by a message on the TX system), it will be necessary to reset the destination system. This is accomplished on the destination computer by depressing both RED keys simultaneously.
This is a system utility designed to generate a 'HEX' file from a 'COM' file, and transfer the contents out of a desired port. Since the PIP program cannot transfer 'COM' files, this utility is useful in effecting file transfers with the PIP program. To initiate the Hexdump facility, type the following at the keyboard: 'HEXDUMP (cr)'. The program will be loaded and then await your instructions.

The first thing that the Hexdump procedure requests is the port to which you wish to dump the file. Here enter '1' for the MAIN port (corresponding to CP/M's PUN: and RDR: device), or '2' for the AUXILIARY port (corresponding to CP/M's LST: device). You must enter either a '1' or a '2', invalid entries will be ignored. Next you may choose whether or not you wish to have the 'HEX' file echoed to the console (this will display the file as transmitted). Enter '1' if you do not wish to have the file echoed on the screen, or '2' if you wish to have the contents echoed. Again, invalid entries will be ignored.

Now you are ready to enter the file name. You must enter the drive designator, the file name and the file type. Separate the drive indicator from the file name with a colon (':'), and.type from the name with a period ('.'). Press the return key after entering the name.

Example:

A>HEXDUMP (cr)

HEXDUMP FILE UTILITY VER. 3.1

SELECT ONE OF THE FOLLOWING: (TYPE THE NUMBER)
  1 - THE MAIN PORT (PUN:)
  2 - THE AUX PORT (LST:)
  2

SELECT ECHO ON THE CONSOLE:
  1 - DO NOT ECHO ON THE CONSOLE
  2 - ECHO TO THE CONSOLE
  1

ENTER DISC,FILE-NAME,AND FILE-TYPE TO BE TRANSFERRED.
A:STAT.COM (cr)

FILE TRANSFER COMPLETED.
In the example above, the file STAT.COM was transfered from disk A through the auxiliary port. HEXDUMP.COM will only transfer files which exist on drives A and B. If you enter an erroneous file-name or disk drive, the program will display an error message. If HEXDUMP.COM is unable to locate the given file, another error message will be given. When the transmission has completed, the screen will indicate this and return to the operating system.
13.7 SYNCHRONOUS COMMUNICATION

Your computer system is factory configured to program the Universal Synchronous/Asynchronous Receiver/Transmitter (USART) to operate in the asynchronous mode. It is possible, however, to change this and permit the Bisync, or byte synchronous, communication mode. You will be responsible for writing the software drivers that send and receive synchronous data through to the MAIN port at the rear of your terminal. This section will instruct you to properly program the USART which is the interface between the CPU and the main port of your computer.

Before proceeding, it would be helpful to read the specification sheet for the 8251-type USART. This is located in Section 12.2 of this manual. On this sheet you are given the control words to reprogram the USART to enable synchronous communication. However, we shall demonstrate with an example of common type. Also, it is important that the blue timing dipswitch, located on the processor board, be set in accordance with procedures found in Section 12.1 of this manual. This is necessary to coordinate the clock pulses between the two terminals communicating in the synchronous mode.

Both the CompuStar and SuperBrain computer systems store the command byte for the 8251 USART in memory. To use a different type of communication, several steps are necessary. The USART command word must be changed in order to change the USART's operating mode. The operating system must also be prevented from resetting the USART during an interrupt cycle. Below is listed a simple assembly language program which, when appended to your communication program, should permit this type of operation. Be certain to execute these instructions prior to any synchronous communication.

SYNC:

FALSE EQU 0
TRUE EQU NOT FALSE
SUPER EQU TRUE ; MODE FOR THE SUPERBRAIN
COMPU EQU FALSE ; CHANGE IF COMPUSTAR
;
IF SUPER
USCMD EQU 0EF01H ; ADDRESS OF SUPERBRAIN COMMAND MODE
USINS EQU 0EF02H ; ADDRESS OF SUPERBRAIN INSTRUCTION
RETPNT EQU 0E5F8H ; ADDRESS FOR BREAK KEY RETURN
POINT
ENDIF
;
IF COMPU
USCMD EQU 0EF01H ; ADDRESS OF COMPUSTAR COMMAND MODE
USINS EQU 0EF02H ; ADDRESS OF COMPUSTAR INSTRUCTION

