OrCAD's Schematic Design Tools operates within the OrCAD/ESP Design Environment. This environment provides many features that make it easier to access and use OrCAD's electronic design automation (EDA) tool sets.

This book is a reference guide to Schematic Design Tools, the tool set used to create schematic designs. For detailed information about the design environment, see the OrCAD/ESP Design Environment User's Guide.

Tools and tool sets

A tool set is a collection of tools designed to perform a set of electronic design automation tasks. There are currently four OrCAD tool sets. They are:

- Schematic Design Tools
- Programmable Logic Design Tools
- Digital Simulation Tools
- Printed Circuit (PC) Board Layout Tools

The tool sets allow you to access the same design in different ways.

Buttons for the OrCAD design tool sets appear on the main design environment screen, even if you have only one tool set installed on your system.

To select the Schematic Design Tools tool set from the main design environment screen, point to the Schematic Design Tools button and double-click. In a moment, you will see the screen for Schematic Design Tools as shown in the figure on the next page.
In tool sets, tools are grouped according to function. The six categories are:

- Editors
- Processors
- Librarians
- Reporters
- Transfers
- User buttons

These functions are described below.

**Editors** Editors modify or create some part of the design database. An example of an editor is the schematic editor, Draft. Another editor is Edit File, which uses a text editor to view reports and enter text.
Processors

Processors read, modify, then rewrite the design database. For example, Annotate Schematic is a processor. Processors generally do not create human-readable reports, but rather create or modify database information. Processors may create data that will be used by tools outside the ESP design environment.

Librarians

Librarians are tools for managing and creating library objects that can be used by all designs, not just the current design. Edit Library is an example of a librarian. It is used to create a new schematic symbol for a component. This component should be available in all future design work, so it is stored in the library database.

Reporters

Reporters create human-readable reports, but do not modify design data in any way. For example, a reporter creates the Bill of Materials report, a list of all the components used in the design. The tools for printing and plotting are also reporters. Reporters may create reports that will be used by tools outside the ESP design environment.

Transfers

Transfer tools manage the steps needed to move design information from one tool set to another. Transfers have two parts. The first updates the database used by the current tool set so that it is current and up-to-date in every respect. The second part changes to the new tool set used to view the design. The transfer tools take care of intermediate steps so that you don’t have to.

For example, the To Digital Simulation transfer tool performs these steps:

- Annotates the reference designators in the design
- Builds the connectivity database
- Builds the link between the schematic and the simulator, so that simulation directives inserted in the schematic can be accessed by the simulator
- Transfers control to Digital Simulation Tools
User buttons

A user button is the most basic way in which the ESP environment can be extended to fit your particular requirements and make your work easier and more convenient.

A user button can be set up to run any system command. You can set up a user button to run a spreadsheet program, which you can use to analyze design information. Or, you can program user buttons to run utility programs, communications programs, other graphical user interfaces and their programs—almost any program you like. You can also write batch files and program user buttons to run them.

ESP places four user buttons inside every tool set. Chapter 4 of the OrCAD/ESP Design Environment User’s Guide explains how to define a user button.

Mouse techniques

You can do all your work in Schematic Design Tools (except typing text and numbers) using the mouse.

You point to an object by moving the pointer until the tip of the arrow touches the object. Do this by moving the mouse.

You click by pointing to an object and then pressing and releasing the left mouse button once. When you click on a button, it becomes highlighted and a menu pops up in the upper left corner of the screen.

In this guide, the words “click,” “highlight,” and “select” all mean the same thing. In every case the action you take is the same: position the pointer, press the left mouse button, and quickly release it.

You double-click by first pointing to an object and then clicking the left mouse button twice. Don’t move the mouse while you double-click.

Left and right mouse buttons

- Clicking the left mouse button is the same as pressing the <Enter> key. In this guide, when you are instructed to “press <Enter>,” you can use either the keyboard or the mouse, whichever you prefer.

- Clicking the right mouse button is the same as pressing the <Esc> key. In this guide, when you are instructed to “press <Esc>,” you can use either the keyboard or the mouse, whichever you prefer.
Many of the explanations and instructions in this book use the mouse terminology explained on the previous page. If you prefer to use the keyboard, however, there are keyboard equivalents to nearly every mouse operation. Instead of moving the mouse to move the pointer from button to button, you can:

- Press <Tab> to move from one tool category to the next.
- Press <Space bar> to move from button to button within a category.
- Press <Shift><Tab> to move the pointer backwards to the next category.
- Press <Enter> to select the button the pointer rests on.

"Enter" and "Type" The instructions in this guide use the terms "enter" and "type" to mean two different things. When the instructions tell you to enter something, you press the appropriate keys and end by pressing <Enter>. When the instructions tell you to type something, you press the appropriate keys, but do not press <Enter>.

About this guide This guide is organized according to function. The basic parts of this guide are:

- Part I: Configuration
- Part II: Editors
- Part III: Processors
- Part IV: Librarians
- Part V: Reporters
- Part VI: Transfers

Each tool is described in a chapter in the appropriate part of this guide. For example, to find information about Draft, look in Part II: Editors.
Conventions

The notation conventions used in this guide are as follows:

**BOLD CAPS** Used for main menu commands.

**Bold** Used for other commands.

**Courier bold** Used for text you enter.

**Italics** Used for references to other sections, chapters, parts of this guide, or other guides.

<B> Brackets <> show a key (or keys) that you press. Here are some examples of how the brackets are used.

- **As shown** **Means**
  - <Esc> Press the escape key.
  - <Ctrl><S> Press the control key, and while still holding it down, press the “S” key.
  - <Esc> <G> Press the escape key and let it go. Then press the “G” key.

"Prompt” Quotation marks show program prompts.

**Boxes**

The shadow box shown below shows a program or system prompt. Any bold type following the prompt shows text that you enter. For example:

```
Abandon edits?
```

This kind of shadow box shows a program menu.

△ **NOTE:** Notes contain important reminders or hints.

△ **CAUTION:** Cautions contain information about preventing damage to equipment, software, or data.
When you install Schematic Design Tools on your system's hard disk, it is configured and ready to run.

Part I explains how to customize Schematic Design Tools configuration.

Chapter 1: Configure Schematic Tools describes how to modify:

- Driver Options
- Printer and Plotter Output Options
- Library Options
- Worksheet Options
- Macro options for both Draft and Edit Library
- Hierarchy Options
- Color and Pen Plotter Table
- Template Table
- Key Fields
- Matrix for Check Electrical Rules
Configure Schematic Tools

OrCAD's ESP environment has three types of configuration, all of which customize and save information used to run OrCAD tools and tool sets.

- **ESP configuration** defines driver options, the text editor, startup design, and monitor display colors. Although ESP is already configured when installed, you can change the configuration whenever you want to change ESP parameters.

  The OrCAD/ESP Design Environment User’s Guide provides detailed instructions for customizing the design environment.

- **Tool set configuration** defines driver, library, work area, and macro options, plus tool set-specific monitor display colors and display drivers. Tool set configuration applies to all tools in a tool set and can be accessed from every button in the tool set except Transfers and User buttons. It has a default configuration when installed but can also be configured anytime you want to change the tool set parameters.

  The remainder of this chapter provides detailed instructions for customizing the Schematic Design Tools configuration.
Local configuration determines input and output files plus special processing options for a particular tool. If a tool runs several processes, each process can be locally configured.

Local configuration is set up when the design is created, with input and output filenames defaulting to the design name in most cases. You usually configure a tool when you begin work on a design, or anytime you want to change the tool’s parameters.

The chapter that describes a tool also provides instructions for customizing its local configuration.
Chapter 1: Configure Schematic Tools

Display the Configure Schematic Design Tools screen

With the Schematic Design Tools screen displayed, select any of the Editors, Processors, Librarians, or Reporters buttons. For example, select Draft.

The menu shown at right displays at the top of the screen. Select Configure Schematic Tools.

The Configure Schematic Design Tools screen is too large to show in one illustration. Each area on the Configure Schematic Design Tools screen is shown in the sections that follow.

Move the pointer down until it touches the lower edge of the display, and the display pans down to show more options. When you get to the bottom, the display only pans up.

If you prefer to use keyboard commands, press <Page Down> to move the window down part of a screen at a time, and <Page Up> to go up again. Press <End> to go to the bottom of the configuration screen, and <Home> to return to the top again.

In various places within the configuration screen, there are boxes or windows in which lists (usually of files) display.

Using the arrow buttons to the right of each list box, these lists can be moved up and down in a manner similar to the scrolling process used for the configuration screen.

When you finish making changes, select OK to save your changes and return to the Schematic Design Tools screen.

If you do not want to save your changes, select Cancel to return to the Schematic Design Tools screen.
The **Driver Options** (figure 1-1) area defines the driver prefix, display driver, printer driver, and plotter driver. These are described on the following pages.

![Figure 1-1. Driver Options area of Configure Schematic Design Tools screen.](image)
Chapter 1: Configure Schematic Tools

Driver Prefix

The Driver Prefix is the directory path or disk drive where Schematic Design Tools finds and loads the display, printer, and plotter drivers.

The driver prefix is set during the installation process and does not need to change unless you move drivers to a different directory or create custom drivers in another directory.

To define the driver prefix, place the cursor in the Driver Prefix entry box and enter the pathname of the directory containing your device drivers.

△ NOTE: Only the drivers that are recognized by name appear in the list box. Custom drivers do not appear and need to be typed into the entry box.

Once you enter a driver prefix, all of the drivers in that directory display in the appropriate list box: Available Display Drivers, Available Printer Drivers, or Available Plotter Drivers. Each of these list boxes is described in the sections that follow.

Example

The Driver Prefix is created during the installation process. If you installed Schematic Design Tools on your C: drive, the prefix is:

Driver Prefix \ORCADESP\DRV\n
This tells Schematic Design Tools to look for the drivers in the ORCADESP\DRV directory on the C: drive.
The Available Display Drivers area of the screen is where you choose which graphics display driver to load. A list box (figure 1-2) lists the different display drivers that are available in the directory path specified in the Driver Prefix entry box.

Select the driver that is appropriate for your system by clicking on it. To see other drivers not displayed in the list box, use the scroll buttons at the right of the list box to scroll the list of drivers up and down.

Once you select the desired display driver, its filename displays in the Configured Display Driver entry box.

You do not have to select a display driver from the Available Display Drivers list box. Instead, simply click in the Configured Display Driver entry box and enter the driver name. However, be sure that the driver is in the directory displayed in the Driver Prefix entry box.

**NOTE:** Only the drivers that are recognized by list name appear in the list box. Custom drivers do not appear, and need to be typed into the entry box.

If you select the EGA Enhanced monitor from the drivers displayed in figure 1-2, the following displays:

\[
\text{Configured Display Driver} \quad \text{EGA16E.DRV}
\]

**NOTE:** If a driver is not configured here, Schematic Design Tools uses the one selected during installation.
Chapter 1: Configure Schematic Tools

Available Printer Drivers

The Available Printer Drivers area of the screen is where you choose which printer driver to load.

A list box (figure 1-3) lists the printer drivers available in the directory path specified in the Driver Prefix entry box.

![Available Printer Drivers list box.](image)

Select the driver for your printer by clicking on it. If you need to see other drivers not displayed in the window, use the scroll buttons at the right of the list box to scroll the list of drivers up and down.

Once you select the desired printer driver, its filename displays in the Configured Printer Driver entry box.

You do not have to select a printer driver from the Available Printer Drivers list box. Instead, simply click in the Configured Printer Driver entry box and enter the driver name. However, be sure that the driver is in the directory displayed in the Driver Prefix entry box.

△ **NOTE:** Only the drivers that are recognized by list name appear in the list box. Custom drivers do not appear, and need to be typed into the entry box.

Example

If you select the Epson printer from the drivers displayed in figure 1-3, the following displays:

Configured Printer Driver **EPSONMX.DRV**
The **Available Plotter Drivers** area of the screen is where you choose which plotter driver to load.

A list box (figure 1-4) lists the different plotter drivers that are available in the directory path specified in the **Driver Prefix** entry box.

![Available Plotter Drivers](image)

**Figure 1-4. Available Plotter Drivers list box.**

Select the driver for your plotter by clicking on it. If you need to see other drivers not displayed in the list box, use the scroll buttons at the right of the list box to scroll the list of drivers up and down.

Once you select the desired plotter driver, its filename displays in the **Configured Plotter Driver** entry box.

You do not have to select a plotter driver from the **Available Plotter Drivers** list box. Instead you can enter the name of a driver in the **Configured Plotter Driver** entry box by simply typing it and pressing <Enter>.

⚠️ **NOTE:** Only the drivers that are recognized by list name appear in the list box. Custom drivers do not appear and need to be typed into the entry box.

**Example**

If you select the first HP driver from the drivers displayed in figure 1-4, the following displays:

```
Configured Plotter Driver [HP.DRV]
```

For additional information about **Schematic Design Tool**'s plotting capabilities and how to plot a file, see *Chapter 25: Plot Schematic.*
Chapter 1: Configure Schematic Tools

Printer/Plotter Output Options

The Printer/Plotter Output Options area (figure 1-5) defines the ports to which your printer and plotter are connected. If you choose a serial port (COM1:, COM2:, COM3:, or COM4:), you define its baud rate, parity, number of stop bits, and number of data bits.

Select the desired output port for your printer or plotter or both.

If you select a parallel port (LPT1:, LPT2:, or LPT3:), the baud rate, parity, data bits, and stop bits options are dimmed. You do not need to define these communications parameters for parallel ports.

If you select a serial port (COM1:, COM2:, COM3:, or COM4:), the baud rate, parity, data bits, and stop bits options become available. Click on the desired settings for your printer or plotter or both. These settings are determined by the needs of your printer or plotter and the serial port to which it is connected. If necessary, see your printer or plotter documentation.

NOTE: The BIOS on some computers does not support COM3: and COM4:. If your computer's BIOS does not support COM3: and COM4:, you cannot use these ports.

Unavailable options

On monochrome screens and in OrCAD manuals, options that are not available are shown with a line through them. On color monitors, the options are dimmed.

Figure 1-5. Printer/Plotter Output Options area of Configure Schematic Design Tools screen.
The Library Options area (figure 1-6) defines the prefix Schematic Design Tools uses to find libraries, and the libraries that load when the tools run. It also specifies whether the name table resides in main memory, EMS memory, or on disk (see Name Table Location and Symbolic Data Location in this chapter); and whether the symbolic data resides in EMS memory or on disk. The active library size is also defined here.

Draft and other schematic design tools load the libraries listed in the Configured Libraries list box when they run. The number of libraries loaded affects the total amount of system memory available for worksheet design. It is possible to configure Schematic Design Tools to load more libraries than can be placed in 640K system RAM. Usually, four to eight libraries are sufficient and leave enough memory for designs.

Draft loads and maintains libraries in the order in which they are listed in the Configured Libraries list box. This is important when retrieving parts while creating schematics. When you ask Draft to get a certain part name, it searches the libraries in the order they are listed in the Configured Libraries window and gets the first part it finds with a matching name.
Duplicate part names can cause problems when you get parts in Draft. Note that OrCAD-supplied parts libraries do not have parts with duplicate names in the same library; however, some libraries, such as the PSPICE.LIB and SPICE.LIB libraries, do contain parts that have the same names as parts in the other library. In these cases, the order in which libraries load can be very important.

If you create your own version of an OrCAD-supplied part, save it in a custom library you create yourself. Then, configure Schematic Design Tools to load this library before any OrCAD libraries by placing it first in the Configured Libraries window. Using custom libraries also makes sure your custom parts are not overwritten if the original library is updated by OrCAD.

To create a custom library, use Edit Library's QUIT Write to File command (described in Chapter 2: Draft). For instructions on how to change the order of the configured libraries list, see Changing the library order in this chapter.

Library Prefix  The Library Prefix is the disk drive or directory path where Schematic Design Tools finds and loads libraries.

To define the library prefix, place the cursor in the Library Prefix entry box and enter the pathname of the directory containing your libraries. Once you enter a library prefix, all of the libraries in that directory display in the Available Libraries list box.

Example  The example below tells Schematic Design Tools to look for libraries in the ORCADESP\SDT\LIBRARY subdirectory on the C: hard disk.

```
Library Prefix  C:\ORCADESP\SDT\LIBRARY\n```

Chapter 1: Configure Schematic Tools
Inserting a library

Before inserting a library in the Configured Libraries window, be sure that the Insert a Library option is selected. When it is, the Available Libraries window displays all of the libraries available in the directory specified in the Library Prefix entry box. In addition, the Insert option becomes highlighted and available for use.

Select the library that you would like to add to the Configured Libraries list by clicking on it. If you need to see other libraries that aren’t displayed in the window, use the arrow keys at the right of the window to scroll the list of libraries up and down.

The Configured Libraries window contains a bar. On color monitors, this bar is green. It shows the position in which the next library will be inserted. To move this bar, point the cursor where you want it to appear and click the left mouse button.

Click the Insert button. The selected library is added to the Configured Libraries list, above the green line.

For information about the order of libraries, see Library Options. For information about changing the order of libraries, see Changing the library order.

Removing a library

Before removing a library from the Configured Libraries window, be sure that the Remove a Library option is selected. When it is, the Available Libraries window is dimmed. In addition, the Remove button becomes active and available for use.

Select the library that you would like to remove from the Configured Libraries list by clicking on its name. If you need to see other libraries that aren’t displayed in the window, use the arrow keys at the right of the window to scroll the list of libraries up and down.

Once you select a library, click the Remove button. ESP removed the selected library from the Configured Libraries list.
Changing the library order

Draft loads and maintains libraries in the order in which they are listed in the Configured Libraries window. This is important when retrieving parts while creating schematics. When you tell Draft to get a certain part name, it searches the libraries in the order they are listed in the Configured Libraries window and gets the first part it finds with a matching name. If you want to change the order in which your libraries are listed, follow these steps:

- Libraries must be reordered one at a time. Determine which library you want to move and remove it from the Configured Libraries window.
- Select the Insert a Library option. Move the green bar in the Configured Libraries list until it is positioned where you want to insert the library.
- Insert the library that you removed earlier. It appears in the Configured Libraries window just above the green line.

Types of libraries

Schematic Design Tools uses two types of libraries: the active library and the on-line library. Both of these libraries contain a name table and a symbolic data table.
Active library

The active library contains information about each part on the schematic. It always resides in main memory and can be configured to be 64–152K.

- The name table contains a list of the parts found on the schematic.
- The symbolic data table contains all of the symbol information for each part on the schematic.

This library is built by copying information from the other libraries as a schematic is loaded or when you get a new part using Draft's GET command, and is discarded when you exit Draft. Because all of the needed information is in one library, redraws and panning are very fast.

On-line library

The on-line library contains information about each configured library. These are the libraries listed in the Configured Libraries list box.

- The name table contains a list of all the parts in each configured library. It can be stored in main memory, EMS memory, or on disk. If you place the name table in EMS, the effective increase in capacity is limited only by how much EMS memory is in your computer. EMS allows for 32 MB of memory. This will handle the 20,000 parts included with Schematic Design Tools many times over.

- The symbolic data table contains all of the symbol information for each part in each configured library. It can be stored in EMS memory or on disk. If you place the symbolic data table in EMS, Draft's GET and LIBRARY Browse commands run more quickly.

If you don't have EMS memory, you can configure the software to keep the symbolic data table on disk. Depending on the speed of your disk, Draft's GET and LIBRARY Browse commands will slow down a little or a lot, but Draft will redraw the screen as fast as always, because the information it uses for redraws is in the active library.
Depending on the performance of your disk drive and your EMS implementation, you can expect the performance impacts shown in Table 1-1.

<table>
<thead>
<tr>
<th>Name Table Location</th>
<th>EMS Memory</th>
<th>Disk</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>Symbol Table Location</td>
<td>√</td>
<td></td>
<td>This is usually the most efficient configuration.</td>
</tr>
<tr>
<td></td>
<td>√</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Name Table Location</td>
<td>√</td>
<td></td>
<td>This is slightly slower than the configuration described above. You can add additional EMS memory to get more parts on line.</td>
</tr>
<tr>
<td>Symbol Table Location</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>√</td>
<td></td>
<td>This is slower yet, but is still tolerable.</td>
</tr>
<tr>

<td>√</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Name Table Location</td>
<td>√</td>
<td></td>
<td>This configuration is very slow, and should only be used for three special cases:</td>
</tr>
<tr>
<td>Symbol Table Location</td>
<td></td>
<td></td>
<td>• Very large worksheets. For example, E-size drawings with many parts.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• Systems with a small amount of EMS memory.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• Systems with a small apparent main memory. This can be caused by running multi-tasking software or a large network driver.</td>
</tr>
<tr>
<td></td>
<td>√</td>
<td></td>
<td>This is a severe compromise to Draft's speed. It should only be used with portable computers that come with 512K memory. If your hard disk drive is fast, this configuration may be more tolerable.</td>
</tr>
</tbody>
</table>

Table 1-1. EMS implementation performance impacts.
Active library size  Each time you load a worksheet, Draft creates a temporary active library file. When you exit Draft, it discards the temporary file.

The active library contains definitions of each part on the worksheet. EMS is reserved for libraries only. By using EMS for libraries, you can have much larger designs and take full advantage of OrCAD’s extensive libraries.

The size of the active library can be between 64-152K. If your worksheet contains few parts, set the active library size to 64K. For example, if your design is a memory board with many 41256 chips or a few types of glue logic chips, the active library can be quite small. If your worksheet contains many different parts, you will have to increase the size of the active library.

Use the CONDITIONS command in Draft to determine whether or not you need to increase or decrease the size of the active library.
Worksheet Options

The Worksheet Options area (figure 1-7) defines the worksheet prefix, the default worksheet file extension, and default title block information.

![Worksheet Options area of Configure Schematic Design Tools screen.](image)

Select any combination of the following options:

- **ANSI title block**
  

  The default title block is shown below.

![Sample OrCAD title block.](image)
The alternative, an ANSI Standard title block, is shown below:

SCALE  SHEET 1 OF 1

Figure 1-9. ANSI title block for sheet sizes A through C.

**Draft** has five worksheet sizes built in: A through E (American) or A4 through A0 (International Standards Organization). Using the **Template Table**, you can tailor the dimensions and many characteristics of each to match your requirements.

The ANSI title blocks for sheet sizes A, B, and C are different from ANSI title blocks for sheet sizes D and E. See the ANSI Y14.1-1980 specification for more information.

ANSI title blocks are larger than the default OrCAD title blocks. On an A-size drawing, they take up a large amount of the drawing area.

Tables 1-2 and 1-3 on the next page list the sizes of ANSI (A-E) and ISO (A4-A0) sheet sizes and drawing areas within the specified borders. Unfortunately, most, if not all, PC-compatible printers and plotters are unable to print as close to the edge of the page as specified in the ANSI and ISO standards.

Tables 1-4 and 1-5 list the reduced dimensions that will work with most printers and plotters. It is possible that your printer or plotter can print closer to the edge of the paper than allowed by these values. Hence, you may wish to adjust the sizes in the **Template Table** area of the **Configure Schematic Design Tools** screen (described later in this chapter).

</tbody>
</table>

*Table 1-6. X and Y grid references. N/A indicates that the value is not applicable because the sheet size does not have grid references per ANSI Y14.1-1980.*
Use alternate worksheet prefix

Do not select this option if you are using ESP. ESP manages all paths and prefixes for you. This option is provided for compatibility with older versions of OrCAD software. When you select this option, the Worksheet Prefix entry box becomes available:

Worksheet Prefix

The Worksheet Prefix is the disk drive and directory path where Draft finds worksheet files containing your schematic designs.

If you make an entry that falls into any of the categories listed below, Draft looks for the worksheet in the location specified in the Worksheet entry box:

- Drive name. For example, A:, B:, C:, or D:.
- Drive name followed by a backslash (\). For example, A:\, B:\, C:\, or D:.
- A backslash (\).
- A pathname that begins with any of the categories listed above.

If you add a directory path that doesn't begin like one of the examples outlined above, Draft treats the directory path as a sub-directory in the current design.

Examples

Use this prefix to find files on the A: floppy disk:

Worksheet Prefix A:

Use this prefix to find files in the \ORCAD\DESIGN5 subdirectory on the C: hard disk:

Worksheet Prefix C:\ORCAD\DESIGN5\

Use this prefix to find files in the subdirectory called SHEET in the current design directory:

Worksheet Prefix SHEET\
Schematic Design Tools Reference Guide

Default worksheet file extension

If you enter a filename that doesn’t end with a filename extension or a period in response to one of Draft’s prompts, Draft appends the extension specified here to the name. For example, if you enter “SHEET” while in Draft, Draft appends the extension specified here.

If you enter a filename that ends with an extension or ends with a period (.), this field is ignored. For example, if you enter “SHEET.” or “SHEET.EXT” while in Draft, Draft does not append the extension specified here.

⚠️ NOTE: The information entered in the remaining fields is used as the default information on a schematic worksheet. For this information to appear on a worksheet, it must be entered before the worksheet is created.

Once a worksheet is created, any changes made here are not reflected on an existing worksheet. To change sheet size, use Draft’s SET command. To change the worksheet’s title block information, use Draft’s EDIT command.

Sheet size

This field must be set to A, B, C, D, or E (American), or to A4, A3, A2, A1, or A0 (International Standards Organization). American dimensions are inches, and International Standards Organization dimensions are millimeters. You specify whether American or European dimensions are used on the Template Table.

Document number

The document number may contain up to 36 characters.

Revision

The revision code may contain up to three characters.

Title

The title may contain up to 44 characters.

Organization name

The organization name may contain up to 44 characters.

Organization address

Each organization address line may contain up to 44 characters.
Macro Options

A macro is a series of commands that executes automatically at the touch of a single key or key combination. Using Schematic Design Tools, you can construct macros and store them in a file for later use with Draft or Edit Library.

**Macro Options** (figure 1-10) defines the macro buffer size, the macro file (a file that can contain many macros), and the name of an initial macro (a macro within the macro file) that runs each time you start Draft or Edit Library.

![Figure 1-10. Macro Options area of Configure Schematic Design Tools screen.](image)

With macros you can dramatically reduce the number of keystrokes required to perform complex or repetitive actions. Macro files can contain many macros. Macro file size is limited by the size of the macro buffer (defined in the **Macro Buffer Size** entry field, described below).

To help you use macros right away, the Schematic Design Tools master disks contain two OrCAD-supplied macro files, MACRO1.MAC and MACRO2.MAC. These macro files are a useful starter set for Draft. Note that they are not designed for Edit Library. MACRO1.MAC and MACRO2.MAC reside in the TEMPLATE directory. They are copied to each new design you create.

**Macro Buffer Size**

The macro buffer is the storage location for macros read in from a file or created but not written to a file. The amount of memory allocated to the macro buffer is entered in the **Macro Buffer Size** entry box. The minimum memory size for the macro buffer is 8192 bytes; the maximum is 65,535 bytes.

**Example**

In the example below, the macro buffer is set at its minimum size.

```
Macro Buffer Size 8192
```
Draft Macro File and Edit Library Macro File

The macro file is the path and filename of the macro file to load automatically whenever you run Draft or Edit Library.

To define a macro file, enter the path and filename of the macro file in the Draft Macro File or Edit Library Macro File entry box. If the macro file is not in the design directory, you must specify a full pathname to the macro file. After you create and save your own macro files, its name can be entered here for automatic loading.

Example

The example below tells Draft to look for the macro file named MACRO1.MAC on the C: hard disk in the \ORCAD\TEMPLATE directory.

Draft Macro File \C:\ORCAD\TEMPLATE\MACRO1.MAC

Draft Initial Macro and Edit Library Initial Macro

The initial macro is a keystroke that Draft or Edit Library issues automatically whenever you run the respective program. This keystroke should be one defined to run a particular macro. For the initial macro to work, a filename (containing the desired macro definition) must be defined in the Macro File entry box.

If a filename is not entered in the Macro File entry box, the Initial Macro entry box is dim.

Examples

The example below tells Draft to execute the macro assigned to function key <F1> automatically whenever you run Draft. To enter <F1>, type <F> and then <1>.

Draft Initial Macro F1

If the macro you want for the initial macro runs when you press the keys <Ctrl> and <A> simultaneously, represent the <Ctrl> key with the caret character (^), which you type by pressing <Shift> <6>. Enter the characters <^> <A> in the Draft Initial Macro entry box:

Draft Initial Macro ^A

For more information, see the MACRO command description in Chapter 2: Draft.
Hierarchy Options

Hierarchy Options (figure 1-11) defines the size of the hierarchy buffer.

![Hierarchy Options](image)

Figure 1-11. Hierarchy Options area of the Configure Schematic Design Tools screen.

Hierarchy Buffer Size

All hierarchical sheet and pathnames are stored in the hierarchy buffer. The amount of memory allocated to the hierarchy buffer is entered in the Hierarchy Buffer Size entry box.

The minimum memory size is 1024 bytes, which allows you to create a hierarchical depth of about 75 to 100 worksheets (depending on sheet and pathname character lengths).

You can increase the size of the hierarchy buffer to 65,535 bytes, large enough for a hierarchical depth of over 200 worksheets.

Example

The hierarchy buffer is set at its minimum size.

![Hierarchy Buffer Size](image)
The Color and Pen Plotter Table (figure 1-12) selects the screen display and plotter pen colors for library parts, pin numbers and names, wires, buses, junctions, connectors, and other objects in the worksheet. The objects are listed in the left column of the table.

<table>

</tr>
<tr>
<td>0</td>
<td>Causes the plotter to pause so you can change pens</td>
</tr>
<tr>
<td>99</td>
<td>Causes the plotter to not plot the object</td>
</tr>
</tbody>
</table>
Examples

Here are some examples showing how to set configuration to suppress plotting the title block's lines, text, or both.

Suppressing title block lines

To suppress title block lines and leave title block text on the worksheet, enter 99 in the Pen entry box to the right of Title Block.

When you open a worksheet in Draft, the title block lines still display. However, they do not appear on the plot, as shown in the figure below.

![Figure 1-13. Plot of a title block with lines suppressed.]

\[\Box\]

NOTE: This also turns off the border around the drawing area during printing.

Suppressing title block text

To suppress title block text and leave title block lines on the worksheet, enter 99 in the Pen entry box to the right of Title Text.

When you open a worksheet in Draft, the title block text still displays. However, it does not appear on the plot, as shown in the figure below.

![Figure 1-14. Plot of a title block with text suppressed.]

Suppressing title block lines and text

There are two ways to suppress title block lines and text:

- Set both the title block and title text to a pen of 99. Using this method, the title block and its text display on the screen, but do not appear on a plot.
- Use Draft's SET Title Block No command. If you use this method, the title block and its text do not display on the screen or appear on a print or a plot.

Helpful hint...

If you are plotting on paper pre-printed with your title block, suppress the title block and its text as described above. Use Draft's PLACE command to place text in the correct position so that when you plot your schematic the text prints in the correct place in your pre-printed title block.

Width

Pen width is the actual width of the pen the plotter uses to draw an object. Plot Schematic uses this value to calculate the number of pen strokes needed to create an object. The value is expressed in inches (0.010 is \(\frac{1}{100}\) of an inch).

If buses or object fills have white spaces when plotting, reduce the pen width to correct the condition. In some cases, the correct setting for your plotter can be determined only by experimentation.

Speed

Enter the pen's velocity in the Speed entry box for the desired object. See your plotter manual to correctly set the speed. The value is expressed in units, a measurement determined arbitrarily by the plotter manufacturer.

Entering DEF in the Speed entry box tells Plot Schematic to use to your plotter's default speed. Plot Schematic makes no change to the pen speed.
Chapter 1: Configure Schematic Tools

1st Part Field through 8th Part Field

The names used to label the 1st Part Field through the 8th Part Field can be changed. Look at the Color and Pen Plotter Table, and notice that the names 1st Part Field through 8th Part Field each have a box around them. This is because you can change these names. To do this, simply click inside the box and edit the name. The new name appears in Draft when using the EDIT Part Name command.

Look at the Template Table on the Configure Schematic Design Tools screen and notice that it also contains the 1st Part Field through 8th Part Field entry fields. If you change these headings in the Color and Pen Plotter Table, they are also changed in the Template Table.
The Template Table (figure 1-15) contains the global settings for the size (in inches or millimeters) of various parameters in schematics. This includes worksheet dimensions, text size, border size, pin-to-pin spacing, and so on.

Draft has five sheet sizes built in: A through E (American) or A4 through A0 (International Standards Organization). Using the Template Table, you can tailor the dimensions and many characteristics of each to match your requirements.

The maximum worksheet dimensions are 65 inches by 65 inches, including the border. Object scaling is controlled by the Pin to Pin values.

To change one of the values, simply click inside the appropriate entry box and edit the value.

Figure 1-15. Template Table area of the Configure Schematic Design Tools screen.
### Units

Select either the **Inches** or **Millimeters** option to choose the unit of measure. If you select **Inches**, all measurements are shown in inches. Note also that the headings above each column are A, B, C, D, and E.

If you select **Millimeters**, all measurements are shown in millimeters. Note also that the headings above each column are A4, A3, A2, A1, and A0.

▲ **CAUTION:** If you change from inches to millimeters or vice versa, all custom settings you may have made are lost, and the default settings for each item are restored.

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Horizontal</strong></td>
<td>Width (horizontal dimension) of the schematic worksheet working area. The maximum width allowed for a schematic worksheet is 65 inches.</td>
</tr>
<tr>
<td><strong>Vertical</strong></td>
<td>Height (vertical dimension) of the schematic worksheet working area. The maximum height allowed for a schematic worksheet is 65 inches.</td>
</tr>
</tbody>
</table>

▲ **NOTE:** The following points refer to both the **Horizontal** and **Vertical** settings:

- The border, if there is to be one, is drawn inside the rectangle defined by the horizontal and vertical dimensions.
- The maximum worksheet dimensions are 65 inches by 65 inches, including the border. When you use **Plot Schematic** to print schematics it will only print schematics up to 32 inches by 32 inches in size. **Plot Schematic** scales anything larger to fit in these dimensions.

<td></td>
</tr>
</tbody>
</table>
| Plot X Offset         | Moves the origin horizontally. Plot Schematic uses the lower left corner of a sheet as its origin point when plotting. Some plotters (such as Hewlett-Packard C, D, and E size plotters) place the origin in the page's center, which results in the worksheet not plotting properly: the lower left corner of the worksheet is plotted in the center of the page. Use this entry box to compensate for this. The correct X offset can be calculated as shown below:  
  \[ Plot X Offset = -\frac{1}{2} \text{ page width} \]

\[ \triangle \text{ NOTE: This is a negative number.} \]

| Plot Y Offset         | Moves the origin vertically. Use it to compensate for plotters that do not use the lower left corner as the origin point. The correct Y offset can be calculated as shown below:  
  \[ Plot Y Offset = -\frac{1}{2} \text{ page height} \]

\[ \triangle \text{ NOTE: This is a negative number.} \]

| Roll Form Size        | Amount of paper to unroll from the spool when done plotting. |
Spacing Ratio

Determines the relationship between a character’s vertical height and horizontal distance between the start of one character and the start of the next character:

\[
\text{Spacing Ratio} = \frac{\text{Pin-to-pin spacing} \times 0.08}{\text{Height} \times 0.1}
\]

This is not the same as the character’s aspect ratio, which is the relationship between a character’s vertical height and its horizontal width.

\[
\text{Aspect Ratio} = \frac{\text{Height}}{\text{Width}}
\]

Changing the spacing ratio lets you fine-tune the appearance of plots when pin-to-pin spacing is changed. For example, if pin-to-pin spacing is set to 0.2 inch (a full-size template), and text height set to 0.156 inch, the spacing ratio is 1.026. This gives a character spacing of 1.026 inch.

\[
\text{Spacing Ratio} = \frac{0.2 \times 0.08}{0.156 \times 0.1} = 1.026
\]

Default settings

Draft’s default is a half-size template (with pin-to-pin spacing at 0.1 inch), all text sizes of 0.060 inch, and a spacing ratio of 1.333. This produces character spacing of 0.08 inch.

\[
\text{Spacing Ratio} = \frac{0.1 \times 0.08}{0.06 \times 0.1} = 1.333
\]
Key Fields

To understand key fields and how to use them, you need to understand part fields.

Associated with every library part are ten part fields. A part field is a slot for holding text or data associated with that part. These fields can be accessed and edited after a part is placed in a design.

Two part fields are reserved for particular types of data:

- The Reference field is reserved for holding reference designator values, such as "U1A" or "Q1."
- The Part Value field is reserved for holding part names, such as "74LS04" or values relevant for the part, such as Ohm (Ω) values for resistors.

To be processed correctly by Schematic Design Tools, every part (including parts not supplied by OrCAD) must have data in the Reference field and in the Part Value field. The only exceptions to this rule are objects whose only pin is of type POWER.

The other eight fields are named 1st Part Field through 8th Part Field.

\[\text{NOTE: You can change the names used to identify 1st Part Field through 8th Part Field. See the section in this chapter about the Color and Pen Plotter Table and the Template Table for instructions on how to do this.}\]

You can store any useful information in the eight part fields: tolerance, vendor name, part number, and so on. Each field can be up to 127 characters long. You can edit the contents of these fields and make them visible or invisible on the schematic using Draft's EDIT command. You can also use the Select Field View processor to make a part field visible or invisible for all parts in a design.
To perform special processing, Draft and several other Schematic Design Tools (that affect or use part field values) can combine and compare the information in these part fields. For example, the way Annotate Schematic designates parts for grouping in component packages can be changed. Or, Create Bill of Materials can list parts grouped by tolerance and value, rather than by value alone.

To tell Draft and the other tools which fields you want to combine and compare, key fields are used (figure 1-16). A key field lists the part fields to combine and compare. Key fields are specific to a particular tool. Schematic Design Tools has sixteen key fields: Annotate Schematic uses one key field; Create Netlist uses two; Create Bill of Materials uses two; Update Field Contents uses nine; and Extract PLDs uses two.

![Figure 1-16. Key Fields area of Configure Schematic Design Tools screen.](image-url)
Chapter 1: Configure Schematic Tools

Key fields can contain:

- The character R to represent the value found in the Reference field.
- The character V to represent the value found in the Part Value field.
- The numerals 1 through 8 for the values found in Part Fields 1 through 8.
- Any combination of text (including blank spaces, commas, and other punctuation). Note that you cannot include V and R in a text string, as those are the characters used to represent the values found in the Reference and Part Value fields. You can, however, use v and r in a text field.

The total length of a key field combination should not exceed 127 characters. For example, if your key field characters are V,1 the total length of the data stored in the Part Value field plus the data in the 1st Part Field, plus the comma cannot be longer than 127 characters.

Now you know how to specify values in the key fields. The next sections explain the different types of key fields, what they do, and how to use them.
Annotate Schematic
Part Value Combine

When you run Annotate Schematic on a schematic design, it puts a reference designator value in the Reference field of each part.

Some parts come in packages containing more than one part. For example, the 7439 package contains four two-input NAND buffers. When annotating schematics with parts that come in packages containing multiple parts, Annotate Schematic groups parts with the same value in their Part Value fields in the same package (until the package is full). Annotate Schematic creates reference designator values naming first the packages the parts come in and then the occurrence of the part within the package.

For example, suppose a design contains six parts with values of "74LS08" in their Part Value fields, and the part library specifies these parts are bundled four per package.

Figure 1-17. How Annotate Schematic normally assigns reference designators.

When you run Annotate Schematic on this design, it assigns reference designators (such as U1A, U1B, U1C, U1D, U2A and U2B) to these parts (figure 1-17). U1 names one package and U2 names a second; the letters A–D name the particular parts within each package. Reference designators are assigned to parts in the order in which you placed them on the worksheet. In this example, the first 74LS08 placed in the worksheet is numbered U1A and the last one placed U2B.
Suppose for physical layout reasons you want to partition the circuit to group these six parts differently. You want three of them in one package, and three in another. This is where Annotate Schematic's key field comes in handy.

First designate which portion of the circuit each part is to be grouped in. Assign the value "MOD_1" or "MOD_2" to the 1st Part Field of every part in the design using Draft's EDIT Part command (figure 1-18). If your worksheet is crowded, hide the information from view by making the field invisible. For more information, see Chapter 12: Select Field View.

Next, configure the key field for Annotate Schematic so that it carries out this scheme in the way it assigns reference designators. In the Key Field area of the Configure Schematic Design Tools screen, enter the characters V1 into the Annotate Part Value Combine edit field. For example:

Annotate Part Value Combine V1
From now on, when Annotate Schematic assigns reference designators to parts in a design, it will not group parts (that come several per package) in the same package unless they have the same Part Value and the same value in Part Field 1.

So, if on three of the 74LS08's, you place the value "MOD_1" in Part Field 1, and on the other three 74LS08's you placed the value "MOD_2" in Part Field 1, Annotate Schematic assigns each set of three its own package. The reference designators for one set would be something like U1A, U1B and U1C, and the reference designators for the other set would be something like U2A, U2B and U2C.

![Figure 1-19. Annotate Schematic assigned reference designators based on Part Value (74LS08) and 1st Part Field data.](image)
Update Field Contents

Combine for Value and Field 1 through Field 8

To understand how these key fields work, you must understand how Update Field Contents works.

Update Field Contents is a search and replace tool. It looks for data (called a match string) and when it finds a match, it replaces the data with new data.

Update Field Contents can update nine of the ten part fields. The Reference field is protected and cannot be updated with Update Field Contents. (You can change the Reference field using EDIT Reference in Draft.) You can use the Reference field as part of the match string, however. You use key fields to tell Update Field Contents where to look for data, and a text file (called an update file, usually with an extension of .UPD) to tell Update Field Contents what to do when it finds a match.

When you run Update Field Contents, you specify which field to update. Only one field can be updated at a time. Each update field can have its own separate search criteria, so there are nine sets of key fields for Update Field Contents listed on the Configure Schematic Design Tools screen. They all work the same way.

Looking up match values

Update Field Contents uses the entries you make in the Combine for Value/Field key fields to construct a text string called a match string.

For example, if you specify Part Field 2 as the destination, Update Field Contents looks at the entry in Combine for Field 2. Suppose the characters V 1 are entered there.

For each part in the design, Update Field Contents builds a text string from the value found in the part’s Part Value field, a blank space, and the value found in the part’s 1st Part Field.

For example, if a part has a value of "74LS04" in its Part Value field, and a value of "14DIP300" in its 1st Part Field, Update Field Contents builds the string:

74LS04 14DIP300

Then, Update Field Contents compares this match string to the first text string of each pair of text strings it finds in the specified update file.
An update file consists of lists of strings. Each string in the update file is enclosed by single quotation marks, like this:

'74LS04 14DIP300' '14 pin Inverter Package'
'74LS138 16DIP130' '16 pin Inverter Package'

**NOTE:** You can use either single quotes (') or double quotes ("") to indicate a text string. You can also use single and double quotes together on the same line to indicate an apostrophe. For example: ‘10H8’ "NATL’P10H8" You can include comments in an update file by enclosing the comments in curly braces ({ }).

Update Field Contents looks at the strings in the stuff file in pairs, and so for readability and clarity, each pair is usually placed on a separate line in the stuff file. The first string in each pair is the **lookup match string**. The second string is what Update Field Contents places into the update part field when it finds a match.

Using the example above, suppose there is a line in the specified update file that contains this pair of strings:

'74LS04 14DIP300' '14 pin Inverter Package'

**Update Field Contents** puts the text, "14 pin Inverter Package" into the **2nd Part Field** of a part whose **Part Value** field reads "74LS04" and whose **1st Part Field** reads "14DIP300".

For more information on **Update Field Contents**, see Chapter 13: *Update Field Contents*. 
Chapter 1: Configure Schematic Tools

Create Netlist Part Value Combine

Configuring this key field tells Create Netlist and Create Hierarchical Netlist to read the Part Value (or combination of values) in the Netlist Part Value field for each part in the design and use this as the Part Value for each part in the netlist. Generally, you should leave this field set to "V" for most netlist formats.

What value, if any, you should substitute for the Part Value depends on the netlist format you want to produce. Different applications require netlists with different types of values in the netlist's Part Value position.

Create Netlist Module Value Combine

This key field tells Create Netlist and Create Hierarchical Netlist to create a module value to show the name of the module to be used for layout. Most layout products refer to the pad shape separately from the part value.

For example, a 74LS00 comes in a 14 pin 0.300-inch center DIP package or in a surface mount package. Accordingly, the module value is used to indicate the package type so the layout can have the correct pad shape.

What value, if any, you create for the module value depends on the particular netlist format you want to produce. Different applications require netlists with different types of module values.

If you do not specify this key field, the module value will be the Part Value field.

△ NOTE: Schematic Design Tools includes an update file that does some of the assignments for PC Board Layout Tools.
Create Bill of Materials
Part Value Combine

To understand how this key field works, you must understand how Create Bill of Materials works.

Create Bill of Materials creates a list of the parts placed in a specified design. It uses the values found in the Part Value field of each part to determine whether parts are the same or different. Create Bill of Materials lists the parts it identifies as the same on the same line.

Configuring this key field instructs Create Bill of Materials to read the Part Value (or combination of values) in the Combine Field for each part in the design and use this as the Part Value for each part in the Bill of Materials. Generally, you should leave this field set to "V" (for Value) for most Bill of Materials formats. An example of how to use this key field follows.

Create Bill of Materials
Include File Combine

The Bill of Materials Include File Combine key field is used to determine how the match string in the include file is applied to the schematic.

For example, if you want the values in the include file to be matched to the contents of Part Field 6, you enter 6 in this key field.

Example

In a design, you placed several capacitors, all with the value of 50pF in their Part Value fields. Some of them are made of a plastic material and others of a ceramic. You want the part list to show this distinction.

To do this, edit Part Field 1 on the plastic capacitors to hold the value "Plastic," and edit Part Field 1 on the ceramic capacitors to hold the value "Ceramic." Then, in Key Fields area, enter the number 1 in the Bill of Materials Include File Combine entry box.

When Create Bill of Materials runs on the design, all capacitors with a Part Field 1 value of "Plastic" and a Part Value of "50pF" appear on one line of the part list, and all capacitors with a Part Field 1 value of "Ceramic" and a Part Value of "50pF" appear on a different line of the part list.
Chapter 1: Configure Schematic Tools

**Extract PLD**

**PLD Part Combine**

**and PLD Type Combine**

Use these key fields in conjunction with Extract PLD, one of the processes in the To PLD transfer to Programmable Logic Design Tools. Extract PLD extracts information from a schematic for use with OrCAD's programmable logic device compiler and places it in a .PLD file. The PLD Part Combine data is placed immediately after the word "Part:" following the pin information in the .PLD file. The PLD Type Combine data is placed immediately after the word "Type:" in the .PLD file.

**Example**

The next example shows how these key fields are used by Extract PLD. Figure 1-20 shows part of a design with a PLD.

**Figure 1-20. Programmable logic device.**

Assume the Extract PLD key fields are configured as shown below.

<table>
<thead>
<tr>

<td>PLD Part Combine</td>
<td>2</td>
</tr>
<tr>
<td>PLD Type Combine</td>
<td>1</td>
</tr>
</tbody>
</table>

47
When you run Extract PLD on the schematic containing the part, it creates a file called HRS.PLD. The contents of HRS.PLD are shown in figure 1-21. In the HRS.PLD output, the PLD Type Combine key field (1st Part Field) is shown in \textit{bold italics}, and the PLD Part Combine key field (2nd Part Field) is shown in \textit{bold}.

The Check Electrical Rules matrix summarizes the rules that Check Electrical Rules uses when testing connections between pins, module ports, and sheet nets. This matrix is shown in figure 1-22.

The pins, module ports, and sheet nets are listed in columns and rows in the table. A test is represented by the intersection of a row and column. The intersection of a row and column is either empty, or contains a “W” or an “E”. An empty intersection represents a valid connection, a W is a warning, and an E represents an error. You can toggle between these three settings by pointing to an intersection and clicking the mouse until the desired setting appears. To return all intersections to their default settings, select the Set to Defaults option.

Connections prefixed with an “m” are module ports. There are four types of module ports: input (mI), output (mO), bidirectional (mB), and unspecified (mU).

Connections prefixed with an “s” are sheet nets. As with module ports, there are four types of sheet nets: input (sI), output (sO), bidirectional, (sB), and unspecified (sU).

Figure 1-22. Check Electrical Rules Matrix area on the Configure Schematic Design Tools screen.

For definitions of pin types, see the PIN Type command description in Chapter 2: Draft.
Example To find the test result value when an output pin is connected to an input pin, use the OUT column (the third column in figure 1-20) and the IN row (the first row). This intersection is empty, which means this type of connection is acceptable. However, if you look at the intersection of the OUT column and the OUT row (the third row), you see an E, which indicates an output pin connected to an output pin is considered an error.
The heart of Schematic Design Tools is Draft, an Editor you use to create or modify schematics. You also use editors to edit or view text files and to access files containing reference information.

Part II describes Editor tools and provides instructions for their use.

Chapter 2: Draft explains how to configure and run Draft. An alphabetical command reference gives detailed descriptions of each of Draft's commands.

Chapter 3: Guidelines for creating netlist connections explains how to name signals, place labels, handle module ports, buses, and power objects correctly so that when a netlist is produced (using Create Netlist or Create Hierarchical Netlist) satisfactory results are achieved.

Chapter 4: Edit File explains how to use Edit File to run the text editor of your choice.

Chapter 5: View Reference describes how to use View Reference to read supplemental reference material provided by OrCAD.
This chapter contains information needed to run Draft, the schematic editor at the heart of Schematic Design Tools.

Within this chapter you will find execution and local configuration information, and a complete command reference. In the command reference section, commands are described in the order in which they appear in Draft's main menu.

Execution

With the Schematic Design Tools screen displayed, select Draft. Select Execute from the menu that displays.

- If you have not specified a source file on Draft's local configuration screen, Draft prompts:

```
load file?
```

Enter the name of the worksheet to create or edit.

- If you have specified a source file in Draft's local configuration, Draft loads the worksheet.

For instructions on how to specify a source file in Draft's local configuration, see the next section of this chapter.

△ NOTE: Schematic Design Tools sets the root schematic of a design to the source file specified on Draft's local configuration screen.

For information about Draft's commands, see the Command reference section in this chapter.
Local Configuration

With the Schematic Design Tools screen displayed, select Draft. A menu displays. Select Local Configuration.

Select Configure Draft. Draft's configuration screen displays (figure 2-1).

![Figure 2-1. Draft's local configuration screen.](image)

**File Options**

File Options specifies a worksheet for Draft to load.

**Prefix/Wildcard**

Enter a prefix and wildcard. These are described in the OrCAD/ESP Design Environment User's Guide. A list of files that match the selection criteria in this entry box displays in the Files list box.

**Files**

This box contains a list of the files matching the search filter entered in the Prefix/Wildcard entry box and those matching the filter in the current design directory. Files in the current directory have .\ before their names. Use the scroll buttons to scroll the list of files up and down.

When you see the file you would like to open, select it. Its filename displays in the Source entry box.
Chapter 2: Draft

Source

The Source is the filename of a worksheet to load. Either select a worksheet from the Files list box or enter the path and name of the worksheet. When running under ESP, the source file is the root of the design.

△ NOTE: If you do not enter a source name, Draft requests a filename when you run Draft.

Processing Options

You may select any combination of the following options:

- Quiet mode
  Turns quiet mode on.

- Disable mouse
  Disables the mouse. This option is normally used when debugging mouse problems while working with Orcad Technical Support. It may also be required when running on older PC-compatible computers.

- Disable <Print Screen> key function
  Disables Draft’s <Print Screen> key function. Use this option when you run other applications (usually RAM-resident) that use the <Print Screen> key. If this option is not selected, Draft uses the <Print Screen> key to capture hard copy output and blocks other uses.

- Decrease mouse sensitivity
  Slows the mouse down. Used for mouse devices that are too sensitive. For example, if you move your mouse a small distance and the pointer moves a large distance on the screen, select this option to make the pointer movement respond more closely to the mouse movement.

- Reverse "Y" axis operation of mouse
  Causes the mouse to respond differently. If this option is selected, the pointer moves up when you pull the mouse toward you, and moves down when you push the mouse away from you.
The remainder of this chapter is a command reference for Draft, the schematic editor. Commands are described in the order in which they appear in Draft’s main menu.

Commands are described in alphabetical order, the order in which they appear in Draft’s main menu. Main menu commands appear at the top of the first page describing the command. Many commands display other menus. Commands on these menus are described under the main menu command.

Some commands in the main menu appear in several other menus. These commands (such as FIND, JUMP, and ZOOM) are described at the main menu level only. When a command occurs in another menu, see the main menu description of the command for an explanation of its use.

Select Draft commands in one of two ways:

- Press the first letter of the command name. Occasionally a menu has more than one command beginning with the same letter. When this happens, use the method of selecting commands explained below.

- Move the highlight bar over the command name, and press <Enter> or click the left mouse button.

Press <Esc> to return to the previous menu.

If you are not sure of the name of a command, use table 2-1 to quickly look up the command alphabetically or use table 2-2 to identify the task you want to accomplish and then identify the command.

Once you know the name of the command, look it up in the command reference.

Table 2-2. Draft commands by function.
AGAIN repeats the last *main menu* command executed. For example, if the last command you selected is PLACE, you may repeat PLACE by selecting AGAIN.

AGAIN repeats commands only from the main menu. For example, if you execute a command in the PLACE menu and then select AGAIN, the PLACE menu displays, ready for you to select another PLACE command.
**BLOCK**

Use **BLOCK** and its commands to manipulate specific areas of your worksheet. Select **BLOCK** to move, rubberband (stretch), make orthogonal (perpendicular to each other), duplicate, import, or export a section of a worksheet.

When you select **BLOCK**, the menu shown at right displays. The commands on this menu are described on the following pages.
**BLOCK Move**

**BLOCK Move** moves selected objects to another location on the worksheet.

Select **BLOCK Move**. **Draft** displays:

```
Begin  Find  Jump  Zoom
```

To select the objects to move, draw a box around them. Place the pointer where you want the corner of the box to start and select **Begin**. The **Begin** command in the command line is replaced with **End**:

```
End  Find  Jump  Zoom
```

Move the pointer. As you do, **Draft** draws a box. When the box encloses or intersects all of the objects you wish to move, select **End**. **Draft** selects the objects and displays:

```
Place  Find  Jump  Zoom
```

You can now move objects within or intersected by the box. The objects are drawn as outlined symbol shapes so that **Draft** can move them quickly. If you selected an area that contains many objects, only the box enclosing the area appears to move. **Draft** keeps the details of the objects in the box and displays them again when you place them in the new location.

Move the box to the new location. The objects within the area being moved still show at their original location. Only the outlined symbols within the selected area move.

Select **Place** to place the moved objects at the new location. **Draft** redraws the screen, placing the objects in their new location. **Draft** returns to the main menu level.

⚠️ **NOTE:** You may move and place a single object by selecting **BLOCK Move**, positioning the pointer inside the object, and then selecting **Begin** and **End**. You do not have to enclose the object in a box. The box can also be drawn as a horizontal line, a vertical line, or a single point, as long as at least part of the box intersects the object you want to move.
**BLOCK Drag**

**BLOCK Drag** moves objects while maintaining connectivity. When you use this command, wires and buses appear to stretch as you move the block of objects on the worksheet. This effect is aptly called “rubberbanding.” When you finally place the block of objects, the wires and buses are extended to maintain their original connectivity.

**BLOCK Drag** works the same as **BLOCK Move**.

To drag a bus, first turn on the **SET Drag Buses** option (see the **SET** command later in this chapter) to maintain bus connectivity.

**BLOCK Fixup**

Use **BLOCK Fixup** to “fix up” wires and buses, making them orthogonal (perpendicular to each other) by adding new wire or bus segments.

Select **BLOCK Fixup**. **Draft** displays the command line:

```
Pick Find Jump Zoom
```

Use **Pick** to select the wire or bus to make orthogonal. Place the pointer so it touches either end of the wire or bus you want to make orthogonal and select **Pick** to select it. **Draft** displays the command line:

```
Drop End Find Jump Zoom
```

Move the pointer to the new endpoint. The end of the wire or bus moves with the pointer. In addition, **Draft** adds a new wire or bus segment that extends from the original wire or bus position to the new position.

Select **Drop** to “drop” a new wire or bus segment when you have it where you want it. You can continue dropping segments by selecting **Drop** as many times as desired.

Select **End** to drop the last segments when you have finished fixing up the wire or bus. **Draft** displays the **BLOCK Fixup** command line, so you can “fix up” another wire or bus. Press `<Esc>` to return to the main menu level.

**NOTE:** Use **BLOCK Fixup** only for adding segments when straightening non-orthogonal wires and buses. Use **BLOCK Drag** for cleanups that do not need additional segments.
Multiple wires or buses

If a node has more than one wire or bus connected, a menu displays that you use to select either Drag All or Pick One wire or bus.

Select Drag All to drag all the wires or buses attached to a common point.

Select Pick One to choose one wire or bus from those connected to the node. Draft displays the menu shown at right.

The wire or bus currently selected with Pick One is highlighted in another color. Select Next or Previous to select one of the other wires or buses. When the desired wire or bus is selected, select This to begin the "fix up."

BLOCK Get

BLOCK Get retrieves objects saved in a buffer (using BLOCK Save, described later) and places them on the worksheet.

Select BLOCK Get. Draft displays:

A box containing the previously saved objects displays. The pointer is attached to this box. Move the box to the desired location. Place the objects on the worksheet by selecting Place.

The box containing the objects remains on the screen. You can place as many copies of the objects as desired. Simply move the box and select Place.
BLOCK Save  

**BLOCK Save** stores a copy of a group of objects in a buffer so that they can be duplicated in another area of the worksheet.

Select **BLOCK Save**. Draft prompts:

```
Begin  Find  Jump  Zoom
```

To select the objects to be saved, draw a box around them. Place the pointer where you want the corner of the box to start and select **Begin**. The command line changes to:

```
End  Find  Jump  Zoom
```

Notice that the **Begin** command has changed to **End**.

Move the pointer. As you do this, **Draft** draws a box enclosing objects on the worksheet. When the box encloses all of the objects to save, select **End**. **Draft** saves a copy of the objects within the box in a buffer and returns to the main menu level.

Saved objects are placed on the worksheet using **BLOCK Get** (described previously).

⚠️ **NOTE:** The buffer used to save objects is also used by **BLOCK Move** and **BLOCK Drag**. Objects saved with **BLOCK Save** are lost after using either **BLOCK Move** or **BLOCK Drag**.

To save objects and still use **BLOCK Move** or **BLOCK Drag** in your editing session, use **BLOCK Export** rather than **BLOCK Save** to store worksheet objects.
**BLOCK Import**

**BLOCK Import** retrieves objects stored in other files (with **BLOCK Export**, described below) and places them in your current worksheet.

Select **BLOCK Import**. **Draft** displays:

![File to Import?](image)

Enter the path and filename of the file to import.

⚠️ **NOTE:** If a pathname is entered in the Worksheet Prefix entry box on the Configure Schematic Design Tools screen, **Draft** uses that pathname. If you do enter a pathname here, **Draft** ignores the pathname specified on the Configure Schematic Design Tools screen.

**Draft** displays:

![Place Find Jump Zoom](image)

Position the pointer on the worksheet where you want to place the contents of the file. Select **Place** to put the contents of the imported file on the worksheet. **Draft** places the imported objects on the worksheet. The pointer is in the same position as it was when the block of objects was exported with **BLOCK Export**. **Draft** returns to the main menu level.
BLOCK Export saves a copy of a group of objects in a file.

Select BLOCK Export. Draft displays:

```
Begin  Find  Jump  Zoom
```

To select the objects to be saved, draw a box around them. Place the pointer where you want the corner of the box to start and select Begin. The starting corner is also the starting corner of the block when it is imported with BLOCK Import.

Draft displays:

```
End  Find  Jump  Zoom
```

Notice that the Begin command has changed to End.

Move the pointer. As you do this, Draft draws a box. When the box encloses all of the objects you wish to save, select End. Draft displays:

```
Export filename?
```

Enter the path and filename to which to export the objects.

△ NOTE: If a pathname is entered in the Worksheet Prefix entry box on the Configure Schematic Design Tools screen, Draft uses that pathname unless you enter one here. When you enter a pathname here, Draft ignores the pathname specified on the Configure Schematic Design Tools screen.

Draft saves a copy of the objects enclosed and intersected by the box in this file and returns to the main menu level. The objects in this file can be placed back on the worksheet using BLOCK Import (described on the previous page).
BLOCK ASCII Import

BLOCK ASCII Import retrieves text stored in a text file and places it on your worksheet. You can create the text file with any editor that can read and write text.

Select BLOCK ASCII Import. Draft displays:

ASCII File to Import?

Enter the path and filename of the file to import. Draft displays the command line:

Place Find Jump Zoom

Position the pointer on the worksheet where you want to place the text. Select Place. The text file’s contents are placed on the worksheet just to the right of the pointer. Each new line is placed below the previous line.

Draft returns to the main menu level.

NOTE: If your text editor supports special formatting and layout of documents, you should make sure these special features are not used to create the text file.
BLOCK Text Export

BLOCK Text Export saves a copy of selected text in a text file. You can then edit this file with any editor that can read and write ASCII text. When you finish editing the text, you can place the contents of the text file back on the worksheet with the BLOCK ASCII Import command (described earlier).

Select BLOCK Text Export. Draft displays:

To define the text to export, draw a box around it. Place the pointer where you want the corner of the box to start and select Begin. Draft displays:

Notice that the Begin command has changed to End. Move the pointer. As you do this, Draft draws a box enclosing the text. When the box encloses all of the text you wish to export, select End. Draft displays:

Enter the path and filename in which to export the text. A copy of the text enclosed and intersected by the box is saved in this file.

Draft returns to the main menu level.

\[\begin{align*}
\text{NOTE: Only text objects can be exported. Labels or other characters associated with other objects cannot be exported.}
\end{align*}\]
CONDITIONS monitors your computer's memory, and the memory available for the worksheet, hierarchy buffer, and macro buffer. When you select CONDITIONS, a status window displays (figure 2-2). The CONDITIONS status window does not respond to mouse commands. Press any key to return to the main menu level.

You can print a copy of the CONDITIONS status window by pressing <Print Screen>. Make sure the Disable <Print Screen> key function option on Draft's local configuration screen is not selected.

Press Enter to continue

Figure 2-2. CONDITIONS status window.

For each of the items listed, Draft displays the location (main memory, EMS memory, or on disk), and the amount of memory—in bytes—allocated, used, and still available. The amount of memory allocated to any given item is specified on the Configure Schematic Design Tools screen. See Chapter 1: Configure Schematic Design Tools for information on how to configure these items.

**Worksheet Memory Size**

This shows how much memory your worksheet uses and how much memory is available in your system. Blank worksheets use memory for border and title block information.
<table>
<thead>
<tr>
<th>Buffer Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Hierarchy Buffer</strong></td>
<td>This shows the status of the hierarchy buffer. Draft uses the hierarchy buffer to keep track of sheet names when managing a hierarchical design. If the hierarchical design becomes too deep for the buffer, Draft is unable to keep track of all sheets in the hierarchy. You set the hierarchy buffer size when you configure Schematic Design Tools. For details, see Chapter 1: Configure Schematic Tools. For most applications, it is not necessary to change the size of the hierarchy buffer.</td>
</tr>
<tr>
<td><strong>Macro Buffer</strong></td>
<td>This shows the status of the macro buffer. Draft stores macros (whether created on line or loaded from a macro file) in the macro buffer. If your macros are too large, the macro buffer is unable to store them. You set the macro buffer size when you configure Schematic Design Tools. For details, see Chapter 1: Configure Schematic Tools.</td>
</tr>
<tr>
<td><strong>Active Library</strong></td>
<td>This shows the status of the active library. The active library is the temporary library Draft creates to hold both the name table and the symbol information for each part on the worksheet. Draft uses one active library. Draft builds this library by copying information from the other libraries as a schematic is loaded or when you get a new part using Draft's GET command, and discards it when you exit Draft.</td>

<tr>
<td><strong>Reference Library</strong></td>
<td>This shows the status of the on-line library. The on-line library is split into two parts: the Name Table and the Symbol Table. These parts contain information about each part in every library configured to load with Draft. The Name Table contains a list of the parts in each library. The Symbol Table contains all of the symbol information for each part in each library. The symbolic data for on-line libraries can be placed in EMS memory or kept on disk. One advantage of using EMS memory is that GET and LIBRARY Browse commands are faster in Draft. A disadvantage is that you must have or install EMS memory.</td>
</tr>
</tbody>
</table>
DELETE

DELETE and its commands erase objects or blocks of objects. Use the Undo command in case you accidentally delete an object and would like to restore it to its original position.

When you select DELETE, the menu shown above displays. Each of the commands on this menu are described on the following pages.

DELETE Object

DELETE Object erases an object from the worksheet.

Select DELETE Object. Draft displays:

Delete  Find  Jump  Zoom

To delete an object, place the pointer on the object you want to delete and select Delete.

\[\text{NOTE: You must place the pointer on or within the body of a part to delete it.}\]

If you want to delete one of two intersecting wires and you have placed the pointer at their intersection, the first wire drawn is the first deleted. To delete the last wire drawn, move the pointer away from the intersection along the wire to delete and select Delete.

If the pointer is pointing to more than one type of object, Draft displays:

Delete which Object?

Draft displays a menu listing objects to delete. Select the object from the menu to delete it.

After deleting an object from the worksheet, Draft returns to the DELETE Object command line, where you may continue to delete objects.

To return to the main menu level and redraw the worksheet, press <Esc>. 

73
DELETE Block

DELETE Block deletes a block of objects on a worksheet.

Select DELETE Block. Draft prompts:

```
Begin Find Jump Zoom
```

To select the objects to delete, draw a box around them. Place the pointer where you want the corner of the box to start and select Begin. The command line changes to:

```
End Find Jump Zoom
```

Notice that the Begin command has changed to End.

Move the pointer. As you do this, Draft draws a box enclosing objects on the worksheet. When the box encloses or intersects all of the objects you wish to delete, select End. Draft deletes objects within or intersected by the box. After deleting the block of objects, Draft returns to the main menu level.

DELETE Undo

DELETE Undo restores your last deletion by restoring an accidentally deleted object or block of objects.

Select DELETE Undo. The object(s) deleted with the last DELETE Object or DELETE Block command is restored.
EDIT

Use EDIT to:

- Edit labels, text, module ports, power objects, sheets, part reference designators, part values, part fields, and the title block.
- Change pin names and numbers on devices with multiple parts-per-package.
- Move part reference designators, part values, and part fields to new locations on the worksheet.
- Make part reference designators, part values, or part fields visible or invisible.
- Change the style of parts, power objects, module ports, labels, and text.
- Change the orientation of parts, text, and labels.
- Change the size of text and labels.
- Edit sheets, sheet names, sheet nets, sheet net types, and sheet filenames. You can use EDIT to add sheet nets or to delete sheet nets.

Select EDIT. Draft displays:

| Edit | Find | Jump | Zoom |

To edit an object, place the pointer on the object you want to edit and select Edit. The menu that displays depends on what you are editing. These menus are described on the following pages.

Editing techniques

When editing text fields, use these techniques:

- Position the cursor with the <-> and <--> keys, or the <Home> and <End> keys, or the mouse
- Erase characters with <Backspace> or <Delete>
- Add new characters with the alphanumeric keys
To edit a label, place the pointer immediately below and within the label, as shown in the figure at the left. Select **Edit. Draft** displays the menu shown at right.

**Name**
Select **Name** to edit the name of a label. After selecting **Name**, the prompt “Name?” displays followed by the current label name.

Edit the name using the editing techniques described at the beginning of the **EDIT** section. When you finish, press <Enter>. The edited name displays on the worksheet.

**Orientation**
Select **Orientation** to specify the label’s orientation. Select the desired orientation: **Horizontal** or **Vertical**.

**Larger**
Select **Larger** to make the label’s character size larger. You may select **Larger** more than once until the text is as large as you desire.

**Smaller**
Select **Smaller** to make the label’s character size smaller. As with **Larger**, you may select **Smaller** multiple times.
Editing module ports

To edit a module port, place the pointer within the module port symbol and select Edit. Draft displays the menu shown at right.

Edit Module Port

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Style</th>
</tr>
</thead>
</table>

**Name**

Select Name to edit a module port name. Draft displays the prompt “Module Port Name?” followed by the current module port name.

Edit the module port name using the editing techniques described at the beginning of the EDIT section. When you finish editing, press <Enter>. The module port name displays on the worksheet.

**Type**

Select Type to change the type of module port (figure 2-3). Select the type of module port: Input, Output, Bidirectional, or Unspecified.

**Style**

Select Style to change how the module port looks (figure 2-3). Choose from: Right pointing, Left pointing, Both pointing, or Neither pointing.

Figure 2-3 shows the different types of module ports and their default styles. A module port’s style is independent from its type. For example, a “both pointing” style does not mean that the module port is bidirectional.

<table>
<thead>
<tr>
<th>Input name</th>
<th>Input module port</th>
</tr>
</thead>
<tbody>
<tr>
<td>Output name</td>
<td>Output module port</td>
</tr>
<tr>
<td>Bidirectional</td>
<td>Bidirectional module port</td>
</tr>
<tr>
<td>Unspecified</td>
<td>Unspecified module port</td>
</tr>
</tbody>
</table>

Figure 2-3. Types of module ports and their default styles.
A power object is a schematic symbol that represents some type of power supply connected to the design.

To edit a power object, place the pointer on a power object and select Edit. Draft displays the menu shown above.

Name: Select Name to edit the name of the power object. Draft displays the prompt "Power Name?" followed by the object's current name.

Edit the name using the editing techniques described at the beginning of the EDIT section. When you finish, press <Enter>. The name displays on the worksheet.

Type: Select Type to change the type of power object. The different types (shown in the figure at the right) are Circle, Arrow, Bar, or Wave.

Orientation: Select Orientation to change the orientation to Top, Bottom, Left, or Right.
Sheet symbols are used in hierarchical designs to represent references to other schematic worksheets.

To edit sheet symbols, place the pointer within a sheet symbol boundary and select Edit. Draft displays:

```
Add-Net  Delete  Edit  Name  Filename  Size  Zoom
```

After you select Edit, pointer movement is restricted to the border of the sheet symbol. This helps you place the pointer at sheet net name locations.

Select Add-Net to add net connections between worksheets. To add a net connection to a sheet symbol, move the pointer to an appropriate position and select Add-Net. Draft displays the prompt “Net Name?” Enter the desired net name. A menu displays listing the types of net symbols: Input, Output, Bidirectional, and Unspecified. Figure 2-4 shows the types of net symbols. Select the appropriate type.

Notice the input net symbol points into the sheet symbol, and the output net symbol points out of the sheet symbol.

To delete a net name, place the pointer on the net name and select Delete.
To edit a net’s name or type, put the pointer on the net name and select Edit. The menu shown at right displays.

- Select Name to change the name of the net. The net name displays on the prompt line. Edit it using the editing techniques described at the beginning of the EDIT section. When you finish, press <Enter>.

- Select Type to change the type of the net. A menu displays listing the types of net symbols: Input, Output, Bidirectional, and Unspecified. Figure 2-4 shows each of these types of net symbols. Select the appropriate type.

Use Name to edit the name of a sheet symbol, located at the top of the sheet. Initially, the sheet name is a question mark. Typically, names identify the function of the worksheet represented by the sheet symbol (such as “Memory Array” or “Dynamic RAM Refresh Circuitry”).

To edit the sheet symbol’s name, select Name. Draft displays “Sheet name?” and shows the current name.

Edit the name using the editing techniques described at the beginning of the EDIT section. When you finish editing the name of the sheet symbol, press <Enter>.

Press <Esc> to cancel any changes to the sheet name.

Use Filename to edit the name of the worksheet represented by a sheet symbol.

Draft automatically creates a filename based on the date and time of day, ensuring no two filenames will be alike. This name displays at the bottom of the sheet symbol as soon as it is created.

To edit the filename, select Filename. Draft displays the prompt “Filename?” followed by the current filename.

Edit the filename using the editing techniques described at the beginning of the EDIT section. When you finish editing the filename, press <Enter>.
Size  Select Size to change the size of the sheet symbol displayed on the screen. Draft displays:

```
End   Jump   Zoom
```

Draft moves the pointer to the lower right corner of the sheet symbol. To change its size, move the pointer until the symbol’s size is satisfactory, then select End.
Editing parts

Use Edit Part to:

❖ Edit and move part reference designators, values, and fields
❖ Select other parts in library parts with multiple parts per package
❖ Change the orientation of the symbol.

Figure 2-5 illustrates a library part with its default reference designator and part value.

![Figure 2-5. CMOS 4013 library part.](image)

To edit a part, place the pointer within the part symbol boundary and select Edit. For a description of a symbol boundary, see *The outline symbol* under the GET command description in this chapter.

When you select Edit, Draft displays the menu shown at right.

Which Device only displays when you edit a device with multiple parts per package.

Reference

Select Reference to edit or move the reference designator values of library parts placed on the worksheet. Draft displays the menu shown at right.

Examples of reference designators are: U1, U2A, Q6, R1, R2, and C12.
See Chapter 6: Annotate Schematic for a method of automatically incrementing reference designators and changing the corresponding pin numbers of parts placed on the worksheet.

Name

Select Name to edit the name of a reference designator. The prompt "Reference?" displays. If the part already has a reference designator name assigned, it also displays on the prompt line.

Edit the name using the editing techniques described at the beginning of the EDIT section. When you finish editing the name, press <Enter>.

△ NOTE: Some library parts contain more than one part per package. For example, a 74LS04 hex inverter contains six parts. The reference designators for the six parts may be U?A, U?B, U?C, U?D, U?E, and U?F. The last letter in the reference designator tells which one of the parts in the package you are editing. You cannot edit this last letter with the EDIT Edit Name command. To edit a different part in a multiple-part package, use the EDIT Edit Which Device command.

Location

Select Location to change the reference designator’s location. Draft highlights the part’s reference designator, value, and part fields, and displays the menu shown at right.

You may move the reference designator anywhere in the worksheet using the arrow keys or the mouse. Select Place to place the reference designator at the new location.
Visible

Select Visible to choose whether the reference designator appears on the screen and on paper prints and plots. When you select Visible, a menu displays Yes and No. Yes makes the reference designator visible; No makes it invisible. The Visible command controls the visibility of reference designators at all zoom scales.

Part Value

Select Part Value to edit or move the part values of components on the worksheet. Examples of part values are: 100K, 1N4004, .01 uf, 2N2222, and 80386.

When you select Part Value, Draft displays the menu shown above.

Name

Select Name to edit a part value. The prompt “Value?” displays. If the part already has a value assigned, it also displays on the prompt line.

Edit the value using the editing techniques described at the beginning of the EDIT section. When you finish editing the part value, press <Enter>.

Location

Select Location to change the part value’s location. Draft highlights the part’s reference designator, value, and part fields and displays the menu shown at right.

You may move the part value anywhere in the worksheet using the arrow keys or mouse. Select Place to place the part value in the new worksheet location.
Visible

Use Visible to choose whether the part value appears on the screen and on paper prints and plots. When you select Visible, Draft a menu displays Yes and No. Yes makes the part value visible; No makes it invisible. Visible controls the visibility of part values at all zoom scales.

1st Part Field through 8th Part Field

Eight part fields may be placed on the schematic worksheet by selecting them from the menu. Use 1st Part Field through 8th Part Field to add information about the part (such as tolerance, part number, vendor information, and so on) to the schematic. When you select one of the eight part fields, Draft displays the menu shown above.

Name

Select Name to edit the information in a part field. The prompt "xx Part Field?" displays. If the part field already contains information, it also displays here.

Edit the information using the editing techniques described at the beginning of the EDIT section. When you finish editing the part field, press <Enter>.

NOTE: If you changed the part field names on the Configure Schematic Design Tools screen, Draft displays their new names in menus and prompts.

Location

Select Location to change the location of the part field on the worksheet. Draft highlights the part’s reference designator, value, and part fields and displays the menu shown at right. Use the arrow keys or the mouse to move the part field anywhere on the worksheet. Select Place to place the part field in the new location.
Visible

Select Visible to choose whether the part field appears on the screen and on paper prints and plots. When you select Visible, a menu displays Yes and No. Yes makes the part field visible; No makes it invisible. Visible controls the visibility of part fields at all zoom scales.

Orientation

Select Orientation to change the view of a part. Draft displays the following command line:

Rotate Convert Normal Up Over Down Mirror Zoom

Rotate

Rotate turns the part 90° counterclockwise from its current position.

Convert

Use Convert to change the form of the part.

Convert only displays when editing a part that contains its normal representation as well as a DeMorgan form. Parts with DeMorgan form actually have two versions of the part in the library. For example, the 74LS02 contains its standard form (a NOR) gate and a DeMorgan form (an inverted AND gate).

See Chapter 17: Edit Library for an explanation of how a part is given a DeMorgan form.

Normal

Normal returns a rotated part to its original orientation, as created in the part library. Normal also cancels the effect of the Convert and Mirror commands.

Up

Up rotates a part 90° counterclockwise from its normal position, equivalent to rotating it once from its normal position.
**Over**

*Over* rotates a part 180° counterclockwise, equivalent to rotating it twice from its normal position.

**Down**

*Down* rotates a part 270° counterclockwise, the equivalent of rotating it three times from its normal position.

**Mirror**

*Mirror* displays a mirror-image of a part. Mirroring is along the horizontal axis.

**Which Device**

*Which Device* only displays when you edit a part containing more than one part per package. An example would be a 74LS04 hex inverter, which contains six inverters. To select a different part in the package, select *Which Device* and then select the device letter of the part to edit.
Editing the title block

To edit title block information, place the pointer inside the title block and select Edit. The title block is in the lower right worksheet corner. Draft displays the menu shown at right.

If a field is empty, simply enter the appropriate information. If the field already contains information, edit the information using the editing techniques described at the beginning of the EDIT section.

Revision Code

Select Revision Code to add or edit the revision code (three characters maximum). Draft displays the prompt “Revision Code?”

Title of Sheet

Select Title of Sheet to add or edit a title (44 characters maximum). Draft displays the prompt “Title of Sheet?”

Document Number

Select Document Number to edit or add a document number (36 characters maximum). Draft displays the prompt “Document Number?”

Sheet Number

Select Sheet Number to add or edit a sheet number (any number up to 32767). Draft displays “Sheet Number?”
### Chapter 2: Draft

<table>
<thead>
<tr>
<th><strong>Number of Sheets</strong></th>
<th>Select <strong>Number of Sheets</strong> to add to the number of worksheets (any number up to 32767). <strong>Draft</strong> displays the prompt “Number of Sheets?”</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Organization Name</strong></td>
<td>Select <strong>Organization Name</strong> to add or edit an organization name (up to 44 characters). <strong>Draft</strong> displays the prompt “Organization Name?”</td>
</tr>
<tr>
<td><strong>Address Lines</strong></td>
<td>Select the address line to edit. Each line can be up to 44 characters long. <strong>Draft</strong> displays the prompt “xxx Address Line?”, where xxx is either 1st, 2nd, 3rd, or 4th, depending on the address line you are editing.</td>
</tr>
</tbody>
</table>
NOTE: See the PLACE command description in this chapter for a definition of the syntax format of the objects described on this page.

Editing stimulus objects

To edit a stimulus object, place the pointer at the location where the stimulus object connects to the wire or pin on which it was placed. Select Edit. The prompt “Stimulus?” displays followed by the current value.

Edit the value using the editing techniques described at the beginning of the EDIT section. When you finish editing, press <Enter>.

Editing trace objects

To edit a trace object, place the pointer at the location where the trace object connects to the wire or pin on which it was placed. Select Edit. The prompt “Trace Name?” displays followed by the current name.

Edit the name using the editing techniques described at the beginning of the EDIT section. When you finish editing, press <Enter>.

Editing vector objects

To edit a vector column, place the pointer at the location where the vector object connects to the wire or pin on which it was placed. Select Edit. The prompt “Vector Column?” displays followed by the current value.

Edit the vector column using the editing techniques described at the beginning of the EDIT section. When you finish editing, press <Enter>.

Editing layout objects

To edit a layout directive, place the pointer where the layout symbol connects to the wire or pin on which it was placed. Select Edit. The prompt “Layout Directive?” displays followed by the current layout directive.

Edit the layout directive using the editing techniques described at the beginning of the EDIT section. When you finish editing, press <Enter>. The edited name displays on the worksheet.
FIND

FIND locates a string of text characters any-where in a worksheet and places the pointer at the object containing the search string. A search string can be any number of characters identifying any of the following items:

- Module ports
- Labels
- Reference designators
- Part values
- Data stored in a part field
- Sheet symbol names
- Power objects
- Text

You must specify a complete character string. For example, if the part value "74LS00" exists in the worksheet and you specify "LS" as the search string, Draft returns the message "<<<Not Found>>> LS". However, if you specify the complete string "74LS00", Draft places the pointer at the object containing the string.

Select FIND. Draft displays "Find?" Enter the character string you want to find. The character string can be entered in upper or lower case; FIND is not case sensitive. Draft searches the worksheet for the desired character string and places the pointer near it.

The next time you select FIND, Draft shows the previous string on the prompt line. To search for a new string, edit the previous entry by positioning the cursor with the <→> and <←> keys and the <Home> and <End> keys, erasing characters with <Backspace> or <Delete>, and adding new characters with the alphanumeric keys. When you finish entering the new string, press <Enter>.

If you are searching for a string identical to the last string (for example, you want to find all 200 Ω resistors on the worksheet), press <Enter> with the current string name on the prompt line. Draft remembers the location of the previous string and searches for the next one.
If you select FIND after finding the last occurrence of the string, Draft "wraps" to the first occurrence of the string. If there is only one occurrence of the string, FIND returns repeatedly to the string when the command is selected.

△ NOTE: FIND works only in the worksheet you are editing.

△ NOTE: To erase the previous string, select FIND and press <Esc>. When FIND is selected again, the field is cleared.
GET retrieves parts from the library database and places them in the worksheet as normal, rotated, or converted symbols. There are two methods you can use with GET to retrieve parts.

<table>
<thead>
<tr>
<th>Method 1</th>
<th>Method 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select GET. Draft displays “Get?”</td>
<td>Select GET. Draft displays “Get?”</td>
</tr>
<tr>
<td>Enter the desired part name exactly as it appears in the library directory. Draft searches the libraries you specified when you configured Schematic Design Tools and finds the part you requested. Once it finds the part, Draft puts its outline on the screen. If there are two parts with the same name in the configured libraries, GET always retrieves the first one. If the name typed does not match any part name in the library directory, Draft shows an error message. To verify the spelling of a part name, use the LIBRARY Directory command.</td>
<td></td>
</tr>
<tr>
<td>Press &lt;Enter&gt;. Draft displays a list of libraries. These are the libraries you specified when you configured SDT. Select the library you want to get a part from. After you select a library, Draft displays a menu listing the library parts. Move the highlight to the part name you want, then press &lt;Enter&gt; to retrieve the part. Draft puts the part’s outline on the screen.</td>
<td></td>
</tr>
</tbody>
</table>

Once the part outline displays, you need to place it on the worksheet. For information on rotating and placing parts on the worksheet, see Rotating and placing parts in this section.
Getting a part by entering a part suffix

If you are using Method 1 (described on the previous page), you can select library part numbers created with a prefix and shorthand string (see *Prefix definition* in Chapter 14: *About libraries*) from the library by entering the suffix. For example, suppose you want to retrieve a 74LS27 from the library. After selecting GET, enter any of the following examples to retrieve the part:

- **Get? 74LS27**
  In this example, the entire part name is used to retrieve the part.

- **Get? LS27**
  In this example, the prefix "LS" (which is the shorthand string for "74LS") is combined with the suffix "27." *Draft* retrieves the part 74LS27.

- **Get? 27**
  In this example, only the suffix "27" is entered. *Draft* looks through all of the configured libraries and displays a menu of all available parts with "27" as a suffix. Select the desired part from the menu.

The outline symbol

After getting the part from the library, the screen shows an outline of the part symbol (figure 2-6). The outline symbol shows the size and shape of the part, but no detail. Its function is to let *Draft* move the part quickly around the worksheet.

![Outline and Detail Symbols](image)

*Figure 2-6. A part's outline symbol and its detailed symbol.*

If the outline symbol remains stationary for a short time, *Draft* shows the detailed part symbol enclosed by the outline symbol. Use this feature to view the position the part will have when it is placed in the worksheet.
Rotating and placing parts

With the part selected and the outline symbol displayed, Draft displays this command line:

```
Place Rotate Convert Normal Up Over Down Mirror
```

Move the symbol to where you want to place it. Use these commands to rotate or place the part in the worksheet.

---

**Place**

Select Place to place the part on the worksheet.

After you place a part on the worksheet, Draft keeps the same part selected, so that you can repetitively place duplicates of a part without repeating the selection process. When you have placed all the parts, press <Esc> to return to the main command level.

When an outline symbol is placed over a copy of the same object already placed on the worksheet, the object may disappear. Moving the outline symbol displays the placed part.

---

**Rotate**

Select Rotate to turn a part counterclockwise $90^\circ$ (figure 2-7). Each time you select Rotate, the part rotates an additional $90^\circ$.

---

**Convert**

Some library parts have a second form, usually (but not always) a DeMorgan equivalent, as well as the standard representation. If an object has a converted form, the Convert command displays on the command line when it is retrieved from the library.

Select Convert to convert the object from its normal form to its converted form. You may see the converted object by leaving the outline symbol stationary.

To return a converted object to its original form, select Normal.

---

**Normal**

Select Normal to rotate an object to its original position, as shown in the library (figure 2-7). This command also returns mirrored or converted parts to their original form.
Select **Up** to turn an object 90° counterclockwise (figure 2-7). This is equivalent to rotating it once from its normal position.

Select **Over** to turn an object 180° counterclockwise (figure 2-7). This is equivalent to rotating it twice from its normal position.

Select **Down** to turn an object 270° counterclockwise (figure 2-7). This is equivalent to rotating it three times from its normal position.

Select **Mirror** to get a mirror image of an object (figure 2-7).
HARDCOPY

HARDCOPY uses fast draft printing mode to send a worksheet to the printer or to a file. HARDCOPY does not produce scaled or compressed output.

HARDCOPY is not used to output to plotters. To plot a schematic, use the Plot Schematic reporter described in Chapter 25: Plot Schematic. To print a schematic in scaled mode, use the Use Scale Factor option, as described in the Local Configuration section of Chapter 19: Plot Schematic.

To make a fast draft print, HARDCOPY assumes a working resolution of 100 units per inch. Therefore, if you are using a printer with 100 dpi (dots per inch) resolution, your HARDCOPY print is at full scale.

For example, there are four Hewlett-Packard LaserJet printer resolutions available with Schematic Design Tools (75, 100, 150, and 300 dpi). If your printer’s resolution is 300 dpi, your print will be 100:300, or ⅓ the actual size. Similarly, if you are using a Toshiba printer with a resolution of 180 dpi, your print will be 100:180, or ⅔ the actual size.

To print a schematic, select HARDCOPY from the main menu.

Draft displays the menu shown at right.

△ NOTES: Some versions of DOS and BIOS do not support ports COM3: and COM4:. If your printer is connected to one of these serial ports and HARDCOPY does not print, try changing to a different serial port or to a parallel port.

For printing the entire design, use the Print Schematic reporter (described in Chapter 20: Print Schematic) or Plot Schematic reporter (described in Chapter 19: Plot Schematic).

For most display drivers, you can also use the Print Screen (<Shift><Print Screen>) key to send the area of the worksheet displayed on the screen to the printer.
You can send a worksheet either to a printer or to a file. This command selects the hardcopy destination.

Select Destination. Draft displays the menu shown above.

LPT: Select LPT: to send your worksheet to the printer port specified on the Configure Schematic Design Tools screen.

File Select File to send the worksheet to a file. Draft displays the prompt “Destination of Hardcopy?” followed by the default filename HARDCOPY.PRN.

Change the default filename using the editing techniques described at the beginning of the EDIT section. When you finish editing, press <Enter>.

You can specify a complete pathname including a drive specification. Because the output file is a graphics file, it requires more disk space than the source schematic file.

To return to the main menu level, press <Esc>.

Files created this way can later be sent to the printer using the DOS COPY command. For example, if you created a printer file called MY.PRN, you can print it with the following DOS command:

```
COPY MY.PRN prn: /B
```

The /B parameter is needed because MY.PRN is a binary file. /B prevents COPY from terminating prematurely when it encounters the first Ctrl-Z character in the file.

⚠️ **NOTE:** Because the hardcopy file is a binary file, the DOS PRINT command cannot be used. For more information on COPY, see your DOS Manual.
File Mode determines whether subsequent HARDCOPY commands append or replace the contents of any existing hardcopy file.

Select File Mode. Draft displays the menu shown above.

- **Appended**: Adds new data to the contents of the destination file. With this command, you can save a series of hardcopies to the same filename.

- **Replaced**: Replaces the contents of the destination file with new data. This command overwrites the current contents of the destination file with the new hardcopy.

Make Hardcopy prints a hardcopy of the worksheet displayed on the screen. It either sends it to your printer or to a file, depending on the setting of File Mode.

To send a copy of your worksheet to your printer, first make sure your printer has power and is on line. Then select Make Hardcopy. Draft displays:

```
:::Creating Hardcopy of Sheet:::
```

After a few seconds, the worksheet starts printing.

- **Width of Paper**: Use Width of Paper to choose between narrow and wide paper.

Select Width of Paper. Draft displays the menu shown at right.

- **Narrow**: Select Narrow if you have narrow paper (8 inches wide).

- **Wide**: Select Wide if you have wide paper (13 inches wide).
INQUIRE displays text associated with stimulus, trace, vector, layout, and error objects. Draft associates text strings, some potentially lengthy, with these objects. INQUIRE keeps the schematic neat and uncluttered by making it possible to see and edit text information belonging to an object when needed.

Move the pointer to an object and select INQUIRE. The text associated with the object displays on the top line of the screen. Press <Enter> or <Esc> to return to the main menu level.

If the text is too large to fit across the top of your screen, scroll the text left and right using the <-> or <-> keys or the mouse.

If you repeat INQUIRE on a position in the schematic and there is more than one object located there, Draft cycles through the texts associated with each object.
JUMP quickly moves the pointer to specific locations on the worksheet. The specific locations can be tags, grid references, or X,Y coordinates.

Select JUMP. Draft displays the menu shown at right.

JUMP A, B, C, D, E, F, G, H Tag

When you select one of the JUMP Tag commands, the pointer jumps to the specified tag on the worksheet (the tag must have been previously set with the Tag command). For information about the Tag command, see the Tag section in this chapter.

NOTE: The error message “Tag does not exist” displays if the tag you select has not been set.

JUMP Reference

The Reference command moves the pointer to a specified grid reference on the worksheet border. Grid references are invisible until you set them using the SET Grid Parameters command. For information on grid parameters, see the SET Grid Parameters section of this chapter.

To jump to a grid reference, follow these steps:

1. Select JUMP Reference.

2. Draft displays “Jump to Reference”. Select the desired Y-axis grid alphabetic reference from the menu. See table 2-1 for the range of letters that can be used as grid references.

3. Select the desired X-axis numeric grid reference from the menu. See table 2-1 for the range of numbers that can be used as grid references.

The pointer jumps to the grid reference location specified and Draft returns to the main menu level.
The X-Location command moves the pointer a specific distance along the X-axis. Each step represents \( \frac{1}{10} \) (0.1) inch on the worksheet if SET Grid Parameters Stay On Grid is turned on. Otherwise it is \( \frac{1}{100} \) (0.01) inch.

To jump to an X-location, follow these steps:

1. Select JUMP X-Location.

2. Draft displays “Jump X”. Enter the number of steps to jump. A number without a plus or minus sign moves the pointer to the actual grid coordinate. A number with a positive sign (+10, +25, +30, and so on) moves the pointer to the right, and a number with a negative sign (-10, -25, -30, and so on) to the left. If you enter +10, for example, the pointer jumps to the right 1 inch from its current position (if you have SET Grid Parameters Stay On Grid turned on). If you enter 10, without a plus or minus sign, the pointer moves to the actual X grid coordinate 10.0.

When you press <Enter>, the pointer jumps to the specified location and Draft returns to the main menu level.

Table 2-1. X and Y grid references. N/A indicates that the value is not applicable because the sheet size does not have grid references per ANSI Y14.1-1980.
JUMP Y-Location  The Y-Location command moves the pointer a specific distance along the Y-axis. Each step represents $\frac{1}{10}$ (0.1) inch on the worksheet if the SET Grid Parameters Stay On Grid command is turned on; otherwise it is $\frac{1}{100}$ (0.01) inch.

The jump to a Y-location, follow these steps:

1. Select Y-Location.

2. Draft displays “Jump Y”. Enter the number of steps to jump. A number without a plus or minus sign moves the pointer to the actual grid coordinate, a number with a positive sign (+10, +25, +30, and so on) moves the pointer up, and a number with a negative sign (−10, −25, −30, and so on) down. If you enter +10, for example, the pointer jumps up 1 inch from its current position (if you have SET Grid Parameters Stay On Grid turned on). If you enter 10, without a plus or minus sign, the pointer moves to the actual Y grid coordinate 10.0.

When you press <Enter>, the pointer jumps to the specified location and Draft returns to the main menu level.
LIBRARY displays part list directories of libraries and displays images of the parts in libraries configured to load with Draft.

Select LIBRARY. Draft displays the menu shown above.

LIBRARY Directory

Use the LIBRARY Directory command to select a library and list its contents. The list can be displayed, printed, or saved in a file.

Select LIBRARY Directory. Draft displays a menu similar to the one at right, listing the libraries currently configured in Draft. From this menu, select the library for which to view a directory.

Draft displays the menu shown at right.

Screen
Select Screen. Draft displays the library directory on the screen.

Printer
Select Printer. Draft prints the library directory on the printer connected to the printer port specified on the Configure Schematic Design Tools screen.

File
Select File. Draft displays "File?" on the prompt line. Enter the path and filename. Draft sends the library directory to the file.
LIBRARY Browse

Use the Browse command to view the contents of a library, or select a part and view it on the screen.

Select Browse. The menu shown above displays.

△ NOTE: Some devices may be too large to fit entirely on the screen. Use the GET command to view these devices.

All Parts

Select All Parts to view all the parts in a library. Draft displays a menu showing a list of the libraries currently configured to load with Draft. Select the library you want to view. Draft displays the menu shown below.

Select Forward or Backward to browse through the library. Select Quit to return to the main menu level.

Specific Parts

Select Specific Parts to view individual parts from the libraries. Draft displays “Part?”

Enter the name of the part you want to view. The part displays on the screen. If you do not know the name of the part, press <Enter> to display a list of parts. See Chapter 17: Edit Library for details.
Macros are recordings of commands that you create and play back to run commands quickly, reducing the number of keystrokes required to perform repetitive and complex tasks. Use the MACRO command to capture, delete, initialize (erase), list, write to, and read macros from a file.

Each macro consists of a name and a script and may contain commands, pauses, other macros, and text. Each macro file contains one or more macros. Macros are stored on your hard disk in a text file.

You can assign macros to function keys, selected keyboard keys, keys used with <Ctrl>, <Shift>, and <Alt>, or the middle mouse button on a three-button mouse.

Schematic Design Tools includes two macro files, MACRO1.MAC and MACRO2.MAC on the product disks. These files include macros for drawing, editing, file management, and setting Draft's environment.

You can create macros two different ways:

- Record entered keystrokes as you select commands in Draft.
- Write a macro script in a text editor.

To create or change macros, select the MACRO command from the main menu level menu. The MACRO menu at right appears.
MACRO Capture

To create a macro, select Capture. Draft displays "Capture macro?".

Press the key or keys to use to call the macro. The key(s) you press appears on the prompt line. See table 2-2 for a list of valid keys that can be assigned as macros.

Press <Enter>. Draft displays "<macro>," showing Draft is in macro capture mode.

In macro capture mode, Draft records any sequence of keystrokes, mouse button clicks, and mouse movements. Commands you normally perform in Draft can be recorded and executed later as macros.

When you finish recording the macro keystrokes, choose one of the following:

- Press <M> or select MACRO to stop the Capture command at the main menu.
- Press <Ctrl><End> to stop the Capture command anywhere in the application.

Valid macro keys

A macro can be called by pressing selected keyboard keys, keys used with <Ctrl>, <Shift>, and <Alt> or the middle mouse button on a three-button mouse. The macro name of the middle button is MMB.

Table 2-2 on the next page shows the keys to which macros can be assigned. The Alt+, Ctrl+, and Shift+ headings indicate the key you press in combination with a key listed in the left-hand column. The Key heading indicates that you press the key alone.
Grouping macros by type of task and assigning an extending key to each type helps organize your macros. For example, use the <Alt><Function> keys to set the environment and the <Ctrl><Alpha> keys to draw schematics.

Within each group of macros, you may assign logical initials for functions. For example, a macro that places a junction may be named <Alt><J>.

Table 2-2. Valid key combinations for macros.

Schematic Design Tools Reference Guide
Nesting macros

A macro can call another macro or call itself from within a macro. When you are capturing a macro, type the key name of a previously saved macro. For example: Suppose you want to nest the macro assigned to F2 within a new macro. Type F2 at the appropriate time while you are capturing the new macro.

You may create a macro that calls itself, however the macro is recursive, or looping, and does not end until you press <Ctrl><Break>. To nest a macro inside another macro, insert the macro name, enclosed by curly brackets, inside the text of another macro. For example:

\{(F3)=sry(F2)\}

Pause

If you want the macro to pause and wait for a command or text, press <Ctrl><Home> followed by <Enter> and continue entering the remaining commands. When a macro containing such a command is running, it pauses for your input and resumes when you press <Enter> or click the left mouse button.

Debugging macros

After capturing or writing a macro, test it for correctness. If you need to fix any problems, you may either capture it again or edit the macro using a text editor. Here are some hints for debugging:

- Print the file containing the macro and use it as a script for entering the commands manually.
- Use <Ctrl><Break> to stop a macro that doesn't stop on its own.
- If a macro does not run, another macro might still be running. When a macro is expecting <Enter> after <Macrobreak> and you use keyboard commands instead, the macro does not stop. If a macro runs the same commands endlessly, it is stuck in a loop. This sometimes happens when you nest macros and specify that a macro calls itself. It can also occur if you mix keyboard and mouse commands when you use macros assigned to the middle button.
**Initial macros**

Initial macros run automatically each time you run Draft. You may use an initial macro to set the environment to suit your preferences or project. You specify the initial macro and the macro file containing it on the Configure Schematic Design Tools screen. You may specify only one initial macro at a time. For information about configuring Draft for macros, see Macro Options in Chapter 1: Configure Schematic Tools.

**MACRO Delete**

To delete a macro, select Delete. Draft displays “Delete macro?” Type the key combination assigned to the macro you wish to delete, then press <Enter>.

**MACRO Initialize**

This command erases all macros in the macro buffer. To erase all of the macros, select the Initialize command. Draft displays the prompt “Erase All Macros?”

Select No to return to the main menu level, or Yes to erase all macros.

**MACRO List**

MACRO List lists all the key combinations assigned to macros. To display the macro list, select List.

**MACRO Read**

MACRO Read loads a macro file into an area of memory called the *macro buffer*, where they can be accessed by Draft. If the macro buffer already contains macros, the macros with unique key combination assignments are added to those in the buffer. Macros in the file with key combination assignments that are identical to key combinations assigned to macros in the buffer overwrite the macros in the buffer.

To load a macro file, select Read. Draft displays the prompt “Read all macros from?”

Enter the path and filename in which the macros are stored. Draft loads the macro file.
MACRO Write

When you capture macros Draft keeps them in memory, in the macro buffer. MACRO Write saves all macros currently in the macro buffer to a file. To save the macros to a file, select Write. Draft displays “Write all macros to?” Enter a filename. If the file you name already exists, it is overwritten.

Macro files can be loaded automatically when Draft runs by entering the macro filename and the name of the initial macro in the Macro Options area of the Configure Schematic Design Tools screen (see Chapter 1: Configure Schematic Tools).

Using macros

Before Draft can use macros in a macro file, it must read the file into the macro buffer. The macro—when called—runs from the buffer.

To use a macro, run Draft and read the macro file into the macro buffer with the MACRO Read command.

Calling a macro

To run a macro, press the key combination for that macro. All instructions in the macro script run.

Macro buffer

The macro buffer defaults to 8192 bytes of memory. If the buffer fills, Draft displays a warning message. To increase buffer memory you can either change the buffer size or delete unused macros. See Macro Options in Chapter 1: Configure Schematic Tools for more information about macro buffer memory.
Macro text files  A macro is a text file, and can be edited or created using a text editor or word processing program such as Edit File. The application you use must be able to save the macro file in text-only format.

Macro syntax  The syntax of a macro definition is shown below.

(Macro Name) = Macro Script { }

- Macro name is a valid key, key combination, or the acronym MMB enclosed in curly brackets.
- The equal sign (=) indicates that commands follow.
- Macro script is the list of commands the macro runs.
- The empty curly brackets ({} ) mark the macro’s end.

The table below lists translations for command keys and macro names.

</tbody>
</table>

Table 2-3. Key translations.

When you create macros using a text editor, you may organize the macros any way you choose, and include any character with these restrictions:

- Use only characters representing OrCAD commands, text, or filenames in macro scripts.
- Avoid line breaks or paragraph breaks in long macros. You may use groups of spaces to force the macro to wrap on the screen.
Use only MMB or valid key combinations from Table 2-2 for macro names.

Do not use curly braces ( or )) or equal signs (=) anywhere except where required by macro syntax.

When you finish writing the macro, name the file and save it in text-only format.

Example: macro for cutting wires

To cut a wire in Draft, use this macro instead of deleting and redrawing the entire wire. This macro places a junction on the wire, drags the junction to break the wire, and deletes the junction. To cut off the extra wire, put the cursor on the extra segment and select DELETE Object Delete.

{{B}=pjp{ESC}bde{U}{D}pdodj{ESC}{}}

Example: macro for placing parts on grid

After using the Cleanup Schematic processor to identify parts that are off grid, you can use this macro to find and move parts back onto the grid. At the Find? prompt, enter the name or part value of the part that is off grid. The macro copies, deletes, and gets the part. The part appears highlighted, ready for you to position it. To place the part, press <Enter>. If a part is already on grid, this macro does not move it off grid.

{{A}=f{macrobreak}bsbedod{esc}sgsybg{macrobreak} p {esc}{}}
Macro comments

Using a text editor, you may add comments to macros that remind you and others what each macro is for. Macros with remarks are also useful for quick reference. Follow these guidelines to add and preserve remarks in macro files.

- Place remarks before or after the macro, or in both positions. You may also insert paragraphs between macros. The remarks in these macros are shown in bold:

```
PLACE Junction {^P}=pjp()
{^P}=pjp() PLACE Junction
PLACE Junction {^P}=pjp() for SuperSquig project
```

- Do not use the left curly brace (\{) in remarks.

- Add remarks, macros, or edit existing remarks or macros with a text editor. Use the editor to alphabetize the list by remark or by macro name. Save the file in text-only format.

- Make a backup copy of the file and store it in a safe location such as another directory or on a diskette.

- Consider changing the extension of original macro files. For example:

```
COPY SAMPLE.MAC SAMPLE.MAS
```

- Avoid writing over original macro files with MACRO Write. When you select MACRO Read, Draft ignores all text outside macros. When you select MACRO Write, Draft erases all comments placed in the file.

- Print the macro file to create a quick reference card.

Once you have a collection of macros, keeping track of what each macro does may get complicated, particularly if you share macro files with other OrCAD users. You may want to organize your macro files by establishing conventions for naming the macros and by adding remarks to your macro files.
This section describes a method for controlling multiple Draft macros using the middle mouse button.

For each macro you assign to the middle button, you need two macros. The first macro contains the commands for doing a task such as placing a junction. You save this macro in its own file. For example, the macro for placing a junction looks like this:

\{mmb\}=pjp{esc} {} 

Save the macro to the following file:

\putjunct.mac

The second macro directs the application to read the macro file containing the first macro. You may either include the second macro in the macro file that you specified during configuration, or you may use the MACRO Read command to read the macro file.

For example, the macro for assigning the junction macro to the middle mouse button looks like this:

\{^j\}=mrputjunct.mac{enter} {} 

The file you save this macro to might be this:

\mymacros.mac

If you develop a number of macros for your three-button mouse, you may find it helpful to create a subdirectory to contain macro files. If you create such a subdirectory, named ORCADESP\SDT\MACRO for this example, the second macro changes to this:

\{^j\}=mrc:\ 
\ORCADESP\SDT\MACRO\putjunct.mac{enter}{} 

Once you set up the macro files, you assign macros to the middle button using keyboard commands. For example:

\{\b\}=mrmacro_b.mac{enter}{} 
\{\d\}=mrmacro_d.mac{enter}{} 
\{\g\}=mrmacro_g.mac{enter}{} 
\{\j\}=mrmacro_j.mac{enter}{} 
\{\k\}=mrmacro_k.mac{enter}{} 
\{\s\}=mrmacro_s.mac{enter}{} 
\{\w\}=mrmacro_w.mac{enter}{} 
\{\z\}=mrmacro_z.mac{enter}{}
**Individual macros**

Chapter 2: Draft
Creating efficient
macros

When you capture a macro, you may press keys or click
the mouse. When you write a macro, you may duplicate
keystrokes and mouse clicks. Macro size and execution
speed depend on the method you use to select commands.
Pressing keys results in fewer macro instructions. In
complex macros, using keystrokes:
.:. Speeds the macro up
.:.

Increases its readability

.:.

Minimizes its size and thereby maximizes the number
of macros that the macro buffer may hold

.:.

Frees more memory for the worksheet

The following examples of initial macros show the
difference between a macro captured with keystrokes and
the same macro captured with mouse clicks .
•:.

Macro captured with keystrokes, 32 bytes:
{Fl}={ENTER}sgvysdysxy{U}{D}{}

.:.

Macro captured with mouse clicks and keystrokes, 364
bytes:
{ F 2 } = {ENTER} { 0 } {D} {D } {D } {D } {D} {D } {D} { D} {D} { 0 } {D}
{D} {D} {ENTER} {D} {D} {D} {D} {D} {D} {D} {D} {D} {D} {R} {D}
{ENTER} {D} {D} {D} {ENTER} {ENTER} {ENTER} {D} {D} {D} {D}
{ D} {D} {D } {D} { D} {D} {D } {D } {D } {D} { ENTER} {U } {U} {R} {U}
{U}{U}{D}{D}{ENTER}{ENTER}{ENTER}{D}{D}{D}{D}{D}
{D} {D} {D} {D} {D} {R} {D} {D} {D} {R} {D} {ENTER} {D} {D} {D}
{D} {D} {D} {D} {D} {D} {D} {L} {D} {U} {U} {L} {D} {ENTER}
{ENTER} {D} {U} {}

You may also increase the speed at which macros run by
selecting SET Macro Prompts No either before running the
macro or as
part of the
macro. Figure

</table>

PLACE Wire

Select PLACE Wire to place wires in the worksheet. Draft displays:

To draw a wire, first place the pointer at the point on the worksheet where you want the wire to start.

Select Begin. Draft displays:

Draw the wire by moving the pointer. Use the following PLACE Wire commands to finish drawing the wire.

Begin

Use the Begin command to:

- Start drawing a wire segment.
- Finish drawing a wire segment and begin a new one (if the wire you are drawing makes a 90° turn).

You can use Begin over and over again to draw a complex wire. As you move the pointer, a dashed line representing the wire is drawn.
To continue drawing the wire from a 90° turn, select **Begin** where the turn starts (point A in figure 2-9). You may also move to the end of the wire (point B in figure 2-9) and select either **Begin**, **End**, or **New** to place a wire segment. When you finish placing a wire segment with **Begin**, **End**, or **New**, the dashed line becomes a solid line. A dashed line shows placement of a wire segment has not been completed with the **Begin**, **End**, or **New** commands.

![Figure 2-9. Drawing a wire.](image)

Continue drawing the wire. To end the wire, select either **End** or **New**.

△ **NOTE:** See the Schematic Design Tools User's Guide for examples of macros that simplify wire placement.

**End** Select **End** when you are done drawing a wire. **Draft** returns to the main menu level.

**New** Select **New** when you are done drawing a wire and would like to start drawing another wire. **Draft** remains in the wire placing mode, and returns to the “Begin Find Jump Zoom” command line.
PLACE Bus

Select **Bus** to place buses on the worksheet. **Draft** displays:

```
Begin  Find  Jump  Zoom
```

To draw a bus, place the pointer at the worksheet location where you want the bus to start. Select **Begin**. **Draft** displays:

```
Begin  End  New  Find  Jump  Zoom
```

Draw the bus by moving the pointer. Select one of the **PLACE Bus** commands to finish drawing the bus.

**Begin**

Use the **Begin** command to:

- Start drawing a bus segment.
- Finish drawing a bus segment and begin a new one (if the bus you are drawing needs to make a 90° turn).

You can use **Begin** repeatedly to draw a complex bus.

To continue drawing the bus from the 90° turn, select **Begin** where the turn starts. You may also move to the end of the bus and select either **Begin**, **End**, or **New** to fill it in.

Continue drawing the bus until you come to where you want it to end. To connect the bus to an end point, select either **End** or **New**.

⚠ **NOTE:** **Buses with module ports attached to them are automatically labeled with the same name as the module port, and therefore do not need an extra label.**

**End**

With the pointer at the end point, select **End**. **Draft** returns to the main menu level.

**New**

With the pointer at the end point, select **New**. **Draft** stays in bus-placing mode and returns to the "Begin Find Jump Zoom" command line. Drawing a bus is identical to drawing a wire (see the **PLACE Wire** command).
On a worksheet, many wires and buses connect or cross each other. Junctions are placed on the worksheet to distinguish a connection from a cross-over. If more than two wires or buses connect to a common node, place a junction there to tell the Check Electrical Rules reporter and Create Netlist processor that the node is a physical connection.

If you don’t place a junction at an intersection of wires or buses, Check Electrical Rules and Create Netlist interpret the intersection as a cross-over.

In many designs, you may want to connect a wire at 90° angles to a bus. If you do, you must place a junction at the connect point. Junctions are not required if you use a bus entry (see the PLACE Entry (Bus) command).

To place a junction in the worksheet, select PLACE Junction. Draft displays:

```
Place Find Jump Zoom
```

Position the pointer where you want the junction and select Place. Draft remains in "PLACE Junction" mode until you press the <Esc> key.
PLACE Entry (Bus)  Use the Entry (Bus) command to place bus entries on a worksheet. Use bus entries are for aesthetic purposes to connect wires or other buses to a bus. In the picture at the left, A shows a series of wire bus entries and B shows a bus entry used for a bus turn.

When you select PLACE Entry (Bus), Draft shows the last bus entry selected, with this command line:

```
Place / \ Wire Bus Find Jump Zoom
```

To place a bus entry, select Place. Select the / or \ commands to change the bus entry angle. Draft shows the last bus entry angle when you select PLACE Entry (Bus).

Select Wire to place wire entries. Use this command when a wire is to exit or enter a bus from another object.

Select Bus to place bus entries. Use this command when a bus makes a turn or is joined to another bus.

△ NOTE: Junctions are not required to connect a bus entry to a bus. (See PLACE Junction.)
PLACE Label

A label is an identifier placed on a worksheet that connects signals (wires and buses) together without actually drawing the wires connecting them. You can place labels horizontally or vertically on a worksheet.

Labels are not comments. Labels have meaning for other tools, such as Create Netlist. To place a comment on the worksheet, use the PLACE Text command.

To place a label, select Label. Draft displays the prompt: “Label?” Enter the name of the label. Draft displays:

| Place Orientation Value Larger Smaller Find |

**Place**

Select Place to place the label on the worksheet.

When the label is placed, the “Label?” prompt returns. You can place another label or press <Esc> to return to the main menu level.

**NOTE:** If you always stay on grid, the label is always correctly positioned to connect to a wire or bus. Just move the pointer on the wire or bus to place the label.

**Orientation**

Select Orientation to change the orientation of the label from Horizontal to Vertical or vice versa.

**Value**

Select Value to enter a value for the label. When you select Value, the prompt “Text?” displays followed by the current value. Edit the value by moving the cursor with the <→> and <←> keys, and the <Home> and <End> keys, erasing characters with <Backspace> and <Delete>, and adding new characters with the alphanumeric keys. When you finish editing the label’s value, press <Enter>.

**Larger**

Select Larger to make a label larger. Select Larger as many times as you like until the label is large enough.

**Smaller**

Select Smaller to make the label smaller. As with Larger, you may select Smaller over and over.
Placing labels correctly

In order for Check Electrical Rules and Create Netlist to associate internal and bus member labels with wires and buses, you must place labels in "contact" with the bus or wire. The bottom edge of the leftmost character is the "hotpoint" of a label. Some portion of it must be right next to the bus or wire to establish contact.

Figure 2-10 shows correct label positions for both vertical and horizontal wires. Notice the hotpoints for each label (bottom edge of the character "L") are next to the wire.

Figure 2-11 shows incorrect label positions. None of the label hotpoints are next to the wire.

Figure 2-10. Correct label positions. The right-pointing arrows indicate the labels' hotpoints.

Figure 2-11. Incorrect label positions.
A module port is used to connect signals on the current sheet to signals on other worksheets. Unspecified module ports may be used to transfer isolated power from one sheet to another. Module ports may be connected to either wires or buses.

Signals remaining internal to the worksheet should use labels, not module ports.

All module ports and labels with the same name are considered to be electrically connected, just as are all labels with the same name.

To place a module port, select Module Port command. The prompt “Module Port Name?” displays. Enter the module port name. Draft displays the menu shown at right.

Select Input if the module port is used as a signal input, Output if the module port is used as a signal output, Bidirectional if the module port is used as a bidirectional signal, or Unspecified if the module port is used to transfer power or “don’t care” signals. Figure 2-12 shows the four types of module ports and their default styles.

After selecting one of the commands shown at right, Draft draws a preliminary version of the module port with its name.

You may move it before placing it.

The following command line displays:

Select Place to place the module port on the worksheet. The prompt “Module Port Name?” displays, so that you may place another module port. Press <Esc> to return to the main menu level.
Before placing the module port, you can also change its Value, Type, or Style. A module port’s value is whatever you typed after “Module Port Name?” Its type is Input, Output, Bidirectional, or Unspecified. Its style is how it looks on the screen. If you select Style, you can choose from the options shown on the next page.

A module port’s style is independent from its type. For example, a Both pointing style does not necessarily mean the module port is Bidirectional.

<table>
<thead>
<tr>
<th>Module Port Style</th>
</tr>
</thead>
<tbody>
<tr>
<td>Right pointing</td>
</tr>
<tr>
<td>Left pointing</td>
</tr>
<tr>
<td>Both pointing</td>
</tr>
<tr>
<td>Neither pointing</td>
</tr>
</tbody>
</table>

NOTE: An unspecified module port must be specified when isolated power is transferred between worksheets. For more information, see Chapter 10: Create Netlist.

The figure below shows the four types of module ports with their default styles.

**Figure 2-12. Types of module ports.**

NOTE: Module ports are not intended to be used as physical connectors, such as DB-9, and so on. Physical connectors are objects that should be created as library parts. For information on working with connectors, see Chapter 10: Create Netlist.
Use **PLACE Power** to place power supply objects on the worksheet.

To place a power object on a worksheet, select **Power**. **Draft** displays:

```
Place Orientation Value Type Find
```

The power object appears on the screen, ready to be positioned and placed on the worksheet. Before placing the power object on the worksheet, you can change its Orientation, Value, or Type.

If you select Orientation, you can choose Top, Bottom, Left, or Right.

△ **NOTE:** The power pin default is a circle with a value of VCC. When you execute **PLACE Power**, the orientation returns to **Top**. However, type and value will be whatever was set previously.

A power object's value is the text (for example, VCC) associated with it. If you select Value, **Draft** displays the prompt “Power Value? xxx” where xxx represents the current value. You can backspace over the current value or append to it. Enter the new value (for example, +5, GND, +5 VDC, -12 VDC, VSS, VEE, or any other text string). **Draft** returns to the main menu level.

A power object’s Type is its appearance on the screen. If you select Type, you can choose **Circle, Arrow, Bar, or Wave**.

Select **Place** to place the power object where you want it on the worksheet. Then, press <Esc> to return to the main menu level.

If you use the **Create Netlist** processor, see Chapter 10: **Create Netlist** for information on handling isolated power such as in battery backup and other applications.
Figure 2-13 shows the four kinds of power objects and their orientations.

<table>
<thead>

</tr>
</tbody>
</table>

Figure 2-13. Circle, Arrow, Bar, and Wave power objects and their orientations.
In Draft you can create hierarchical designs using sheet symbols. A sheet symbol, which represents a worksheet in a hierarchy, contains net names. The net names connect signals on the active worksheet to the sheet the symbol represents.

A sheet net is the way a connection is made between the signal attached to the sheet net on the current sheet and the module ports on the worksheet represented by the sheet symbol.

To place a sheet symbol, select Sheet. Draft displays:

```
Begin Find Jump Zoom
```

Select Begin, outline the area, then select End to finish it. Draft then displays:

```
Add-Net Delete Edit Name Filename Size
```

Pointer movement is now restricted to the left and right sides of the box of the hierarchical sheet, the proper locations for sheet names and nets.

Use Add-Net to add sheet nets so that connections can be made between worksheets. To add a net sheet, place the pointer at the location where you want the name and select Add-Net. Draft displays the prompt “Net Name?” Enter the net name. Draft displays the menu shown below. Select the appropriate type for your sheet net.

For more information, see Editing sheets earlier in this chapter, and the discussion of hierarchies in the Schematic Design Tools User’s Guide.

To delete sheet nets, place the pointer at the net’s location and select Delete.
To edit a sheet net, place the pointer at the net's location and select Edit. Draft then displays a menu allowing you to choose between Name and Type.

To edit the net name, select Name. Edit the net name by positioning the cursor with the ←→ and ←→ keys or the <Home> and <End> keys, erasing characters with <Backspace> and <Delete>, and adding new characters with the alphanumeric keys. When you finish editing the net name, press <Enter>.

To edit the net type, select Type. You can then choose Input, Output, Bidirectional, or Unspecified.

Use the Name command to edit the sheet name. The initial sheet name is a question mark (?) located at the top of the sheet. Typical sheet names are "Memory Array" or "Dynamic RAM Refresh circuitry."

To specify a sheet name, select Name. Draft displays "Sheet Name?" followed by the current sheet name. Edit the sheet name using the editing techniques discussed above. When you finish editing the sheet name, press <Enter> to place it at the top of the sheet.

Use Filename to change the filename of the file representing the hierarchical worksheet. Draft automatically produces a filename based on the date and time of day the sheet symbol was placed in the schematic. This ensures no two filenames will be the same.

Edit this filename using the editing techniques discussed above. When you finish, press <Enter>.

Size increases or decreases the sheet size. When you select Size, Draft displays:

<table>
<thead>
<tr>
<th>End</th>
<th>Jump</th>
<th>Zoom</th>
</tr>
</thead>
</table>

Draft automatically positions the pointer on the lower right corner of the sheet. To change sheet size, move the pointer until you reach the desired size. Then select End.
Chapter 2: Draft

PLACE Text

This is text

Comments are useful for including revision history, tolerance, and other information in the worksheet.

When you select Text, Draft displays the prompt "Text?" Enter the text you want as a comment. When you finish, press <Enter>. Draft displays the command line:

Place

Select Place to place the text on the worksheet.

Orientation

Select Orientation to change the orientation of the text from Horizontal to Vertical or vice versa.

Value

Select Value to enter a value for the text. When you select Value, the prompt "Text?" displays followed by the current value. Edit the value by positioning the cursor with the <-> and <--> keys, and the <Home> and <End> keys, erasing characters with <Backspace> and <Delete>, and adding new characters with the alphanumeric keys. When you finish editing the value, press <Enter>.

Larger

Select Larger to make the text larger. You may select Larger more than once until the text is as large as you like.

Smaller

Select Smaller to make the text smaller. As with Larger, you may select Smaller over and over.
PLACE Dashed Line  Dashed Line places a dashed line on the worksheet. This is useful for setting off sections of your design. You can then label sections with comments constructed with PLACE Text.

Placing a dashed line is similar to placing a wire. When you select Dashed Line, Draft displays:

| Begin | Find  | Jump | Zoom |

To draw a dashed line, select Begin. Then move the pointer to draw the line. End the line using End and change direction using Begin. Use New to end the current line, and begin a new line at a different location with Begin.
PLACE Trace Name

A trace is a special marker placed on a worksheet that identifies a node to be traced in the digital simulation of the design. To keep the design from being cluttered, the trace name is not visible on the schematic. To view the contents of a trace, use the INQUIRE command.

To place a trace, select Trace Name. Draft displays the prompt: “Trace Name?” Enter the name you wish this signal to be displayed as in the simulator. Draft displays:

```
Place Value Find Jump Zoom
```

Place

Select Place to place the trace on the worksheet. After placing the trace, the “Trace Name?” prompt returns. You can place another trace or press <Esc> to return to the main menu level.

△ NOTE: If you always stay on grid, the trace is always correctly positioned to connect to a wire or bus. Just move the pointer on the wire to place the trace.

Value

Select Value to edit value for the trace before you place the trace. When you select Value, the prompt “Trace Name?” displays followed by the current value. Edit the value using the editing techniques describe previously. When you finish editing the trace name, press <Enter>.

Trace name format

A trace may be placed on either a net or a bus. The trace name may consist of any printable characters including spaces, except a period. If the display name contains a left or right square bracket, then the name is considered to be a bus name and the trace must be placed on a bus. For buses, the format of the bus may be specified after the right square bracket in the name. The format is a single character from the following list:

- B  Binary format
- H  Hexadecimal format
- D  Decimal format
- O  Octal format

Examples

```
ADD 5
DATA[0..15]D
```
PLACE Vector

A vector is a special marker placed on the worksheet that identifies a node to be stimulated by a test vector. The test vectors are referred to by column number, therefore, the vector placed on the worksheet has a vector column value. To keep the design from being cluttered, the vector column is not visible on the schematic. To view the vector column number of a particular vector, use the INQUIRE command.

To place a vector, select Vector. Draft displays the prompt: “Vector Column?” Enter the column number of the vector. Draft displays:

Place Value Find Jump Zoom

Place  Select Place to place the vector on the worksheet.

When the vector is placed, the “Vector Column?” prompt returns. You can place another vector or press <Esc> to return to the main menu level.

△ NOTE: If you always stay on grid, the vector is always correctly positioned to connect to a wire or bus. Just move the pointer on the wire to place the vector.

Value  Select Value to edit the vector column. When you select Value, the prompt “Vector Column?” displays followed by the current value. Edit the value by positioning the cursor with the <→> and <←> keys, and the <Home> and <End> keys, erasing characters with <Backspace> and <Delete>, and adding new characters with the alphanumeric keys. When you finish editing the vector column, press <Enter>.

Vector column format  The vector column indicates which column of the test vector file to use when the simulation is run. The column number is a decimal whole number such as 5.
A stimulus is a special marker placed on a worksheet that identifies a node to be stimulated by in the digital simulation of the design. The stimulus is an expression describing the pattern of logic states. To keep the design from being cluttered, the stimulus pattern is not visible on the schematic. To view the contents of the stimulus, use the INQUIRE command.

To place a stimulus, select Stimulus. Draft displays the prompt: “Stimulus?” Enter the value of the stimulus. Draft displays:

```
Place Value Find Jump Zoom
```

**Place**
Select Place to place the stimulus on the worksheet.

When the stimulus is placed, the “stimulus?” prompt returns. You can place another stimulus or press <Esc> to return to the main menu level.

⚠️ NOTE: If you always stay on grid, the stimulus is always correctly positioned to connect to a wire or bus. Just move the pointer on the wire to place the stimulus.

**Value**
Select Value to edit the value of the stimulus. When you select Value, the prompt “Stimulus?” displays followed by the current value. Edit the value by positioning the cursor with the ← and → keys, and the <Home> and <End> keys, erasing characters with <Backspace> and <Delete>, and adding new characters with the alphanumeric keys. When you finish editing the value, press <Enter>.

**Stimulus value format**
The stimulus describes the pattern of logic states to be applied to a net in the simulation. The pattern is described using a series of functions. A value must have a minimum of one function. The maximum is limited to the number of functions that can be placed in the text associated with the stimulus object.

There are two types of functions: set and branch. At least one space is required between each function.
Set function

A set function consists of two variables: the time and the value. These two variables are separated by a colon. The time is an unsigned whole number. The value is a single letter from the following list:

- 0  Set to 0
- 1  Set to 1
- U  Set to undefined
- Z  Set to high impedance
- T  Toggle

For example, the function to set the signal to a 1 at time 50 is 50:1.

\[ \text{NOTE: Separate multiple functions with spaces.} \]

Branch function

The branch function consists of two variables: the time the branch is to occur and the time to branch to. The two variables are separated by :G:. Both of the time values are unsigned whole numbers.

For example, the function to branch from time 450 back to time 400 is 450:G:400.

\[ \text{NOTE: Only one branch function is allowed per stimulus value.} \]

Examples

The following examples show proper stimulus expressions:

- 0:0 100:T 200:G:100
- 0:U 37:1 59:Z 83:G:37
- 0:U 50:0 100:Z 150:1 200:Z 250:U 255:0
- 0:1 20:0 40:Z 60:U 80:G:0
PLACE NoConnect

A no-connect is a special symbol that identifies a pin on a device that is intentionally to be left unconnected. This object causes reports that show unconnected pins to ignore pins with no-connect symbols. No-connect pins should not be connected together. No-connects may not be placed on buses, sheet nets, module ports, labels, power objects, or bus entries. You can place no-connects anywhere, but the other tools will not recognize the no-connect.

To place a no-connect, select NoConnect. Draft displays:

Place  Find  Jump  Zoom

Select Place to place the no-connect on the worksheet.

You can place another no-connect or press <Esc> to return to the main menu level.

NOTE: If you always stay on grid, the no-connect is always correctly positioned to connect to a pin. Just move the pointer on the pin to place the no-connect.
A layout object is a special marker used to give a layout directive to PC Board Layout Tools. The layout directive specifies the routing conditions to be used with the net on which the layout object is placed. To keep the design from being cluttered, the layout directive is not visible on the screen, but the symbol is. To view the contents of the layout directive, use the INQUIRE command.

To place a layout object on the worksheet, select Layout. Draft displays the prompt: "Layout Directive?" Enter the layout directive. Layout directives and their format are described below.

**Draft displays:**

```
Place Value Find Jump Zoom
```

The Place and Value commands are described at the end of this section.

**Layout directive format**

The layout directive consists of a series of characteristics that describe the conditions the net is to have when routing in OrCAD's Release IV PC Board Layout Tools. There are six net characteristics. If any of the six are not specified, the net characteristics not specified default to the net conditions specified in the PC Board Layout Tools configuration. At least one net characteristic must be present and up to all six may be present. A minimum of one space is required between layout directives.

The six conditions are: width, isolation, via, layers, pattern, and strategy. A net characteristic is followed by net conditions enclosed in a pair of parenthesis ( ). The general format for a layout directive is:

```
NetCharacteristic(NetConditions)
```

When you have more than one layout directive, use a space to separate layout directives.

⚠️ **NOTE:** Use the abbreviations: in to specify inches, and mm to specify millimeters. in and mm should not be followed by a period.
The layout directives are:

- **Width**(*trackwidth units*) where *trackwidth* is a decimal number and *units* is either in or mm.
  
  *Examples*
  
  Width(.010in)
  
  Width(.25mm)

- **Isolation**(*metaltometal units, viatovia units*) where *metaltometal* and *viatovia* are decimal numbers and *units* is either in or mm.
  
  *Examples*
  
  Isolation(.025in,.050in)
  
  Isolation(.60in,1.2mm)

- **Via**(*type, diameter units, drillsize units*) where *type* is one of Through, Buried, or Blind; *diameter* and *drillsize* are decimal numbers; and *units* is either in or mm.
  
  *Examples*
  
  Via(Through,.035in,.022in)
  
  Via(Buried,.80mm,.50mm)

- **Layer**(*first, second*) where *first* and *second* are unsigned whole numbers.
  
  *Examples*
  
  Layer(1,4)
  
  Layer(2,3)

- **Pattern**(*type*) where *type* is one of Tree, Chain, or Comb.
  
  *Example*
  
  Pattern(Tree)

- **Strategy**(*type*) where *type* is one of Normal, Flexible, Extensive, NoVia, 90Degree, or Power.
  
  *Example*
  
  Strategy(Extensive)
NOTE: For an explanation of the various conditions and their effects in routing, see the PC Board Layout Tools Reference Guide.

**Place**
Use **Place** to place the layout object on the worksheet.

When the layout object is placed, the "Layout Directive?" prompt returns. To place another layout object, enter another layout directive. If you don’t want to place another layout object, press <Esc> to return to the main menu level.

NOTE: If you always stay on grid, the layout symbol is always correctly positioned to connect to a wire or bus. Just move the pointer on the wire to place the layout symbol.

**Value**
Select **Value** to edit the layout directive. When you select **Value**, the prompt "Layout Directive?" displays followed by the current value. Edit the value using the editing techniques described previously. When you finish editing the label’s value, press <Enter>. 
Use QUIT to enter and leave hierarchical worksheets, load, update, and write to files, clear the worksheet, suspend to DOS, and abandon edits.

Select QUIT. The menu shown at right displays.

---

**QUIT Enter Sheet**

Use the Enter Sheet command to view a schematic represented by a sheet symbol in a hierarchical design. To edit the schematic nested inside the one you are working on, select Enter Sheet.

If you have made any changes to the current worksheet without saving it, Draft displays “Enter - Abandon changes made?”

This message means that unless you save your changes you will lose them. Select No to cancel the Enter Sheet command. If you select Yes, all changes made during this work session are lost, and Draft displays:

EnterLeaveFindJumpZoom

Place the pointer inside the sheet symbol for the subsheet you wish to enter and select Enter sheet. For information about saving your latest design session to a file, see the QUIT Update File command.

Draft returns the Enter Sheet menu, so you can enter other subsheets. Press <Esc> to return to the main menu level.

---

**QUIT Leave Sheet**

To leave a subsheet, select Leave Sheet. When you invoke this command, you move one level up in the schematic hierarchy. If you are at the top of the schematic hierarchy, Draft briefly displays the error message “ERROR : Already at the Root Level.”
QUIT Update File  
Update File writes your latest worksheet design session to a file.

To update a file, select Update File. If the current worksheet had been previously loaded from a file, the file is updated. If the current worksheet is unnamed, Draft responds “Write to File?” Enter the desired filename.

To update a file other than the current file, use the QUIT Write to File command.

Press <Esc> to return to the main menu level.

QUIT Write to File  
Write to File saves the current worksheet to any file you specify. When you choose Write to File, Draft displays “Write to File?”

Enter the desired filename. Draft saves the worksheet to the file specified and then returns the QUIT menu.

Press <Esc> to return to the main menu level.

QUIT Initialize  
Initialize either loads a worksheet file or erases everything from it, thus clearing it. To perform these tasks, select QUIT Initialize.

If there are parts on the worksheet and you have made changes since the file was loaded or saved, Draft displays “Initialize - Are you sure?” Select No to cancel the Initialize command and return to the main menu level. Select Yes to clear the worksheet.

With a blank worksheet, Draft displays “Load File?” Enter the name of the file to load. If the file exists, the worksheet loads and displays. If the file does not exist, Draft displays a blank worksheet and the message “<<<new worksheet>>>.”

Press <Esc> to return to the main menu level.
QUIT Suspend to System

Suspend to System temporarily leaves Draft and the worksheet, saves the worksheet in memory, and returns to the operating system. Once you have suspended Draft, you may run operating system commands, including using other programs, so long as there is enough system memory.

▲ CAUTION: Always save your worksheet to a disk file before using Suspend to System.

To suspend to the operating system, select Suspend to System. Draft suspends operation, loads the system command interpreter, and adds an additional “>” to the system command prompt. This is a reminder that Draft is suspended and in the “background.”

To return to Draft, type EXIT at the system prompt. Draft then returns to the “foreground” and the worksheet you were working on displays.

QUIT Abandon Edits

Select Abandon Edits to exit Draft and return to the Schematic Design Tools screen. If parts have been placed on the worksheet since the last update, Draft displays “Abandon - Are you sure?”. Select No to cancel the command. Select Yes to quit and return to the Schematic Design Tools screen.
QUIT Run User Commands

Use this command to quickly exit Draft and run an externally-defined operating system command.

Select Run User Commands. Draft suspends to the operating system and issues the command DRAFTUSR. DRAFTUSR should be an executable (compiled) program or a set of operating system commands. DRAFTUSR may be located in the current design directory or elsewhere in the system, in which case, the path the operating system searches must be set to find DRAFTUSR. For more information on setting the search path, see your operating system’s configuration documentation.

After DRAFTUSR runs to completion, Draft prompts “Press any key to continue.” Press any key to return to Draft.

△ NOTE: It is possible to use macros and the BLOCK ASCII Export command to create DRAFTUSR commands. For example, you can set up a macro to move to a clear area of a schematic, place one or more lines of text, and do a BLOCK ASCII Export of this text to the current directory. The macro could then select QUIT Run User to perform the tasks specified in the exported text.
REPEAT

Use REPEAT to duplicate the last entered object, label, or text string and place it on the worksheet.

The location of the duplicate object, label, or text is determined by the Repeat parameters specified with SET Repeat Parameters. You can also use SET Repeat Parameters to automatically increment or decrement the numeric suffix of a duplicated module port, label, or text string. For details on the SET Repeat Parameters command, see the SET command on the next page.

For an example of how to use the REPEAT command, see chapter 6 in the Schematic Design Tools User's Guide.
SET

Use SET to control the following Draft options:

- Panning the screen automatically
- Creating backup files
- Dragging buses when rubberbanding
- Ringing the error bell
- Having the left mouse button execute <Enter> when released
- Macro prompting
- Drawing non-orthogonal wires
- Showing pin numbers
- Turning off the standard title block
- Displaying pointer coordinates, grid dots, and grid references
- Release the pointer from the stay-on-grid constraint
- Setting repeat parameters
- Changing the worksheet size, A through E
- Making certain items visible or invisible in zoom scale 2

To change the status of an option, select SET. Draft displays the menu shown at right.

If you prefer options other than the defaults, you may change them automatically every time Draft runs using an initial macro. See the MACRO command in this chapter and Chapter 1: Configure Schematic Tools for information about initial macros.
SET Auto Pan  

**Auto Pan** controls movement past the screen boundary. While **Auto Pan** is turned on, when the pointer crosses a screen boundary, the screen pans in that direction.

When you select **Auto Pan**, you then choose between **Yes** and **No**. **Yes** turns on auto panning; **No** turns it off.

![Logic and Display Circuit](image)

*Figure 2-14. Panning changes the area of the schematic that displays.*

SET Backup File  

**Backup File** controls whether or not **Draft** creates a backup file of your worksheet when you write or update files using the **QUIT** command. The backup file contains the previous version of your edited worksheet.

When you select **Backup File**, you then choose between **Yes** and **No**. **Yes** turns on the creation of backup files; **No** turns it off.

⚠️ **NOTE**: Turning off **Backup File** can be dangerous. If your file should accidentally be damaged or erased, you will be unable to recover it.
**SET Drag Buses**
Use **Drag Buses** to stretch buses, rubberband-like, when you use the **BLOCK Drag** command. Because there are more points to locate when rubberbanding, system performance slows down when you use **BLOCK Drag** with **Drag Buses** turned on.

When you select **Drag Buses**, you then choose between **Yes** and **No**. **Yes** turns on rubberbanding buses; **No** turns it off.

**SET Error Bell**
**Error Bell** turns the error bell (your computer's speaker) on and off. When you turn this option on, error messages and errors sound the speaker.

When you select **Error Bell**, you then choose between **Yes** and **No**. **Yes** turns on the error bell; **No** turns it off.

**SET Left Button**
When **Left Button** is on, releasing the left mouse button executes the <Enter> key for command line commands only. Pressing the left mouse button continues to select the command highlighted in pop-up menus.

For example, suppose you select the **PLACE Wire** command and the "Begin Find Jump Zoom" command line displays at the top of the screen. To select **Begin** with the mouse when **SET Left Button** is turned off, you click the left button once to display the pop-up menu and once again to select **Begin**. When **SET Left Button** is turned on, you instead press the left button and hold it down while you move the highlight to **Begin**, then release the left button. This selects **Begin** and saves one button click.

When you select **Left Button**, you then choose between **Yes** and **No**. If you select **Yes**, releasing the left button on your mouse executes <Enter>. If you select **No**, releasing the left button on your mouse does not execute <Enter>. 
SET Macro Prompts  When Macro Prompts are turned on, the commands making up your macros display on the screen when the macro runs. Turn Macro Prompts on when debugging macros or to watch the commands being performed when you run the macro.

After selecting Macro Prompts, you choose between Yes and No. Yes turns on macro prompts; No turns them off.

△ NOTE: Setting Macro Prompts to No turns screen redraws off when a macro runs. This speeds up macro execution. As a result, Auto Pan is set to No during macro execution and macros using the ZOOM command won't work.

SET Orthogonal  When Orthogonal is on, wires and buses are drawn orthogonally (perpendicular to each other). When turned off, wires and buses can be drawn at any angle.

As the above figure shows, when you select Orthogonal, you then choose between Yes and No. Yes restricts wires and buses to connections at 90° angles; No places no restrictions on the angles and so you can draw wires and buses at any angle.
### SET Show Pin Numbers

When Show Pin Numbers is turned on, pin numbers for library parts are shown on the screen and in worksheet hardcopies. When disabled, pin numbers are not shown on the screen or in hardcopies.

<table>
<thead>
<tr>
<th>Yes</th>
<th>No</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image1.png" alt="Diagram" /></td>
<td><img src="image2.png" alt="Diagram" /></td>
</tr>
</tbody>
</table>

After you select Show Pin Numbers, you then choose between Yes and No. As the figure above shows, Yes turns on the display of pin numbers; No turns it off.

### SET Title Block

When Title Block is turned on, Draft puts the standard title block on the worksheet. With the option turned off, you may create a custom title block using the PLACE Wire/Bus and PLACE Text commands.

<table>
<thead>
<tr>
<th>Yes</th>
<th>No</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image3.png" alt="Diagram" /></td>
<td><img src="image4.png" alt="Diagram" /></td>
</tr>
</tbody>
</table>

When you select Title Block, you then choose between Yes and No. Yes turns on the display of the title block; No turns it off.
SET Worksheet Size

Use **Worksheet Size** to select the worksheet size, A through E.

After you select **Worksheet Size**, choose a letter from A through E. The exact dimensions of each worksheet size are defined in the **Template Table** on the Configure Schematic Design Tools screen. For more information, see **Chapter 1: Configure Schematic Tools**.

SET X,Y Display

When **X,Y Display** is turned on, the upper right part of the prompt line shows the pointer coordinates. The worksheet origin (0,0) is the upper left corner. Coordinates do not appear on the screen until the pointer is moved.

![Diagram of X,Y Display](image)

When you select **X,Y Display**, you then choose between **Yes** and **No**. **Yes** displays pointer coordinates; **No** doesn’t.

⚠️ **CAUTION:** When grid coordinates are not displayed, it is easy to make small errors when placing parts, wires, and buses. These errors may cause problems when using the **Check Electrical Rules** reporter and **Create Netlist** processor. This is because wires and buses may look as if they are connected when they are not. **Check Electrical Rules** and **Create Netlist** interprets these incomplete connections as opens. Do not place parts, wires, or buses in the worksheet with X,Y Display disabled or with **Stay on Grid** turned off (described on the next page).
**SET Grid Parameters**

Select Grid Parameters. Draft displays the menu shown at right. Use Grid Parameters to display grid references, keep the pointer on grid, and display grid dots.

**Grid References**

When Grid References are turned on, Draft displays an alphanumeric border on two of the four worksheet sides. The top border shows grid reference numbers, and the left border shows reference letters. The borders are scaled to the size of the worksheet. Grid references can be used as destination for the JUMP command.

**Stay on Grid**

When Stay on Grid is turned on, the pointer location is confined to the predefined grid. When disabled, the pointer may be moved off-grid to any position on the worksheet at a resolution ten times that of the grid.

After you select Stay on Grid, you select either Yes or No. Yes restricts the pointer to the grid; No does not.

\[\text{\textbf{CAUTION:}}\] Placing parts, wires, and buses with Stay on Grid turned off may cause problems, because wires and buses may look as if they are connected when they are not. Unconnected wires and buses are reported as errors by the Check Electrical Rules reporter and Create Netlist processor. To avoid trouble, do not place parts, wires, or buses in the worksheet with Stay on Grid turned off.

**Visible Grid Dots**

When Visible Grid Dots are turned on, grid dots display on the worksheet. When grid dots are visible and SET Stay on Grid is turned on, it is easier to place parts at specific points on the worksheet.

The distance between grid dots depends on the current zoom scale. The table at right lists the grid dot spacing at different zoom scales.

<table>
<thead>
<tr>
<th>Zoom scale</th>
<th>Grid dot spacing</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>(\frac{1}{10}) of an X or Y unit</td>
</tr>
<tr>
<td>2</td>
<td>(\frac{2}{10}) of an X or Y unit</td>
</tr>
<tr>
<td>5</td>
<td>(\frac{1}{2}) of an X or Y unit</td>
</tr>
<tr>
<td>10</td>
<td>1 X or Y unit</td>
</tr>
<tr>
<td>20</td>
<td>2 X or Y units</td>
</tr>
</tbody>
</table>

After you select Visible Grid Dots, you select either Yes or No. Yes displays grid dots; No does not.
Chapter 2: Draft

**SET Repeat Parameters**

Repeat Parameters are used to determine how the REPEAT command works.

Select Repeat Parameters. Draft displays the menu shown above.

<table>
<thead>
<tr>
<th>Set Repeat Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>X Repeat Step</td>
</tr>
<tr>
<td>Y Repeat Step</td>
</tr>
<tr>
<td>Label Repeat Delta</td>
</tr>
<tr>
<td>Auto Increment Place</td>
</tr>
</tbody>
</table>

**X Repeat Step**

X Repeat Step determines the number of unit steps in the X direction the object being repeated is offset from the original object. The X direction goes horizontally across the worksheet, with positive to the right and negative to the left of the current pointer position. A unit step in the X direction is defined as \( \frac{1}{10} \) of an X unit when SET Stay on Grid is turned on and \( \frac{1}{100} \) of an X unit when SET Stay on Grid is turned off. You can view the change in X units as the pointer moves on the display by turning on the SET X,Y Display option.

When you select X Repeat Step, the prompt “X Repeat Step?” displays. Enter any integer.

**Y Repeat Step**

Y Repeat Step determines the number of unit steps in the Y direction the repeated object is offset from the original object. The Y direction goes vertically on the worksheet, with positive above and negative below the current pointer position. A unit step in the Y direction is defined as \( \frac{1}{10} \) of a Y unit when SET Stay on Grid is turned on and \( \frac{1}{100} \) of a Y unit when SET Stay on Grid is turned off. You can view the change in Y units as the pointer moves on the display by turning on the SET X,Y Display option.

When you select Y Repeat Step, the prompt “Y Repeat Step?” displays. Enter any integer.
**Label Repeat Delta**

Label Repeat Delta determines how much the numeric suffix information on labels, module ports, and text changes, and in what direction, when they are repeated.

When you select Label Repeat Delta, the prompt "Label Repeat Delta?" displays. Enter a whole number. If you enter a positive number, the numeric suffixes on labels, module ports, and text are incremented by that number when they are placed with the PLACE command or the REPEAT command. If you enter a negative number, label suffixes are decremented by that number when placed with the PLACE command or the REPEAT command.

**Auto Increment Place**

When Auto Increment Place is turned on, the numeric suffix (if it exists) of labels, module ports, and text is automatically incremented or decremented when the objects are placed on the worksheet with the PLACE command. After a label, module port, or text string is placed, its numeric suffix is changed by the amount specified by the Label Repeat Delta command.

When you select Auto Increment Place, you then choose between Yes and No. Yes turns on automatic incrementing or decrementing of labels, module ports, and text; No turns it off.

**SET Visible Lettering**

You can choose to have some items on the worksheet display in zoom scale 2. When you select Visible Lettering, the menu shown at right displays.

To make an item visible, select it and choose Yes. To make it invisible, select it and choose No.

This option only affects how the lettering of the object appears on the screen in zoom scale 2.
The **TAG** command identifies and remembers locations on the worksheet. You can specify eight locations (A through H) using the pointer. Tagged locations can be used as destinations for the **JUMP** command. Tags are invisible when set on the worksheet and are not saved with the worksheet.

To set a tag, place the pointer at a location you want to remember. Then select the **TAG** command. **Draft** displays the menu shown above.

When the **TAG** menu displays, select the tag to set from the menu. Once selected, **Draft** remembers the tag location. Once the tag is set, **Draft** returns to the main menu level.
ZOOM: ZOOM zooms in or out from the worksheet, changing the amount of detail you see on the screen. You can select from the five zoom levels described below.

Scale 1: The most detailed zoom scale. All lettering is visible.

Scale 2: The second most detailed zoom scale, representing $\frac{1}{2}$ of scale 1.

Scale 5: The third most detailed zoom scale, representing $\frac{1}{5}$ of scale 1.

Scale 10: The fourth most detailed zoom scale, representing $\frac{1}{10}$ of scale 1.

Scale 20: The least detailed zoom scale, representing $\frac{1}{20}$ of scale 1.

To change the zoom scale, select ZOOM. Draft displays the menu shown at right.

ZOOM Center: Selecting ZOOM Center centers the displayed portion of the sheet around the pointer. This command is useful for centering an object on the screen so you can easily edit it.

For example, if the display of an object is partially off the screen, center it by placing the pointer near the object and selecting ZOOM Center.

The number in parentheses shows the current zoom scale.

ZOOM In: ZOOM In zooms in on the worksheet for a more detailed view. The number in parentheses shows what the zoom scale will be the next time you select ZOOM In.

ZOOM Out: ZOOM Out zooms out to display a larger worksheet area. The number in parentheses shows what the zoom scale will be the next time you select ZOOM Out.

ZOOM Select: Use ZOOM Select to select any one of five zoom scales (1, 2, 5, 10, or 20) from a menu.
Guidelines for creating designs

This chapter is intended to help you automatically create netlists from your schematics. To obtain predictable results, several simple rules need to be followed. When the rules are followed, you can use the Create Netlist and the Create Hierarchical Netlist processors to create netlists in over thirty formats. If you plan to use your schematics with any of OrCAD's other tools, such as PC Board Layout Tools, following these rules greatly simplifies the task of creating a usable netlist.

If these rules are not followed, the database that contains the connectivity of all of the components may contain incorrect connections.

Label names

Draft is quite liberal concerning label names: it accepts any of the standard ASCII printable characters in naming labels and buses. Some netlist formats are more restrictive. You should be aware of any naming restrictions imposed by your target netlist format. For instance, PC Board Layout Tools does not allow spaces, left parentheses or braces, or right parentheses or braces.

Wire labels

Use labels to connect signals from one worksheet area to another without using wires or buses.

For example, assume you have a signal labeled ABC in your worksheet and you would like to connect another object on the worksheet to the same signal. Instead of drawing a wire from ABC on one side of the worksheet to the other object, you can identify each signal with a label, as shown in figure 3-1.
Bus labels

Labels are also used for naming buses and bus members. For Create Netlist and Create Hierarchical Netlist to properly associate a bus with its individual members, both the bus and the wires (bus members) branching from the bus must be labeled following a specific format.

Bus labels must be in the form:

```
BUSNAME[x..y]
```

The prefix of the label, indicated above by BUSNAME, represents the name of the bus. The suffix of the label, indicated above by [x..y], specifies a range of decimal integers representing the number of wires branching from the bus. x represents the first wire number in the bus; y represents the number of the last wire branching from the bus. y must be greater than or equal to x. There will be \((y - x + 1)\) wires in the bus. The prefix and suffix must not have spaces between them.

Examples are:

- ADDR[0..31] (This bus has 32 members.)
- DATA[16..31] (This bus has 16 members.)
- CONTROL[1..4] (This bus has 4 members.)
- A[100..190] (This bus has 91 members.)
Figure 3-2 shows a bus label properly positioned.

A bus label may be placed anywhere on the bus, as long as the label's hotpoint is touching the bus. See the PLACE Label command in Chapter 2: Draft for a description of label hotpoints. A bus may have more than one label placed on it.

Wires branching from a bus must be labeled in a form corresponding to the bus. For example, suppose a bus is labeled as follows:

\[
\text{BUSNAME}[0..9]
\]

Then the wires branching from the bus must have labels of the form shown below:

\[
\text{BUSNAME}x
\]

where \( x \) is a decimal integer in the range of 0-9. BUSNAME and \( x \) must not have space between them.

Figure 3-3 shows an example of a properly labeled bus and its members.

\[
\text{ADDR}[0..31]
\]

Figure 3-3. Label format required by Create Netlist and Create Hierarchical Netlist for buses and bus members.
Multiple labels on a bus

A bus may have more than one label placed on it. In actual applications, bus labels may be placed anywhere on the bus and still be associated with their respective bus signal labels. As a rule, you may place any number of labels on a bus or wire. However, only the busname in the form:

```
BUSNAME[x..y]
```

will be used for the netname. The other labels are strictly for your convenience. They are not used in netlists.

Combining labels

Often times it is necessary to refer to bus members by names other than that of the bus. For instance, one member of a bus might be MEM10, but you still want to refer to it as C\S\ (this notation represents CS with a bar over it, meaning the complement of CS). This is an example of combining labels. Figure 3-4 shows label MEM[0..11] as a bus containing 12 members. U1 is connected to the bus via labels MEM0 through MEM11.

Notice on the left side of the figure that label MEM10 has label C\S\ placed next to it, and that label MEM11 has label W\E\ next to it. On the other side of the figure, C\S\ and W\E\ are labels that have been placed on pins 8 and 10 of U2 and U3.

![Figure 3-4. Combining labels.](image)
Chapter 3: Guidelines for creating designs

This example shows how to connect signals MEM10 and MEM11 to U2, by labeling them as C\S\ and W\E\, respectively. In the case of U3, C\S\ and W\E\ signals are connected to the 2114 device without being physically connected to the bus.

For the netlist processors to list inter-worksheet connections properly, they must be specified on the worksheets following certain conventions.

Lateral inter-sheet connections, as in flat file structures, are established by placing complementary module ports with the same names on different sheets.

Vertical inter-sheet connections, as in hierarchical designs, are established by placing module ports having the same names as nets placed in a sheet symbol one level up in the hierarchy.

When buses connect to module ports or nets, the bus-range format explained in the previous section must be used in both module port names and net names. The ranges specified in module port and net names must match the ranges of the buses to which they connect.

The prefix of a module port name or net name need not be identical to the prefix of the label on the bus to which it connects. However, making them the same is a good practice, unless there is a reason for doing otherwise.

Figure 3-5 shows three examples of buses properly connected to module ports. Notice the bus label suffix, [0..15], is identical to the module port suffix.

![Figure 3-5. Connecting buses to module ports.](image)
Figure 3-6 shows a more detailed example of connecting bus signals to module ports.

![Schematic Diagram](image)

**Figure 3-6. Connecting buses to module ports.**

The main bus in figure 3-6 is labeled BUS[0..10]. Electrical connection between the wires branching from this bus and component U1 is established by labeling the wires BUS0 through BUS10.

The signal labeled BUS8 is conducted off the worksheet through the module port named W\E. The wire label for this signal is based on the format of the bus label. But, as shown, the name of the module port on this wire does not have to match the wire label. However, to establish connection with a module port on some other worksheet, the other module port must also be named W\E.

The bus BUS[0..10] also leaves the worksheet. It connects to a module port having the same name. While the prefix, BUS, could legally be different, the suffix specifying the number of signals must be identical.

The signal labeled R\A\S\ can be connected to a wire elsewhere in the worksheet simply by giving the other wire the same label. Because the R\A\S\ signal is transferred through the bus, BUS[0..10], it must also have a label based on the format of the bus label; in this case, BUS10.

Module ports connected to individual, non-bus wires may be named in any format. They are not required to have a suffix. Figure 3-7 shows typical examples of non-bus signals connected to module ports.
NOTE: It is not necessary to place the label BUS[0..10] on the bus since the module port BUS [0..10] is on the bus. At every module port, a label with the same name is assigned when the connectivity database is constructed.

You can split buses in your worksheet. Figure 3-8 shows an example.

As shown in figure 3-8, you can split the same signal off a bus multiple times by attaching more than one wire with the same label.
Handling and isolating power

Power connections are handled in a number of ways. Most parts in the libraries supplied by OrCAD have defined power and ground pins. These pins are hidden from the drawing, but nonetheless are part of the symbol definition.

To make connections from the outside world to the hidden power pins in the library part, Draft uses a power object (placed with the Place Power command).

For example, assume you have a CMOS device placed in the worksheet. In the CMOS library source file, this device is defined to have a VDD and VSS power pin. To connect another signal from the outside world to the same VDD potential as in the CMOS device, just connect the signal to a power object named VDD.

Power objects are global in scope. A global object is one whose signal (power in this case) connects to all other global signals of the same name. Connectivity between global objects of the same name holds for all worksheet file structures.

The programs that build the connectivity database connect all power objects and signals of the same name. This power handling ability makes it easy to isolate different power sources.

These programs also treat certain parts in part libraries as power objects if they are defined a special way. The four types of grounds in the DEVICE.LIB library (Earth, Field, Power, and Signal grounds) are good examples.

To be treated as a power object, a device is defined as having zero parts per package, only one pin and no reference designator. The pin is defined to be of type PWR. Figure 3-9 shows the source file definition of the GND POWER symbol found in the DEVICE.LIB part library. Significant entries appear in bold. When a part has these characteristics, Draft treats the part from the library as a power object.
Chapter 3: Guidelines for creating designs

Figure 3-9. Source file for the GND POWER symbol.

In the example in figure 3-9, notice the pin name is GND. If this power ground symbol is placed on a worksheet, it represents it as being connected to any other object with a power pin named GND.

There are several ways to create different power supplies in a design. One way is to simply place a power object on the worksheet with the Place Power command, select the Value command and change the value to be whatever you want to distinguish it from other power objects.

Another approach is to create a custom power object and give its pin a unique name using the OrCAD part library editor, Edit Library.

Or, edit the definition of a power object in a library source file and give its pin a unique name. Then, update the binary form of the library by running the Compile Library tool.
For example, in the part library source file, you could edit the signal ground definition, changing the name of its pin from GND to SGND. Or, you could edit the power ground definition, and change its pin name from GND to PGND. Each type of ground will then be connected to any other object with a power pin defined as SGND or PGND.

To find power pin numbers on library components, use the LIBRARY Browse command in Draft or Edit Library.

In OrCAD libraries, many of the devices are defined with the positive supply voltage pin named VCC. Others are defined with the positive supply voltage pin named VDD. To operate pins of both types from the same power supply, you must connect those pins to one another.

Similarly, many of the libraries have return power pins defined as GND or as VSS. The same requirement applies for connecting both types to the same potential.

To connect power supply pins together, or connect a power supply pin to any other supply voltage, you place a separate power object for each different supply in the worksheet. Name one power object with the same name as one of the supply voltages, VDD for example. Name the other power object with the same as the remaining supply voltage, VCC for example. Finally, connect the two power objects together with a wire. The following figure shows how this is accomplished.

![Figure 3-10. Power supply connections.](image-url)
Example A shows a power object named VCC connected to a +5 volt power supply. In the connectivity database, every object with a VCC pin is connected to a +5 volt power supply. This assumes your design contains a power supply with a power object named +5V attached.

Example B shows two power objects, VCC and VDD, connected to a +5 volt power supply through a power object named +5V.

Example C shows a power object, VEE, connected to a −5.2 volt power supply through a power object named −5.2V.

Example D shows a power object, VSS, connected to a power object named GND. This electrically connects the two types of grounds in the net list.

One way to isolate power in the worksheet is to edit parts in the source library file, giving their power pins new names, then update the library with Compile Library. This is time consuming and makes it difficult to keep track of which parts are to be used on which schematic for any particular supply. There is, however, another way to isolate power.

To isolate power without editing the part libraries, connect a module port to a power object. When the connectivity database is built, the name of the module port supersedes the library name of the power object. Only the module port name is used in conducting the power signal from one worksheet to another.

If a power object is to transfer isolated power from one worksheet to another, either in a linked file or hierarchical structure, it must be connected to a module port of type Unspecified. The Check Electrical Rules step in Create Netlist does not accept other types of module ports.

Figure 3-11 shows three examples of power objects connected to module ports.
Handling power in a hierarchy

Power in a hierarchy is handled in much the same way as it is in a linked file design. Power objects connect to all other objects with the same name. If a module port is connected to a power object, the module port supersedes the power object for conducting the signal off the worksheet.

When passing power from a worksheet through a module port up to a sheet symbol, you must place a sheet net in the sheet symbol to conduct the power signal.

Example of isolating power: battery backup

In battery backup applications, main power can be supplied throughout the design with power objects. Backup power can be isolated from the main source by using a module port. Figures 3-12 through 3-14 show this approach to a battery backup application.

This design is a three-sheet hierarchy. The root sheet, shown in figure 3-12, contains the CPU and control circuitry of the design. Two sheet symbols are also placed in the root worksheet. One sheet symbol represents the power supply; the other represents the memory backed up by battery.

Notice a VDD power object is placed in the root worksheet and connects to a +5V power object. Since the 80C51 and the 82C82 power pins are labeled as VDD in their library source files, the +5V and VDD power objects connect +5 volts from the power supply (shown in figure 3-13) to the VDD pins of both devices.

Figure 3-14 shows the battery backed CMOS memory. The memory control signals are conducted from the CPU root sheet through module ports AD[0..7], WE, and A[0..7]. In the POWER SUPPLY worksheet, the power signal to the CMOS MEMORY worksheet is isolated from the +5V supply through a module port named BACKUP.
In the CMOS MEMORY sheet (figure 3-14), another module port named BACKUP connects to a power object named VDD, isolating VDD on this sheet from VDD on all of the other sheets.

Figure 3-12. Root CPU sheet.
GND and VSS power objects are also placed in the CMOS MEMORY worksheet. This connects the VSS power return pins from the memory devices to the Power Ground object.
To summarize, isolate power in a design by conducting it through module ports connected to power objects selectively named to match the names of power pins in library source files.

Although this example design is a hierarchy, it could have been created as a flat file structure. In applications where you isolate power, place all of the circuitry to be isolated in a separate worksheet. This keeps isolated power specific to one worksheet.
Handling physical connectors

Module ports are not intended to be used as physical connectors in a design. Use module ports to connect signals from one worksheet to another. Physical connectors are library parts, since connectors require a reference designator and part value.

To make schematics easier to read, don't separate individual pins in a connector and place them all over the worksheet. This makes finding connector pins difficult, especially in multiple sheet designs. Instead, place a connector on one worksheet and use module ports or labels to connect its pins to other signals in the design. Figure 3-15 shows an example.

Make large connectors with alphanumeric pin names using a block symbol with zero parts per package.

Figure 3-16 shows part of a library source file definition for an IBM PC 62-pin edge connector. Because of its large size, only part is shown. Since there are no pin numbers defined in the source file, Create Netlist will use pin names instead to identify the pins when it builds the connectivity database. In this definition, B1-B31 and A1-A31 are the pins on the 62-pin edge connector.

```

Edit File

About Edit File

The Edit File button runs a text editor. When you receive your ESP software from OrCAD, it is configured to run a text editor called M2EDIT. However, you can configure ESP to run the text editor of your choice.

For instructions on how to configure ESP to run your text editor, see the ORCAD/ESP Design Environment User's Guide. To use the M2EDIT editor, see the Stony Brook M2EDIT Text Editor User's Guide.

Execution

With the Schematic Design Tools screen displayed, select Edit File. Select Execute from the menu that displays. The screen for the configured text editor displays.
The View Reference button runs a text editor in a reference material directory provided by OrCAD. This directory contains supplemental “read me” files of product information. These files contain information such as:

- List of drivers supported by ESP
- List of drivers that can be made using GENDRIVE
- List of parts found in each library

When you receive your ESP software from OrCAD, it is configured to run a text editor called M2EDIT. However, you can configure ESP to run the text editor of your choice.

For instructions on how to configure ESP to run your text editor, see the OrCAD/ESP Design Environment User’s Guide. To use the M2EDIT editor, see the Stony Brook M2EDIT Text Editor User’s Guide.

With the Schematic Design Tools screen displayed, select View Reference. Select Execute from the menu that displays. Select Execute. The screen for the configured text editor displays. Use the text editor to open and read the reference file of your choice.
**PART III: PROCESSORS**

Schematic Design Tools includes seven Processors that read, modify, and then rewrite the design database. Processors generally do not create human-readable reports, but rather create or modify database information.

Part III describes Processor tools and provides instructions for their use.

- **Chapter 6:** *Annotate Schematic* describes how *Annotate Schematic* scans a design and automatically updates the reference designators of all parts in the worksheet.
- **Chapter 7:** *Back Annotate* describes how *Back Annotate* scans a design and updates part reference designators according to the instructions you provide in a "Was/Is" file.
- **Chapter 8:** *Cleanup Schematic* describes how *Cleanup Schematic* scans a design and checks for wires, buses, junctions, labels, module ports, and other objects that are placed on top of each other.
- **Chapter 9:** *Creating a netlist* gives an overall description of incremental netlisting.
- **Chapter 10:** *Create Netlist* describes how to create a linked and flattened netlist.
- **Chapter 11:** *Create Hierarchical Netlist* describes how to create a hierarchically formatted netlist.
- **Chapter 12:** *Select Field View* describes how to use *Select Field View* to change visible attributes of specified fields on a worksheet.
- **Chapter 13:** *Update Field Contents* describes how to use *Update Field Contents* to load user-defined information into the fields of parts on a worksheet.
The Annotate Schematic processor scans a design and automatically updates the reference designators of all parts in the worksheet. This includes updating the corresponding pin numbers (associated with a particular instance of a part) with multiple devices in the package.

Annotate Schematic updates reference designators in the order the parts were placed in the worksheet. When the worksheet is annotated, all parts may be assigned a new reference designator, including any manually edited parts. To selectively change reference designators and leave others unmodified, use the Back Annotate tool or Draft.

With the Schematic Design Tools screen displayed, select Annotate Schematic. Select Execute from the menu that displays.

While Annotate Schematic runs, messages display on the screen. When the annotation is complete, the Schematic Design Tools screen displays.
<table>
<thead>
<tr>
<th>Key fields</th>
<th>Annotate Schematic has one key field. It is shown on the Key Fields area on the Configure Schematic Design Tools screen as follows:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>ANNOTATE</strong> Part Value Combine</td>
</tr>
</tbody>
</table>

This key field determines how Annotate Schematic will group parts in devices that have multiple parts per package. If the parts have empty key fields and matching part values, Annotate Schematic assigns parts to the same package. If the parts have data in their key fields, Annotate Schematic assigns parts to the same package only if their key fields match. For this reason, if you use the Annotate Schematic key field, you should include the part value as part of the key field.

For more about key fields, see Chapter 1: Configure Schematic Tools.

| Before annotation and after annotation | Figure 6-1 illustrates a worksheet that is not annotated. Figure 6-2 shows the same worksheet, after annotation. |
Chapter 6: Annotate Schematic

Figure 6-1. Worksheet before annotation.

Figure 6-2. Annotated worksheet.
With the Schematic Design Tools screen displayed, select Annotate Schematic. Select Local Configuration from the menu that displays.

Select Configure ANNOTATE. A configuration screen appears (figure 6-3).

![Annotate Schematic's local configuration screen](image)

Figure 6-3. Annotate Schematic's local configuration screen.

**File Options**

**Source**

The Source is the root of the design or the filename of a single sheet. It may have any valid pathname.

After entering the source filename, select one of the following options:

- **Source file is the root of the design**
  
  Specifies that the source file is the root sheet name of a hierarchical or flat design. If the root sheet contains sheet symbols, then the design is hierarchical. If it contains a Link, it is a flat design.

- **Source file is a single sheet**
  
  Specifies that the source file is a single worksheet and you want to process the single sheet only.
Chapter 6: Annotate Schematic

Processing Options

You may select any combination of the following options:

- **Quiet mode**
  
  Turns quiet mode on.

- **Do NOT change the sheet number**
  
  Causes the sheet number set in the title block to remain unchanged. If this option is not selected, Annotate Schematic renumbers all of the schematics in the design.

- **Unannotate schematic**
  
  Resets all reference designators in the design. When parts were first placed, the reference designator had a numeric component of "?". This option resets all number to "?".

- **Report the last assigned reference values**
  
  Tells Annotate Schematic to report the last reference designator assigned to a design, after it is done annotating. The report is placed in a file with the same name as the source, ending with the extension .END.

- **Reset reference numbers to begin with 1 on each sheet of the hierarchy**
  
  Restarts all reference designators used at 1 for each sheet of the design instead of only on the first sheet. Use this option to annotate a complex hierarchy. If you are using OrCAD's Digital Simulation Tools and your design is a complex hierarchy, this option is recommended.
Select one of the following options:

- **Incremental annotation (only update reference designators shown as ?)**
  Updates only the reference designators that have a "?". When new parts are placed on a sheet, the reference is not assigned a numeric value, but rather is given the unassigned designation of "?". If you do not wish to renumber all reference designators, including all previously set references, use this option.

- **Unconditional annotation (update all reference designators)**
  Updates all reference designators in the order in which they are placed in the worksheet. All references are updated, even those that may have been assigned previously.

If desired, select this option:

- **Ignore warnings**
  Causes Annotate Schematic to continue running when it encounters warnings, instead of halting.
Back Annotate

Execution

Back Annotate scans a design or a single sheet and updates part reference designators. To run Back Annotate, you must provide a text file that lists old and new reference designators. This file is called a “Was/Is” file.

Was/Is file format

A Was/Is file is a text file containing the old and new reference designators. You create it using a text editor.

A Was/Is entry begins with the old reference designator that you want to modify, followed by any number of space, tab, or new line characters, which is in turn followed by the new reference designator value. Make a Was/Is entry for each reference designator you want to change. A new line is not required after each entry.

The following is an example of a typical Was/Is file:

R1    R5
R2    R12
R3    R6
C5    C1
C12   C2
U5C   U1A
U3B   U3A

In the above example, the occurrence of R1 in the design is changed to R5, R2 becomes R12, and so on.

Running Back Annotate

With the Schematic Design Tools screen displayed, select Back Annotate. Select Execute from the menu that displays.

When the reference designators are changed, the Schematic Design Tools screen displays.
With the Schematic Design Tools screen displayed, select Back Annotate. Select Local Configuration from the menu that displays.

Select Configure BACKANNO. A configuration screen displays (figure 7-1).

File Options define the source file and its type, and the Was/Is file.

Source

The Source is the root of the design or the filename of a single sheet. It may have any valid pathname.

After entering the source filename, select one of the following options:

- Source file is the root of the design
  Specifies that the source file is the root sheet name of a hierarchical or flat design. If the root sheet contains sheet symbols, then the design is hierarchical. If it contains a Link, it is a flat design.

- Source file is a single sheet
  Specifies that the source file is a single worksheet and you want to process the single sheet only.

Was/Is

Was/Is specifies the name of the text file containing the old and new reference designator pairs. It may have any valid path and name. The format of this file is discussed at the beginning of this chapter.
Chapter 7: Back Annotate

Processing Options

You may select any combination of the following options:

☑ Quiet mode

Turns quiet mode on.

☑ Ignore warnings

Causes Back Annotate to continue running when it encounters warnings, instead of halting.
Cleanup Schematic

Execution

Cleanup Schematic scans a file and checks for wires, buses, junctions, labels, module ports, and other objects that are placed on top of each other. It can scan an entire design or a single sheet.

Cleanup Schematic removes duplicate or overlapping wires, buses, and junctions, and displays warning messages advising you of other duplicate objects. It does not check for objects overlapping part leads, wires overlapping buses, or wire bus entries overlapping bus bus entries.

Use Cleanup Schematic whenever you want to check for and correct drawing errors in the worksheet. Check all worksheets with Cleanup Schematic to reduce errors and warnings that may occur when you use other utilities.

Running Cleanup Schematic

With the Schematic Design Tools screen displayed, select Cleanup Schematic. Select Execute from the menu that displays.

When the schematic is “cleaned up,” the Schematic Design Tools screen displays.

When Cleanup Schematic processes a very large worksheet, the tool may display the message: “CLEANUP will need to be repeated for this file”. This means there was not enough memory to complete the cleanup process in one pass. If this occurs, run Cleanup Schematic again.

Cleanup Schematic renames the original schematic files (the files as they existed before Cleanup Schematic was run) with a .BAK extension. It saves the changed schematic files using the filenames of the original files.
If your disk becomes full during the cleanup operation, you will always have your original design intact. The original design is preserved because Cleanup Schematic does not rename the original file until after it has been successfully processed. After the process is complete, the original file is renamed to a .BAK extension and the processed version of the file is given the original name.
Local Configuration

With the Schematic Design Tools screen displayed, select Cleanup Schematic. Select Local Configuration from this menu that displays.

Select Configure CLEANUP. A configuration screen displays (figure 8-1).

![Figure 8-1. Cleanup Schematic's local configuration screen.](image)

File Options

File Options defines the source file and its type, and the destination file.

Source

The Source is the root of the design or the filename of a single sheet. It may have any valid pathname.

After entering the source filename, select one of the following options:

- Source file is the root of a hierarchy
  
  Specifies that the source file is the root sheet name of a hierarchical or flat design. If the root sheet contains sheet symbols, then the design is hierarchical. If it contains a Link, it is a flat design.

- Treat source file as a one-sheet file
  
  Specifies that the source file is a single worksheet and you want to process the single sheet only.

Destination

The Destination is any valid pathname where the output of Cleanup Schematic is placed. This entry is optional.
### Processing Options

You may select any combination of the following options:

- **Quiet mode**
  
  Turns quiet mode on.

- **Report off-grid parts**
  
  Causes Cleanup Schematic to check the entire worksheet for parts that are placed off grid and report them.

- **Repeat CLEANUP if sheet is too large to complete in one pass**
  
  Causes Cleanup Schematic to repeat until the whole worksheet is completed.

- **Ignore warnings**
  
  Causes Cleanup Schematic to continue running when it encounters warnings, instead of halting in the middle of execution.
Traditionally, EDA tools exchanged design information using netlists and translators. Netlists and translators are limited, though, because they contain only a small part of the information in the complete design database.

With the support of the ESP design environment, OrCAD tools now relate in a new and powerful way—by exchanging design information primarily through the design database itself, rather than using netlists and translators.

To exchange information with tools created by third-party vendors with their own proprietary input formats, Schematic Design Tools can, as before, create netlists in a variety of industry-accepted formats.

OrCAD's Release IV design database is incremental. The incremental approach speeds up the design process, especially during revision, verification, and maintenance cycles for hierarchical designs. This means less time waiting for the tools—time that can be spent designing.

The incremental netlist process is composed of three steps:

- Compile
- Link (when necessary)
- Format (when necessary)

Incremental netlisting resembles the compile and link process used to create executable computer programs from a source language (C, Pascal, or Modula-2 for instance). As in the process of creating a computer program, the schematic (source) files are processed by the compiler into an intermediate form, and are then linked together to
produce a file that contains all of the connectivity information from all of the schematic files. This process is called building the connectivity database.

Compile: INET

First, the schematic files are processed by a compiler (called INET) into an intermediate form, called the incremental connectivity database.

The first time it runs, INET compiles all the sheets in a design. From then on, it compiles only sheets that have changed since the last time it ran. When INET runs, it compares the time stamp for a sheet against the one for the incremental connectivity database belonging to that sheet. If the sheet’s time stamp is more recent than the incremental connectivity database, INET recompiles the sheet.

Link: ILINK

Then, the increments are linked together (by the linker ILINK) to make a file that contains all the connectivity information from all of the schematic files. The result is the linked connectivity database.

Format:

IFORM or HFORM

Finally, the connectivity database is translated and formatted for use by other tools that cannot read the design database directly. There are two formatters: IFORM makes flat format netlists, and HFORM makes hierarchical format netlists (EDIF 2.00 and Spice). A programming language that you use to design your own netlist formats is included, along with source code for the formats already supported.

Figure 9-1 on the next page shows the process flow for creating a netlist. All netlists originate with the compile process, INET. After compilation, the incremental connectivity database can be linked or formatted or both to produce flat or hierarchical netlists for use by other tools. OrCAD’s Digital Simulation Tools uses the incremental connectivity database directly for input. OrCAD’s PC Board Layout Tools uses the linked version of the connectivity database, but does not use the formatting process.
If the file structure is a complex hierarchy, and a flat netlist is desired, the design must be converted to a simple hierarchy.

Ready to go to OrCAD's Digital Simulation Tools.

Ready to go to OrCAD's PC Board Layout Tools Release IV (with Produce a linked connectivity database button selected).

Ready to go to OrCAD's Programmable Logic Design Tools, OrCAD/PCB II v. 2.x, plus many other formats.

NOTE: Figure 9-1 shows the process flow for creating a netlist. If the file structure is a complex hierarchy, it must be converted into a simple hierarchy using Complex to Simple before it can be flattened and annotated with unique references. Complex to Simple is a function provided on the Design Management Tools screen. This tool creates a new design with all sheets referenced only once. In this new design, a flattened netlist is then created. The OrCAD Design Environment User’s Guide explains this process.
The compiler: INET

The first step in creating either flat (one-sheet, or many sheets) or hierarchical (complex or simple) netlists is to create the incremental connectivity database.

The incremental connectivity database

INET creates the incremental connectivity database. It consists of an .INF file for each sheet in the design and one .INX file for the entire design, as shown in figure 9-2.

Figure 9-2. INET produces the incremental connectivity database.

The .INF file

Compiling the root sheet of the design creates a compact database of the connectivity information for each sheet referenced by the design, which is stored in an .INF file for each sheet. This representation includes all the devices on the sheet, the connectivity between parts, the pipe commands on the sheet, and information entered in the title block.

You don’t need to keep track of which sheets you’ve changed and therefore have to be re-compiled. INET does this for you. When INET runs, it compares the time stamp (that is, the date and time) for each sheet against the
time stamp of any pre-existing .INF file for that sheet. If the sheet is more recent than its .INF file, then INET recompiles that sheet.

▲ CAUTION: The proper functioning of INET depends on the clock in your computer being set properly. If your clock must be reinitialized each time your computer is started, please take the time to set it properly.

The .INX file

While processing the file structure, INET constructs an .INX file from the sheet name you give it. Each sheet in the file structure is listed in the .INX file, and any sheets that were recompiled are marked with an asterisk. The .INX file is important to INET, ILINK, and IFORM. Its purpose is to speed processing and organize the database. You can use Edit File to view the .INX file and see the files in the design, but do not modify the .INX file in any way.

The ILINK command

How does INET know what files belong in a file structure?

For a hierarchical file structure, the answer is simple. When a sheet is added to the hierarchy via the PLACE Sheet command, a name is created and stored with the sheet. Thus, the process of compiling a hierarchy becomes an iterative process of compiling a sheet, then compiling all of the sheets referenced on the sheet just compiled.

Designs that are flat, however, do not have sheet symbols to refer to the other sheets in the design. Rather, a different mechanism is used: the ILINK command. On the root sheet of the design, a series of text lines must be placed in the following format:

```
|LINK
| SHEET2
| SHEET3
```
This tells INET that the root sheet, SHEET2, and SHEET3 are all part of the design. If new sheets are added to the design, simply add new text entries to the root sheet in the same vertical column as the other ILINK text. The order of the sheet names from top to bottom is the order in which all of the processors, reporters, and transfers process the design.

**The linker: ILINK**

ILINK performs one of two processes:

- It creates the intermediate netlist structure. This consists of the .INS, .RES, and .PIP files. These files are used by the flat formatter, IFORM.

- It creates the linked connectivity database. This file has an extension of .LNF and is used by PC Board Layout Tools.

Figure 9-3 shows these processes.

![Diagram of ILINK processes](image)

*Figure 9-3. ILINK produces the intermediate netlist structure or the linked connectivity database.*

\[\text{\(\Delta\)}\]

**NOTE:** ILINK is not used for hierarchical netlist formats. See The hierarchical formatter: HFORM in this chapter.
It isn't always necessary to use ILINK. If tool sets are designed to access the incremental connectivity database directly, formatting is not needed. Some tool sets (such as Digital Simulation Tools) are designed to access the database in its unlinked form. Other tool sets (such as PC Board Layout Tools) require a linked connectivity database for all of the design. In such instances, use ILINK to create a .LNF file.

**Intermediate netlist structure**

The intermediate netlist structure consists of three binary files: the .INS, .RES, and .PIP files. These are the files used by the flat formatter, IFORM.

**The .INS file**

One of the files produced by ILINK is the instance (.INS) file. This file contains information on all the parts in all the .INF files.

**The .RES file**

Another file produced by ILINK is the resolved (.RES) file. This file contains information about the connectivity of the parts in the .INF file.

**The .PIP file**

The .PIP file is only produced when pipe commands are present on a root sheet. Several netlist formats allow pipe commands to be present on the schematic and written to the netlist. One such command is the `ISPIICE` command used by the SPICE netlist formats.

**The linked connectivity database**

OrCAD's PC Board Layout Tools uses the linked connectivity database (.LNF) directly.

**The .LNF File**

The .LNF file is a giant version of all the .INF files. It has a .LNF extension because a .INF already exists for the root sheet. Producing the .LNF file from ILINK is discussed in *Chapter 10: Create Netlist*. 
If you are transferring design information to a third-party EDA tool, you will probably need to format ILINK's output to make it readable by your destination tool.

The last step formats the .INS, .RES, and .PIP files into any of over thirty different netlist formats. These formats are discussed in Appendix B: Netlist Formats. Chapter 10: Create Netlist explains how to create a netlist in one of these formats. Figure 9-4 shows the IFORM process.

Creating a hierarchical netlist is similar to creating a flat netlist except that ILINK is not used. HFORM reads the .INF files directly. These formats are discussed in Appendix B: Netlist Formats. Chapter 11: Create Hierarchical Netlist explains how to create a netlist in one of these formats. Figure 9-5 shows the HFORM process.
Caveats

As previously mentioned, INET is incremental. It compiles one sheet at a time. This can lead to what appear to be anomalies, but aren't.

For instance, say you have a multi-sheet file structure, and INET reports that two sheets have errors. If you fix the errors in one of those sheets, then rebuild the netlist, no errors show up. There should still be errors in the other sheet. Why didn't INET report them? Since the second sheet was not altered, it was not recompiled. If you check the .INX file, you will see that the sheet you fixed was recompiled (it has an asterisk next to it), but the other sheet was not. For this reason, when you are making a final netlist, if you are uncertain whether you have corrected all of the errors in the design, set configuration to force INET to compile all files. Chapter 10: Create Netlist and Chapter 11: Create Hierarchical Netlist and the chapters about transfers discuss this fully.
There are two basic types of netlist formats:

- A linked format where all ports and signals have been resolved across the entire design (the design is totally flat at this point). **Create Netlist**, discussed in this chapter, creates this type of netlist.

- A hierarchical format where all sheets and subsheets remain intact and are used to reference subnets. **Create Hierarchical Netlist**, discussed in Chapter 11: *Create Hierarchical Netlist*, creates this type of netlist.

These netlists are intended primarily for use in interfacing to tools outside the ESP design environment. If you are using OrCAD's Digital Simulation Tools or PC Board Layout Tools, the connectivity database is managed using the transfer buttons to those tools. A netlist is not produced when transferring to PC Board Layout Tools or Digital Simulation Tools.

**Linked format**

The linked form reproduces the sheets giving all parts unique references and, hence, all nodes unique names. This view is the "actual" view of the design since each part is unique. However, a linked view of a design removes any evidence of the structure of the design as well as any evidence of design reuse. The design may be either a simple hierarchy or a flat file structure.
Create Netlist consists of three processes to create linked and flattened netlists. They are:

1. Process the design with the incremental compiler, INET, to produce the incremental connectivity database for the design. INET updates the incremental connectivity database efficiently by updating the database only for those sheets that have changed.

2. Next, link the incremental connectivity database into a single database that can be used by the formatting process. This is done by the netlist linker, ILINK. ILINK produces either intermediate netlist structure files that require formatting or the linked connectivity database that is ready to go to OrCAD's PC Board Layout Tools.

3. Finally, produce the final flattened netlist in one of over thirty netlist formats (Wirelist, PCAD, etc.). The netlist formatter is IFORM.

For example, if the design is called root and the format is contained in my_format, the following processes run:

1. INET root.sch
2. ILINK root.inf
3. IFORM root my_format

The formatter is actually an interpreter that uses a format specification file (my_format in item 3 above) to produce the final netlist. You can write your own netlist format specification file, if you like: see Appendix D.

Create Netlist reads a design or single sheet and creates a flat netlist.