11
The above example will set up the USART for synchronous communication, with 1 sync character, and a word length of eight bits. By referencing the specification sheet for the 8251, you may alternately change the mode word to allow 2 sync characters, a different word length, or some other set up. Note that the return instruction stored at RETPNT will disable the BREAK key from resetting the USART line; clever programming will be needed to allow this.
13.8 USING THE "INP:" AND "OUT:" FEATURES OF PIP TO FACILITATE FILE TRANSFERS TO AND FROM THE COMPUSTAR

The CompuStar is equipped with a 'MAIN' RS-232-C serial interface port on the rear panel. This interface should be programmed for the following mode:

Asynchronous
1200 Baud
8 bits
1 Stop Bit
No Parity

This port is also wired so that the CompuStar appears as a processor rather than as a terminal. If it is to be used as a terminal, pins 2 and 3 in the RS-232-C cable must be interchanged.

Files can be transferred using the PIP program as described in Section 6.4 of the Operator's Manual entitled "An Introduction to CP/M Features and Facilities." When the CompuStar transmits serial data, the destination is designated as a list (LST:) device; when receiving, the source device is considered a reader (RDR:).

The serial port may also be considered as an input (INP:) or output (OUT:) port. When used in this mode, the operator has the option of communicating to the sending/receiving device via the CompuStar console before actual files are transferred.

Files transferred via the serial port must be in Intel hex format or ASCII. Binary files must be converted to hex files by utilizing the HEXGEN.ASM program before being sent to the CompuStar. BASIC files must be saved in the ASCII format if they are to be transferred to the serial interface.

(NOTE: When ASCII files are transferred using the INP: or OUT: format, all data entered by the Operator on the console will also appear in the ASCII file. Undesired data must then be edited by using ED.COM.)

Sequence of Operation:

1. Connect CompuStar MAIN port to console input of host computer. Be sure host computer is set to 1200 baud.

2. The largest program that can be transferred by PIP is 25K. If programs are larger than 25K, then programs must be broken down into smaller segments.

3. All commands must be entered on the CompuStar in the following sequence.

   A. To transfer ASCII file - ABC.ASM - from CompuStar to host:
A> PIP OUT: = ABC. ASM (cr)  (Keyboard entry)
ECHO (Y/N) Y  (Keyboard entry)
+  (Computer responds)

Now the CompuStar will act like a dumb terminal for host computer. Any keyboard entry will be sent to host computer and displayed on screen.

+ PIP ABC.HST = CON: (cr)  (Keyboard entry)
(CTRL) (B)  (Computer responds)

NOTE: Underlined characters are typed by customer. 
"(cr)" represents a carriage return.

Now the file is being transferred and should be displayed on the screen. When the file has been transferred the operating system will show the prompt symbol.

A> PIP OUT: = EOF: (cr)  (Keyboard entry)
ECHO (Y/N) Y  (Computer responds)
+  (Computer responds)
(CTRL) (B)  (Keyboard entry - these two keys at the same time)

Now the file transfer has been completed; both computers should return to the operating system.

B. To transfer binary file - ABC.COM - from CompuStar to host:
A> PIP ABC.TST = INP: (cr) (Keyboard entry)
ECHO (Y/N) Y (Computer responds)
+ (Keyboard entry)

Now the CompuStar will act like a dumb terminal for the host computer. Any keyboard entry will be sent to the host computer and displayed on the screen.

+ PIP ABC.HEX = CON: (cr) (Keyboard entry)

NOTE: The binary file on the CompuStar will be transferred in INTEL HEX format. After the transfer use LOAD or DDT and SAVE to change. HEX file to a binary, COM file.

(CTRL) (Z) (Keyboard entry - these two at the same time)
End of file, Control Z?
(CTRL) (Z) (Computer responds)

Now the host computer is set up to input a file. The CompuStar will return to the operating system with its prompt.

A> HEXDUMP ABC.COM (cr) (keyboard entry)

At this point the file will be transferred in HEX format and displayed on the screen. When the transfer is complete the CompuStar will return to the operating system.

C. To transfer ASCII file - ABC.PRN - to CompuStar from host:

A> PIP ABC.PRN = INP: (cr) (Keyboard entry)
ECHO (Y/N) Y (Computer responds)
+ (Keyboard entry)

Now the CompuStar is ready for input form host. The keyboard entry will be sent to the host and displayed on the screen. Now set up commands to output from the host.

+ PIP CON: = ABC.PRN (cr) (Keyboard entry)

The file ABC.PRN on the host is now being input to the CompuStar and displayed on the screen. After the file has been transferred, the CompuStar should return to the operating system; if it does not, then type (CTRL) (Z) simultaneously.
D. To transfer binary file - ABC.COM - to CompuStar from host:

(NOTE: Before transferring to CompuStar, either HEXGEN.ASM or HEXDUMP.COM must be transferred to the host.)