△ NOTE: If the source design is a complex hierarchy, it must first be changed into a simple hierarchy, using Complex to Simple on the Design Management Tools screen. To create a hierarchical netlist of a complex hierarchy, see Chapter 11: Create Hierarchical Netlist.
**Running Create Netlist**

With the Schematic Design Tools screen displayed, select Create Netlist. Select Execute from the menu that displays.

When the netlisting process is complete, the Schematic Design Tools screen displays again.

---

**Local Configuration of Create Netlist**

Since INET, ILINK, and IFORM are each configured individually, Create Netlist has three configuration screens. To configure Create Netlist, select Create Netlist. Select Local Configuration from the menu that displays.

The menu shown at right displays. Use this menu to choose the Create Netlist process to configure. You can also use it turn processes on or off. When you run Create Netlist, only the processes that are turned on run. For most cases, you must have INET, ILINK, and IFORM all turned on.

To turn a process on or off, choose the desired process from the menu. For example, to turn IFORM off, select IFORM on from the menu. ESP prompts:

```
Select the new status of the executable item
```

A menu with the options on and off displays. Select off to turn the process off.
NOTE: If you are creating a netlist for either Digital Simulation Tools or PC Board Layout Tools, use the transfer buttons To Digital Simulation and To Layout, because they are already properly set up to perform the appropriate netlist processes when you transfer to the respective tool.

To duplicate the process of creating an incremental connectivity database to use with Digital Simulation Tools, turn both ILINK and IFORM off.

To duplicate the process of creating a linked connectivity database for PC Board Layout Tools, turn IFORM off.
Chapter 10: Create Netlist

Local Configuration of INET

With the Schematic Design Tools screen displayed, select Create Netlist. Select Local Configuration from the menu that displays, and then select Configure INET. A configuration screen displays (figure 10-1).

![Figure 10-1. INET's local configuration screen.](image)

**File Options**

File Options defines the source file from which the incremental database files are created. It also defines the name of a file to contain data created by INET.

**Source**

The Source is the root of the design or the filename of a single sheet. It may have any valid pathname. One .INF file is created for each sheet referenced by the root sheet.

**Reports Destination**

The Reports Destination is the name of a file where the report is to be placed. This specification is optional. If a Reports Destination is not specified, the report is sent to the screen and the file #ESP_OUT.TXT.
You may select any combination of the following options:

- **Quiet mode**
  - Turns quiet mode on.

- **Descend into sheet path parts**
  - Tells INET to descend into parts defined as sheetpath parts. That is, it treats a sheetpath part as a sheet. This option, while designed for complex hierarchies, may be used in simple hierarchies. It is not recommended for use except for FPGA, ASIC, or other designs that require a complex hierarchy.

- **Assign a net name to all pins**
  - Tells INET to assign a net name to all pins, including unconnected ones.

- **Report off-grid parts**
  - Tells INET to check the worksheet for parts, sheets, labels, module ports, and power objects that are off-grid.

- **Report all connected labels and parts**
  - Tells INET to report all connected labels and module ports.

- **Report all unconnected wires, pins, module ports**
  - Tells INET to report all unconnected wires, pins, and module ports.

- **Run ERC on all sheets processed**
  - Runs an electrical rules check on all sheets that INET processes. This is the same process provided by the Check Electrical Rules tool.
Chapter 10: Create Netlist

- **Do not report warnings**
  
  This option is available if you select the **Run ERC on all sheets processed** option. It tells INET to not test some of the conditions for which it normally issues warnings. The conditions are:
  
  - Two power objects connected
  - Single node nets
  - Input signals without a driving source

  These conditions are always checked—unless you select the **Do not report warnings** option—and cannot be changed with the **Check Electrical Rules Matrix**.

  Use this option with caution. You may end up with a netlist containing conditions that are not acceptable.

- **Check all module port connections**
  
  Tells INET to check all module ports for correctness after tests and processing are completed.

- **Rebuild file stack**
  
  Tells INET to rebuild the file stack that is used to determine the sheets that are in the incremental connectivity database. This file stack speeds the processing of the database when incremental updates occur. It may be viewed, but should not be modified. The file stack is given a .INX extension.

- **Unconditionally process all sheets in design**
  
  Tells INET to ignore the incremental aspect of normal connectivity database processing. All sheets in the design are recompiled, even if the current database is up to date.
Do NOT create .INF files (report only)

When processing the design, you may wish to leave the incremental connectivity database unchanged and only review the reports. This option causes all checks to be run and reports to be created, but does not update the incremental connectivity database.

Process one sheet only (This forces Rebuild file stack on the next run)

Tells INET to produce an incremental connectivity database for a single sheet in a design. This option is useful for troubleshooting netlist problems. The next time INET runs, it will also rebuild the file stack used to determine the sheets that are in an incremental connectivity database.

Ignore warnings

Causes INET to continue running when it encounters warnings, instead of halting in the middle of execution.
Local Configuration of ILINK

With the Schematic Design Tools screen displayed, select Create Netlist. Select Local Configuration from the menu that displays. Select Configure ILINK. A configuration screen displays (figure 10-2).

![Figure 10-2. ILINK's local configuration screen.](image)

File Options defines the source file.

**Source**

The Source is the incremental connectivity database root file. There must be an extension on the filename. The source file is the output from the INET process discussed previously and should have the recommended extension of .INF. It may have any valid pathname.
Processing Options  Select any combination of the following:

- Quiet mode
  Turns quiet mode on.

- Produce a linked connectivity database
  Tells ILINK to produce a linked connectivity database (.LNF). This text file is read by PC Board Layout Tools. If a destination file is not supplied, the output is placed in a file with the same name as the source, except with a .LNF extension.

  A Destination may be supplied to override the default output file. This file may have any valid pathname.

  If this option is not selected, ILINK produces the intermediate netlist structure files (.INS, .RES, and .PIP). These binary files are used by IFORM.

- Force ILINK to always link the database
  Tells ILINK to force a link of the database to occur, even if the database is up to date.

- Report single net nodes
  Reports all nodes that have only a single pin. This report is used to identify nodes that still need to be connected in the design.

- Ignore warnings
  Causes ILINK to continue running when it encounters warnings, instead of halting.
Local Configuration of IFORM

With the Schematic Design Tools screen displayed, select Create Netlist. Select Local Configuration from the menu that displays. Select Configure IFORM. A configuration screen displays (figure 10-3).

![Configuration Screen](image)

**Figure 10-3. IFORM's local configuration screen.**

**File Options** defines the source and destination files.

**Source**

The Source is the intermediate netlist structure from the ILINK process discussed previously and should not have any extensions. It may have any valid DOS pathname.

**Destination 1 & Destination 2**

These are the destination files for the formatted netlist files created by IFORM. All of the netlist formats use the first destination file for the netlist. A few of the netlist formats also create a component or part file. This file, if created, is placed in the second destination. If a filename is not provided where one is needed, its data is sent to the screen.
Processing Options

The Format prefix/wildcard entry box is the path from which formatting files are displayed in the Netlist format list box. Additionally, it provides a filter to selectively display files from the given directory. The filter defaults to *.CF, which displays only valid flat formatter files.

The desired netlist format file is selected by clicking its name in the list box or by typing its name in the Selected Format entry box. If the formatter name is typed into the Selected Format entry box, the path in the Format prefix/wildcard entry box must be valid.

Select any of the following:

- Quiet mode
  - Turns quiet mode on.

- Force IFORM to always create a formatted netlist
  - Tells IFORM to force a format to be performed, even if the database shows the current format is up to date.

- Ignore warnings
  - Causes IFORM to continue running when it encounters warnings, instead of halting.

Format Specific Options

Schematic Design Tools provides formatters to create netlists in over thirty formats. When a format is selected from the Netlist Format list box, its formatting options are displayed in this area. Appendix B: Netlist formats explains each of the formats and any available options.

You may write your own netlist formats and have them appear in the Netlist Format list box along with the ones supplied by OrCAD. Appendix C: Creating a custom netlist explains this process.
There are two basic types of netlist formats:

- A hierarchical format where all sheets and subsheets remain intact and are used to reference subnets. Create Hierarchical Netlist creates this type of netlist and is discussed in this chapter.

- A linked format where all ports and signals have been resolved across the entire design (the design is totally flat at this point). Create Netlist creates this type of netlist and is described in Chapter 10: Create Netlist.

The hierarchy presents the design as it was first partitioned, replete with all subsheets (children) and non-unique references and nodes. This form is generally the way "top down" designs are done and maintained. However, the design does not contain unique references nor node (signal) names (unless the "path" to the part or node is used). Hierarchies represent the "designers" viewpoint rather than the "stuff the board" view. Create Hierarchical Netlist is used to produce hierarchically formatted netlists.
Create Hierarchical Netlist consists of two processes:

1. Process the design with the incremental compiler, INET, to produce the incremental connectivity database for the design. INET updates the incremental connectivity database efficiently by updating the database only for those sheets that have changed.

2. Produce the final hierarchical netlist in the desired format (EDIF or SPICE). The netlist formatter is HFORM.

For example, if the design is called root and the format is contained in my_format the following processes are run:

1. INET root.sch
2. HFORM root my_format

Since there are various final formats for netlists, a method for rapidly producing different formats is required. Further, it would be nice if you could produce the desired format without too much effort. As a result, the formatter is actually an interpreter that uses a format specification file (my_format in item 3 above) to produce the final netlist.

Execution

Create Hierarchical Netlist reads a hierarchical file structure and creates a hierarchical netlist. First, it scans the file structure and creates an incremental connectivity database for the design. Then it formats the incremental connectivity database into a hierarchical (simple or complex) netlist. See Chapter 9: Creating a netlist for more information on the netlisting process.

Running

Create Hierarchical Netlist

With the Schematic Design Tools screen displayed, select Create Hierarchical Netlist. Select Execute from the menu that displays.

When the netlisting process is complete, the Schematic Design Tools screen displays again.
Since INET and HFORM must each be configured individually, Create Hierarchical Netlist has two configuration screens. To configure Create Hierarchical Netlist, select Create Hierarchical Netlist. Select Local Configuration from the menu that displays.

The menu shown at right displays. Use this menu to choose which Create Hierarchical Netlist process to configure. You can also use it to turn each process on or off. When you run Create Hierarchical Netlist, only the processes that are turned on run. For most cases, you must have both INET and HFORM turned on.

To turn a process on or off, choose the desired process from the menu. For example, to turn HFORM off, select HFORM on from the menu. Schematic Design Tools prompts:

A menu with the options on and off displays. Select off to turn the process off.

△ **NOTE:** If you are creating an incremental connectivity database to use with Digital Simulation Tools, turn HFORM off. To Digital Simulation is set up in this manner so that when you transfer to Digital Simulation Tools, the appropriate netlist processes are performed.
With the Schematic Design Tools screen displayed, select Create Hierarchical Netlist. Select Local Configuration from the menu that displays and then select Configure INET. A configuration screen displays (figure 11-1). The configuration of INET within Create Hierarchical Netlist is the same as within Create Netlist. It is repeated here for your convenience.

File Options defines the source file from which the incremental connectivity database files are created. It also defines the name of a file to contain the data INET creates.

**Source**
The Source is the root of the design or the filename of a single sheet. It may have any valid pathname. One .INF file is created for each sheet referenced by the root.

**Reports Destination**
The Reports Destination is the name of a file where the report is to be placed. This specification is optional. If a Reports Destination is not specified, the report is sent to the screen and the file #ESP_OUT.TXT.
Chapter 11: Create Hierarchical Netlist

**Processing Options**

You may select any combination of the following options:

- **Quiet mode**
  
  Turns quiet mode on.

- **Descend into sheet path parts**
  
  Tells INET to descend into parts defined as sheetpath parts. That is, it treats a sheetpath part as a sheet. This option, while designed for complex hierarchies, may be used in simple hierarchies. It is not recommended to be used except for FPGA, ASIC, or other designs that require a complex hierarchy.

- **Assign a net name to all pins**
  
  Tells INET to assign a net name to all pins, including unconnected ones.

- **Report off-grid parts**
  
  Tells INET to check the worksheet for parts, sheets, labels, module ports, and power objects that are off-grid.

- **Report all connected labels and parts**
  
  Tells INET to report all connected labels and module ports.

- **Report unconnected wires, pins, module ports**
  
  Tells INET to report all unconnected wires, pins, and module ports.

- **Run ERC on all sheets processed**
  
  Runs an electrical rules check on all sheets that INET processes. This is the same process provided by the Check Electrical Rules tool.
☐ Do not report warnings

This option is available if you select the Run ERC on all sheets processed option. It tells INET to not test some of the conditions for which it normally issues warnings. The conditions are:

- Two power objects connected
- Single node nets
- Input signals without a driving source

These conditions are always checked—unless you select the Do not report warnings option—and cannot be changed with the Check Electrical Rules Matrix.

Use this option with caution. You may end up with a netlist containing conditions that are not acceptable.

☐ Check module port connections

Tells INET to check all module ports for correctness after tests and processing are completed.

☐ Rebuild file stack

Tells INET to rebuild the file stack that is used to determine the sheets that are in the incremental connectivity database. This file stack speeds the processing of the database when incremental updates occur. It may be viewed, but should not be modified. The file stack is given a .INX extension.

☐ Unconditionally process all sheets in design

Tells INET to ignore the incremental aspect of normal connectivity database processing. All sheets in the design are recompiled, even if the current database is up-to-date.
Chapter 11: Create Hierarchical Netlist

- Do NOT create .INF files (report only)
  
  When processing the design, you may wish to leave the incremental connectivity database unchanged and only review the reports. This option causes all checks to be run and reports to be created, but does not update the incremental connectivity database.

- Process one sheet only (This forces Rebuild file stack on the next run)
  
  Tells INET to produce an incremental connectivity database for a single sheet in a design. This option is useful for troubleshooting netlist problems. The next time INET runs, it will also rebuild the file stack used to determine the sheets that are in an incremental connectivity database.

- Ignore warnings
  
  Causes INET to continue running when it encounters warnings, instead of halting in the middle of execution.
Local Configuration of HFORM

With the Schematic Design Tools screen displayed, select Create Hierarchical Netlist. Select Local Configuration from the menu that displays. Select Configure HFORM. A configuration screen displays (figure 11-2).

![Configuration screen](image)

Figure 11-2. HFORM's local configuration screen.

File Options

File Options defines the source and destination files.

Source

The Source is the root file of the design, without an extension. It may have any valid pathname.

Destination 1

Destination 1 is the destination file for the formatted netlist file created by HFORM. If a filename is not provided, its netlist is sent to the screen.

Destination 2

Some netlist formats produce two destination files. Destination 2 specifies the second destination file. If a filename is not provided and the format produces a second destination file, the file is sent to the screen.
Chapter 11: Create Hierarchical Netlist

Processing Options

The Format prefix/wildcard entry box is the path from which formatting files are displayed in the Hierarchical Netlist Format list box. It also provides a filter to selectively display files from the given directory. The filter defaults to *.CH, which displays only valid hierarchical formatter files. The desired netlist format file is selected by clicking its name in the list box or by typing its name in the Selected Format entry box. If the formatter name is typed into the Selected Format entry box, the path in the Format prefix/wildcard entry box must still be valid.

You may select any combination of the following options:

- Quiet mode
  Turns quiet mode on.

- Force HFORM to always create a formatted netlist
  Tells HFORM to create a formatted netlist, even if the database indicates the current format is up-to-date.

- Ignore warnings
  Tells HFORM to exit normally rather than with a warning, if warnings are issued, but there are no errors.

Format Specific Options

Schematic Design Tools provides formatters to create netlists in different formats. When a format is selected from the Netlist Format list box, its formatting options are displayed in this area. Appendix B: Netlist formats explains each of the formats and any available options.

You may write your own hierarchical netlist formats and have them appear in the Hierarchical Netlist Format list box, along with the ones supplied by OrCAD. Additionally, you can provide up to six check box options for your netlist format. Appendix D: Creating custom netlist formats explains this process.
**Select Field View**

**Execution**

Select Field View scan a design or a single sheet and changes the visible attribute of the specified field.

**Running Select Field View**

Select Select Field View from the Schematic Design Tools screen. Select Execute from the menu that displays.

When the specified field attributes are changed, the Schematic Design Tools screen displays.

**Local Configuration**

With the Schematic Design Tools screen displayed, select Select Field View. Select Local Configuration from the menu that displays.

Select Configure FLDATTRB. A configuration screen displays (figure 12-1).

![Figure 12-1. Select Field View's local configuration screen.](image)
### File Options

**File Options** defines the source file and its type.

**Source**

The **Source** is the file on which **Select Field View** operates. It may have any valid pathname.

After entering the source, select one of the following options:

- **Source file is the root of the design**
  
  Specifies that the source file is the root sheet name of a hierarchical or flat design. If the root sheet contains sheet symbols, then the design is hierarchical. If it contains a Link, it is a flat design.

- **Source file is a single sheet**
  
  Specifies that the source file is a single worksheet and you want to process the single sheet only.

### Processing Options

Select one of the following options to define which visible attribute is to be changed:

- **Reference**
- **Part Value**
- **Part Field 1**
- **Part Field 2**
- **Part Field 3**
- **Part Field 4**
- **Part Field 5**
- **Part Field 6**
- **Part Field 7**
- **Part Field 8**

If desired, select the following:

- **Quiet mode**
  
  Turns quiet mode on.

Select an option to set the field’s visibility attribute:

- **Set specified field to visible**
- **Set specified field to invisible**
Select either or both of the following:

- **Unconditionally set attribute**
  
  All parts attributes are affected when this option is selected, regardless of the current contents of the field. When this option is not selected, only those parts with information in the field are affected.

- **Ignore warnings**
  
  Causes **Set Field View** to continue running when it encounters warnings, instead of halting.
**Update Field Contents**

**Execution**

Update Field Contents loads information you define into the fields of parts on a specified schematic.

Update Field Contents constructs a string from the key field designators for a specified field. Then, if that string equals a match string in a designated update file, it replaces the specified field with the update value.

**Running Update Field Contents**

With the Schematic Design Tools screen displayed, select Update Field Contents. Select Execute from the menu that displays.

When the specified field contents are changed, the Schematic Design Tools screen displays again.

**Update file format**

Update Field Contents requires an update file. You create this text file using a text editor.

The update file is composed of a list of strings. Strings are delimited with single quotes. The strings are separated with any number of space, tab, or return characters. A string may not contain a single quote.

The first string serves as the match string. The second string is its corresponding update field. The third string is another match string; the fourth, its corresponding update field, and so on.

Figure 13-1 shows an example of a typical update file. To improve readability, typically a match string and its corresponding update field are placed on the same line.
In figure 13-1, match strings are in the left column and their corresponding update fields are in the right column. For example, 74ls00 is a match string; its corresponding update field is 14DIP300.

| '74ls00' | '14DIP300' |
| '74ls138' | '16DIP300' |
| '74ls163' | '16DIP300' |
| '74ls373' | '20DIP300' |
| '8259a' | '28DIP600' |

Figure 13-1. Typical update file.

If the update file is too large, Update Field Contents does not modify the schematic file. Instead, it suggests that you split your update file into smaller update files and then rerun Update Field Contents with each of the new update files.
Local Configuration

With the Schematic Design Tools screen displayed, select Update Field Contents. Select Local Configuration from the menu that displays.

Select Configure FLDSTUFF. A configuration screen displays (figure 13-2).

![Configuration Field Contents]

Figure 13-2. Local configuration screen for Update Field Contents.
**File Options**  
File Options defines the source file and its type. It also defines the update file.

**Source**  
The Source is the root of the design or the filename of a single sheet. It may have any valid pathname. After entering the source filename, select one of the following options:

- Source file is the root of the design  
  Specifies that the source file is the root sheet name of a hierarchical or flat design. If the root sheet contains sheet symbols, then the design is hierarchical. If the root sheet contains a \Link pipe command, it is a flat design.

- Source file is a single sheet  
  Specifies that the source file is a single worksheet and you want to process the single sheet only.

**Update-file**  
The Update-file is the name of a text file that you create. It is described at the beginning of this chapter.

**Processing Options**  
Select one of the following options to define which field is to be updated:

- Part Value
- Part Field 1
- Part Field 2
- Part Field 3
- Part Field 4
- Part Field 5
- Part Field 6
- Part Field 7
- Part Field 8

The field parameter selected above also identifies a key field designator. Update Field Contents has nine key field designators, one for the part’s value, and one for each of the eight part fields. They are shown on the Configure Schematic Design Tools screen as shown in figure 13-3.
Update Field Contents constructs a string from the key field designator set up for the field parameter selected. For example, if you select "Part Field 3" and the Update Field Contents Combine for Field 3 is V 2, then Update Field Contents constructs a string consisting of the part's value, a space, and Part Field 2.

Update Field Contents then tries to match that string with the match strings listed in the update file. Each match string has a corresponding update field. If a match is found, Update Field Contents replaces the contents of the field parameter (selected above) with the corresponding update field.

For more information about key fields, see Chapter 1: Configure Schematic Tools.

Figure 13-3. Key field designators for Update Field Contents.
Processing Options

Select any combination of the following options:

☐ Quiet mode
  
  Turns quiet mode on.

☐ Create an update report
  
  Creates a report listing all the parts on each sheet and whether a field is updated for each part. If this option is selected, the Destination entry box is used to specify where the report is written.

☐ Unconditionally update field (Normally stuffed only if empty)
  
  Unconditionally changes the specified field. By default, a field is only updated if it is empty. That is, fields with values already in them are not updated.

Select one of the following to indicate whether you want the updated field to be visible, invisible, or to stay in its current state:

☐ Leave visibility of specified field unaltered

☐ Set specified field to visible

☐ Set specified field to invisible

Select either or both of these options:

☐ Convert match string to uppercase

☐ Ignore warnings
  
  Causes Update Field Contents to continue running when it encounters warnings, instead of halting.
Included with Schematic Design Tools are extensive part libraries containing more than 20,000 of the most commonly used devices in the electronics industry. These OrCAD-supplied libraries include many parts used in many types of schematic designs, so for most design work, OrCAD libraries contain all the parts you need. Sometimes, though, you may want to create your own custom parts that meet special requirements in a particular design.

Part IV describes library parts, library part files, and the librarian tools used to create and maintain your own custom parts.

Chapter 14: About libraries introduces the two forms of a library file: library source files and compiled library files. This chapter also describes two ways to edit a library part and lists the basic components of a part.

Chapter 15: List Library describes how to list a library's contents with List Library.

Chapter 16: Archive Parts in Schematic describes how to use Archive Parts in Schematic to make a library source file or a library string file containing only those parts used in a particular schematic worksheet.

Chapter 17: Edit Library describes the Edit Library graphical part editor and its commands.

Chapter 18: Decompile Library describes how Decompile Library converts a compiled library file into a library source file.

Chapter 19: Creating a library source file with a text editor describes, in detail, how to create a library source file with a text editor.

Chapter 20: Symbol Description Language explains how to define a part in a custom library using OrCAD’s Symbol Description Language (SDL).

Chapter 21: Compile Library describes how Compile Library converts a library source file into a compiled library file.
CHAPTER 14

About libraries

This chapter introduces library files and library parts. It describes the two forms of a library file, two ways to create library files, and the components of a library part.

Library files

Libraries are used to group and organize the more than 20,000 parts supplied with Schematic Design Tools.

Parts in a particular library have common characteristics, such as parts produced by one manufacturer, parts with a common application, or parts in a family. Some examples are: TTL.LIB, INTEL.LIB, ANALOG.LIB, PCBDEV.LIB, or PLDGATES.LIB.

Some libraries contain hundreds of parts; some contain just a few. Schematic Design Tools includes many libraries.

The libraries have been created over time. Old parts are not deleted because you may want to look at a design containing an old part. Also, some pre-release parts (from various manufacturers) are included.

Library files come in two forms: library source files and compiled library files.
Library source file  A library source file is much like the source code for a computer program. It is a text file containing instructions in the OrCAD’s Symbol Description Language, which is described in Chapter 20: Symbol Description Language. These instructions specify how to represent a part graphically.

You can create and modify a library source file with the Edit File editor. You then run the tool called Compile Library on the library source file to produce a compiled library file.

Decompile Library and Archive Parts in Schematic tools can also produce library source files. For details on Compile Library, Decompile Library, and Archive Parts in Schematic, see chapters 21, 18, and 16, respectively.

Compiled library file  A compiled library file is the compiled version of a library source file. This type of file is produced by Compile Library or the Edit Library graphical part editor (described in chapter 17). This is the type of library file the schematic editor, processors, reporters and transfer tools can read. A compiled library file takes much less disk space than its corresponding library source file and is faster to load and access.

By convention, the names of compiled library files have .LIB as the file extension. For example, MOTO.LIB is the name of the OrCAD-supplied library of Motorola components. Also, by convention, library source files have a .SRC file extension. Note, however, the .LIB and .SRC extensions are conventions, not requirements.

When you configure Schematic Design Tools, you specify which of the compiled libraries are loaded when you run a schematic editor, processor, reporter or transfer tool. For details, see Chapter 1: Configure Schematic Tools.

NOTE: Libraries can be loaded into main system memory (RAM), EMS memory, or your disk. See Chapter 1: Configure Schematic Tools for details.
You may have parts with the same name in different libraries. If you do and these libraries are selected during configuration, when Draft looks for a part, it searches the libraries in the order that they are listed in the Configured Libraries list box on the Configure Schematic Design Tools screen. The first part Draft finds with that name is the part Draft gets.

**List parts in a library**

You can view the names of the parts in a library using the List Library tool. For example, one of the OrCAD libraries is called TTL.LIB. To find out what parts are in this library, follow these steps:

1. Display List Library's local configuration screen.
2. Select a library from the list shown in the Files list box. Click on its name or type its name in the Source text entry box.
3. Click OK.
4. Double-click on List Library.

List Library displays a list of the part names in TTL.LIB in the window at the bottom of the screen. You can also tell List Library to send its output to a file instead of the screen. For details on List Library, see Chapter 15.

**Creating library files**

There are two ways to create your own custom libraries or modify existing libraries.

**CAUTION:** Avoid changing parts and saving them in libraries with the same names as OrCAD libraries. Instead, create your own custom libraries with unique names. This way you can avoid the risk of losing your parts when OrCAD updates the libraries in the future.
Edit Library  One way is to use Edit Library, a graphical part editor. With Edit Library, you use commands similar to Draft’s to construct or modify a part graphically and add it to a new or existing library. The part being edited appears on Edit Library’s screen exactly as it will appear when you place it on a schematic worksheet with Draft. Edit Library automatically converts the graphical screen symbols to the compiled format the schematic editor, processors, reporters, and transfer tools use.

You can use OrCAD libraries as the starting point for your own custom libraries. Make a copy of the OrCAD library file and then modify the parts with Edit Library. Chapter 17 describes Edit Library.

Text editor  Another way to create a custom library is using a text editor. You create a library source file, then run Compile Library on it to produce a compiled library file. Library source files are described in chapter 19. Compile Library is described in chapter 21.

Figure 14-1 shows the development process using Compile Library to create a custom part library.

![Diagram](image)

Figure 14-1. How to use Compile Library to develop a library.
You can also use OrCAD libraries as the starting point for your custom library. Select a library file, convert it to source form using Decompile Library, and then edit it using Edit File. When you are done editing, compile the file using Compile Library. Figure 14-2 shows this process.

Figure 14-2. How to use Decompile Library and Compile Library together to develop a library.
Whether you use Edit Library or a text editor along with Compile Library and Decompile Library, you build library parts from the same basic components.

A library part is made up of the following components:

- Body
- Pins
- One or more names
- An optional sheetpath designator
- An optional reference designator
- Optional text

These components are described on the next pages.

**Body**

Every part has either a block, a graphic, or an IEEE body.

**Block**

A block part is one whose body is a square or rectangle. For example, a memory chip is a block part. Figure 14-3 shows examples of parts with block bodies. A block part can be up to 12.7 inches by 12.7 inches in size.

![Figure 14-3. Parts with block bodies.](image-url)
Chapter 14: About libraries

**Graphic** A graphic part is one whose body contains graphical information such as circles, arcs, and filled areas. It may also contain lines and text. A graphic part can be a simple square or rectangle, or it can be something more complex, such as an OR gate. A graphic part has no visible pin names.

If your part is larger than 1.2 inches by 1.2 inches, it must be an IEEE part (rather than a graphic part). However, if a graphic part's X axis is less than 1.2 inches, its Y axis can be larger than 1.2 inches, and vice versa. Think of it as a rubber band . . . if you stretch it in one direction, it thins out in the other.

Figure 14-3 shows examples of parts with graphic bodies.

![Figure 14-3. Parts with graphic bodies.](image)

**IEEE** An IEEE part is one that complies with the ANSI/IEEE standard. IEEE parts differ from graphic parts in that they may not contain arcs or fills, and they may be larger. You must always create an IEEE part (rather than a graphic part) if the part will be larger than 1.2 by 1.2 inches. An IEEE part can be up to 12.7 inches by 12.7 inches in size.

---

1 See ANSI/IEEE Std 91-1984: *IEEE Standard Graphic Symbols for Logic Functions*, © 1984, or *Graphic Symbols for Electrical and Electronics Diagrams*, © 1975; both published by The Institute of Electrical and Electronics Engineers, Inc.
Pins

Each pin has a type, a shape, a name, and possibly a number.

Pin type

Pin types are:

- Input
- Output
- Bidirectional
- Power
- Passive
- 3 state
- Open collector
- Open emitter

A pin can have only one type. Pin type is not apparent from the representation of the part on the screen. Power pins are invisible.

Pin shape

The pin shape determines how the pin appears. A pin can have either a normal or a short lead. A normal lead can also have a clock symbol and an inversion bubble (called a dot); a short lead cannot.

The figure above shows a part with each type of pin shape. A clock symbol is shown as a “>” on the lead. An inversion bubble, or dot, is shown as a circle on the lead.

Pin number

If the part has pin numbers they appear outside the part beside the pins. Figures 14-3 and 14-4 show parts with pin numbers.

Pin name

The pin name is associated with the pin function. For example, A0 represents an address line, and CLR represents the clear function. In Block parts, pin names appear inside the part beside the pins. In IEEE parts, pin names appear outside the body of the part near the pin when the part is viewed using Edit Library; however, the IEEE part’s pin names do not display in Draft, nor will they print or plot. Graphic parts do not display pin names. They are, however, stored with the part.
Chapter 14: About libraries

Names

A part has one or more names. Parts with identical symbols are represented in a library as one part with multiple names. For example, 2114, 2146, and 2149 identify the same symbol and represent a 1K x 4 static RAM.

Sheetpath designator

A sheetpath designator is a filename referencing a schematic file that is used as a part. As such, a sheetpath part should be saved in the library directory so it can be used in any schematic.

The sheetpath designator is optional. Sheetpath designators provide a higher level of abstraction for the circuit under construction and are useful for frequently used circuits of macro functions, such as gate arrays or FPGAs.

Reference designator

The reference designator specifies the default reference used when the part is first placed on a worksheet with Draft.

The prefix of the reference designator represents the class of the part. For example, U is normally used for ICs, Q is for transistors, C is for capacitors, and R is for resistors. The reference designator is optional and will default to "U" if one is not specified.
List Library

Execution

List Library lists the names of the parts in a library. The list can be shown on the screen or sent to a text file you view using Edit File.

Running List Library

With the Schematic Design Tools screen displayed, select List Library. Select Execute from the menu that displays.

- If a destination is not specified on List Library's configuration screen, the parts are listed in the monitor box at the bottom of the screen. If the report is configured to report the total number of devices in the library, the parts are not listed (See Local Configuration in this chapter).

- If a destination is specified on List Library's configuration screen, use the Edit File editor to view the file created by List Library.

When List Library is complete, the Schematic Design Tools screen appears again.

Figure 15-1 shows a sample of one kind of list produced by List Library. Follow the prefix column down to the number on the left that corresponds to the library part you want. Two asterisks (**) mean the part is in the library you listed. Two periods (..) mean the part is not in the library you listed.
For example, follow the column under "74AS" down to the "04" row. The double asterisks means the part 74AS04 is in the TTL.LIB library.

Local Configuration

With the Schematic Design Tools screen displayed, select List Library. Select Local Configuration from the menu that appears.

Select Configure List Library. A configuration screen displays (figure 15-2).
Chapter 15: List Library

**File Options**

File Options tells the library to be listed and the destination of the output.

**Prefix/Wildcard**

Enter a pathname and wildcard to indicate which files to display in the list box with scroll buttons. The asterisk character (*) is used as a wildcard.

The default is:

```
\ORCADESP\SDT\LIBRARY\*.LIB
```

If you erase the entire field, the entry is restored to the prefix specified in Configure Schematic Design Tools.

**Files**

The files that match the search filter entered in the Prefix/Wildcard entry box and those that match the filter in the current design directory are listed in this box. Files in the current directory are shown with \ before their names. Use the scroll buttons at the right of the box to scroll the list of libraries up and down.

When you see the library you would like to list, select it. Its path and filename display in the Source entry box.

**Source**

The Source names an existing compiled library file.

Specify the source file by selecting it from the list box or by simply entering its name in the Source entry box.

**Destination**

The Destination is any valid pathname and is where the list is placed. If you name an existing file, when you run List Library, it asks if you want to overwrite the existing file. You cannot append to an existing file.

If a Destination is not specified, the output displays in the monitor box at the bottom of the screen.
NOTE: A question mark (?) in an entry box tells ESP to default to the Startup Design name. This simplifies changing between designs: all you need do is change the Startup Design on the Configure ESP screen, exit ESP, then restart ESP by entering ORCAD.

For example, if you enter ?.LIB in the Source entry box and the Startup Design is configured as “TUTOR,” the next time you look at the local configuration, the Source entry box will be configured as “TUTOR.LIB.” If you then change the Startup Design to “DESIGN2” and restart ESP, the Source entry box will be configured as “DESIGN2.LIB.”

Processing Options

You may select any combination of the following options:

- Quiet mode
  
  Turns quiet mode on.

- Report the total number of devices in the library

  Causes List Library to simply report how many parts are in the library, rather than create a list of parts.

- Output is a string file

  Causes List Library to list the names of the parts in the design in string file format. String files are used to create libraries with Compile Library.

  String files can be used to create libraries with a subset of parts, or as the “left” column of a stuff file.

  Below is an example of a short string file:

  ```
  'GND'
  '74LS00'
  'RESISTOR'
  'SW SPDT'
  ```
Archive Parts in Schematic

Execution

Archive Parts in Schematic takes all the library parts used in a set of schematic files and makes a library source file or a library string file containing only those parts used in the schematic files.

The Archive Parts in Schematic tool scans a design or a single sheet.

Running Archive Parts in Schematic

With the Schematic Design Tools screen displayed, select Archive Parts in Schematic. Select Execute from the menu that displays.

The monitor box at the bottom of the screen displays messages while Archive Parts in Schematic creates the source file or the string file.

When Archive Parts in Schematic is complete, the Schematic Design Tools screen appears. You may look at the file created by Archive Parts in Schematic using a text editor.
Local Configuration

With the Schematic Design Tools screen displayed, select Archive Parts in Schematic. Select Local Configuration from the menu that displays. The menu below displays.

**Archive Parts in Schematic** is a two-process function. The first process is called **LIBARCH**. **LIBARCH** builds a library of all the components in the design or sheet.

The second process, called **COMPOSER**, compiles the source file produced by **LIBARCH** into a form usable by the schematic editor, processors, reporters, and transfer tools. Each of the two processes can be configured and each can be turned on and off.

To configure **LIBARCH**, follow the instructions in the Configure LIBARCH section on the next page.

To configure **COMPOSER**, see the Configure COMPOSER section in this chapter or the Local Configuration section of Chapter 21: Compile Library.

If you want to run both tools at the same time, leave both **LIBARCH** and **COMPOSER** on. Otherwise, set **LIBARCH** to on, and **COMPOSER** to off.
Select Configure LIBARCH. A configuration screen appears (figure 16-1).

![Configure Library Archive Screen](image)

**Figure 16-1. Archive Parts in Schematic's local configuration screen.**

**File Options** defines the source filename and its type. It also defines the destination filename and its type.

**Source**

The **Source** may be the root sheet name of a hierarchical or flat design, the filename of a one-sheet file, or a string file. If a pathname is not given, **Archive Parts in Schematic** looks for the file in the current design directory.

**NOTE:** A question mark (?) in an entry box tells ESP to default to the **Startup Design** name. This simplifies changing between designs: All you need do is change the **Startup Design** on the Configure ESP screen, exit ESP, then restart ESP by entering ORCAD.

For example, if you enter ? SCH in the **Source** entry box and the **Startup Design** is configured as "TUTOR," the next time you look at the local configuration, the **Source** entry box will be configured as "TUTOR.SCH." If you then change your **Startup Design** to "DESIGN2" and restart ESP, the **Source** entry box will be configured as "DESIGN2.SCH."
After entering the source filename, select one of the following options:

- **Source file is the root of the design**
  
  Specifies that the design consists of more than one worksheet. If the root sheet contains sheet symbols, the design is a hierarchy. If the root sheet contains `|LINK` followed by a list of files, the design is flat.

- **Source file is a single sheet**
  
  Specifies that the source file is a single worksheet and you want to process the single sheet only.

- **Source file is a string file**
  
  Specifies that the source file is a string file. Archive Parts in Schematic creates a library source file containing the parts listed in the string file.

  You can create a string file from a design by running Archive Parts in Schematic with the Output is a string file option selected in the tool’s local configuration.

  To create a special library with the string file output of Archive Parts in Schematic, run the tool again on the string file created the first time you ran Archive Parts in Schematic. This time, make the output a library file, and the source the string file you created the first time you ran Archive Parts in Schematic.

**Destination**

The Destination is any valid path and filename and is where the library source file or string file is placed. If a filename is given without a pathname, Archive Parts in Schematic places the resulting library source file or string file in the current design directory. The default name for the file is `design.SRC`, where `design` is the name of the current design.

If Destination is not specified, the output is directed to the monitor box at the bottom of the screen. If the destination is the name of an existing file, Archive Parts in Schematic asks if you want to overwrite the existing file.
After entering the destination filename, select one of the following options:

- **Output is a library source file**
  
  Tells *Archive Parts in Schematic* to make a source file (a text file describing the parts using OrCAD's Symbol Description Language).

- **Output is a string file**
  
  Tells *Archive Parts in Schematic* to make a string file. A string file is a text file consisting of the names of all the parts used in a schematic file. The names are delimited with single quotes and each appears on a separate line. A string file can be used to create an include file for the *Create Bill of Materials* reporter, or to create a file to be used to create a special library.

To create a special library with the string file output of *Archive Parts in Schematic*, run the tool again on the string file created the first time you ran *Archive Parts in Schematic*. This time, make the output a library file, and the source the string file you created the first time you ran *Archive Parts in Schematic*.

**Processing Options**

You may select any combination of the following options:

- **Quiet mode**
  
  Turns quiet mode on.

- **Descend into sheetpath parts**
  
  Tells *Archive Parts in Schematic* to descend into any parts defined as sheetpath parts. Without this option selected, *Archive Parts in Schematic* treats the sheetpath itself as a part to be archived and does not archive the parts within a sheetpath.

- **Ignore warnings**
  
  Causes *Archive Parts in Schematic* to continue running when it encounters warnings, instead of halting in the middle of execution.
Select Configure COMPOSER. A configuration screen appears (figure 16-2).

![Configuration screen for Compile Library.](image)

**File Options**

File Options defines the library source file and the resulting library file.

**Prefix/Wildcard**

Enter a pathname and wildcard to indicate which files to display in the list box with scroll buttons. The asterisk character (*) is used as a wildcard.

The default is:

```
\ORCADESP\SDT\LIBRARY\*.SRC
```

If you do not specify a prefix, Compile Library looks for files in the current design directory.

If you erase the entire field, the entry will be restored to whatever prefix is specified in Configure Schematic Design Tools.
Chapter 16: Archive Parts in Schematic

Files
The files that match the search filter entered in the Prefix/Wildcard entry box and those that match the filter in the current design directory are listed in this box. Files in the current directory are shown with \ before their names. Use the scroll buttons to scroll the list of files up and down.

When you see the file you would like to compile, select it. Its filename displays in the Source entry box.

Source
The Source is the text file describing your custom parts using OrCAD's Symbol Description Language. The default is the file design.SRC, where design is the name of the current design. The convention is to name source file with .SRC extensions, although this is not a requirement.

Specify the source file by selecting it from the list box described above, or enter its name by simply typing it in this entry box and pressing <Enter>.

NOTE: A question mark (?) in an entry box tells ESP to default to the Startup Design name. This simplifies changing between designs: all you need do is change the Startup Design on the Configure ESP screen, exit ESP, then restart ESP by entering ORCAD.

For example, if you enter ?.SRC in the Source entry box and the Startup Design is configured as “TUTOR,” the next time you look at the local configuration, the Source entry box will be configured as “TUTOR.SRC.” If you then change the Startup Design to “DESIGN2” and restart ESP, the Source entry box will be configured as “DESIGN2.SRC.”

Destination
The Destination is the library file to be created by Compile Library. If you give the name of an existing file, Compile Library asks if you want to overwrite the existing file. You cannot append to an existing file. The default destination is design.LIB, where design is the name of the current design.

Destination may be a complete pathname.
Processing Options

Select either or both of the following options:

- **Quiet mode**
  
  Turns quiet mode on.

- **Do not sort library**
  
  Tells Compile Library to save parts in the source file in the order they were entered (rather than sorting them alphabetically, which is the default).
Edit Library is a graphical part editor used to create and edit library parts. This chapter describes how to configure and run Edit Library, tells how Edit Library uses bitmaps and vectors, and lists some part limitations you should consider when using Edit Library. A detailed description of the Edit Library commands is given in the Command Reference section in this chapter.

Use Edit Library to:

- Create a new part and add it to an existing or a new library.

- Create a part similar, but not identical, to a part in an OrCAD library. You run Edit Library, get the similar part, write it out to a new or existing library, edit it, and then save the changes to the library.

- Modify an existing part in an existing library.

See Chapter 5: Creating a custom component in the Schematic Design Tools User's Guide for an example that shows how to use Edit Library to create a new part and add it to an existing library file.
CAUTION: Avoid changing parts and saving them in libraries with the same names as OrCAD libraries. Instead, create your own custom libraries with unique names. This way you can avoid losing your parts when OrCAD updates the libraries.

To modify parts in one of OrCAD's libraries, extract the parts (using GET PART), export them to a temporary data file, import the data from the temporary data file into a custom library, edit the parts' definitions, and then write them to the custom library.

**Bitmaps and vectors**

The body of a library part can be defined in vector form and bitmap form. Edit Library only reads the vector description of a part. Before you use Edit Library, you should become familiar with vectors and bitmaps and how Edit Library uses them.

A vector is a set of numbers that describe the starting and ending coordinates, size, and so on, of a graphic object. For example, the following vector describes a straight line:

```
LINE +1.0 +2.0 +1.0 +4.0
```

The first two numbers (+1.0, +2.0) are the X and Y coordinates of the beginning of the line. The second two numbers (+1.0, +4.0) are the X and Y coordinates of the end of the line. Circles, arcs, and text can be specified in a similar way.

Although vectors are a precise way to specify graphic objects, bitmaps are a faster way to send the objects to a screen or printer. A bitmap is a set of bits in memory correlating to pixels on a screen or dots on a printer. A bitmap tells which pixels to "turn on" on a screen and which dots to print on a printer. Unlike vectors, bitmaps require little processing before being displayed or printed.
NOTE: A disadvantage of bitmaps is that a bitmap of a large object requires a lot of memory. This is true even if most of the pixels are not used.

IEEE parts are represented by vectors. Although the main purpose for IEEE type parts is to support drawing to the IEEE standard, IEEE type parts are also useful for handling parts that are not practical as bitmaps.

If you use Edit Library to create or edit a part and then write it out to a library, the part is stored in both vector and bitmap form. The bitmap description is used by Draft and Print Schematic to bypass the time-consuming process of converting vectors to bitmaps. The vector description is used by Plot Schematic to produce high quality plots.

CAUTION: Although the parts in the OrCAD libraries use bitmap and vector definitions, parts in other libraries may not use vectors. Be careful when using Edit Library to edit a part without a vector description. If you do, you will not see the part's shape on the screen. The bitmap defining the shape is still there, but Edit Library is not designed to read bitmaps. If you write the part back to the library with the LIBRARY Update Current command followed by QUIT Update or QUIT Write, you save the part as it appears on the screen—that is, without a body. You lose the bitmap.

If you're not sure whether a part has a vector definition, run Decompile Library on the library file containing the part. Then use a text editor to look at the library source file produced by Decompile Library. If the part has a vector definition, it always appears at the end of the part's definition.

To create or edit a part in a library, follow these steps:

1. Select Edit Library's Local Configuration option. Select the library to edit from the Files list box. If you want to create a new library, enter its name in the Source text entry box.

2. Run Edit Library. Edit Library reads the library file into memory or creates the new one you named. This is not necessary if you are creating a new library.
3. Retrieve a part with the GET PART command and edit it. The changes you make are stored in a temporary work area; the copy of the library in memory remains unchanged.

<table>
<thead>
<tr>
<th>Work area</th>
<th>Edit Part keeps the part you are working on in a temporary memory location.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Library buffer</td>
<td>Using the LIBRARY Update Current command moves the part from the temporary work area to this buffer.</td>
</tr>
<tr>
<td>Disk storage</td>
<td>Using the QUIT Update File command writes the contents of the buffer to disk.</td>
</tr>
</tbody>
</table>

4. Select the LIBRARY Update Current command. The copy of the library in memory gets the new or modified part. You could instead decide to create an export file and not modify the library (See the Export command description in this chapter).