1) Using HEXDUMP.COM

A> PIP ABC.HEX = INP: [H] (cr) (Keyboard entry)
ECHO  (Y/N) Y (Computer responds)
+ (Keyboard entry)
+ (Computer responds)

Now the CompuStar is ready to accept input. NOTE: Since a binary file is transferred in INTEL HEX format, the .HEX file on the CompuStar can be changed using LOAD or DDT and SAVE, to a binary file.

+ HEXDUMP ABC.COM (cr) (keyboard entry)

The file is now being transferred and also displayed on the screen. When the transfer is complete, the CompuStar will return to the operating system.

2) Using HEXGEN.ASM

Look at source listing:

```
ORG 6000H
LXI SP 6400H
LXI D, 6000H *ending address
LXI H, 100H *beginning address
```

The origin and the SP will need to be modified for your particular system. (For example: 32K systems use ORG 5000H, and SP, 5400H.) You may also change H,D to suit program size; register H is loaded with the end address of the program to be transferred, and register D has the beginning address (most programs begin at 100H). Now run assembler to generate HEXGEN.HEX. You are ready to begin.

A> PIP ABC.HEX = INP: [H] (Keyboard entry)
ECHO  (Y/N) Y (Computer responds)
+ (Keyboard entry)
+ (Computer responds)

At this point the CompuStar is ready for input and the host must be set up to output the HEX file.
Now we have loaded DDT into the host system.

```
+DDT
Version 1.4
```

(Keyboard entry)

(Computer responds)

```
IABC.COM (cr)
-R (cr)
NEXT PC
0A00 0100
```

(Keyboard entry)

(Computer responds)

```
These two numbers are the end and starting address)
```

```
-IHEXGEN.HEX (cr)
-R (cr)
NEXT PC
60B8 0100
```

(Keyboard entry)

(Computer responds)

At this point the host computer has 2 programs loaded into memory, one above the other. One is the program to be transferred, and the other to generate the INTEL HEX format.

```
-G6000 (cr)
```

(Keyboard entry)

(The number is the same as ORG in the source listing)

Now the file is being transferred and will be displayed on the screen. After the program has been transferred, the CompuStar will return to the operating system.

3) To change back to a binary file, follow this procedure:

```
A> LOAD ABC.HEX (cr)
```

(Keyboard entry)

```
LAST ADDRESS XXXX
FIRST ADDRESS XXXX
BYTES READ XXXX
RECORDS WRITTEN XX

A>
```

Now there are two files: one HEX and one binary.

or

```
A> DDT ABC.HEX (cr)
```

(Keyboard entry)

(Computer responds)

```
Version 1.4
Next PC
ABCD 0100
```

(Keyboard entry - both keys at same time)
A> SAVE XX ABC.COM (cr) (Keyboard entry)

NOTE:  XX = A times 16 + B
       under NEXT

Now there are two files:  one .HEX and one binary.
The Disk Operating System on many Intertec computer systems now features many enhancements. This new DOS will run on any SuperBrain or SuperBrain QD video computer system which is in current production. These software changes are designed to provide greater operator efficiency, more powerful software, and more flexible computer usage. These changes are listed below, and a further explanation of their use is described later in this document.

- Audible feedback with each key depression (selectable)
- Key repeat after key is held down
- Type-ahead permitting 128 characters to be entered ahead of computer
- Time of day maintained by the operating system
- Date kept by the operating system, including end-of-month and end-of-year checks
- Synchronous communication capability via the MAIN serial I/O port
- Data Set Ready (DSR) can be checked prior to output on the MAIN port before transmission to enable 'handshaking' (selectable)
- Redefinable Numeric Keypad, allowing any value to be assigned to any key on the pad
OPERATION ENHANCEMENTS

Audible Feedback

The audible feedback feature is designed to provide a tone with each key depression. The purpose of the feedback is to allow faster data entry by informing the operator whenever a key is depressed. This feature can be easily selected during terminal operation or can be automatically selected upon system power-up.

To enable the feedback feature, simply display a Control-B (02H). This will 'toggle' the key click feature and turn it on if it is off, or vice versa. The CONFIGUR program will permit you to set the click on or off on system power-up, and hence, relieve you of any further action. (See Technical Bulletin concerning CONFIGUR operation.)