5. Select the QUIT Update File command (saves the modified library to the same file) or QUIT Write to File command (saves the entire modified library to a new file you specify).

Issuing either of these commands without previously issuing LIBRARY Update Current results in no modification to the library, even if you have retrieved and modified or constructed a part.

⚠️ CAUTION: Update the library using the LIBRARY Update Current command before you select QUIT Update File or QUIT Write to File or the current part will be lost.

It is often convenient to create a new part by editing an existing part. To do this, follow these steps:

1. Get the part.

2. Use the Name Add command to give it the new name. Use the Name Delete command to delete the old name. Do this before other editing to protect the old part from being overwritten.
Chapter 17: Edit Library

3. Edit the part using Edit Library’s commands.
4. Select LIBRARY Update Current and QUIT Update File as needed.

Limit on a part’s complexity

Using Edit Library, you construct a part from lines, arcs, circles, and so on. Each part has a maximum number of such elements allowed. The limit is for each part body; that is, the limit for a normal part is distinct from the limit for its converted form. Also, the limit does not depend on the number of parts per package.

For example, consider a part with four parts per package and a converted form. There are two limits pertinent for this part, one for the normal version and one for the converted form version. If you edit the part so it has only two parts per package, the limits do not change.

The limits for graphic parts are as follows:

<table>
<thead>
<tr>
<th>Object</th>
<th>Limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lines</td>
<td>127</td>
</tr>
<tr>
<td>Circles</td>
<td>127. The IEEE symbol ⊖ (negation) counts as a circle</td>
</tr>
<tr>
<td>Text</td>
<td>255 strings. Each string has a maximum of 10 characters</td>
</tr>
<tr>
<td>Arcs</td>
<td>63</td>
</tr>
<tr>
<td>Fills</td>
<td>31</td>
</tr>
</tbody>
</table>

IEEE parts are constructed in an area of 4096 bytes. The number of bytes required for each type of object are:

<table>
<thead>
<tr>
<th>Object</th>
<th>Bytes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lines</td>
<td>9</td>
</tr>
<tr>
<td>Circles</td>
<td>8</td>
</tr>
<tr>
<td>IEEE Symbols</td>
<td>8</td>
</tr>
<tr>
<td>Text</td>
<td>7 + length of text (8–17)</td>
</tr>
</tbody>
</table>
Hence, the total number of objects within an IEEE part is dependent on the mixture of the different type of objects in the part. At most, an IEEE part can have:

- **Lines**: \( \frac{4096}{9} = 455 \)
- **Circles**: \( \frac{4096}{8} = 512 \)
- **IEEE Symbols**: \( \frac{4096}{8} = 512 \)
- **Text**: \( \frac{4096}{8^{17}} = 512-240 \)

### Limit of total library size
Each library consists of several parts, each of which occupies its own block in memory. Each block can occupy up to 65536 bytes. As you add parts to the library, you may fill one of these blocks. At this point, the library is full. As you approach the memory limit, Edit Library displays a warning message so you do not lose any work. For information about checking the amount of remaining memory in these blocks, see the **CONDITIONS** command later in this chapter.

### Execution
With the Schematic Design Tools screen displayed, select Edit Library. Select Execute from the menu that displays.

Edit Library's work area displays. Press <Enter> to display Edit Library's main menu. These commands and the menus and commands accessed by the main menu commands are described in the **Command reference** section in this chapter.

When you are finished editing library parts and leave the Edit Library tool, the Schematic Design Tools screen appears.
Chapter 17: Edit Library

Local Configuration

With the Schematic Design Tools screen displayed, select Edit Library. Select Local Configuration from the menu that displays.

Select Configure LIBEDIT. Edit Library's configuration screen appears (figure 17-1).

![Figure 17-1. Edit Library's local configuration screen.]

File Options

File Options defines a library for Edit Library to open.

Prefix/Wildcard

Enter a pathname and wildcard to indicate which files to display in the list box with scroll buttons. The asterisk character (*) is used as a wildcard.

The default is:

```
\ORCADESP\SDT\LIBRARY\*.LIB
```

If you erase the entire field, the entry will be restored to whatever prefix is specified in Configure Schematic Design Tools.
List box with scroll buttons

The files that match the search filter entered in the Prefix/Wildcard entry box and those that match the filter in the current design directory are listed in this box. Files in the current directory are shown with .\ before their names. Use the scroll buttons to scroll the list of libraries up and down.

When you see the library you would like to edit, click on it to select it. Its path and filename display in the Source entry box.

Source

The Source names a library file. The file can already exist, or you can enter a name for a new library here.

Specify Source by selecting a name from the list box, or enter a new name by simply typing it in this entry box and pressing <Enter>.

\triangle

NOTE: A question mark (?) in an entry box tells ESP to default to the Startup Design name. This simplifies changing between designs: all you need do is change the Startup Design on the Configure ESP screen, exit ESP, then restart ESP by entering ORCAD.

For example, if you enter ?.LIB in the Source entry box and the Startup Design is configured as “TUTOR,” the next time you look at the local configuration, the Source entry box will be configured as “TUTOR.LIB.” If you then change the Startup Design to “DESIGN2” and restart ESP, the Source entry box will be configured as “DESIGN2.LIB.”
Chapter 17: Edit Library

Processing Options

You may select any combination of the following options:

☐ Disable mouse

Disables the mouse. This option is normally used when attempting to debug mouse problems while working with OrCAD Technical Support. It may also be required when running on older PC-compatible systems.

☐ Disable <Print Screen> key function

Disables Edit Library’s <Print Screen> key function. Use this option when you run other applications (usually RAM-resident) that make use of the <Print Screen> key. If this option is not selected, Edit Library uses the <Print Screen> key to capture hardcopy output and blocks other uses.

☐ Decrease mouse sensitivity

Slows the mouse down. Used for mouse devices that are too sensitive. For example, if you move your mouse a small distance and the pointer moves a large distance on the screen, select this option to make the pointer movement respond more closely to the mouse movement.

☐ Reverse “Y” axis operation of mouse

Changes the way the mouse responds. If this option is selected, the pointer moves up when you pull the mouse toward you, and moves down when you push the mouse away from you.
Command reference

The remainder of this chapter is a command reference for Edit Library, the graphical parts editor. Commands are described in the order in which they appear in Edit Library's main menu.

Many commands in the main menu display other menus. The name of each main menu command appears at the top of the first page describing the command. Any other commands displayed by the main menu command are described with the main menu command.

You can find the description of a particular command two ways:

- If you know the main menu command that causes the command to appear, skim the pages describing the main menu command until you find the heading for the command below it.
- Look in the table of contents.

Some commands in the main menu also appear in several other menus. These commands (such as FIND, JUMP, and ZOOM) are described at the main menu level only. When a command occurs in another menu, see the main menu level description of the command for an explanation of its use.

Press the <Esc> key or click the right mouse button at any time to back out of a menu.

Selecting commands

Select Edit Library commands in one of two ways:

- Press the first letter of the command name. Do this when the command displays in a menu or in a command line at the top of the screen. Main menu commands can also be selected in this way when no menu displays. Occasionally a menu will have more than one command beginning with the same letter. When this happens, use the method of selecting commands explained below.

- Move the highlighted bar over the command name (using either the mouse or the arrow keys) and press <Enter> or click the left mouse button.
AGAIN

AGAIN repeats the last main menu command executed. For example, if the last command you selected is BODY, you may repeat BODY by selecting AGAIN.

AGAIN does not repeat commands from menus below the main menu. For example, if you execute a command in the BODY menu and then select AGAIN, the BODY menu displays, ready for you to select another BODY command.
BODY displays a menu used for drawing a part. Depending on previous settings, the BODY command displays one of three menus: the Block, Graphic, or IEEE menu (figure 17-2).

<table>
<thead>
<tr>
<th>BODY &lt;Block&gt;</th>
<th>BODY &lt;Graphic&gt;</th>
<th>BODY &lt;IEEE&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>Size of Body</td>
<td>Line</td>
<td>Line</td>
</tr>
<tr>
<td>Kind of Part</td>
<td>Circle</td>
<td>Circle</td>
</tr>
<tr>
<td></td>
<td>Arc</td>
<td>Text</td>
</tr>
<tr>
<td></td>
<td>Text</td>
<td>IEEE Symbol</td>
</tr>
<tr>
<td></td>
<td>IEEE Symbol</td>
<td>Delete</td>
</tr>
<tr>
<td></td>
<td>Fill</td>
<td>Erase Body</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Size of Body</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Kind of Part</td>
</tr>
</tbody>
</table>

Figure 17-2. BODY's Block, Graphic and IEEE menus.

You cannot mix the different types of objects. A part must be a block, a graphic, or an IEEE part. It cannot be a combination of any of these.

- A block part is one whose body is a square or rectangle. For example, a JK flip-flop is a Block part. A block part can be up to 12.7 inches by 12.7 inches.

- A graphic part is one whose body contains graphical information such as circles, arcs, and filled areas. It may also contain lines and text. A graphic part can be a simple square or rectangle, or it can be something more complex, such as an OR gate. A graphic part has no visible pin names.

If your part is larger than 1.2 inches by 1.2 inches, it must be drawn as an IEEE part (rather than a graphic part). However, if a graphic part's X axis is less than
1.2 inches, its Y axis can be larger than 1.2 inches, and vice versa. Think of it as a rubber band . . . if you stretch it in one direction, it thins out in the other.

• An IEEE is one that complies with the ANSI/IEEE standard. IEEE parts differ from graphic parts in that they may not contain arcs or fills, and they are typically larger. You must always create an IEEE part (rather than a graphic part) if the part will be larger than 1.2 by 1.2 inches. An IEEE part can be up to 12.7 by 12.7 inches.

NOTE: If Block, Graphic, or IEEE was not previously specified, Edit Library requests the kind of part as described below. Depending on whether you select Block, Graphic, or IEEE, different questions are asked. These questions are described on the next page.

BODY Kind of Part? The first time you select BODY, the menu shown at the right displays. You must tell Edit Library which type of part you want to edit. Select Block, Graphic, or IEEE.

---

2 See ANSI/IEEE Std 91-1984: IEEE Standard Graphic Symbols for Logic Functions, ©1984, or Graphic Symbols for Electrical and Electronics Diagrams, ©1975; both published by The Institute of Electrical and Electronics Engineers, Inc.
<table>
<thead>
<tr>
<th>BODY Kind of Part?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Block</strong></td>
<td>A block part is one whose body is a square or rectangle. For example, a JK flip-flop is a block part.</td>
</tr>
<tr>
<td><strong>Graphic</strong></td>
<td>A graphic part is one whose body contains curves or arcs. For example, an OR gate is a graphic part.</td>
</tr>
<tr>
<td><strong>IEEE</strong></td>
<td>An IEEE part is one that complies with the ANSI/IEEE standard. IEEE parts differ from graphic parts in that they may not contain arcs or fills, and they are typically larger.</td>
</tr>
</tbody>
</table>

**Number of Parts per Package**
- If you choose Block, Edit Library requests the number of parts per package. Choose a number from 0 to 16.
- If you choose Graphic, Edit Library requests the number of parts per package. Choose a number from 0 to 16.

**Is Part a GRID ARRAY?**
- This displays only if the number of parts per package is 1. Select No or Yes.
  - The Place command displays (described on the next page).

**Does Graphic Part have CONVERT?**
- Select Yes or No:
  - If you choose Yes, Edit Library can assign a converted form for your part (a converted form is used to store a DeMorgan equivalent symbol of the part). It is the version of the part that appears when you issue Draft's GET Convert command.
  - If you choose No, Edit Library does not create or store a converted form of the part.
  - The Place command displays (described on the next page).
Place

Once you have selected Block, Graphic, or IEEE, and responded to any prompts that display (as described on the previous page), the following command displays:

```
Place
```

To increase or decrease the part size, move the pointer. When the part size is what you want, select Place. Edit Library fixes the size of the part and displays the appropriate menu, as shown in figure 17-2.

If SET Show Body is turned on, a solid line represents vector-drawn parts (IEEE and Block), and a dashed line indicates a bit-mapped part (Graphic or IEEE).

Once you have defined the part body, use the displayed menu to place objects on the part, thereby building the part.

For most parts, you should place objects inside the part body. For Graphic parts, only the area within the body displays in Draft. It is possible for objects such as circles to be placed so that they are partially outside the body. These will usually appear different on a plot. For example, the plotter often draws the entire circle.

For IEEE parts, some objects have to be placed outside the body. In particular, the Active_Low IN and OUT symbols are normally placed on pins outside the body. Most objects should be inside the body in order to conform to the IEEE standard.
BODY command reference

In the following command reference, the BODY <Block> commands are described first, followed by the BODY <Graphic> commands, and finally by the BODY <IEEE> commands.

BODY <Block> commands

The BODY <Block> command are shown at the right. Descriptions of each of the commands on this menu follow.

Body <Block>

Size of Body

Use the Size of Body command to change the size of the edited part. To increase or decrease the part size, move the pointer. When the part size is what you want, select Place. The BODY <Block> menu displays (shown above).

Kind of Part

If you want to draw a different type of part, select Kind of Part. Edit Library displays:

Changes to Current Part may be lost. Continue?

Select Yes. The menu shown at right displays. Select the type of part to draw, as described previously in this section.
Chapter 17: Edit Library

**BODY <Graphic> commands**

The **BODY <Graphic>** commands are shown at the right. Descriptions of the commands on this menu follow.

<table>
<thead>
<tr>
<th><strong>BODY &lt;Graphic&gt;</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Line</td>
</tr>
<tr>
<td>Circle</td>
</tr>
<tr>
<td>Arc</td>
</tr>
<tr>
<td>Text</td>
</tr>
<tr>
<td>IEEE Symbol</td>
</tr>
<tr>
<td>Fill</td>
</tr>
<tr>
<td>Delete</td>
</tr>
<tr>
<td>Erase Body</td>
</tr>
<tr>
<td>Size of Body</td>
</tr>
<tr>
<td>Kind of Part</td>
</tr>
</tbody>
</table>

**BODY <Graphic> Line**

Use the **Line** command to draw lines. This command is similar to the **PLACE Wire** command in **Draft**. When you select **Line**, the following command line displays:

```
Begin Jump Origin Tag Zoom
```

To draw a line, select **Begin**. This command line displays:

```
Begin End New Jump Origin Tag Zoom
```

Drag the pointer to draw the line. To continue or complete the line, select **Begin**, **End**, or **New**.

**Begin**

Ends the current line and begins a new line where the previous line ended.

**End**

Ends the current line and displays the **BODY <Graphic>** menu.

**New**

Ends the current line. You can begin a new line at a different location with **Begin**.
Use the Circle command to place a circle within the part outline. When you select Circle, the following command line displays:

Center Jump Origin Tag Zoom

To place a circle, move the pointer to the point that will be the center of the circle. Select Center. The following command line displays:

Edge Jump Origin Tag Zoom

Move the pointer. As you do this, a circle expands and contracts.

△ **NOTE:** Press <Esc> from the Edge command line to discard the circle and return to the Circle command line.

Move the pointer to where you want the edge of the circle to be and select Edge. You have now placed a circle. The Circle command line displays.

△ **NOTE:** Circles may appear elliptical on your screen, depending on the type of monitor you have, because of variations between monitors. They will print or plot correctly, though.
BODY *Graphic* > Arc

Use the Arc command to place an arc within the part outline. An arc is a section of a circle. With Arc, you can draw an arc ranging from 0 to 90 degrees. When you select Arc, the Arc command line displays:

```
Center Jump Origin Tag Zoom
```

This command line is identical to the Circle command line.

To place an arc, move the pointer to the center of the circle from which the arc is to be taken. Then, select Center. The following command line displays:

```
Edge Jump Origin Tag Zoom
```

This command line is identical to the Edge command line appearing under Circle.

Move the pointer. As you do this, a circle expands and contracts. A radius extends from the center of the circle to the pointer. Move the pointer to where you want one end of the arc and select Edge. Then, move the pointer to where you want the other end of the arc.

Note that you can only move within a quadrant. (A circle is divided into four quadrants by horizontal and vertical lines through the center. Each quadrant is 90 degrees.)

⚠️ **NOTE:** Press <Esc> from the Edge command line to discard the arc and return to the Arc command line.

Select Edge again. You have now placed an arc. The Arc command line displays.

⚠️ **NOTE:** For finer control when drawing an arc, zoom in to 1/2 or 1/4 scale.
Use the **Text** command to place text within the part outline. The text is a comment. It is not intended to be a reference designator for the part or a name for a pin.

When you select Text, the following prompt appears:

```
Text?
```

Enter the comment text. The text appears at the pointer position. The command line shown below displays:

```
Place Larger Smaller Jump Origin Tag Zoom
```

Select **Larger** to make the text larger and **Smaller** to make it smaller. Move the pointer to the position where you want the text.

Select **Place** to place the text. The "Text?" prompt reappears, ready for you to enter another text item.

△ **NOTE:** Although you can place text to identify a pin, *Schematic Design Tools* does not recognize the text as a pin definition. You may wish to use Text to make the pin names visible on graphic parts. If you do this, the text will rotate and mirror with the graphic image.

You should normally place the text within the part outline. However, it is sometimes necessary to place text for IEEE parts outside the outline. If you do this, you run the risk of a messy or ambiguous situation on the final worksheet. If you can't see the part outline, set the **SET Show Body Outline** command to **Yes**. The part outline then displays as a dotted line on the screen. **SET Show Body Outline** is described later in this chapter.
Use the IEEE Symbol command to place IEEE/ANSI special symbols within the part outline. For more information about what these symbols mean, see ANSI/IEEE Std 91-1984.

When you select IEEE Symbol, a menu listing IEEE symbols appears. This menu and the menus its commands display are shown in figure 17-3. Figure 17-3 also shows the IEEE symbols placed by each menu command.

\[\text{NOTE: }\text{Edit Library treats the negation symbol as a circle. That means a Negation symbol counts toward the maximum number of circles allowed in a part definition.}\]
Select the name of the symbol to include in your part. If another menu displays, click on the desired selection.

The **Place** command line displays:

```
Place Larger Smaller Jump Origin Tag Zoom
```

This command line is identical to the **Text** command line. Select **Larger** to make the symbol larger and **Smaller** to make it smaller. Move the pointer to the position where you want the symbol. Select **Place** to place the symbol. You can place copies of the symbol as many times as desired. When you are done placing the symbol, select **<Esc>**. The **IEEE Symbol** menu displays (see figure 17-2).

\[ \square \]  **NOTE:** In **Edit Library**, when the zoom scale is 1, you may not easily distinguish between a pointer position actually on an item and a pointer position just close to a graphic item. When you zoom in, you may place objects in positions that are off grid points. At zoom scale 1, you may not be able to place the pointer on the object because the pointer stays on grid points at this scale. If so, zoom in once or twice to get the fine control needed.

**BODY <Graphic> Fill**

Use the **Fill** command to shade an enclosed area around the current pointer position. For example, **Fill** can be used to darken the triangular shape in the symbol of a diode.

Select **Fill** and the following command line displays:

```
Fill Jump Origin Tag Zoom
```

To darken an enclosed area, move the pointer inside the area and then select **Fill** from this menu.

\[ \square \]  **NOTE:** If you edit a part after using **Fill**, you lose your fills. This protects against overflowing the entire part with a fill if you delete the fill boundary. Therefore, use **Fill** at the end of your editing session.
BODY <Graphic> Delete

Use the Delete command to delete an item.

▲ **CAUTION:** Be careful when deleting an item; you cannot undo the deletion.

Select Delete and the following command line displays:

```
Delete Jump Origin Tag Zoom
```

To delete an item, place the pointer on the item and select Delete. For the item to be deleted, the pointer must actually be on a pixel in the part.

BODY <Graphic> Erase Body

Use the Erase Body command to delete all objects within a part’s graphic body. Use this command when you want to start over drawing the graphic body.

When you select Erase Body, Edit Library asks you to confirm your choice. Select Yes to delete the graphic body. Select No to return to the BODY menu.

BODY <Graphic> Size of Body

Use the Size of Body command to change the size of the part being edited. To increase or decrease the part size, move the pointer. When the part size is what you want, select Place. The BODY <Graphic> menu displays.

▲ **CAUTION:** Once objects are inside the body of the part, changing the size of the body can have undesirable results.

BODY <Graphic> Kind of Part

To draw a different type of part, select Kind of Part. Edit Library displays:

```
Changes to Current Part may be lost. Continue?
```

Select Yes. The menu shown at right displays. Select the type of part to draw, as described previously in this section.
The **BODY <IEEE> commands** are shown at the right. Descriptions of each of the commands on this menu follow.

<table>

<tr>
<td>Erase Body</td>
</tr>
<tr>
<td>Size of Body</td>
</tr>
<tr>
<td>Kind of Part</td>
</tr>
</tbody>
</table>

**BODY <IEEE> Line**

Use the **Line** command to draw lines. This command is similar to the **PLACE Wire** command in Draft. When you select **Line**, the following command line displays:

```
Begin Jump Origin Tag Zoom
```

To draw a line, select **Begin**. This command line displays:

```
Begin End New Jump Origin Tag Zoom
```

Drag the pointer to draw a line. To continue or complete the line, select **Begin**, **End**, or **New**.

**Begin**

Ends the current line and begins a new line where the previous line ended.

**End**

Ends the current line and displays the **BODY <IEEE>** menu.

**New**

Ends the current line. You can begin a new line at a different location with **Begin**.
Use the *Circle* command to place a circle. When you select *Circle*, the *Circle* command line displays:

```
Center Jump Origin Tag Zoom
```

To place a circle, move the pointer to the point that will be the center of the circle. Select **Center**. The following command line displays:

```
Edge Jump Origin Tag Zoom
```

Move the pointer. As you do this, a circle expands and contracts.

**△ NOTE:** Press <Esc> from the *Edge* command line to discard the circle and return to the *Circle* command line.

Move the pointer to where you want the edge of the circle to be and select *Edge*. You have now placed a circle. The *Circle* command line displays.
Use the Text command to place text within the part outline or near the part. The text is a comment. It is not intended to be a reference designator for the part or a name for a pin.

When you select Text, the following prompt appears:

Enter the comment text. The text appears at the pointer position. The command line shown below displays:

Select Larger to make the text larger and Smaller to make it smaller. Move the pointer to the position where you want the text.

△ **NOTE:** IEEE text is limited to ten characters per text object. If you enter more than ten characters in response to the "Text?" prompt, the extra characters are discarded. You can place two or more text objects together to create a string that is longer than ten characters.

Most of the time, you place the text within the part outline. It is sometimes necessary, however, to place text for IEEE parts outside the outline. If you do this, you risk a possibly messy or ambiguous situation later on the schematic worksheet. If you can’t see the part outline, set the SET Show Body Outline command to Yes. The part outline then displays as a dotted line on the screen. SET Show Body Outline is described later in this chapter.

Select Place to place the text. The "Text?" prompt reappears, ready for you to enter another text item.

△ **NOTE:** Although you can place text to identify a pin, Schematic Design Tools does not recognize the text as a pin definition. You may wish to use Text to make the pin names visible on graphic parts. If you do this, the text will rotate and mirror with the graphic image.
Use the **IEEE Symbol** command to place IEEE/ANSI special symbols. For more information about what these symbols mean, see *ANSI/IEEE Std 91-1984.*

When you select **IEEE Symbol**, a menu listing IEEE symbols appears. This menu and the menus it displays are shown in figure 17-3.

Select the name of the symbol to include in your part. If another menu displays, make an appropriate selection.

The **Place** command line displays:

```
Place Larger Smaller Jump Origin Tag Zoom
```

Use **Larger** and **Smaller** to change the size of the symbol. Move the pointer to the position where you want the symbol and select **Place**. You can place copies of the symbol as many times as desired. When you are done, press <Esc>. The **IEEE Symbol** menu (figure 17-2) displays.

The current size specified by **Larger** or **Smaller** affects both IEEE symbols and text. The size retains its last setting, so you can place objects at the same relative scale.

Use the **Delete** command to delete an item.

**CAUTION:** Be careful when deleting an item; you cannot undo the deletion.

When you select **Delete**, this command line displays:

```
Delete Jump Origin Tag Zoom
```

To delete an item, place the pointer on the item and select **Delete**. For the item to be deleted, the pointer must actually be on a pixel in the part.

Note that at **Zoom** scale 1, it’s not easy to distinguish between a pointer position actually on an item and a pointer position just close to a graphic item.

---

3 See ANSI/IEEE Std 91-1984: *IEEE Standard Graphic Symbols for Logic Functions*, © 1984, or *Graphic Symbols for Electrical and Electronics Diagrams*, © 1975; both published by The Institute of Electrical and Electronics Engineers, Inc.
Use the **Erase Body** command to delete all lines, circles, IEEE symbols, and comment text associated with a part. Use **Erase Body** when you want to start over drawing the body.

When you select **Erase Body**, **Edit Library** asks you to confirm your choice. Select **Yes** to delete the graphic body. Select **No** to return to the **BODY** menu.

**BODY <IEEE>**

**Size of Body**

Use the **Size of Body** command to change the size of the part being edited. To increase or decrease the part size, move the pointer. When the part size is what you want, select **Place**. The **BODY <IEEE>** menu displays.

⚠ **CAUTION**: Once objects are in the body of the part, changes to its body size can have undesirable results.

**BODY <IEEE>**

**Kind of Part**

To draw a different type of part, select **Kind of Part**. **Edit Library** displays:

```
Changes to Current Part may be lost. Continue?
```

Select **Yes**. The **Kind of Part?** menu displays. Select the type of part to draw, as described earlier in this section.
CONDITIONS

CONDITIONS monitors your computer's memory, and the memory available for the worksheet, hierarchy buffer, and macro buffer. When you select CONDITIONS, a status window displays (figure 2-2). The CONDITIONS status window does not respond to mouse commands. Press any key to return to the main menu level.

You can print a copy of the CONDITIONS status window by pressing <Print Screen>. Make sure the Disable <Print Screen> key function option on Edit Library's local configuration screen is not selected.

The types of information CONDITIONS displays are described below.

No Parts

If there are no parts currently displayed on the screen, information similar to the following displays:

<table>
<thead>
<tr>
<th>Press Enter to continue</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONDITIONS:</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>Allocated</td>
</tr>
<tr>
<td>Macro Buffer: 8192</td>
</tr>
<tr>
<td>Free System Memory:</td>
</tr>
<tr>
<td>Library:</td>
</tr>
<tr>
<td>Objects: 1023</td>
</tr>
<tr>
<td>General Control Information: 65520</td>
</tr>
<tr>
<td>Bit Map Images: 65520</td>
</tr>
<tr>
<td>Vectors (Circles, Lines, etc): 65520</td>
</tr>
</tbody>
</table>

Figure 17-4. CONDITIONS status window.

\(\triangle\) NOTE: The numeric values displayed on the CONDITIONS screen vary with the content of the libraries and the work in progress.

Notice that for each item listed, Edit Library shows the amount of memory allocated, the amount of memory used, and the amount of memory still available. The amount of memory allocated to any given item is specified on the Schematic Design Tools Configuration screen. See Chapter 1: Configure Schematic Tools for information on how to configure these items.
Macro Buffer

This shows the amount of memory available in the macro buffer. The buffer contains user-created macros—both those created on line and loaded from a macro file.

Free System Memory

This shows how much unused memory remains in your computer.

Library Objects

This tells how many names you can add to the current library. A library can have up to 1023 names (more if you use prefixes). Note the number represents names, not parts. Also, a part may have multiple names. However, extra names resulting from prefix definitions do not count. For more information about prefix definitions, see Chapter 14: About Libraries in this guide.

Library General Control Information

This shows the number of bytes available for additional library symbols. General Control Information symbols include part names, pin names, pin positions, block symbols, and so on.

Library Bit Map Images

This shows the number of bytes available for additional library bitmaps. When you make a part with Edit Library, you use vectors. However, bitmaps are needed for screen work. For example, Draft requires a bitmap to display a graphic part. Consequently, when you add a graphic part to a library, a bitmap version is stored as well as a vector version.

Library Vectors (Circles, Lines, etc)

This shows the number of bytes available for additional library vectors. Edit Library vectors include lines, circles, arcs, IEEE symbols, text, and files.
Export

Export writes the current part definition (the one being edited) to a file. The file is called an export file and is formatted as a library source file without a prefix-end statement. Export writes only one part per export file.

To add the part in the export file to an existing library, run Edit Library and specify the desired destination library as the current library. Then, use the Import command to read the export file. You can then make changes to the part using Edit Library commands if necessary. Then, you can add the part to the library with the Library Update Current command.

△ NOTE: A part must have a name before you can write it to an export file. Use the Name command to give the part a name.

Example

To modify a part from TTL.LIB, and write it to a new file, follow these steps:

1. In Edit Library's Local Configuration screen, configure Source to be the library from which you will copy the part—in this case, TTL.LIB.
2. Execute Edit Library.
3. Select GET PART from the main menu. Edit Library displays the prompt:

   get?

4. Enter the name of the part, or press <Enter> to see a menu of parts to select from. The selected part displays on the screen.
5. Now, select EXPORT. Edit Library displays the prompt:

   Export to?

6. Enter the name of a temporary file for the data to be stored—in this case, TEMP.
△ NOTE: The temporary file created by exporting a part from Edit Library is not yet a library file. It is only a data file used by Edit Library, when you import the data, to create a library file.

7. Select QUIT Initialize. Edit Library prompts:

   Read Library?

8. Enter the new library name.

9. Now, import the data from the temporary file. Select IMPORT. Edit Library prompts:

   Import From?

10. Enter the name of the temporary data file in which you stored the exported data—in this case, TEMP.

The part is now ready for you to edit. When you have completed your editing, save the new library as follows:

1. Select LIBRARY Update Current. This modifies the copy of the library in memory, NOT the copy on disk.

2. Now, select QUIT Update File. This writes the latest copy of the library from memory to disk.

3. Select Abandon Edits.
GET PART retrieves a part from a library for editing. There are two methods you can use to retrieve parts.

<table>
<thead>
<tr>
<th>Method 1</th>
<th>Method 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select GET PART. Edit Library displays &quot;Get?&quot;</td>
<td>Select GET PART. Edit Library displays &quot;Get?&quot;</td>
</tr>
<tr>
<td>Enter the desired part name exactly as it appears in the library directory. Edit Library searches the library you specified when you configured Edit Library and finds the part you requested. Once it finds the part, Edit Library displays it on the screen. To verify the spelling of a part name, use the LIBRARY Directory command.</td>
<td>Press &lt;Enter&gt;. Edit Library displays a menu listing the library parts. Move the highlight to the part name you want, then press &lt;Enter&gt; to retrieve the part. Edit Library displays the part on the screen.</td>
</tr>
</tbody>
</table>

**Getting a part by entering a part suffix**

If you are using Method 1 (as described above), you can select library part numbers created with a prefix and shorthand string (see Prefix definition in Chapter 14: About Libraries) from the library by entering the suffix. For example, suppose you want to retrieve a 74LS27 from the TTL.LIB library. After selecting GET, enter any of the following examples to retrieve the part:

- **Get? 74LS27**
  - The entire part name is used to retrieve the part.

- **Get? LS27**
  - The prefix "LS" (which is the shorthand string for "74LS") is combined with the suffix "27." Edit Library retrieves the part 74LS27.

- **Get? 27**
  - Edit Library lists all parts in the library that have "27" in their names. Select the 74LS27 from the menu that displays the part names. Edit Library retrieves the part 74LS27.
IMPORT

IMPORT reads a part from an export file created with the EXPORT command. Export files contain only one part definition per file. IMPORT reads in the part definition as the current active part. It overwrites the existing current part.

When you select IMPORT, the following prompt appears:

Import From?

If you press <Enter> or <Esc> without entering a filename, Edit Library returns to the main menu.

△ NOTE: If you made any changes to the current part since the last GET or LIBRARY Update, a message displays that warns you about losing your changes. Select No or press <Esc> to cancel the Import command.
Use JUMP to quickly move the pointer to a different location in your work area. The specific locations can be tags or (X,Y) coordinates. When you select JUMP, the commands shown in the figure at the right appear.

When you select one of the JUMP Tag commands, the pointer jumps to the specified tag on the drawing (the tag must have been previously set with the TAG command). For information on the TAG command, see the Tag section in this chapter.

NOTE: The error message “Tag does not exist” displays if the specified tag has not been set.

The X-Location command moves the pointer a specific distance along the X-axis. Each step represents 1/100 (0.01) inch on the worksheet (if the pin-to-pin spacing on the template table in the Configure Schematic Design Tools screen is set to the default value of 0.100 inch).

To jump to an X-location, follow these steps.

1. Select JUMP X-Location.
2. Edit Library displays “Jump X”. Enter the number of steps to jump. A number without a plus or minus sign moves the pointer to the actual grid coordinate, a signed positive number (+10, +25, +30, and so on) moves the pointer to the right, and a negative number (−10, −25, −30, and so on) to the left. If you enter +10, for example, the pointer jumps to the right 1 inch. If you enter 10, without a plus or minus sign, the pointer moves to the actual X grid coordinate 10.0.
When you press <Enter>, the pointer jumps to the specified grid reference location and Edit Library returns to the main menu level.

**JUMP Y-Location**

The Y-Location command moves the pointer a specific distance along the Y-axis. Each step represents \( \frac{1}{100} \) (0.01) inch on the worksheet. If the pin-to-pin spacing on the template table on the Configure Schematic Design Tools screen is set to the default value of 0.100 inch (if the pin-to-pin spacing on the template table on the Configure Schematic Design Tools screen is set to the default value of 0.100 inch).

To jump to a Y-location, follow these steps.

1. Select Y-Location.
2. Edit Library displays "Jump Y". Enter the number of steps to jump. A number without a plus or minus sign moves the pointer to the actual grid coordinate, a signed positive number (+10, +25, +30, and so on) moves the pointer up, and a negative number (-10, -25, -30, and so on) down. If you enter +10, for example, the pointer jumps up 1 inch. If you enter 100, without a plus or minus sign, the pointer moves to the actual Y grid coordinate 10.0.

When you press <Enter>, the pointer jumps to the specified location and Edit Library returns to the main menu level.

\( \triangle \) **NOTE:** The coordinates used by the JUMP X-Location and JUMP Y-Location commands are independent of the origin set with the ORIGIN command. When using JUMP X-Location and JUMP Y-Location the origin is always 0,0.

**LIBRARY**

LIBRARY updates the current library, lists the part names in the library, browses through the library, deletes a part from the library, and defines prefixes.
When you select the LIBRARY command, the menu shown at right appears.

<table>
<thead>
<tr>
<th>Library filename</th>
</tr>
</thead>
<tbody>
<tr>
<td>Update Current</td>
</tr>
<tr>
<td>List Directory</td>
</tr>
<tr>
<td>Browse</td>
</tr>
<tr>
<td>Delete Part</td>
</tr>
<tr>
<td>Prefix</td>
</tr>
</tbody>
</table>

`LIBRARY`  
`Update Current`  

Updating the library means either changing the definition of an existing part or adding a new part.

To change the definition of an existing part, retrieve the part with the GET PART command, edit it, and then select LIBRARY Update Current.

To add a new part, build the part (you may find it easier to retrieve a similar part and edit it), name the part with the NAME command, and select Update Current.

Updating the library with the Update Current command modifies the copy of the library in memory, not the copy on disk. To change the copy of the library on disk, use the QUIT Update File command (which saves the library on disk without renaming it) or the QUIT Write to File command (which saves the library on disk under a new name).
Schematic Design Tools Reference Guide

LIBRARY

List Directory lists the names of the parts in a library. The list can be displayed, printed, or saved in a file.

Select List Directory. Edit

Library displays the menu shown at the right.

Screen
Select Screen. The library directory displays on the screen.

Printer
Select Printer. The library directory prints on the printer.

File
Select File. Edit Library displays "File?" on the prompt line. Enter the path and filename. The library directory is sent to a file.

Directory of EXAMPLE.LIB
Prefix - 74LS 74S 74ALS 74AS 74HCT 74HC 74ACT 74AC
Shorthand- LS S ALS AS HCT HC ACT AC
Prefix - 74AHCT 74FCT 74F 74C 74
Shorthand- AHCT FCT F C

Figure 17-5. Partial Listing of EXAMPLE.LIB.
Chapter 17: Edit Library

LIBRARY Browse

The Browse command in Edit Library works like the Browse command in Draft does. Use it to view the contents of a library, or select an object and view it on the screen.

Select Browse. The menu shown above displays.

All parts

Select All parts to view parts starting at the beginning of the library and proceeding toward the end. The parts are arranged in ascending numeric or alphabetic order. When you select All parts, the menu shown above appears.

Select Forward or Backward to browse through the library. Select Quit to return to the main menu. The last part displayed remains on the screen, ready for editing.

Specific parts

Select Specific parts when you know the name of the part you want to view. When you select Specific parts, the "Part?" prompt appears.

If you know the name of the part you want to look at, type its name, then press <Enter>. Edit Library gets the part and shows the part on the screen.

If you don't know the part name, press <Enter>. Edit Library displays a list of part names. You can then select the desired part from the list.

△ NOTE: Use the ↓ and ↑ keys with the <Enter> key, or the left mouse button to scroll through the list of parts.

When you select a part, the "Part?" prompt returns. You can display another part or a list of part names as described above. If you press <Esc> without a part name, Edit Library returns to the main menu level. The last part displayed remains on the screen, ready for editing.
LIBRARY Delete Part

Use the Delete Part command to delete parts from a library. When you select Delete Part, the following prompt appears:

```
Delete Library Part?
```

To delete a part, type the suffix of the part name and press <Enter>. If you press <Enter> without specifying a part, Edit Library displays a list of part names. You can then select the part you want to delete.

The Delete Part command only deletes a part from the library in memory. The part is not deleted from the library on disk until you issue the QUIT Update File command (saves the modified library to the same file) or QUIT Write to File command (saves the modified library to a new file you specify).

If a part definition has multiple names (or suffixes) associated with it, this command only deletes the particular suffix you type. The part is only deleted when the last of its suffixes is deleted.
LIBRARY Prefix

Use the Prefix command to edit a library's prefix definition.

Select Prefix. Edit Library displays a command line, a list of prefixes, and their associated shorthand:

```
Add Delete Edit Quit

PREFIX      SHORTHAND
74LS        LS
74S         S
74ALS       ALS
74AS        AS
74HCT       HCT
74HC        HC
74ACT       ACT
74AC        AC
74AHCT      AHCT
74FCT       FCT
74F         F
74C         C
74
```

**Draft** uses a library's prefix definition when you get a part with the GET command. Instead of entering the long name of a part, you can enter just the part's suffix. For example, if TTL.LIB is one of Schematic Design Tool's libraries, and you enter the suffix 04, a menu similar to the one shown at right lists the parts.

The prefix definition is specifically designed to handle the various TTL logic families. For example, the 74LS00, the 74S00, and the 74ALS00 have different prefixes (74LS, 74S, and 74ALS), but the same suffix (00). When you use a prefix definition, you reduce the memory needed to store multiple families of parts that have different prefixes, but the same suffix. For more information, see Prefix definition in Chapter 14: About libraries.
Add  To add a prefix to the library, move the highlight to the position where the new prefix will go and then select Add. The prompt “Prefix?” appears. Enter the prefix you want to store.

The prompt “Shorthand Prefix?” then appears. Enter the abbreviation you want to use for the part prefix.

The prefix and its shorthand equivalent are added at the location of the highlight.

△  **NOTE:** Up to sixteen prefixes can be defined in each library.

Delete  To delete a name, place the highlight on the prefix or shorthand name and select Delete.

Edit  To edit an existing prefix or shorthand prefix, place the highlight on the name and select Edit. The prompts “Prefix?” or “Shorthand Prefix”? appear followed by the current name. Backspace over the current name and type the new name followed by <Enter>.

Quit  Quit saves your entries or changes and displays the LIBRARY menu.
MACRO

A macro is a set of keystrokes you assign to a particular key. You can run all the commands represented by those keystrokes by pressing just the assigned key. With the MACRO command, you can capture keystrokes, delete macros, write defined macros to a file, read macros from a file, list the active macro keys and erase (initialize) the macro file.

Edit Library's MACRO command works just like Draft's MACRO command. For more information about writing macros, see the description of the MACRO command in the Chapter 2: Draft in this guide.

To define and load a macro file that loads whenever Edit Library runs, enter the filename in the Edit Library Macro File entry box on the Configure Schematic Design Tools screen.

Initial Macro

Initial macros run automatically each time you load Edit Library. To define and load an initial macro, follow the instructions given in the MACRO section of Chapter 2: Draft. Enter the initial macro name in the Edit Library Initial Macro entry box on the Configure Schematic Design Tools screen.
NAME

Use NAME to assign a name to a part.

When you edit a part from an OrCAD-supplied library, it comes into Edit Library with its own name or list of names. If you update the library with the LIBRARY Update Current command, you overwrite the existing part.

Suppose you want, instead, to construct a new part. If the part is similar to an existing part, the best way to build it is to read in the existing part, rename the part, edit it, and then update the library.

A part may have a list of names. For a part to be unique, each name in the list must be unique. For example, assume you do the following:

- Retrieve a part with the names A, B, and C.
- Change one of its names (for example, C to D).
- Edit the part definition.
- Add the part (now with names A, B, and D) to the library.

The library now contains two parts: one with the names A, B, and D (the new part) and one with the name C (the old part). Adding a new part replaces existing parts with the same name. Because the new part doesn’t have the name C, one instance of the original part is kept with the name C. To delete C from the library, use the LIBRARY Delete Part command.

When you select NAME, the menu shown at right appears.

<table>
<thead>
<tr>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add</td>
</tr>
<tr>
<td>Delete</td>
</tr>
<tr>
<td>Edit</td>
</tr>
<tr>
<td>Prefix</td>
</tr>
</tbody>
</table>

\[\text{△} \text{NOTE: The maximum length allowed for part names is 127 characters. However, it is recommended that you use much smaller part names. On a 640 x 480 screen at zoom scale 1, a name longer than 78 characters is clipped short. Also, many netlist formats place restrictions on the length of names. Check the name length requirements for the netlist format you are using. This information is available using the View Reference Material tool.}\]
NAME Add  To add a name to a part, select Add. The prompt “Name?” appears. Enter the name to give the part. The prompt “Sheet Path?” then appears. If the part represents a sheet, enter the name of the schematic file. If the part does not represent a sheet, just press <Enter>. For more information about sheet parts, see Editing sheets and PLACE Sheet in Chapter 2: Draft in this guide.

NAME Delete  To delete a name, select Delete. The list of names appears. Select the name to delete.

NAME Edit  To edit an existing name, select Edit. The list of names appears. Select the name you want to edit. The prompt “Name?” appears followed by the current name. Edit the name by positioning the cursor using the <→> and <←> keys and the <Home> and <End> keys. Erase characters with the <Backspace> and <Delete> keys. When you are done editing, press <Enter>.

The prompt “Sheet Path?” then appears. If the part represents a sheet, enter the pathname of the schematic file. If the part does not represent a sheet, just press <Enter>. If the part already has a sheetname, it appears after the prompt and may be edited.

NAME Prefix  To determine what prefixes are assumed for a part name, select Prefix. The list of part names appears. Select the part name whose prefixes you want to determine.

The list of prefix strings defined for the library appears (see right). Beside each prefix string is a Yes or a No, which determines whether the prefix string is valid or invalid for the selected part name. To change the setting of a prefix string, select the prefix string. Then select Yes to make the string valid or No to make it invalid.
ORIGIN sets the current pointer position as the new X,Y origin (X=0.0, Y=0.0). The default origin is the upper left of the part’s body. When building a part, it is sometimes useful to redefine the origin to be at a particular point within the part outline. In this way, you can easily make relative measurements when constructing graphic parts.
Use the PIN command to add, delete, or edit pins. Select PIN. Edit Library displays:

```
Add Delete Name Pin-Number Type Shape Jump Zoom
```

**PIN Add**
To add a pin to a part, place the pointer where you want the new pin and select Add. Edit Library then queries you for the Name, Pin Number, Type (Input, Output, Bidirectional, Power, Passive, 3-state, Open Collector, or Emitter), and Shape (Line, Clock, Dot, Dot Clock, or Short) of the pin you are adding.

These pin attributes are explained below.

**PIN Delete**
To delete a pin in a part, place the pointer at the unwanted pin and select Delete.

**PIN Name**
Use the Name command to edit the string definition of an existing pin.

To enter a name with a bar over it (indicating negation), type backslash characters after the letters. For example, type:

```
R\E\S\E\T
```

to define the name:

```
RESET
```

**PIN Pin-Number**
Use the Pin-Number command to change the pin number of a pin.
PIN Type  To change the type of a pin, move the pointer to the pin’s location and select Type. A menu listing the available pin appears (see right). The pin’s current type is shown above the menu.

Select the type you want. The available types are described below and on the next page.

<table>
<thead>
<tr>
<th>Pin Type</th>
<th>Input</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Output</td>
</tr>
<tr>
<td></td>
<td>Bidirectional</td>
</tr>
<tr>
<td></td>
<td>Power</td>
</tr>
<tr>
<td></td>
<td>Passive</td>
</tr>
<tr>
<td></td>
<td>3 State</td>
</tr>
<tr>
<td></td>
<td>Open Collector</td>
</tr>
<tr>
<td></td>
<td>Open Emitter</td>
</tr>
</tbody>
</table>

**Input**
An input pin is one to which you apply a signal. For example, pins 1 and 2 on the 74LS00 NAND gate are input pins.