Key Repeat

When a key remains depressed for more than 600 milliseconds, the key value will repeat at a rate of approximately 30 per second. This will allow faster data entry for applications such as word processing, text editing, and program displays where a 'banner' is required.

Type-ahead

The input on DOS version 3.1 is saved if the operator enters data faster than the computer can accept it. Up to 128 characters are stored when typed, and delivered only when needed. It is now possible to enter commands to an application program as it is being loaded from the disk and not lose any characters. Your input will appear after the program has been loaded, and the program will execute the commands as if you had just entered them. If you type more than 128 characters ahead of the computer system, the bell will ring. This indicates that the buffer is full, and further typing will be ignored by the system.

Contact the Customer Service Department at the address above for additional information on this bulletin.
Notes

It should be noted that some programs will not work with the type-ahead feature. An example is the 'DIR' command, which displays the directory contents of a diskette. By definition, a directory display is interrupted if a key is depressed during the display. If the 'DIR' command receives a key from the type-ahead feature, it doesn't know if the key was just entered, or if it came from the buffer. In either case, the display is disrupted and a character is lost. Experiment with the system to see which programs will not tolerate type-ahead.

ADDED CONVENIENCES

Time

The Operating System will now keep the time of day. The time is maintained in ASCII, and therefore, its contents are displayable at any time and no conversion is necessary. The location of the time is 42 through 4A Hexadecimal so these locations cannot be used by the programmer. The time is kept in military format with values ranging from 00:00:00 to 23:59:59. At midnight the time resets itself and also changes the value of the date. (See the subsection entitled 'Date' for more information.)

The time may be displayed upon the screen in the upper right corner. This feature may be disabled if such a display is not desired. By displaying a Control-T (14H), the time display is 'toggled' either on or off. Also, the display can be made to remain on or off upon system power-up via the CONFIGUR program. The time is always maintained by the operating system even if the time display is disabled.

The time may be set with the 'TIME' command. This is a system program supplied on the distribution diskette. To set the time type 'TIME' followed by the current time. The time must be entered in military format (hh:mm:ss), and separating colons must be supplied. If an invalid number is entered for the time, then the operator is warned, and the time is not set.

Contact the Customer Service Department at the address above for additional information on this bulletin.
Note that when the time display is enabled, it takes precedence over anything which may be displayed upon the screen and will over-write any characters which would have been displayed on the last nine positions of the first line. It is not possible to use these positions for data display if the time display is enabled. Note also that this is a 'software clock' and may be inaccurate as much as several seconds per day.

Date

The Operating System will now keep the date. The date is located at locations 4B through 4D Hexadecimal. These locations are now reserved and may not be used by the programmer. The date is maintained in packed binary-coded decimal, or BCD, format. The three bytes storing the date are for the month, day, and year, respectively (the year is the last two digits only). At midnight, the Operating System will increment the day by one, and then check for end of month. If it is the end of the month, the month is incremented. The system will also check for the end of the year.

The date may be queried or set with a new command called 'DATE'. This is a system program located on the distribution diskette. To set the date, type in 'DATE' followed by the new date in the form of mm/dd/yy. If you enter an invalid date, you will be warned so and the date will not be set. To view the date, type in 'DATE' by itself. This will display the current date.

Other Commands

The suffix '-22', which was appended to system commands on previous software releases, has been omitted from all programs on version 3.1. This suffix was to distinguish CP/M version 2.2 programs from CP/M version 1.4 programs. The suffix is no longer needed and will be excluded.

Contact the Customer Service Department at the address above for additional information on this bulletin.
INPUT/OUTPUT ENHANCEMENTS

Synchronous Communication

The MAIN serial port on the rear of the computer can now be programmed for limited synchronous (Bi-Sync) communication. Synchronous protocol sends the data over the transmission lines at a timed rate and does not rely upon start- and end-of-data indicators. When data is not available for transmission, the universal synchronous/asynchronous receiver/transmitter (USART) enters the 'synchronous idle' mode and transmits a SYNC byte in lieu of data. The receiving USART will intercept this and enter the 'hunt' mode awaiting resumption of data transmission.

The USARTs must be programmed upon power-up in order that proper operating mode and other parameters can be determined. When the initial programming command indicates that the operating mode is synchronous, the USART next expects a SYNC character that will be transmitted when the USART enters synchronous idle mode. The value of this SYNC character is stored with the operating system, and can be set via the CONFIGUR program. Also, you may specify whether one or two SYNC characters should be sent to the USART.