**Output**
An output pin is one to which the part applies a signal. For example, pin 3 on the 74LS00 NAND gate is an output.

**Bidirectional**
A bidirectional pin is either an input or an output. For example, pin 2 on the 74LS245 bus transceiver is a bidirectional pin. The value at pin 1 (an input) determines the active type of pin 2 as well as others.

**Power**
A power pin expects either supply voltage or ground. For example, on the 74LS00 NAND gate, pin 14 is Vcc, and pin 7 is GND (ground).

**NOTE:** Power pins are invisible.

**Passive**
A passive pin is typically connected to a passive device. A passive device does not have a source of energy. For example, a resistor lead is a passive pin.

**3 State**
A 3-state pin has three possible states: low, high, and high impedance. When it is in its high impedance state, a state pin looks like an open circuit. For example, the 74LS373 latch has 3-state pins.
Chapter 17: Edit Library

Open Collector

An open collector gate omits the collector pull-up. Use an open collector to make "wire-OR" connections between the collectors of several gates and to connect with a single pull-up resistor. For example, pin 1 on the 74LS01 NAND gate is an open collector gate.

Open Emitter

An open emitter gate omits the emitter pull-up. The proper resistance is added externally. ECL logic uses an open emitter gate and is analogous to an open collector gate. For example, the MC10100 has an open emitter gate.

PIN Shape

To specify the shape of a pin, move the pointer to the pin location and select Shape. A menu listing available pin shapes appears (shown below). The pin's current shape appears above the menu.

Select the shape you want.

The shape Line represents a normal pin with 3 grid unit leads. Short represents a pin with 1 grid unit lead.

Dot indicates the inversion bubble while Clock indicates the clock symbol. The combination Dot Clock represents a clock symbol with an inversion bubble.

PIN Move

To move a pin, select Move. "Pin to Move?" displays.

Place the pointer on the pin you need to move, and click the mouse button. "New Pin Location?" displays.

Move the pointer to the new location, and click the mouse button once. Edit Library places the pin in the new location.
QUIT

Use the QUIT command to leave Edit Library and return to the Schematic Design Tools screen. With QUIT, you can also write to a file, update the current library, initialize the current Edit Library session, and suspend to the operating system.

When you select QUIT, the menu shown above appears.

QUIT Update File

The Update File command writes the latest copy of the library being edited to disk. This command is not the same as the LIBRARY Update Current command.

The procedure for modifying a library is as follows:

- Run Edit Library using the desired library. Edit Library then reads the library into memory.
- Get and edit a part definition, or define a new part.
- Select LIBRARY Update Current to modify the copy of the library in memory.
- Select QUIT Update File to write the copy of the library in memory to disk.

△ NOTE: QUIT Update File writes a compiled library file. It does not change any corresponding library source file. To update the library source file to reflect the changes you made with Edit Library, run Decompile Library on the new compiled library file to make a new source file.
Chapter 17: Edit Library

QUIT Write to File

Write to File writes the latest copy of the library being edited to any file you specify. When you select Write to File, the following displays:

Write to?

Enter the path and filename you want to write to.

QUIT Initialize

The Initialize command abandons the edits since the last file update. When you select Initialize, the current library is removed from memory, and the following prompt appears:

Read library?

Enter the path and filename of the file you want to edit.

△ NOTE: If you have made changes since the file was loaded or saved, Edit Library displays “Initialize - Are you sure?” Select No to cancel the Initialize command and return to the main menu level. Select Yes to allow the initialize command to continue.

QUIT Suspend to System

Suspend to System temporarily leaves Edit Library and the part you are creating and returns to the operating system. Once you have suspended Edit Library, you may perform operating system functions, including using other software programs as long as there is enough computer memory.

To suspend to the operating system, select Suspend to System. Edit Library suspends operation, loads the operating system command interpreter, and adds an additional “>” to the system command prompt. This is a reminder that Edit Library is suspended and in the background.

To return to Edit Library, type EXIT at the operating system prompt. Edit Library then comes to the foreground and the part you were working on when you suspended Edit Library returns to the screen.
QUIT Abandon Edits  Use the Abandon Edits command to end your Edit Library session and return to the Schematic Design Tools screen.

If you changed the library currently in memory (with the LIBRARY Update Current command), Abandon Edits asks you to confirm your decision to leave.

Select No to return to the main command level. Select Yes to exit Edit Library.
REFERENCE

Use REFERENCE to define or edit a part's reference designator.

The default reference designator is "U?". The "?" is a placeholder for the number representing the occurrence of the device. The Annotate Schematic tool replaces "?" with a number indicating the instance of the part. If the part is a multiple-part package, Annotate Schematic adds a one-character alphabetic suffix to the reference designator and increments it A, B, C, and so on, once for each part of the package used.

When you select REFERENCE, this prompt appears:

```
Initial Reference Designator? U
```

"U" is the current reference designator. To replace U with another letter or sequence of letters and numbers, backspace over U, type the new reference designator, and press <Enter>.

Press <Enter> without typing anything to return to the main menu level.

△ NOTE: If a part is zero parts per package and you delete the "?", the reference designator and part value are not shown in Draft. See the GND symbol for an example. In addition, these types of parts are not shown in the Bill of Materials report.
Use SET to turn Edit Library options on and off. When you select SET, the menu shown at right appears.

<table>
<thead>
<tr>
<th>Set</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Auto Pan</td>
<td>YES</td>
</tr>
<tr>
<td>Backup File</td>
<td>YES</td>
</tr>
<tr>
<td>Error Bell</td>
<td>YES</td>
</tr>
<tr>
<td>Left Button</td>
<td>NO</td>
</tr>
<tr>
<td>Macro Prompts</td>
<td>YES</td>
</tr>
<tr>
<td>Power Pins Visible</td>
<td>NO</td>
</tr>
<tr>
<td>Show Body Outline</td>
<td>NO</td>
</tr>
<tr>
<td>Visible Grid Dots</td>
<td>NO</td>
</tr>
</tbody>
</table>

**SET Auto Pan**

Auto Pan controls movement past the screen boundary. While Auto Pan is turned on, when the pointer crosses a screen boundary, the screen pans in that direction.

When you select Auto Pan, you then choose between Yes and No. Yes turns on auto panning; No turns it off.

**SET Backup File**

When you set Backup File to YES, Edit Library creates a backup file when you write or update files using the QUIT command. The backup file contains the previous version of the library being edited.

**SET Left Button**

When Left Button is on, releasing the left mouse button executes the <Enter> key for command line commands only. Pressing the left mouse button continues to execute the command highlighted by the video bar in menus.

For example, suppose you select the PLACE Wire command and the “Begin Find Jump Zoom” command line displays at the top of the screen. To select Begin with the mouse when SET Left Button is disabled, you click the left button once to display the pop-up menu and once again to select Begin. When SET Left Button is turned on, you would instead press the left button and hold it down while you moved the highlight to Begin, then release the left button to select Begin, thus saving one button click.

When you select Left Button, you then choose between Yes and No. If you select Yes, releasing the left button on your mouse executes <Enter>. If you select No, releasing the left button on your mouse does not execute <Enter>.
<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>SET Error Bell</strong></td>
<td><strong>Error Bell</strong> turns the error bell (your computer's speaker) on and off. When you turn this option on, error messages and errors sound the speaker. When you select <strong>Error Bell</strong>, you then choose between Yes and No. Yes turns on the error bell; No turns it off.</td>
</tr>
<tr>
<td><strong>SET Macro Prompts</strong></td>
<td>When you select <strong>Macro Prompts</strong>, commands making up your macros display on the screen when macros run.</td>
</tr>
<tr>
<td><strong>SET Power Pins Visible</strong></td>
<td>When you select <strong>Power Pins Visible</strong>, the part's power pins appear on the screen. For example, if you set <strong>Power Pins Visible</strong> to Yes and display the part 74LS00 in the TTL library, pins 14 and 7 appear. For the 74LS00, 14 is Vcc and 7 is GND. Note power pins may overlap existing pin names or the part name. Typically, power pins do not display. Power pins do not display in the Draft schematic editor.</td>
</tr>
<tr>
<td><strong>SET Show Body Outline</strong></td>
<td>When you select <strong>Show Body Outline</strong>, the part's body outline appears as a dotted line. When editing a graphic part, you must edit within the body outline or unpredictable results occur. It's a good idea to display the part's body outline unless you have a compelling reason not to.</td>
</tr>
<tr>
<td><strong>SET Visible Grid Dots</strong></td>
<td>When you select <strong>Visible Grid Dots</strong>, grid dots display on the screen. The spacing of the grid dots depends on the current zoom scale.</td>
</tr>
<tr>
<td><strong>Scale 1</strong></td>
<td>The grid dots appear every grid unit.</td>
</tr>
<tr>
<td><strong>Scale Half</strong></td>
<td>The grid dots still appear every grid unit but, because <strong>Scale Half</strong> shows twice as much detail as scale 1, the grid dots appear twice as far apart.</td>
</tr>
<tr>
<td><strong>Scale Quarter</strong></td>
<td>The grid dots are placed every 0.1 grid unit apart.</td>
</tr>
</tbody>
</table>
The TAG command identifies and remembers locations on Edit Library's screen. You can specify eight locations (A through H) using the pointer. Tagged locations can be destinations for the JUMP command. They are used when you want to quickly move the pointer to pre-defined locations. Tags do not appear on the part display, and they are not saved with the part.

To set a tag, place the pointer at a location you want to remember. Then select the TAG command. Edit Library displays the menu shown above.

When the TAG menu displays, select the tag to set from the menu. Once selected, Edit Library remembers the tag location. Once the tag is set, Edit Library returns to the main menu level.
ZOOM

ZOOM zooms in or out from the part display, changing the amount of detail you see on the screen. You can select three zoom levels: 1 (the default), Half, and Quarter. Half shows more detail than 1, and Quarter shows more detail still.

When you select ZOOM, the menu shown at right appears.

<table>
<thead>
<tr>
<th>Zoom (present scale=1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Center (1)</td>
</tr>
<tr>
<td>In (Half)</td>
</tr>
<tr>
<td>Out (1)</td>
</tr>
<tr>
<td>Select</td>
</tr>
</tbody>
</table>

The number or word in parentheses after Center shows the current zoom scale.

ZOOM Center Center re-centers the displayed portion of the part around the pointer. This command is useful for centering a part on the screen for easy editing.

For example, if a part displays partially off the screen, you may center it by placing the pointer near the part’s center and selecting ZOOM Center.

ZOOM In In selects the next more detailed scale (the part appears larger).

ZOOM Out Out selects the next less detailed scale (the part appears smaller).

ZOOM Select Select chooses a current zoom level. The selected zoom level is shown in parentheses after Center.

Selecting 1 shows the part in normal scale. Then, Out has no effect because no less-detailed scale exists. In increases detail to the Half scale.

Selecting Half shows the part in two times the drawing resolution. Then, Out returns the scale to 1, and In increases detail to the Quarter scale.

Selecting Quarter shows the part in four times the drawing resolution. Then, Out returns the scale to Half, and In has no effect because no more-detailed scale exists.
Decompile Library

**Execution**

Decompile Library takes a compiled library file and produces a library source file.

You can then edit the library source file, and use Compile Library to make a compiled library file. You can think of Decompile Library as the inverse of Compile Library.

**Running Decompile Library**

Select Decompile Library from the Schematic Design Tools screen. Select Execute from the menu that displays.

Decompile Library creates the library source file from the library file usable by Draft.

When Decompile Library completes its task, the Schematic Design Tools screen appears.
With the Schematic Design Tools screen displayed, select Decompile Library. Select Local Configuration from the menu that displays.

Select Configure DECOMP. A configuration screen appears (figure 18-1).

![Figure 18-1. Decompile Library's local configuration screen.](image)

### Local Configuration

**File Options**

**File Options** names the library to decompile and the library source file to produce.

**Prefix/Wildcard**

Enter a pathname and wildcard to define which files to display in the list box with scroll buttons. The asterisk character (*) is used as a wildcard. The default is:

```
\ORCADESP\SDT\LIBRARY\*.LIB
```

If you erase the entire field, the prefix specified on the Configure Schematic Design Tools screen is restored.

**Files**

The files that match the search filter entered in the **Prefix/Wildcard** entry box and those that match the filter in the current design directory display in this box. Files in the current directory are shown with .\ before their names. Use the scroll buttons to scroll the list of libraries up and down.

Select the file to decompile by clicking on its name. Its path and filename display in the **Source** entry box.
Chapter 18: Decompile Library

Source

The Source names an existing compiled library file.

Specify Source by selecting a name from the Files list box, or enter a name by simply typing it in this entry box and pressing <Enter>.

△ NOTE: A question mark (?) in an entry box tells ESP to default to the Startup Design name. This simplifies changing between designs: all you need do is change the Startup Design on the Configure ESP screen, exit ESP, then restart ESP by entering ORCAD.

For example, if you enter ?.LIB in the Source entry box and the Startup Design is configured as "TUTOR," the next time you look at the local configuration, the Source entry box will be configured as "TUTOR.LIB." If you then change the Startup Design to "DESIGN2" and restart ESP, the Source entry box will be configured as "DESIGN2.LIB."

Destination

The Destination is the full path and filename of the library source file that Decompile Library produces. It is a text file that describes the parts in the specified library. If you give the name of an existing file, Decompile Library asks if you want to overwrite the existing file. You cannot append to an existing file.

The Destination can be a complete pathname.

Processing Options

If desired, select the following option:

- Quiet mode

  Turns quiet mode on.
A library source file consists of the following:

- A prefix definition. You can only have one prefix definition per library, and it occurs at the beginning of the library.

- A series of part definitions. There are three types of part definitions: Block, Graphic, and IEEE.

Block part definitions represent parts that are either square or rectangular. These parts are typically memory chips, microprocessors, peripheral controllers, and many TTL and CMOS devices.

Graphic part definitions are used for small parts that have curved perimeters or whose function can be suggested by internal lines, circles, arcs, and fills. They include such parts as resistors, diodes, transistors, MOSFETS, relays and many others. A graphic part can be up to 1.2 inches by 1.2 inches in size.

If your part is larger than 1.2 inches by 1.2 inches, it must be an IEEE part (rather than a graphic part). However, if a graphic part’s X axis is less than 1.2 inches, its Y axis can be larger than 1.2 inches, and vice versa. Think of it as a rubber band . . . if you stretch it in one direction, it thins out in the other.
IEEE part definitions

IEEE part definitions represent parts that follow ANSI/IEEE standard. An IEEE part is similar to a graphic part, but it cannot contain arcs or fills. An IEEE part can also be larger than a graphic part. An IEEE part can be up to 12.7 inches by 12.7 inches.

△ NOTE: For more information, see ANSI/IEEE Std 91-1984: IEEE Standard Graphic Symbols for Logic Functions, ©1984, or Graphic Symbols for Electrical and Electronics Diagrams, ©1975; both published by The Institute of Electrical and Electronics Engineers, Inc.

Prefix Definition

The prefix definition is specifically designed to handle the various TTL logic families. For example, the 74LS00, the 74S00, and the 74ALS00 have different prefixes (74LS, 74S, and 74ALS), but the same suffix (00). When you use a prefix definition, you reduce the memory required to store multiple families of parts with different prefixes, but the same suffix.

All source files must begin with a prefix definition. If you do not want a prefix definition in your custom library, you must still supply a null prefix.

Use of the prefix definition

Draft uses the prefix definition when you obtain a part with the GET command. Instead of entering the entire name of the part, you can enter just the suffix. Draft displays a menu listing all the valid part names constructed by appending the suffix you provided with the prefixes in the prefix definition. For example, if TTL.LIB is one of your libraries and you enter the suffix 04, the menu lists the parts shown in figure 19-1.

<table>
<thead>
<tr>
<th>Prefix</th>
<th>Suffix</th>
<th>Part Name</th>
</tr>
</thead>
<tbody>
<tr>

<td>04</td>
<td>7404</td>
</tr>
</tbody>
</table>

Figure 19-1. Valid part names displayed by entering the suffix "04".
Constructing a prefix definition

You can construct a prefix definition in a text editor as follows:

1. Enter the PREFIX keyword.

2. Begin the first prefix string by typing a single quote '<'. Type the prefix string. It consists of a string of text characters no more than seven characters long. Draft does not distinguish between upper- and lowercase. Close a prefix string with another single quote.

3. Type an equal sign '<=>'. To improve readability, you can enter any number of space or <Tab> characters before and after the equal sign.

4. Type the shorthand string. The shorthand string consists of no more than seven text characters. After you have entered the shorthand string, press <Enter> and type the next line. You can define a maximum of sixteen unique prefix strings.

   The shorthand string is used to bypass the prefix menu and still enter an abbreviated part name. For example, you can obtain the part 74HC04, by supplying the GET command with the abbreviated name HC04. This is possible because HC is a shorthand string for 74HC.

5. Close the prefix definition by typing the keyword END alone on a line, followed by <Enter>. 
Example 1  This example below shows the prefix definition in the TTL.LIB library:

```
PREFIX
'74LS' = 'LS'
'74S' = 'S'
'74ALS' = 'ALS'
'74AS' = 'AS'
'74HCT' = 'HCT'
'74HC' = 'HC'
'74ACT' = 'ACT'
'74AC' = 'AC'
'74AHCT' = 'AHCT'
'74FCT' = 'FCT'
'74F' = 'F'
'74C' = 'C'
'74'
END
```

⚠️ NOTE: To view the prefix definition of a library file, use Decompile Library to convert the file to a library source file. See Chapter 18: Decompile Library for details.

Example 2  This is an example of a null prefix:

```
PREFIX
END
```

If you do not want prefixes in your library source file, you must use a null prefix at the beginning of the file.
Part definition

The part definition defines the following characteristics of a part:

- Part name
- Part size (in grid unit lengths on the screen and in tenths of an inch on the printed worksheet, unless the template table changes during configuration)
- Number of parts per package
- Pin functions (input, output, open collector, etc.).

Three types of part definitions

There are three types of part definitions: block symbol definitions, graphic definitions, and IEEE definitions. You don’t have to group your block definitions, graphic definitions, and IEEE definitions together. For example, your source file may contain a block definition, followed by a graphic definition, followed by another block definition.

Block, graphic, and IEEE definitions follow much the same syntax. A graphic definition looks like a block or IEEE definition followed by bitmap and vector definitions. When Compile Library sees a bitmap, it uses the bitmap to represent the part, rather than defaulting to a square or rectangle.

Components of a part definition

A part definition has the following fields:

- One or more part name strings. A name is a text string enclosed in single quotes. If you have more than one part name string, delimit them with a blank space or put them on separate lines. When obtaining a part, you can use any of the name strings.
- An optional sheet path designator. You can define a schematic file as a library part. This feature is useful for frequently used circuits.
Symbol size. Each unit represents a grid unit length on the screen and 0.1 inch on the printed worksheet (unless the pin-to-pin spacing was changed in the template table during configuration). The X size is given first, followed by the Y size. Also included on this line is one of the following:

- The number of parts per package
- The keyword GRIDARRAY if the part is a pin grid array
- The keyword IEEE if the part is an IEEE part

Pin definition. Each pin is defined on a separate line. A pin definition consists of the following fields:

- Pin position.
- Pin number or GRIDARRAY pin name enclosed in single quotes.
- Optional keywords:
  - DOT Puts an inversion bubble at the pin position.
  - CLK Puts a clock symbol at the pin position.
  - SHORT Puts leads one grid unit long at the pin position (instead of standard three-grid-unit leads).

  If DOT and CLK are used together, DOT must come first. SHORT cannot be used with DOT or CLK.

- Pin function (input, output, input/output, open collector, open emitter, power, passive, hi-z).
- Pin name string enclosed in single quotes.

An example of a pin definition is shown in figure 19-2.
Chapter 19: Creating a library source file with a text editor

Figure 19-2. Pin definition line.

For specific details about defining a pin, see Chapter 20: Symbol Description Language.

- An optional bitmap definition. Use this if the symbol you want is not a square or rectangle.
- An optional vector definition. This describes a graphic part in vector format. Edit Library and Plot Schematic use vector definitions for screen display and plotting.
- An optional converted form bitmap definition. This only has meaning if you’ve defined a bitmap. The most common use for converted bitmaps is to specify the DeMorgan equivalent symbol of the defined part.
- An optional converted form vector definition. This describes the converted form of a graphic part in vector format.
Defining a block symbol

Figure 19-3 is an example of a block symbol definition. The example does not represent a real part, although it is similar to a JK flip-flop. Figure 19-4 shows the symbol produced by this block definition.

<table>
<thead>
<tr>
<th>Part name string</th>
<th>'74EXAMP'</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reference designator</td>
<td>'LATCH'</td>
</tr>
<tr>
<td>Grid unit size (6 x 10) and number of parts per package (2)</td>
<td>6 10 2</td>
</tr>
</tbody>
</table>
| Pin definitions | L1 3 11 SHORT IN 'J'
| | L5 1 13 DOT CLK IN 'CLK'
| | L9 2 12 SHORT IN 'K'
| | B3 15 14 DOT IN 'CL'
| | T3 4 10 DOT IN 'P'
| | R1 6 7 OUT 'Q'
| | R9 5 9 OUT 'Q'
| | T0 16 16 PWR 'VCC'
| | B0 8 8 PWR 'GND'

Figure 19-3. Block symbol definition for 74EXAMP.

Figure 19-4. The block symbol for 74EXAMP.

Note the components making up the part definition. The first line is the part name string, 74EXAMP. The next line is the reference designator, LATCH. The third line represents the grid unit size and the number of parts per package. The remaining lines, starting with line four, are the pin definitions.
Chapter 19: Creating a library source file with a text editor

Part name string

The example on the previous page has only one part name string, '74EXAMP'. If you want to refer to the same part with different names you can list a number of part names. For example, to use the same part definition for the 8031, 80C31, 8051, 80C51, and 8751 components, put all five part name strings at the beginning of the part definition, as shown in figure 19-5.

```
'8031'
'80C31'
'8051'
'80C51'
'8751'
{X Size =} 13 {Y Size =} 25 {Parts per Package =} 1
L1  31  IN 'E:\A\VP'
L3  19  IN 'X1'
L6  18  IN 'X2'
.
.
```

Figure 19-5. Block symbol definition with multiple part names.

Notice that comments are enclosed in curly braces, as in figure 19-5. The X and Y coordinates are preceded by comments, as is the number of parts per package.

Sheetpath keyword

The example in figure 19-3 does not have a SHEETPATH keyword. If you need to have a part reference a schematic sheet, place the following line after the part name strings:

```
SHEETPATH 'schematic_filename'
```

where `schematic_filename` is the name of a schematic you have already drawn. Then, whenever you place a sheetpath part on your design, you actually place a copy of this schematic. Use sheetpath parts to represent frequently used circuits.

Normally, the filename does not include a pathname. If it doesn't, Draft looks for the schematic in the current library directory. If the sheetpath references a sub-circuit that is common to many designs, you can include a full pathname along with the filename.
Reference keyword

If a reference designator is used, it comes after the part name string (and sheetpath designator, if there is one).

In the example in figure 19-3, the reference designator appears as “LATCH.” When you run Annotate Schematic on a design containing the part, the question mark is replaced with a number. For example, if the reference designator for a resistor is R? and there are sixteen resistors in your design, Annotate Schematic changes the designators to R1, R2, . . . R16. You can also manually replace the question mark when you place the part in a worksheet with Draft.

This example has more than one part per package, so the reference designator appears with an A after the question mark. Annotate Schematic then sequences the letters. Annotate Schematic converts the A of the second part into a B. For example, after running Annotate Schematic, the first two occurrences of the 74EXAMP appear as LATCH1A and LATCH1B, the next two as LATCH2A and LATCH2B, etc.

If you omit the REFERENCE line, the default designator U?A appears on the schematic.

What appears for the reference designator when you get a part is determined as follows:

1. If the device has zero parts per package and you do not specify a REFERENCE keyword, no reference or part name appear.

2. If the device has zero parts per package and you specify a REFERENCE keyword, the reference appears. It consists of the string you specified followed by a question mark. The part name also appears.

3. If the device has one or more parts per package, and you do not specify a REFERENCE keyword, a default reference designator (U?A) appears. The part name also appears.

\[\text{NOTE: If, for some reason, you want a part without pin numbers, use a device with zero parts per package.}\]
Chapter 19: Creating a library source file with a text editor

4. If the device has one or more parts per package, and you specify a REFERENCE keyword, the reference appears. It consists of the string you specified followed by ?A (assigned and displayed by Draft). The part name also appears.

Table 19-1 shows the relationship between the number of parts per package and the reference designator appearing on the part. You must specify a part name; the name is what Draft uses to get a device from the library. The REFERENCE keyword is optional, however. If the REFERENCE keyword is not specified, it defaults to U.

<table>

<tr>
<td>Uses &quot;REFERENCE&quot; keyword</td>
<td>Uses reference keyword you enter in source library</td>
<td>Uses reference keyword you enter in source library</td>
</tr>
</tbody>
</table>

Table 19-1. Controlling display of reference designators.

Grid unit size and parts/package

The next line in figure 19-3 contains the three numbers 6 10 2. The first two numbers (6 and 10) represent the size. The size of the part is 6X by 10Y, where each unit represents one screen unit or 0.1 inch on the printed worksheet (if the pin-to-pin spacing in the Template Table section of the Configure Schematic Design Tools screen is 0.1 inch). The third number (2) indicates there are two parts per package. If the part is a pin-grid array, supply the keyword GRIDARRAY in place of the number of parts per package. If the part is an IEEE part, supply the keyword IEEE in place of the number of parts per package.
Pin definitions

The remaining lines in the example in figure 19-3 consist of the pin definitions. Consider the second pin position as an example.

The first field L5 locates the pin on the left side of the part in the fifth position counting down from the top. The previous line in figure 19-3 defined the Y dimension as 10. This means that there are 11 possible vertical positions, 0 through 10. The first possible position on the left side of the part is L0 and the last is L10. Likewise, the right side of the part contains positions R0 through R10. The specified pin position (L5) is on the left side of the part, 5 grid units from the top of the part.

The next two fields for pin position L5 identify the pin numbers. L5 is numbered 1 on the first part of the package and 13 on the second part of the package.

The fourth field for pin position L5 specifies DOT to obtain the inversion bubble and CLK to get the clock symbol. In this case, DOT and CLK are modifiers of the pin function, IN.

Finally, the last field for pin position L5 gives the pin a name of 'CLK'.

Refer back to figure 19-4 and locate pin L5 on the two parts in the package. They are both labeled "CLK".

As further examples, consider R9 and B3. R9 puts a pin on the right side in the ninth position, and B3 puts a pin on the bottom in the third position counting from the left. The two power supply connections are at the top and bottom in the zero position.

Note the vertices of a part have two possible representations. For example, L0 and T0 specify the same pin location (the upper left-hand corner).

\[\text{CAUTION: If you place a power pin at T0 and another power pin at L0, those pins are electrically connected.}\]
Figure 19-6 shows a grid representing the possible pin positions for the 74EXAMP library part.

Note the SHORT keyword in the L1 pin position in figure 19-3. Pins with the SHORT keyword have one-grid-unit leads rather than the default three grid units. The SHORT keyword, however, cannot be used with DOT or CLK keywords.

![Grid of a 6X by 10Y block symbol](image)

Figure 19-6. The grid of a 6X by 10Y block symbol.

**Pin type**

One possible pin type is PWR for power. Power pins do not appear on the screen. The connectivity database, however, does categorize all power pins connected to library parts.

If you wish to make parts with visible power pins, use the IN or PAS pin type instead of PWR. Remember to position the pin name (if it is a block part) so that it does not overlap other pin names.
Selectively displaying pins

If the device has more than one part per package, you can selectively display the pins. For example, assume you want to display the pins VCC and GND, but only on the second part of the device, not on the first. You can do this by coding the last two lines of the block symbol as follows:

\[
\begin{array}{c}
T0 & 0 & 16 & \text{PAS 'VCC'} \\
B0 & 0 & 8 & \text{PAS 'GND'} \\
\end{array}
\]

When you place this symbol on the screen, the passive pins do not display because the first column of pin locations contains a 0. When you place another symbol on the screen, it looks identical to the first. Both are called FF7A, and neither shows the power pins.

However, if you use Draft's EDIT command to change the reference designators to FF1A and FF1B, the power pins appear only on the second part of the device, FF1B. You can also use Annotate Schematic to change the reference designators.

This technique also works for other types of pins. By specifying a pin number of 0, you can cause a pin not to appear for the part of a package. But if your device has one part per package, specifying a pin number of 0 does not prevent the pin from appearing. The pin appears with a pin number of 0.

\(\text{△}\)

**NOTE:** If you want a part without pin numbers, use a device with zero parts per package.

If your device has zero parts per package, you do not specify pin numbers. Figures 19-7 and 19-8 illustrate how the number of parts per package, the pin number, and the Annotate Schematic tool affect the screen symbol.

The device 74ONE is identical to 74EXAMP, except it has only one part per package. Note the Annotate Schematic tool affects both the pinout and reference designator for 74EXAMP, but only the reference designator for 74ONE.
Also note the definition of 74EXAMP was modified so the power pins only appear in the second part of the package. In both 74ONE and 74EXAMP the locations of the power pins were moved from T0 and B0 to R3 and R7, so they would not overlap existing pins.

Figure 19-7. Before annotation.
Pin-grid array  
If the part is a pin-grid array, you supply the grid array pin name instead of the pin number. A grid array pin name consists of any string of up to 15 alphanumeric characters enclosed in single quotes.

Figure 19-9 is an example of a pin-grid array part definition. The example is the 68020 from the Motorola library, MOTO.LIB. The definition is quite long so only a few lines are shown. Notice the keyword GRIDARRAY on the second line, and the pin names in the second field on each pin definition line.

Figure 19-10 shows the resulting screen figure.
Chapter 19: Creating a library source file with a text editor

Figure 19-9. Pin-grid array part definition.

Figure 19-10. The block symbol for the 68020 defined in figure 19-9.
**Pin string** The pin string is delimited by single quotes. If you want a single quote as part of the pin string, you must use two single quotes. For example, 'CLK"s' defines the string CLK's. Also, a backslash after the pin string name puts a bar over the name. 'Q\' results in Q with a bar over it (\( \overline{Q} \)). If you have a multi-letter pin name, you must put a \ after each letter. For example, if you wanted the pin name IPL0 to have a bar above all four letters, the corresponding pin string entry in the part definition would be 'I\P\L\0\'. 
Defining a graphic symbol

A graphic symbol definition is composed of two parts: a bitmap definition and a vector definition. Both definitions are optional. However, Draft requires a bitmap, while Plot Schematic requires vectors. A bitmap definition specifies which screen pixels should be "turned on" when the part displays in Draft. A vector definition specifies the shape of the part in vector format. The vector definition is used by the Edit Library and the Plot Schematic tools.

Defining a bitmap

Creating a bitmap is an easy way to represent non-rectangular parts such as resistors, diodes, transistors, MOSFETs, relays, and many others. Draft draws complex parts by selectively turning on pixel bits representing the library part. Activating the correct pixel bit is controlled by a bitmap in the library source file you created.

To define a part with a bitmap, you define the part just as if it were a block symbol, but you include a bitmap after the last pin definition. You can either draw the bitmap with periods (.) and pound signs (#) (see figure 19-11 for an example), or you can reference a previously drawn bitmap. "Previously drawn" means the bitmap was defined earlier in the library source file.

Refer to a previously drawn bitmap if two parts have different pinouts, but the same symbol. For example, the 7439 and the 7400 have the same symbol, but different pinouts. Assume you've defined the 7400 and you're now defining the 7439. Instead of drawing another bitmap, you can use the 7400's for the 7439 by including the line:

```
BITMAP '7400'
```

If you don't reference a previously drawn-out bitmap, you must specify the part's own bitmap. The bitmap begins after the last pin definition. A pound sign (#) indicates the pixel bit is turned on, and a period (.) indicates the pixel bit is turned off.
Each . or # in the bitmap represents a screen pixel spacing of 0.01 inch in the X direction. Each line of the bitmap represents 0.01 inch in the Y direction. Remember, the X and Y sizes in the part definition are given in units of 0.1 inch. For example, if you specify X and Y to be 3 and 2, your bitmap actually is 31 characters in the X direction and 21 lines in the Y direction. The extra 1 results because the bitmap starts counting at zero. Figure 19-11 shows the bitmap for a graphic.

Defining a vector

Following the bitmap definition, you can specify a vector definition of the part. A vector definition is a set of circle, arc, line, text, and fill specifications that define the shape of the part in vector form.

Each line in the vector definition specifies one graphical piece of the part. For example, the following lines define an AND gate:

```
VECTOR
LINE +4.0 +0.0 +0.0 +0.0 {Top}
LINE +0.0 +0.0 +0.0 +4.0 {Left}
LINE +0.0 +4.0 +4.0 +4.0 {Bottom}
ARC +4.0 +2.0 +0.0 -2.0 +2.0 +0.0 +2.0
ARC +4.0 +2.0 +2.0 +0.0 +0.0 +2.0 +2.0
END
```

The first line identifies the beginning of the vector definition. The next three lines specify the beginning and ending points of the top, left, and bottom lines in the AND gate. The next two lines define the two arcs making up the half circle on the right side of the part. Finally, the last line denotes the end of the vector definition. For details on defining vectors, see Chapter 20: Symbol Description language.
### Graphic symbol considerations

There are a few points you should keep in mind when creating a graphic symbol, as opposed to a block symbol.

1. You have to pay close attention to pin placement. For example, if you wanted to build the part shown at right, you would need to be very careful placing pin 3.

   ![Diagram](image)

   The reason for this is that the pin will be placed on the part boundary. This means that your custom part will have blank space between itself and the body of the part. You will probably want a graphic line between the part boundary side of the pin and the part body.

   You will probably prefer to build this custom part in Edit Library.

   **NOTE:** To make your custom part look nice, place a short pin on the part boundary as you usually would. Then, draw a graphic line from the pin to the line you need to connect it to.

2. Although you can put a pin name in the pin definition, the pin name does not appear on the screen. The pin name is, however, recognized connectivity database.

3. A graphic symbol can include a converted form of the symbol. Graphic devices always have a normal form; optionally, they can have a converted form. Usually (but not always), the converted form is the DeMorgan equivalent symbol of the normal form.

   When you use the GET command in Draft, and extract a graphic part from a library, it appears in normal form. From the menu that displays, you can also choose its converted form instead. You define what the converted form is when you create the library source file.

   Block and IEEE symbols cannot have converted forms.
4. The maximum number of bits allowed in a bitmap is 16,384. However, bitmaps are allocated in blocks of eight. So consider a bitmap consisting of 21 rows of 31 bits. Rather than $21 \times 31 = 651$ bits, the space actually taken up by such a bitmap is $21 \times 32 = 672$ bits.

5. The Edit Library and Plot Schematic tools use vector definitions. So, although vectors are optional, you won’t be able to edit the part with Edit Library or plot it with Plot Schematic if you don’t use vectors.

**Converted form graphic symbol**

After defining a graphic symbol, you have the option of defining a converted form graphic symbol. As stated previously, the typical use of a converted form graphic symbol is to supply a DeMorgan equivalent symbol, but more generally a converted form specifies another graphic symbol to display on the screen whenever you choose the Convert option of the GET command. You can return to the original graphic symbol by selecting Normal.

Begin the specification of a converted form graphic symbol with the keyword CONVERT. The converted form graphic symbol consists of pin definitions followed by a bitmap and a vector definition. If the converted form is already defined, you can reference it by including the name of the part with the converted form in single quotes.

Here’s a more detailed example showing how to use the converted form graphic symbols. The definition of the 7400 is shown first. Then, the converted form graphic symbol—the DeMorgan equivalent of the 7400—is shown. Figure 19-11 and figure 19-12 show both the normal and converted symbols resulting from this part definition.

The 7400 has five pins, two of which are power pins not appearing in the symbol. The screen size is 6 X-units and 4 Y-units. It has four parts per package.

The converted form graphic symbol uses the same XY size and parts per package as the normal graphic symbol. You must, however, redefine the pin types. Note the DOT keyword missing from the redefinition of the pin at R2.
Also note that the converted form graphic symbol has the same number of parts per package as the normal graphic symbol. The number of parts per package determines how many columns of pin numbers appear in the definition. The converted definition must have the same number of columns as the normal definition.

Note that the part definition in figure 19-11 contains both the bitmap and vector definition of the part.
Figure 19-11. The 7400 symbol.
Figure 19-12. The converted form of the 7400 symbol.
Defining an IEEE symbol

An IEEE symbol is composed of the following parts: a name string, a size and type definition, a pin definition, and a vector definition.

Part name string

The part name string is defined the same as for block and graphic symbols. To refer to the same part with different names, you can list multiple part names as shown below.

```
'74ALS114'
'74ALS114A'
'74AS114'
'74F114'
'74HC114'
'74L114'
'74S114'

{X Size =} 8 {Y Size =} 12 {Part is a} IEEE
T6 14 PWR 'VCC'
B6 7 PWR 'GND'

TEXT +8.0 +11.0 1 ACTIVE_LOW_L
END
```

Figure 19-13. IEEE symbol definition for 74114 parts.
Size and type definitions

The line following '74S114' in figure 19-13 contains the numbers 8 and 12, followed by the letters IEEE. The comments inside the curly braces (see figure 19-13) show the X Size, Y Size, and the keyword IEEE.

The keyword IEEE means the part is an IEEE-type symbol and, therefore, has one part per package and does not have a convert.

Pin definitions

Following the size and type definitions is the pin definitions section.

For example, look at the fourth position. The first field, L2, locates the pin on the left side of the part in the second position from the top. The next field defines the pin number: pin 13. The third field describes the function of the pin and defines how it will be drawn. "CLK IN" defines an input pin drawn with the clock symbol (»). Finally, the last field for pin position L2 names the pin "CLK."

Vector definitions

Vector definitions are similar to those of a graphic symbol with the following exceptions:

- The allowed vector types include only: CIRCLE, LINE, and TEXT. ARC and FILL are not allowed.
- You have more freedom when drawing the vector components. In particular, some components must be placed outside the part body. For example, an input ACTIVE_LOW must be placed to the left of the part body, as shown by pins 1, 4, 10, and 13 in figure 19-14. Inputs placed to the left of the part body have a negative X offset in the vector section of the IEEE symbol definition. See figure 19-13.
Defining a vector

A vector definition for an IEEE part is a set of circle, line, and text specifications that define the shape of the part in vector form. Each line in the vector definition specifies one piece of the part’s body.

The first line of the vector section identifies the beginning of the vector definition with the keyword “VECTOR.” In figure 19-3, the next twelve lines—beginning with the keyword “LINE,”—specify the starting and ending points of all the lines in the body of the part.

The nine lines beginning with the keyword “TEXT,” specify the locations of the text on the part. Finally, the last line denotes the end of the vector definition. For details on vectors, see Chapter 20: Symbol Description Language.

△ NOTE: Plot Schematic draws IEEE parts using Vector commands in the order they are defined in the vector section of the IEEE symbol definition. You can minimize plotter pen travel and Up-Down commands by careful ordering. This can save quite a bit of plotting time.

IEEE standards

IEEE symbols are designed to create parts that meet the IEEE drawing standards in ANSI/IEEE Std 91-1984. Some of the requirements of this standard are not entirely intuitive. It is an excellent idea to study the standards before beginning any major effort to draw a new set of IEEE parts.

Size

IEEE symbol dimensions can be up to 12.7 x 12.7 inches. The symbols can contain many internal vector objects. All but the very largest ASIC devices can be drawn as IEEE parts.

In some cases, though, it may be more practical to use SHEET symbols on actual designs. In particular, if an ASIC device has a large number of signals which can be represented as buses, it may be easier and clearer to show the device with a small number of bus connections and a reasonable number of control signals.
Chapter 19: Creating a library source file with a text editor

Pin placement

In general, the IEEE standard wants pins placed only on the left and right side of parts: inputs on the left, and outputs on the right. Schematic Design Tools does allow you to place pins on the top and bottom, however, to support ASIC devices with more than 255 pins. See Size above for information on the use of SHEET symbols for handling ASIC devices.

Building the IEEE body outline

IEEE symbols usually have a rectangular outline. They often consist of a control section on top of a main signal section. There are usually indentations in the outline near the bottom of the control section. Normally the indentations are 0.1 inch high. Figure 19-14 shows an example.

Defining this visual aspect cannot be done automatically. You have to specify the outline with LINE commands.

IEEE Vector Objects

Use TEXT commands to place IEEE objects such as those shown at right. The objects are drawn to be eight units high when used with a size argument of one. This is the same height as text of size one. It also fits nicely between pins which are normally spaced ten units apart. The horizontal component was chosen to match the suggestions contained in the IEEE standard. This height and width makes the objects easy to read in Draft at Zoom scale 1 and for plots or hardcopy that is done at 100 dots per inch.
Placing ACTIVE_LOWs  The IEEE standard suggests an ACTIVE_LOW be drawn so that it is 1.5 times as wide as it is high. Since OrCAD's IEEE objects are 8 units high by default, this means the ideal width of and ACTIVE_LOW is 12 units. In a TEXT command, "1.2" represents 12 units. ACTIVE_LOW inputs are usually placed with -1.2 X offset in order to get the point of the triangle on the outline.

The IEEE standard implies that ACTIVE_LOWs should only be used external to a part body. Signals internal to the body are intended to be logical, not physical. Hence, Negation or CIRCLEs should be used where a logical inversion operation is needed inside a part.

△ NOTE: When a part is IEEE type, you have considerable leeway in deciding where the vector objects should be placed. As a result of various aspects of the IEEE standard, they can be either inside or outside the part's body outline. Any time you draw a library part with objects outside the part's body, however, you increase the chances of creating a messy and possibly confusing schematic. For this reason, add Vector objects outside the part's body only if there's no other way to define the part properly.
This chapter describes how to define a part in a custom library. It presents OrCAD's Symbol Description Language (SDL) in the form of syntax diagrams. A syntax diagram consists of identifiers (enclosed in ovals) and tokens (enclosed in rectangles).

Syntax diagram

Figure 20-1 is an example of a syntax diagram. It represents the complete syntax for a library source file.

Figure 20-1. Syntax diagram for a library source file.

To read a syntax diagram, follow these rules:

1. Read the diagram from left to right.

2. The direction of the arrows on a path represent correct syntax forms.

3. Junctions represent a connection point where you have the choice of selecting another path. For example, the syntax diagram for the library source file shown in figure 20-1 has a junction after a Part Definition. You can choose to complete the diagram or to make another Part Definition.
4. You cannot travel a path going against the arrows. For example, in figure 20-1, you cannot return to the prefix definition after you make a part definition.

5. Text enclosed in ovals represents an identifier. Text enclosed in squares represents a token. Identifiers and tokens are described below.

**Identifiers**

Identifiers serve as placeholders for a more detailed level of syntax structure. They do not represent command syntax or tokens. Rather, they provide the ability to give an overview of the syntax. When you create the part, you must work down through all the nested identifiers. For example the syntax diagram for a library source file shown in figure 20-1 has two identifiers (Prefix Definition and Part Definition) and no tokens.

**Tokens**

Tokens are the building blocks of a library source file. Just as a sentence is made up of words, a library source file is made up of tokens. A token belongs to one of the following categories:

- **Numeric constants.** A numeric constant consists of one or more whole-number digits.

Examples:

\[
\begin{array}{ll}
15 & 127 \\
2 & 98
\end{array}
\]

- **Character strings.** A character string consists of one or more alphanumeric characters.

Examples:

\[
\begin{array}{ll}
74ALS04 & L5 \\
CLOCK & ZENER
\end{array}
\]
Keywords. A keyword is one of the following:

BITMAP        Takes an argument (a text string representing a part name) and represents the bitmap of the identified part.
CLK           Represents the clock symbol in a pin definition.
CONVERT       Introduces a converted graphic symbol definition. With an argument, it refers to the converted bitmap and vector definitions of a graphic symbol.
DOT           Represents the inversion bubble in a pin definition.
END           Specifies the close of a prefix or vector definition.
GRIDARRAY     Specifies the device is a pin-grid array. Used in place of the number of parts per package.
HIZ           Identifies the pin as a high impedance (state) output.
IEEE          Specifies that the object is an IEEE object, and will conform to IEEE drawing standards.
IN            Identifies the pin as an input.
I/O           Identifies the pin as input/output.
OC            Identifies the pin as open collector.
OE            Identifies the pin as open emitter.
OUT           Identifies the pin as an output.
PAS           Identifies the pin as passive.
PREFIX        Specifies the beginning of a prefix definition.
PWR           Identifies the pin as a power pin. The PWR keyword prevents a pin from displaying.
<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>REFERENCE</td>
<td>Takes an argument (a text string representing a reference value). Overrides the default reference value.</td>
</tr>
<tr>
<td>SHORT</td>
<td>Specifies the pin lead lengths be 1 grid unit instead of the standard 3 grid units.</td>
</tr>
<tr>
<td>VECTOR</td>
<td>Specifies the beginning of a part's vector definition.</td>
</tr>
</tbody>
</table>
Syntax described in this chapter is shown following these conventions:

**UC** Text in uppercase represents a keyword.

*italics* Text in italics represents either a character string or a numeric constant.

[ ] Text enclosed in brackets is optional. You choose whether to type it in or not. Don’t type the brackets.

{} Text enclosed in braces is required. You must enter what’s represented within the braces. Don’t type the braces.