It is the responsibility of the user to write his own routines to initiate Start-of-Header (SOH), Start-of-Text (STX), End-of-Text (ETX), and End-Of-Transmission (EOT) sequences for Bi-Sync communication. The support offered by the Operating System is only to insure that the USART will be properly programmed upon power-up whenever the BREAK key is depressed. Also take care in selecting the clock settings on the blue dipswitch located on the upper right corner of the processor board. This switch will select the TX clock and the RX clock - refer to Technical Bulletin #B010009 found elsewhere in the Operator's Manual for explicit instructions.
Synchronous communication is complicated to implement, and it is advised that the user be well educated on this subject before attempting to communicate in synchronous mode. Currently, the Operating System performs no check for parity error, framing error, or overrun error. You will have to modify the BIOS listing supplied on your distribution diskette and merge it into the Operating System to include these checks and any re-transmission of data as required. Most peripherals use asynchronous communication, and you should ensure that your peripheral will permit synchronous communication before attempting to program the MAIN port.

Data Set Ready on MAIN Port

Quite often a peripheral device will signal the host computer when it is able to receive a character for processing. This is known as handshaking, because the computer and the device are in constant communication with each other. The MAIN port will now accept the DSR to be checked prior to any transmission of data. If the peripheral device is not ready to accept characters, the computer will wait until it is. If this check is not desired, it can be bypassed. This setting can be selected in the CONFIGUR program.

KEYPAD REPROGRAMMING

The 18 keys on the numeric keypad can now be reprogrammed to return different values other than those shown on the face of the key cap. This feature allows the user to assign any value to any key and provides greater flexibility in using your computer's keyboard. Applications using this include word processors, text editors, and custom application programs which recognize special values as conditional input. By reassigning the key values and changing the key caps, the user can configure his system in literally hundreds of ways.

Contact the Customer Service Department at the address above for additional information on this bulletin.
Special note is needed concerning the cursor keys on the extreme right of the keypad. These keys will position the cursor upon input, i.e., when the key is depressed. After the cursor has been moved by these keys, the input value is substituted with another value, namely, the ASCII value corresponding to the action taken. If you change the values of these keys, then input cursor positioning will not occur. However, if any key is assigned 81H, 82H, 83H, or 85H, then the cursor will be positioned upon input left, right, up, or down, respectively.

The keys on the keypad can be changed with the CONFIGUR program. You may assign any key a value of from 00H to FFH. When reassigning the keys, note that the following values have special meaning to the input routine in the Operating System:

- 17H (Control-W) Turns on/off the computer's ability to scroll the video display. If any key is assigned this value and that key is depressed, the cursor may disappear after the 24th line on the screen.
- 80H Begins the BREAK sequence out of the MAIN port. The BRK line on the USART will become high for approximately 250 milliseconds and will interrupt any data transmission. The USART is also reset and is sent the command word.
- 81H Cursor Left. The cursor is moved one position to the left, and the value 08H is returned.
- 82H Cursor Right. The cursor is moved one position to the right, and the value 06H is returned.
- 83H Cursor Up. The cursor is positioned one line up, and the value 0BH is returned.
- 85H Cursor Down. The cursor is positioned one line down, and the value 0AH is returned.
Control Code Chart

The following is a list of the hexadecimal equivalents of the control codes. The CONFIGUR program accepts only hexadecimal values when reassigning the keypad, so these are listed as a programmer convenience. Use caution when reassigning the values on the keypad, and recall that you may enter 'R' to restore the pad to its original configuration if you desire.

- Ctrl-A 01H
- Ctrl-B 02H
- Ctrl-C 03H
- Ctrl-D 04H
- Ctrl-E 05H
- Ctrl-F 06H
- Ctrl-G 07H
- Ctrl-H 08H
- Ctrl-I 09H
- Ctrl-J 0AH
- Ctrl-K 0BH
- Ctrl-L 0CH
- Ctrl-M 0DH
- Ctrl-N 0EH
- Ctrl-O 0FH
- Ctrl-P 10H
- Ctrl-Q 11H
- Ctrl-R 12H
- Ctrl-S 13H
- Ctrl-T 14H
- Ctrl-U 15H
- Ctrl-V 16H
- Ctrl-W 17H
- Ctrl-X 18H
- Ctrl-Y 19H
- Ctrl-Z 1AH

Contact the Customer Service Department at the address above for additional information on this bulletin.
INFORMATION CONCERNING CONFIGUR.COM VERSION 3.2

The system program CONFIGUR has been changed in order to support the new Operating System version 3.1. This new version of CONFIGUR performs all of the functions of the previous version. However, new functions have been added to enhance operational characteristics. This technical bulletin will describe the operating of the CONFIGUR utility. Below are listed the new features that CONFIGUR will perform.

- Enable/Disable Time Display upon system power-up
- Enable/Disable Key-Depressed Feedback upon system power-up
- Enable/Disable DSR check on the MAIN serial port
- Select Synchronous or Asynchronous operating mode for the MAIN serial port
- Select Number of SYNC Characters for MAIN port operating in Synchronous mode
- Select SYNC Character value for MAIN port operating in Synchronous mode
- Reprogram the 18-key numeric keypad for any new values, including special cursor-positioning keys

Contact the Customer Service Department at the address above for additional information on this bulletin.
OPERATION

Operating Frequency

Your computer system can operate at either 50 or 60 Hertz. You may select either frequency. It is important that the correct frequency be chosen or the USARTs and the real-time clock will not properly operate.

Disk Write Verification

You may select to have the Operating System perform disk read-back verification after each floppy disk write. This feature will 'double-check' the write operation, and attempt an automatic retry if the disk write did not occur properly.

Time Display Enable/Disable

If you wish for the time of day to be constantly displayed in the upper right corner of the screen upon power-up, you may select this feature here. Note that the time is always maintained internally, even if you choose not to display it. Also note that this setting is only for power-up, and you may select/deselect the time during operation by displaying a Control-T (14H).

Key Click Enable/Disable

You may choose to have the audible feedback feature enabled upon system power-up. Whenever the audible feedback is enabled, the computer will inform the operator with a slight 'click' at each key depression. Note that this setting is only for system power-up, and the key click feature can be changed during operation by displaying a Control-B (02H).
Main and Aux Port Operation

Choosing these selections will permit you to change the operating parameters of the MAIN and AUX serial I/O ports located on the rear of your computer. The details of this selection are covered below including which ports are applicable for a given feature.

Operating Mode (MAIN Port Only)
The MAIN port operating mode selections are synchronous and asynchronous. Be certain that the peripheral with which you are communicating is capable of operating in the same mode; they cannot be different. Note also that when changing to synchronous mode, you may need to change the number of SYNC Characters and the SYNC Character value. When changing to the asynchronous mode, you may need to change the number of stop bits.

Baud Rate (MAIN and AUX Ports)
A wide range of baud rates can be selected for the port including rates from 9600 baud (approximately 960 characters/second) to 50 baud (5 characters/second). Select the baud rate needed to communicate with your peripheral.

Number of SYNC Characters (MAIN Port Only)
This selection will affect the number of SYNC Characters sent to the USART upon system power-up. Select either one or two.

Number of Stop Bits (MAIN and AUX Ports)
This selection will choose the number of stop bits sent after each character when the port is operating in asynchronous mode. Select either 1, 1.5, or 2 stop bits.
Character Length (MAIN and AUX Ports)

You may select the length of the character to be transmitted and received. Many selections are provided to insure compatibility with older TTY and Baudot machines. Usually eight bits is the standard character length. You may, however, select 5, 6, 7, or 8 bit character lengths.

Parity (MAIN and AUX Ports)

You may choose to check parity with each transmission. This will provide a limited 'checksum' to help insure that proper transmission has occurred. However, if parity is enabled, the application program will have to test the USART status register for parity error. You may also select Even or Odd parity. If you choose to check parity, be certain that the device with which you are communicating matches your setting.

Handshaking (MAIN and AUX Ports)

If you wish to check Data Set Ready prior to each character transmission, you should enable this function. This will permit a peripheral device to signal the computer whenever it cannot receive anymore characters.

SYNC Character Value (MAIN Port Only)

The SYNC Character is the byte that is sent to the USART after it has been programmed for synchronous communication. Generally, the ASCII value of 13H (SYN) is used, but any binary value may be substituted. Make certain that the SYNC Character value matches that of the peripheral device with which you are communicating. Enter the hexadecimal number desired.

Contact the Customer Service Department at the address above for additional information on this bulletin.
KEYPAD REPROGRAMMING

The 18 key numeric keypad on the right side of the keyboard can be reprogrammed to any input values desired. You may, for example, wish to invert the numeric keys on the pad. They will then correspond to 'telephone style' with 1-2-3 on the top row and 7-8-9 on the bottom. You may wish to replace the keys with control-codes which are accepted by a word processing or text editing program. The key cap values could then be changed to descriptive messages which are easier to learn and understand. Any value from OOH to FFH can now be assigned to the numeric keys with version 3.2 of CONFIGUR.

When this selection is entered, an image of the keypad appears on the screen. To change the value of any key, depress the 'TAB' key until the cursor is over the key you wish to change. Then press the escape (ESC) key to indicate the change needed. The cursor will position itself on the last line, and a blinking asterisk will replace the cursor on the key being changed. Enter the new hexadecimal value for this key. Your input must be valid hex numbers between 0-F as invalid numbers will not be accepted. Press the 'RETURN' key when you are finished.

To restore the keypad to its original values press the 'R' key instead of the ESC or TAB keys. The screen will be updated instantly, and the cursor will be repositioned at the beginning of the display. When all changes have been entered, pressing the 'RETURN' key (instead of the ESC or TAB keys) will return you to the main menu of selections.

Special note is needed concerning the cursor keys on the extreme right of the keypad. These keys will position the cursor upon input, i.e., when the key is depressed. After the cursor has been moved by these keys, the input value is substituted with another value, namely, the ASCII value corresponding to the action taken. If you change the values of these keys, then input cursor positioning will not occur. However, if any key is assigned 81H, 82H, 83H, or 85H, the cursor will be positioned left, right, up, or down, respectively.
Control Code Chart

The following is a list of the hexadecimal equivalents of the control codes. The CONFIGUR program accepts only hexadecimal values when reassigning the keypad, so these are listed as a programmer convenience. Use caution when reassigning the values on the keypad, and recall that you may enter 'R' to restore the pad to its original configuration if you desire.

After all corrections have been entered, pressing the 'RETURN' key will save your new parameters on the disk. This must be done at the main menu of selections. Then press both RED keys when instructed to force a 'cold boot' of the Operating System and properly load your newly changed parameters.
STATEMENT OF LIMITED WARRANTY

For ninety (90) days from the date of shipment from our manufacturing plant at 2300 Broad River Road, Columbia, South Carolina, Intertec warrants, to the original purchaser only, that its products, excluding software products, will be free of defective parts or components and agrees to replace or repair any defective component which, in Intertec's judgment, shall disclose to have been originally defective. Intertec neither offers nor implies any warranty whatsoever on any software products. Furthermore, Intertec's obligations under this limited warranty are subject to the following conditions:

LIMITED WARRANTY REPAIRS

Unless authorized by written statement from Intertec, all repairs must be done by Intertec at our plant in Columbia, South Carolina. Return of any and all parts and/or equipment must be freight prepaid and accompanied by an Intertec Return Material Authorization number which must be clearly visible on the customer's shipping label. Return of parts or equipment contrary to this policy shall result in the material being refused, and the customer being invoiced for any replacement parts, if any were previously issued, at Intertec's standard prices.

When making repairs or replacing parts in accordance with this limited warranty, Intertec reserves the right to alter and/or modify specifications of this equipment.

Upon completion of the repairs, Intertec will return the equipment, freight collect, directly to the customer from whom it was sent via UPS or equivalent ground transportation.

Authorization to return equipment for repair can be obtained by writing Intertec at the address stated herein or by calling our Customer Service Department at 803/798-9100.

In the event Intertec shall authorize repair of its equipment, in writing, by an authorized repair agent, then Customer shall bear all shipping, packing, inspection and insurance costs necessary to effectuate repairs under this warranty.

EXCLUSIONS

The Limited Warranty provided by Intertec Data Systems Corporation does not include:

(a) Any damage or defect caused by injuries received in shipment or any damage caused by unauthorized repairs or adjustments. The risk of loss or damage to the equipment shall pass to the Customer upon delivery by Intertec to the carrier at Intertec's premises.

(b) Repair, damage or increase in service time caused by failure to continually provide a suitable installation environment including, but not limited to, the failure to provide, or the failure of, adequate electrical power, air-conditioning, or humidity control.

(c) Repair, damage or increase in service time caused by accident or disaster, which shall include, but not be limited to, fire, flood, water, wind, lightning, transportation neglect, misuse and alterations, which shall include, but not be limited to, any deviation from the original physical, mechanical or electrical design of the product.

(d) Any statements made about the equipment by salesman, dealers or agents unless such statements are in a written document signed by an officer of Intertec Data Systems Corporation. Such statements do not constitute warranties, shall not be relied on by the buyer, and are not part of the contract for sale.

(e) Any damage arising out of any application for its products other than for normal commercial and industrial use, unless such application is upon request, specifically approved in writing by Intertec. Intertec products are sophisticated data processing units and are not sold or distributed for personal, family or household purposes.

This Class A equipment generates, uses, and can radiate radio frequency energy and if not installed and used in accordance with the instructions manual, may cause interference to radio communications. As temporarily permitted by regulation it has not been tested for compliance with the limits for Class A computing devices pursuant to Subpart I of Part 15 of FCC Rules, which are designed to provide reasonable protection against such interference. Operation of this equipment in a residential area is likely to cause interference in which case the user at his own expense will be required to take whatever measures may be required to correct the interference.

(f) Software, including either source code, object code or any computer program used in connection with our equipment, whether purchased directly from Intertec or from an independent source.

WAIVER OF ALL EXPRESS OR IMPLIED WARRANTIES

Our limited warranty to repair or replace defective parts or components for ninety (90) days after shipment from our Columbia plant is being offered in lieu of all express or implied warranties. INTERTEC MAKES NO EXPRESS WARRANTY OTHER THAN THE LIMITED WARRANTY SET FORTH ABOVE, CONCERNING THIS PRODUCT OR ITS COMPONENTS, NOR DO WE IMPLYLY WARRANT ITS MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE.

All statements, technical information and recommendations contained in this and related documents are based on tests we believe to be reliable, but the accuracy or completeness thereof is not guaranteed.

THE FOREGOING LIMITED WARRANTIES ARE IN LIEU OF ALL OTHER WARRANTIES, EXPRESS OR IMPLIED, EXCEPT AS TO CONSUMER GOODS IN WHICH CASE THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE APPLY ONLY FOR THE PERIOD OF THE LIMITED WARRANTY.

PURCHASERS OF CONSUMER PRODUCTS SHOULD NOTE THAT SOME STATES DO NOT ALLOW FOR THE EXCLUSION OF CONSEQUENTIAL DAMAGES OR THE LIMITATION OF IMPLIED WARRANTIES SO THE ABOVE EXCLUSION AND LIMITATION MAY NOT BE APPLICABLE.

THIS LIMITED WARRANTY GIVES THE PURCHASER SPECIFIC LEGAL RIGHTS, AND THE PURCHASER MAY ALSO HAVE OTHER RIGHTS WHICH MAY VARY FROM STATE TO STATE.

LIMITATION OF REMEDIES

INTERTEC SHALL NOT BE LIABLE FOR ANY INJURY, LOSS OR DAMAGE, DIRECT OR CONSEQUENTIAL, TO PERSONS OR PROPERTY CAUSED EITHER DIRECTLY OR INDIRECTLY BY THE USE OR INABILITY TO USE ITS PRODUCTS AND/OR DOCUMENTS. SUCH LIMITATION IN LIABILITY SHALL REMAIN IN FULL FORCE AND EFFECT EVEN WHEN INTERTEC MAY HAVE BEEN ADVISED OF THE POSSIBILITY OF SUCH INJURIES, LOSSES OR DAMAGES.

Before purchasing or using, the Customer shall determine the suitability of Intertec's products and documents for his intended use and assumes all risk and liability whatsoever in connection therewith.

THE LIMITED WARRANTY TO REPLACE OR REPAIR PARTS OR COMPONENTS FOR NINETY (90) DAYS IS THE EXCLUSIVE REMEDY PROVIDED TO THE CUSTOMER AND THE LIABILITY OF INTERTEC WITH RESPECT TO ANY OTHER CONTRACT, SALE OR ANYTHING DONE IN CONNECTION THERewith, WHETHER IN CONTRACT, IN TORT, UNDER ANY WARRANTY, OR OTHERWISE, SHALL NOT EXCEED THE PRICE OF THE PART OR COMPONENT ON WHICH SUCH LIABILITY IS BASED.

Rights under this warranty are not assignable without the express prior consent, in writing, of Intertec Data Systems Corporation, and, regarding the terms of such consent in writing, the assignee shall have no greater rights than his assignor.

In the event the Customer has any problem or complaints arising out of any breach of our limited warranty, including a failure to make repairs in accordance with the warranty, or unsuccessful repair attempts by an authorized repair facility, the Customer is encouraged to inform Intertec, in writing, of his or her problem or complaint. Any such writing should be addressed to Intertec Data Systems Corporation, 2300 Broad River Road, Columbia, South Carolina 29210, and should be marked with the phrase "Warranty Claim."