, If items within square brackets or braces are separated by commas, you choose one of them only. Don’t type the comma.

... Ellipses mean you can repeat the last item. How many times you can repeat the item depends on the context. Don’t type the periods.

Vertical lists of options mean that you can choose any one of the options in the list.

Explanations follow each syntax definition. Within these definitions, keywords, character strings, and numeric constants are shown in the left margin with an arrow:

**⇒** **KEYWORD** This is an example of a keyword definition.

**⇒** **Character string** This is an example of a character string definition.

**⇒** **Numeric constant** This is an example of a numeric constant definition.

**Example** Here is an example of syntax represented in text:

```
[pos pin#,...,grid,...]
```

The entire line is enclosed in brackets, which means it is optional. The `pos`, `pin#`, and `grid` parameters are in italics, so each must be replaced with a valid character string or numeric constant. The comma between `pin#` and `grid` specifies either `pin#` or `grid`, but not both, may be used on the same line. The ellipses following `pin#` and `grid` specify that more than one occurrence of `pin#` or `grid` may appear on the same line.
Prefix definition

PREFIX
[ "prefix string" [ = "shorthand string"] ]
  •
  •
END

⇒ prefix string A string of up to seven text characters. You can have a maximum of sixteen prefix strings.

⇒ shorthand string A string of up to seven text characters.

△ NOTE: The equal sign may be separated by one or more space or tab characters.

Figure 20-2. Syntax diagram for a prefix definition.
Example 1

PREFIX
'74LS' = 'LS'
'74S' = 'S'
'74ALS' = 'ALS'
'74AS' = 'AS'
'74HCT' = 'HCT'
'74HC' = 'HC'
'74ACT' = 'ACT'
'74AC' = 'AC'
'74F' = 'F'
'74' = 'F'
END

[vector definition]
[converted form bitmap definition]
[converted form vector definition]

Figure 20-3. Syntax diagram of a part definition.

Figure 20-4. Syntax diagram of a part name string.
Chapter 20: Symbol Description Language

△ NOTE: To type an apostrophe, use two single quotes. For example, to type:
   'John's'
   type:
   'John''s'

△ NOTE: To improve readability, you can include comments within a part definition. Comment text is enclosed within curly brackets. For example:

    (This is a comment)

You can also place blank lines within a source file. Typically blank lines are placed between different part definitions.

**part name string**

A character string of up to 127 text characters identifying the part. This is the string used as an argument for the GET command in Draft.

It is a good idea to stay well below the maximum number of characters. Two reasons for this recommendation are:

- On a 640 x 480 screen, a name longer than 78 characters will have some characters clipped at zoom scale 1.
- While OrCAD's connectivity database is extremely flexible, some destination tools cannot accept long names. If you have a particular destination in mind, refer to the netlist format file for information about the limits of the destination tool. This information is available using the View Reference Material tool.

**ref string**

A string of text characters. If present, the reference designator replaces the default reference designator.

**path and filename**

The name of a schematic referenced by a sheetpath part.

**X size**

A numeric constant in the range 1 to 127. The horizontal size of the part as it appears on a printed worksheet. Each entry corresponds to one grid unit.
| **Y size** | A numeric constant in the range 1 to 127. The vertical size of the part as it appears on a printed worksheet. Each entry corresponds to one grid unit. |
| **parts-per-package** | A numeric constant in the range 0 to 16. If you specify a 0, the pins are not numbered on the symbol. If you specify GRIDARRAY, an alphanumeric string of up to 15 characters enclosed in single quotes is allowed as pin numbers. If you specify IEEE, you automatically get one part per package. |
| **pin definition** | See the pin definition description later in this section. |
| **bitmap definition** | This definition describes the part body in bitmap form. See the bitmap definition description later in this section. |
| **vector definition** | This definition describes the part body in vector form. See the vector definition description later in this section. |
| **converted form bitmap definition** | This definition describes the part body of the part's converted form (for example, its DeMorgan equivalent) in bitmap form. See the converted form bitmap definition description later in this section. |
| **converted form vector definition** | This definition describes the part body of the part's convert (for example, its DeMorgan equivalent) in vector form. See the converted form vector definition description later in this section. These examples shows two part name strings. These may be on the same or separate lines. |

Figure 20-5. Syntax diagram for a pin definition.
**pos** Defines pin position. A letter followed by a number. The letter is one of the following:

- **T** indicates the top of the symbol.
- **L** indicates the left side of the symbol.
- **R** indicates the right side of the symbol.
- **B** indicates the bottom of the symbol.

The number represents the distance along the indicated side. The distance is measured in grid unit lengths. For example, if the block symbol were 6X by 10Y the grid used for placing pins is as follows. Figure 20-6 shows the location of L3.

![Diagram of grid](image)

*Figure 20-6. The grid of a 6X by 10Y block symbol.*
Figure 20-7. The Position syntax number diagram.

- **pin #** If present, this is a numeric constant representing the pin number. This is the pin number appearing in the symbol. The range for the pin numbers is 0 to 255.

- **grid** A letter followed by a number. *grid* represents the pin-grid array pin number (figure 20-8). You can only choose a pin-grid array pin number if you chose the keyword GRIDARRAY, instead of parts-per-package. A pin-grid array pin number is an alphanumeric string of up to 15 characters enclosed in single quotation marks.

Figure 20-8. Gridarray pin number syntax diagram.

- **SHORT** A keyword that places a short lead at the specified pin. A normal lead is 3 grid units long; a SHORT one is 1 grid unit long. The SHORT keyword cannot describe a pin also having either the CLK or DOT keywords.

- **DOT** A keyword for placing the inversion symbol (the bubble, see right) at the specified pin location. The DOT keyword cannot describe a pin also having the SHORT keyword. The primary use of the bubble is to identify pins with logic negation, either at an input or at an output.
Chapter 20: Symbol Description Language

- **CLK** A keyword for placing the clock symbol (see right) at the specified pin location. The CLK keyword cannot describe a pin also having the SHORT keyword.

  Use the CLK keyword together with the DOT keyword to produce a DOT CLK symbol (see right).

- **IN** A keyword identifying the pin as an input.

- **OUT** A keyword identifying the pin as a standard totem-pole output.

- **I/O** A keyword identifying the pin as a dual function input/output pin.

- **OC** A keyword identifying the pin as an open collector or open drain.

- **OE** A keyword identifying the pin as an open emitter.

- **PWR** A keyword identifying a power pin, such as VCC, GND, VSS, VDD, and others. Power pins are not displayed on library parts when they appear on the screen or printed worksheet. However, the connectivity database connects all power supply pins defined in library files.

- **PAS** A keyword identifying a pin as passive. Passive pins are typically pins on passive devices such as resistors, capacitors, inductors, and others.

- **HIZ** A keyword identifying a pin as a high-impedance (state) output.
A character string representing a name for the specified pin. For block symbols, this name appears on the screen or the printed worksheet. Pin names do not appear on the screen or the printed worksheet when they are part of pin definitions for a graphic symbol. However, you may still choose to use pin names in graphic symbols. The Create Netlist tool requires them, and you may find them useful to identify specific pins.

You can enter pin names either in upper- or in lowercase, but they always appear in uppercase.

The backslash (\) and single quote (') are special characters. A backslash (\) after a character indicates the character has a bar over it. If you want to bar multiple characters, you must place a backslash after each character. The single quote delimits the part name string. If you want a single quote as part of the pin string, you must delimit it with another single quote. Figure 20-9 shows the syntax for the pin name string.

![Pin name string syntax diagram](image)

**Figure 20-9. Pin name string syntax diagram.**
Chapter 20: Symbol Description Language

Example 1

Example 1

Example 2

Example 3

Example 2

Example 3
**Bitmap definition**

\[
[ (.,#) \ldots, \text{BITMAP} \ 'part\ name' , \text{CONVERT} \ 'part\ name' ]
\]

---

**Figure 20-10. The bitmap syntax diagram.**

**Figure 20-11. The bitmap line.**

- A . represents a cleared pixel bit not displayed on the screen.

- A # represents a set pixel bit.
Chapter 20: Symbol Description Language

**part name**  A previously-defined part name with a bitmap. If you specify *part name* with the BITMAP keyword, the bitmap and vector definitions of the normal form of the previously-defined part are used. If you specify *part name* with the CONVERT keyword, the definitions of the converted form of the previously defined part are used.

Keep these limitations in mind:

- Maximum bitmap size is 16384 pixels.
- Each pixel represents 0.1 of a grid unit. Therefore, it takes 10 bitmap pixels to represent one grid unit. Remember, pin placement is determined according to grid units.
  
  For example, L0 identifies a pin on the left side of the bitmap line in the zero position. L1 identifies a pin on the left side of the tenth bitmap line. Pin placements are at lines 0, 10, 20, 30, etc.
  
  - The lines and character positions of a bitmap start numbering at 0. Hence, a symbol with X=2 and Y=3 has 21 lines, each with 31 character positions.
  - If a line contains only periods (a clear line), you need only place a period in the first column.
  - You need not include clear lines (lines containing only periods) at the end of a bitmap.
  - Periods are not required after the last # in a line.
  - If you use the BITMAP 'part name' option, be sure the part name you refer to is previously defined.
Example 1

'CAPACITOR'
Reference 'C'
{X Size = } 2 {Y Size = } 1 {Parts per Package = } 0
T1 SHORT PAS '1'
B1 SHORT PAS '2'

Notice how comments ---------
are used to label both
the horizontal and
vertical axis.

Example 2

BITMAP '7400'
This uses the bitmap and vector definitions for the
normal form of the 7400 device.

Example 3

CONVERT '7400'
This uses the bitmap and vector definitions for the
converted form of the 7400 device. The 7400 part must
have a converted form if the library source file is to
compile without errors.
Vector definition

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VECTOR</td>
<td>ARC</td>
</tr>
<tr>
<td>CIRCLE</td>
<td>X center Y center</td>
</tr>
<tr>
<td>FILL</td>
<td>X start Y start</td>
</tr>
<tr>
<td>LINE</td>
<td>X start Y start X end Y end</td>
</tr>
<tr>
<td>TEXT</td>
<td>X start Y start</td>
</tr>
</tbody>
</table>

\[\text{NOTE: If you use the BITMAP 'part name' option (as described in the "Bitmap Definition" section), you don’t need to specify a separate vector definition. The bitmap and vector definitions of the part referred to by part name are used.}\]

**ARC**
An ARC line defines a section of a circle. The first pair of X,Y coordinates specifies the center of the circle from which the arc is taken. The second pair of X,Y coordinates (edge1) defines one ending point on the arc. The third pair of X,Y coordinates (edge2) defines the other ending point on the arc. The edge1 and edge2 coordinates are relative to the center of the circle; they are not absolute coordinates.

**CIRCLE**
The X,Y coordinates specify the center of the circle. radius specifies the distance from the center to the outside of the circle.

**LINE**
The first pair of X,Y coordinates specifies the beginning of the line. The second pair of X,Y coordinates specifies the end of the line.
FILL shades the enclosed area around the X,Y coordinates. One use of FILL is to darken the triangular shape in the symbol of a diode.

TEXT The X,Y coordinates specify the point at which the lower left corner of the first character of the text starts. height defines the multiplier of the text size defined in the template table on the Configure Schematic Design Tools screen. For example, if pin text is set to 0.06 inches in the template table, and the height is 2, then the actual plotted height is 0.12 inch. The remainder of the TEXT line can be either text enclosed in single quotes or a keyword.

Keywords are IEEE/ANSI special symbols. If you use one of these keywords, the symbol corresponding to the keyword appears instead of text. Possible keywords are:

- ACTIVE_LOW_L
- ACTIVE_LOW_R
- AMP_L
- AMP_R
- ANALOG
- ARROW_L
- ARROW_R
- BIDIRECTIONAL
- DYNAMIC_L
- DYNAMIC_R
- GENERATOR
- HYSTERESIS
- NON_LOGIC
- OPEN_O
- OPEN_H
- OPEN_L
- POSTPONED
- PULL_UP
- PULL_DOWN
- SHIFT_L
- SHIFT_R
- THREE_STATE

For more information about these symbols, see ANSI/IEEE Std 91-1984.
Figure 20-12. Converted form syntax diagram.

**part name**
The part name of a previously-defined part. If you specify part name with the BITMAP keyword, the bitmap and vector definitions of the normal form of the previously-defined part are used. If you specify part name with the CONVERT keyword, the definitions of the converted form of the previously defined part are used.

**pin definition**
See the pin definition description earlier in this section. Note the pin definition for a converted bitmap has the same value for parts-per-package as the normal bitmap.

**bitmap definition**
This specifies a new bitmap for the converted form of the part. See the bitmap definition description earlier in this section. If you use bitmap definition, do not use the BITMAP or CONVERT keywords.
**vector definition** This specifies a new vector for the converted form of the part. See the vector definition description earlier in this section. If you use vector definition, do not use the BITMAP or CONVERT keywords.

△ **NOTE:** If you use the CONVERT 'part name' option, be sure the part name you refer to is previously defined.
Compile Library

Compile Library takes a library source file and produces a compiled library file used by the schematic editor, processors, reporters, and transfers.

Creating a custom library with Compile Library

A custom library is a library that you modify or create. To create a custom library with Compile Library, follow these two steps:

1. Create a library source file. The source file is a text file containing instructions in OrCAD's Symbol Description Language (described in chapter 20).

   You can use any text editor to create the library source file. The only requirement is that it produce a text file without hidden formatting characters.

   You can also use the Archive Parts in Schematic tool to create a library source file. Another way to get a library source file is to use Decompile Library or an existing library.

2. Compile the source file using the Compile Library tool. It produces a compiled library file.
△ NOTE: The maximum length for a part name is 127 characters. Use much smaller part names if you possibly can, however. On a 640 x 480 screen at ZOOM level 1, a name longer than 78 characters will be clipped. Also, many netlist formats place severe restraints on the length of names. Check the name length requirements for the netlist format you are using. This information is available using the View Reference Material tool.

Running Compile Library

With the Schematic Design Tools screen displayed, select Compile Library. Select Execute from the menu that displays.

Compile Library creates the new library. When Compile Library is complete, the Schematic Design Tools screen appears.

Local Configuration

With the Schematic Design Tools screen displayed, select Compile Library. Select Local Configuration from the menu that displays.

Select Configure COMPOSER. A configuration screen appears (figure 21-1).

![Configure Compile Library](image)

Figure 21-1. Compile Library's local configuration screen.

File Options

File Options defines the library source file and the resulting library file.
Chapter 21: Compile Library

Prefix/Wildcard

Enter a pathname and wildcard to indicate which files to display in the list box with scroll buttons. The asterisk character (*) is used as a wildcard. The default is:

\ORCADES\SDT\LIBRARY\*.SRC

If you do not specify a prefix, Compile Library looks for files in the current design directory.

If you erase the entire field, the entry will be restored to whatever prefix is specified in Configure Schematic Design Tools.

Files

The files that match the search filter entered in the Prefix/Wildcard entry box and those that match the filter in the current design directory are listed in this box. Files in the current directory are shown with .\ before their names. Use the scroll buttons to scroll the list of files up and down.

When you see the file you would like to compile, select it. Its filename displays in the Source entry box.

Source

The Source is the text file describing your custom parts using OrCAD's Symbol Description Language.

Specify the source file by selecting it from the Files list box described above, or enter its name by simply typing it in this entry box and pressing <Enter>.

⚠️ NOTE: A question mark (?) in an entry box tells ESP to default to the Startup Design name. This simplifies changing between designs: All you need do is change the Startup Design on the Configure ESP screen, exit ESP, then restart ESP by entering ORCAD.

For example, if you enter ?.SRC in the Source entry box and the Startup Design is configured as "TUTOR," the next time you look at the local configuration, the Source entry box will be configured as "TUTOR.SRC." If you then change the Startup Design to "DESIGN2" and restart ESP, the Source entry box will be configured as "DESIGN2.SRC."
**Destination**

The **Destination** is the library file created by **Compile Library**. If you give the name of an existing file, **Compile Library** asks if you want to overwrite the existing file. You cannot append to an existing file.

The **Destination** may be a complete pathname.

**Processing Options**

You may select either or both of the following options:

- **Quiet mode**
  
  Turns quiet mode on.

- **Do not sort library**
  
  Tells **Compile Library** to save parts in the source file in the order they were entered (rather than sorting them alphabetically, which is the default).
Reporters are tools that produce human-readable reports, but do not modify design data in any way.

Part V describes the Reporter tools that change the design to a format you can read.

Chapter 22: Check Electrical Rules describes how Check Electrical Rules checks a design for conformity to basic electrical rules.

Chapter 23: Cross Reference Parts describes how Cross Reference Parts scans through the design, gathers information for all parts used in the design, and creates a cross reference listing telling you where each part is located.

Chapter 24: Convert Plot to IGES describes how Convert Plot to IGES translates a plot of a single worksheet or a complete design into IGES format.

Chapter 25: Plot Schematic describes how Plot Schematic plots designs.

Chapter 26: Print Schematic describes how Print Schematic prints designs.

Chapter 27: Create Bill of Materials describes how Create Bill of Materials creates a summary list of all parts used in a design.

Chapter 28: Show Schematic Structure describes how Show Schematic Structure scans the worksheets in a design and displays the sheet names and their associated worksheet filenames.
The Check Electrical Rules reporter checks a design for conformity to basic electrical rules. It does not check for other types of errors in your design.

Check Electrical Rules scans a design and checks the sheets for unused inputs on parts and invalid connections, such as two part pins defined as outputs wired together. An example of the electrical rules checked by this reporter is included at the end of this chapter. Check Electrical Rules reports two categories of electrical rules violations:

- Errors that must be fixed
- Warnings of situations that may or may not be all right in your design

Always carefully examine any problems reported by Check Electrical Rules.

You specify the conditions to be checked using the Check Electrical Rules matrix on the Configure Schematic Design Tools screen. See How to specify conditions to check in this chapter for more details.

Unless you tell it otherwise on the configuration screen, Check Electrical Rules is incremental. This means that if you run Check Electrical Rules twice on the same design without fixing anything, no errors are reported the second time it runs since there is nothing new to report.
If Check Electrical Rules finds warnings or errors, it marks them in the schematic file. If Check Electrical Rules reports "Program did not complete successfully." after running, go to Draft to fix the errors. Every warning or error is marked with a circle as shown in the figure below. Note that the wire coming from pin 5 on U1B and the wire coming from pin 3 of U1A have circles on them.

![Image of a schematic with two warnings marked with circles.]

**Find and repair errors**

Use the INQUIRE command to see the error message or warning for any trouble spots. Fix the problems, update the schematic file, and run Check Electrical Rules again.

**Discard error markers**

To discard error markers without making any changes to the schematic, select QUIT Update File.

**Running Check Electrical Rules**

Select Check Electrical Rules from the Schematic Design Tools screen. Select Execute from the menu that displays.

While Check Electrical Rules runs, messages display in the monitor box at the bottom of the screen. When it is done, the Schematic Design Tools screen appears.
Typical messages and resolutions

Table 22-1 on the next page lists the most common error messages produced by Check Electrical Rules and possible solutions to resolve the errors.

How to specify conditions to check

Figure 22-1 shows the decision matrix that tells Check Electrical Rules the conditions to check for when evaluating connections between pins, module ports, and sheet net names.

To configure the decision matrix to check for certain conditions, go to the Check Electrical Rules Matrix section of the Configure Schematic Design Tools screen. For more information on Configure Schematic Design Tools, see Chapter 1: Configure Schematic Tools.

The matrix shows the pins, module ports, and sheet net names in columns and rows. A connection is represented by the intersection of a row and column. The intersection of a row and column is either empty, or contains a "W," or an "E." An empty intersection represents a valid connection, a W is a warning, and E represents an error.

![Check Electrical Rules Matrix](image)

*Figure 22-1. The decision matrix used by Check Electrical Rules to check a connection.*
### Schematic Design Tools Reference Guide

#### Table 22-1. Error messages created by Check Electrical Rules and possible solutions.

<table>
<thead>
<tr>
<th>Message</th>
<th>Check for</th>
</tr>
</thead>
<tbody>
<tr>
<td>WARNING: Unconnected MODULE PORT “........” at X=.... at Y=...</td>
<td>A bus may not be labeled properly. It must be named in the form: BUSNAME[m..n]. Any module port connected to a bus must also be named in the proper form: BUSNAME[m..n]. For further information, see Chapter 9: Creating a netlist.</td>
</tr>
<tr>
<td>WARNING: POWER Supplies are CONNECTED .... &lt;-&gt; ....</td>
<td>If you connected two power supplies together, this warning appears. This condition may be acceptable in your design. If you did not mean to connect two power supplies together, this indicates a problem may exist. If you intentionally connected two power supplies together, you may ignore this warning.</td>
</tr>
<tr>
<td>WARNING: INPUT has NO Driving Source ....</td>
<td>If you did not connect wires to the input pins of a library part, this warning appears. Again, this condition may be acceptable in your design. If wires are connected to an input pin and this message appears, you may have two wire ends overlapping or a wire overlapping a part pin. Wires must be connected end-to-end. If you intentionally did not connect wires to the input pins of a library part, you may ignore this warning.</td>
</tr>
<tr>
<td>ERROR: Module Port on a bus does not have a proper format.... can not process....</td>
<td>When a module port is connected to a bus, it must be in the format: BUSNAME[m..n].</td>
</tr>
<tr>
<td>ERROR: Bus Label does not have a proper format.... can not process...</td>
<td>When a label is placed on a bus, it must be in the format: BUSNAME[m..n].</td>
</tr>
<tr>
<td>ERROR: Sheet Net on a bus does not have a proper format... can not process...</td>
<td>This error typically results from a bus connected to a hierarchical sheet net. The sheet net and module port must have the same name and number of members, but the sheet net and bus may differ at the root level. The form should be: BUSNAME[m..n].</td>
</tr>
</tbody>
</table>
You can toggle between these three settings by pointing to an intersection and clicking the mouse until the desired setting appears. To return all intersections to their default settings, click the Set to Default button.

For example, if you have an output pin connected to an input pin, find the Check Electrical Rules value in the matrix by starting in the OUT column (the third column) and going down to the IN row (the first row). The box is empty, which represents an acceptable connection. However, if you follow the OUT column down to the OUT row (the third row), you see an E, which indicates this condition will be detected as an error.

Connections prefixed with an "m" are module ports. You can have four types of module ports: input (mI), output (mO), bidirectional (mB), and unspecified (mU).

Connections prefixed with an "s" are sheet net names. As with module ports, you can have four types of sheet net names: input (sI), output (sO), bidirectional (sB), and unspecified (sU).

NC means Not Connected.

For definitions of the pin types, see the PIN Type command description in Chapter 2: Draft.

Example

The following example shows the type of errors Check Electrical Rules looks for in schematic sheets. Figure 22-2 shows a schematic sheet containing a 74LS245 part from the TTL.LIB library. Notice pins 2, 3, 4, 7, and 8 are tied together and pins 5, 6, and 9 are tied together. These connections are electrically sound because pins 2 through 9 are bidirectional (I/O) type pins. Though this may not be a particularly useful circuit, it doesn't violate any electrical rules, so Check Electrical Rules doesn't report any errors.
Suppose you add a 74LS00 part (also from TTL.LIB) to the sheet shown in figure 22-3. This introduces two potential electrical violations to the sheet because pin 6 on U2B and pin 3 on U2A are output type pins. Output pins usually are not connected to bidirectional pins. If you run Check Electrical Rules on the design with the decision matrix set to its defaults, it reports the following warnings:

**Warning, Possible conflict I/O connected TO OUTPUT U2B,0**
**Warning, Possible conflict I/O connected TO OUTPUT U2A,0**
**WARNING - INPUT has NO Driving Source U2B,10**
**WARNING - INPUT has NO Driving Source U2B,11**
**WARNING - INPUT has NO Driving Source U2A,10**
**WARNING - INPUT has NO Driving Source U2A,11**
With the Schematic Design Tools screen displayed, select Check Electrical Rules. Select Local Configuration from the menu that displays.

Select Configure ERC. A configuration screen appears (figure 22-4).

**Figure 22-4. Check Electrical Rules's local configuration screen.**

**File Options**

File Options defines the source file, its type, and the destination file.

**Source**

The Source can be the root sheet name of the design, or the filename of a single sheet. It may have any valid pathname.

⚠️ NOTE: To have ESP configure the source filename for you, enter a question mark instead of the filename, followed by the file extension. For example, if you enter `? .SCH`, ESP changes the `?` to the name of the Startup Design (configured in the Design Options section of the Configure ESP screen) when you leave the local configuration screen.
After entering the source filename, select one of the following options:

- **Source file is the root of the design**
  
  Specifies that the source file is the root sheet name of a hierarchical or flat design. If the root sheet contains sheet symbols, then the design is hierarchical. If it contains a Link, it is a flat design.

- **Source file is a single sheet**

  Specifies that the source file is a single worksheet and you want to process the single sheet only.

**Destination**

The Destination can be any valid path name where the list of errors is to be placed. If a destination is not specified, the list of errors display in the monitor box at the bottom of the screen.

\[\text{\textit{NOTE:}} \text{ The errors and warnings are automatically saved to the schematic. The destination would be used for review, but is optional.}\]

**Processing Options**

You may select any combination of the following options:

- **Quiet mode**
  
  Turns quiet mode on.

- **Descend into sheetpath parts**

  Causes Check Electrical Rules to descend into any parts defined as sheetpath parts. If this option is not selected, Check Electrical Rules treats the sheetpath itself as a part to be cross-referenced and does not cross reference the parts within a sheetpath.
Chapter 22: Check Electrical Rules

- Unconditionally process all sheets in design
  Forces Check Electrical Rules to check all sheets in the design regardless of whether or not the sheets changed since Check Electrical Rules ran last.

- Report off-grid parts
  Lists all off-grid parts in the report.

- Report all connected labels and ports
  Lists all connected labels and ports in the report.

- Report unconnected wires, pins, module ports
  Lists all unconnected wires, pins, and module ports in the report.

- Check module port connections
  Causes Check Electrical Rules to check all module ports and make sure they have a corresponding connection.

- Do not report warnings
  Causes Check Electrical Rules to run without reporting warnings.

- Ignore warnings
  Causes Check Electrical Rules to continue running when it encounters warnings, instead of halting in the middle of execution.
Cross Reference Parts

Execution

The Cross Reference Parts reporter scans through the specified schematic files, gathers information for all parts used in the schematic files, and creates a cross reference listing telling you where each part is located. Cross Reference Parts scans a multiple-sheet file structure or a one sheet file structure.

By default, Cross Reference Parts produces two types of output listings. These listings differ in the order in which the parts are sorted. The first type of listing is sorted first by part values, then by reference designators. The second type of listing is sorted first by reference designators, then by part values.

Running Cross Reference Parts

Select Cross Reference Parts from the Schematic Design Tools screen. Select Execute from the menu that displays.

While Cross Reference Parts runs, messages display in the monitor box at the bottom of the screen. When the report is complete, the Schematic Design Tools screen appears.
Sample Output  Figure 23-1 shows a sample report created by Cross Reference Parts.

<table>

</table>

*Figure 23-1. Report created by Cross Reference Parts.*

Local Configuration  With the Schematic Design Tools screen displayed, select Cross Reference Parts. Select Local Configuration from the menu that displays.

Select Configure CROSSREF. A configuration screen displays (figure 23-2).

*Figure 23-2. Local configuration screen for Cross Reference Parts.*
File Options

File Options defines the source file, its type, and the destination file.

Source

The Source can be the name of the root sheet of the design, or the filename of a single sheet. It may have any valid pathname.

△ NOTE: To have ESP configure the source filename for you, enter a question mark instead of the filename, followed by the file extension. For example, if you enter ?.SCH, ESP changes the ? to the name of the Startup Design (configured in the Design Options section of the Configure ESP screen) when you leave the local configuration screen.

After entering the Source, select one of the following:

- Source file is the root of the design

  Specifies that the source file is the root sheet name of a hierarchical or flat design. If the root sheet contains sheet symbols, then the design is hierarchical. If it contains a \Link, it is a flat design.

- Source file is a single sheet

  Specifies that the source file is a single worksheet and you want to process the single sheet only.

Destination

The Destination can be any valid path name where the listings are to be placed. If a Destination is not specified, the listings are displayed in the monitor box at the bottom of the screen.
Processing Options

You may select any combination of the following options:

- **Quiet mode**
  
  Turns quiet mode on.

- **Descend into sheetpath parts**
  
  Causes Cross Reference Parts to descend into any parts defined as sheetpath parts. If this option is not selected, Cross Reference Parts treats the sheetpath itself as a part to be cross referenced and does not cross reference the parts within a sheetpath.

- **Report identical part reference designators**
  
  Tells Cross Reference Parts to check for identical part references in addition to creating the usual report. You should not have identical part references in your design. Remove them by editing them with Draft or running Annotate Schematic.

- **Report unused parts in multiple-part packages**
  
  Tells Cross Reference Parts to list all unused parts in multiple-part packages in addition to its usual report.

- **Report the X, Y coordinates of all parts**
  
  Tells Cross Reference Parts to list the X,Y coordinates for all parts.

- **Place each part entry on a separate line**
  
  Tells Cross Reference Parts to place each part entry on a separate line.
Report type mismatch parts

This feature tells Cross Reference Parts to report type mismatches in addition to the usual report. Two kinds of mismatches are possible:

- Parts with the same part name, but different numbers of parts per package.
  For example, a U1 and a U1A. This would mean that the U1 has one part per package, while the U1A has more than one part per package.

- Parts with similar reference numbers, but different part names.
  For example, a 74LS00 with the reference number U1A and a 54LS00 with reference number U1B.

Select either of the following options:

- Sort output by part value, then by reference designator
  This tells Cross Reference Parts to list all parts sorted first by part values and then by reference designators.

- Sort output by reference designator
  This tells Cross Reference Parts to list all parts sorted first by reference designators and then by part values.

Select either of the following options to specify whether or not to place a header on each page of the report:

- Insert a header for each page
- Do not insert a header for each page
Select either of the following options to specify whether
the report is single- or double-spaced:

Report is
   ○ single-spaced
   ○ double-spaced

If desired, select this option:

☐ Ignore warnings

Causes Cross Reference Parts to continue running when
it encounters warnings, instead of halting in the
middle of execution.
CHAPTER 24

Convert Plot to IGES

Execution

Convert Plot to IGES translates a plot of a single worksheet or a complete design into IGES, Initial Graphic Exchange Specification, text format. The IGES data format is application-independent and includes information about geometric and topological shapes, physical dimensions, tolerances, and other intrinsic properties.

To learn more about IGES, read the Initial Graphics Exchange Specification (IGES) Version 3.0, Number PB86-199759, published by the National Bureau of Standards, Washington D.C.

After you run Convert Plot to IGES, the file can be used with other applications that accept IGES input—such as VersaCad®—or stored on a mainframe computer.

Plot the file

Before you run Convert Plot to IGES, plot your worksheet with the GENERIC.DRV plotter driver configured. See Chapter 1: Configure Schematic Tools and Chapter 25: Plot Schematic for information on configuring plotter drivers and plotting.

Running Convert Plot to IGES

With the Schematic Design Tools screen displayed, select Convert Plot to IGES. A menu displays. Select Execute.

While Convert Plot to IGES runs, messages display in the monitor box at the bottom of the screen. When the report is complete, the bottom of the Schematic Design Tools screen displays.
Sample output  Figure 24-1 shows a sample report created by Convert Plot to IGES.

<table>

</tbody>
</table>

Figure 24-1. Output created by Convert Plot to IGES.
With the Schematic Design Tools screen displayed, select Convert Plot to IGES. Select Local Configuration from the menu that displays.

Select Configure PLT2IGES. A configuration screen appears (figure 24-2).

File Options defines the source file and the destination of the IGES plot.

Source

The Source is the name of the plot file or group of plot files to be translated into IGES format.

The source may be a single plot file or a wildcard specification. The suggested wildcard specification is *.PLT. When Plot Schematic runs, it should be configured with a destination of ?.*.PLT so that all of the sheets will be ready to convert to IGES format.

Destination

The Destination is any valid path name where the output of Convert Plot to IGES is to be placed.

If the source is a wildcard specification, the destination should also be a wildcard specification. The suggested destination wildcard specification is *.IGS.
Plot Schematic plots schematic sheets.

There are two types of output devices that can be used with OrCAD Schematic Design Tools: plotters and printers. These devices are categorized by the type of input they require.

If a device accepts *vector* commands, it is considered to be a plotter. A vector is a series of points with a specific function defined. For example, a line has a beginning point and an ending point. A circle has a center and a radius. The device needs to know what the vector information is but does not need every point along the vector.

If a device accepts *raster* commands, it is a printer. A raster is an array of dots. When you draw a line to a raster device, you must specify each and every dot.

Plots are higher resolution than prints and usually take longer to produce (because there is more mathematical calculation needed). For these reasons, use Plot Schematic to plot the schematic when design work is complete. Use Print Schematic (described in chapter 26) to print working copies of your schematic during the design process.

Plot Schematic can plot all sheets in a multiple-sheet file structure or just one sheet. It makes one copy of each sheet referenced more than once in a complex hierarchy.

Before you run Plot Schematic, be sure the appropriate plotter is configured on the Configure Schematic Design Tools screen. For more information about configuring your plotter, see Chapter 1: Configure Schematic Tools.
Running Plot Schematic

With the Schematic Design Tools screen displayed, select Plot Schematic. Select Execute from the menu that displays.

While Plot Schematic runs, messages display in the monitor box at the bottom of the screen. When Plot Schematic completes the plot, the Schematic Design Tools screen appears.

Plots can include grid references in the output. Plot Schematic plots all Stimulus, Trace, Vector, Layout, and No-Connect objects.

NOTE: Plot Schematic does not check to see if the plot will fit in the plot area of a plotter, nor does it split a design into several pages on a plotter if its image does not fit on a single page. If you choose the Send output to printer option, however, Plot Schematic prints a large image on multiple sheets.

Suppressing the title block, border, and text

You can make Draft and Configure Schematic Design Tools cause the title block, title block text, and the design’s border to not appear on the plot. These settings are summarized below.

- To cause the title block and its text to not appear on Draft’s screen, select SET Title Block No in Draft. Note that the design’s border is not removed.
- To cause the title block or title text to not appear on a plot, display the Color and Pen Plotter Table of the Configure Schematic Design Tools screen and set the pen number to 99 for the title block or the title text. If you set the title block’s pen number to 99, the design’s border is also removed from the plot.
- To cause the title block or title text to not appear on Draft’s screen, display the Color and Pen Plotter Table of the Configure Schematic Design Tools screen and set the color to black for the title block or the title text. With the title block’s color set to black, the design’s border does not show on Draft’s screen.
Sample output  Figure 25-1 shows a sample plot created by Plot Schematic.

Figure 25-1. Plot created by Plot Schematic.
Local Configuration

Select Plot Schematic from the Schematic Design Tools screen. A menu displays. Select Local Configuration.

Select Configure PLOTALL. A configuration screen appears (figure 25-2).

File Options define the source file and its type and the destination of the plot.

Source

The Source can be the root sheet name of the design, or the filename of a single sheet, with any valid pathname.

△ NOTE: To have ESP configure the source filename for you, enter a question mark instead of the filename, followed by the file extension. For example, if you enter ? .SCH, ESP changes the ? to the name of the Startup Design (configured in the Design Options section of the Configure ESP screen) when you leave the local configuration screen.
After entering the source filename, select one of the following options:

- **Source file is the root of the design**
  
  Specifies that the source file is the root sheet name of a hierarchical or flat design. If the root sheet contains sheet symbols, then the design is hierarchical. If it contains a Link, it is a flat design.

- **Source file is a single sheet**
  
  Specifies that the source file is a single worksheet and you want to process the single sheet only.

Select one of the following three options:

- **Send output to plotter**
  
  Use this option only if your sheet dimensions are 32 inches by 32 inches or less. Make sure you have configured the plotter driver on the Configure Schematic Design Tools screen to the plotter you want to use. See Chapter 1: Configure Schematic Tools for more information.

- **Send output to printer**
  
  Use this option to create a scaled print of your schematic. Make sure you have configured the printer driver on the Configure Schematic Design Tools screen to the printer you want to use. See Chapter 1: Configure Schematic Tools for more information.

\( \text{NOTE: When plotting to a printer, make the pen width for buses small enough to make the lines thin. This makes the print neater and more readable. For example, if you have a printer with a resolution of 180 DPI, set the pen width to be:} \)

\[
\left( \frac{1}{180} \right) \frac{2}{2} = 0.00277 \text{ inches}
\]

Round the result up to 0.003 inches for best results. The same value is also used for the part body pen width and during FILL commands in the vector stream of the part definition.
○ Send output to a file

Sends the Plot Schematic output to a file, rather than to a printer or plotter.

If the Send output to a file option is selected, you can select one of the following options:

○ Create a PRINT file

  File [Box]

○ Create a PLOT file

  File Extension [Box]

If either of these options is selected, the output is stored in a file (or files) containing the formatting codes required by your printer or plotter. Be sure you have configured the printer or plotter driver on the Configure Schematic Design Tools screen for the printer or plotter you want to use. See Chapter 1: Configure Schematic Tools for more information.

Create a PRINT file creates one large file containing print information for every sheet in the design, separated by page breaks. Enter a name for the file in the File entry box.

Create a PLOT file creates one file per worksheet in the design, with the filename extension you specify in the File Extension entry box appended to the sheet name—except when the option Plotter uses roll feed paper is selected. (This exception is described in the next paragraph.) You can then plot single sheets, or send the set of files to the plotter sequentially to plot the entire design.

When the option Plotter uses roll feed paper is selected, Create a PLOT file, like Create a PRINT file, produces one large file containing plot information separated by page breaks (roll feed commands).
Chapter 25: Plot Schematic

Processing Options

You may select any combination of the following options:

- Quiet mode
  Turns quiet mode on.

- Descend into sheetpath parts
  Causes Plot Schematic to descend into parts defined as sheetpath parts. Without this option selected, Plot Schematic treats the sheetpath itself as a part and does not plot the referenced sheets.

- Plot grid references around the worksheet border
  Tells Plot Schematic to include grid references in the plotted output.

- Ignore "fill" commands
  Specifies that parts with fills should not be filled in when plotted. It is a good idea to use this switch when you are reducing a plot or when you want to plot a draft version of your design quickly.

Select one of the following options:

- Produce 1:1 scale plot

- Automatically scale and set X, Y offsets for specified sheet size
  A  B  C  D  E

  Tells Plot Schematic to use the X,Y offsets of the specified sheet size, as configured in the template table. Select one of the following: A, B, C, D, or E.
○ Manually set scale factor and/or X, Y offsets

☐ Set scale factor

Tells Plot Schematic to scale the plot by the scale factor you enter in Set scale factor entry box. The scale factor is a decimal number in the form: #.###. The default scale factor is 1.000. The allowed range is 0.10 to 10.000.

Table 25-1 shows the scale factors to use to plot worksheets on different sizes of plotter paper. The scale factors shrink or expand the image so the widest axis (horizontal or vertical) fits on the plotter paper. The narrow axis will have some blank area.

<table>
<thead>
<tr>

<td>0.638</td>
</tr>
<tr>
<td>C</td>
<td>0.474</td>
</tr>
<tr>
<td>D</td>
<td>0.301</td>
</tr>
<tr>
<td>E</td>
<td>0.224</td>
</tr>
</tbody>
</table>

Table 25-1. Plot Schematic scale factors.

△ NOTE: Table 25-1 assumes you are using the default Template Table values for Horizontal and Vertical paper dimensions. These values are set on the Template Table section of the Configure Schematic Design Tools screen. For more information, see Chapter 1: Configure Schematic Tools.
To scale the size of Plot Schematic's plot, find the scale factor in Table 25-1 corresponding to the worksheet size and plotter paper size you are using. Enter the number in the Set scale factor.

Scaling is also controlled by your plotter. Plotter scaling is typically controlled by the size of the paper used, rotation settings, and the other settings on the plotter.

If you change the size of the worksheets you are plotting (for example, plotting a C-size, then a B-size worksheet), always RESET the plotter first to return the plotter to a known state. If you have further scaling questions, see your plotter manual.

- Set X, Y offsets X ___ Y ___

Specifies the plot's X and Y offset. Enter a decimal number, measured in inches from the center. The allowed range is -30.000 to 30.000. For example, when X is -3.600, it means the origin is 3.6 inches to the left of the plot's center.

Some plotters have their origin in the center rather than the lower left corner. If your schematic appears in the upper-right quadrant of the paper, set the X and Y offsets to negative values to move the origin to the lower left corner. Note X and Y are not affected by scaling.

Some plotter drivers (for example, HP.DRV) produce a divide error when you specify a D or E-size and do not specify an X,Y offset.

The plotter driver converts inches into plotter units and for large size plots the resulting number exceeds the 16-bit integer limit. Hence, large paper plotters compensate by having the origin in the center of the paper. You must adjust the origin back to the lower left corner with the X and Y offsets. Typically, the offsets are $-\frac{1}{2}$ the paper dimension.
△ **NOTE:** The X and Y custom offsets are measurements after scaling is applied. For example, if you have a C-size worksheet you want to plot on B-size paper, you must use the Use scale factor option and specify 0.638 as the Scale factor. However, the X and Y values are B-size measurements.

Select one of the following if **Send output to Plotter** or **Create a PLOT file** is selected:

- Plotter uses single sheet paper
- Plotter uses roll feed paper

Tells Plot Schematic that the plotter you are using has a roll feed. Plot Schematic inserts the commands necessary to roll the paper after each sheet. **Note:** Not all plotters have roll-feed capability.

Select one of the following if **Send output to Printer** or **Create a PRINT file** is selected to specify whether wide (13-inch) paper or narrow (8-inch) paper is used to plot to a printer:

- Printer has narrow paper
- Printer has wide paper
Print Schematic

Print Schematic prints schematic sheets. Use Print Schematic to print interim (working) copies of your design during the design process. Use Plot Schematic to plot the schematic when design work is complete.

Print Schematic prints one copy of each sheet that is referenced in a complex hierarchy, even if that sheet is referenced more than once.

There are two basic types of output devices that can be used with Schematic Design Tools: plotters and printers. These devices are categorized by the type of input they require.

If a device accepts vector commands, it is considered to be a plotter. A vector is a series of points with a specific function defined. For example, a line has a beginning point and an ending point. A circle has a center and a radius. The device needs to know what the vector information is but does not need every point along the vector.

If a device accepts raster commands, it is a printer. A raster is an array of dots. When you draw a line to a raster device, you must specify each and every dot.
Running Print Schematic

Select Print Schematic from the Schematic Design Tools screen. Select Execute from the menu that displays.

While Print Schematic Runs, messages display in the monitor box at the bottom of the screen. When the report is complete, the Schematic Design Tools screen appears.

Sample output

Figure 26-1 shows a sample printout created by Print Schematic.

Figure 26-1. Output created by Print Schematic.
With the Schematic Design Tools screen displayed, select Print Schematic. Select Local Configuration from the menu that displays.

Select Configure PRINTALL. A configuration screen appears (figure 26-2).

![Configuration Print Schematic](image)

**Figure 26-2. Print Schematic's local configuration screen.**
File Options

File Options defines the source file and type and the destination of the print.

Source

The Source can be the root sheet name of the design, or the filename of a single sheet. It may have any valid pathname.

△ NOTE: If you want ESP to configure the filename of the source for you, enter a question mark instead of the filename, followed by the file extension. For example, if you enter \?.SCH, ESP changes the ? to the name of the Startup Design configured in the Design Options section of the Configure ESP screen when you leave the local configuration screen.

After entering the source filename, select one of the following options:

○ Source file is the root of the design
  Specifies that the source file is the root sheet name of a hierarchical or flat design. If the root sheet contains sheet symbols, then the design is hierarchical. If it contains a Link, it is a flat design.

○ Source file is a single sheet
  Specifies that the source file is a single worksheet and you want to process the single sheet only.

Select one of the following options:

○ Send output to printer

○ Send output to a file
  If you select Send output to a file, enter the path and filename of the output file in the File entry box.
Processing Options

You may select any combination of the following options:

- Quiet mode
  
  Turns quiet mode on.

- Descend into sheetpath parts
  
  Tells Print Schematic to descend into parts defined as sheetpath parts. Without this option selected, Print Schematic treats the sheetpath itself as a part and does not print the referenced sheets.

- Print grid references around the border
  
  Tells Print Schematic to include grid references in the plotted output.

- Suppress pin numbers on print
  
  Tells Print Schematic to print the schematic without pin numbers.

Select either of the following options:

- Printer has narrow paper

- Printer has wide paper

Specifies whether wide (13-inch) paper or narrow (8-inch) paper is used to plot to a printer.
Create Bill of Materials

Execution

The Create Bill of Materials reporter creates a summary list of all parts used in a design. Create Bill of Materials scans a design or only a single sheet.

Optionally, special information specific to your application may be added in a text file called an "include file." If this special information is included, Create Bill of Materials lists the parts found in the order in which they appear in the include file. Any parts not in the include file are placed at the end of the report.

Running Create Bill of Materials

With the Schematic Design Tools screen displayed, select Create Bill of Materials. Select Execute from the menu that displays.

While Create Bill of Materials runs, messages display in the monitor box at the bottom of the screen. When the report is complete, the Schematic Design Tools screen appears.
Sample output  Figure 27-1 shows a sample parts list created by Create Bill of Materials.

Revised: October 11, 1990
Revision: A

Figure 27-1. Bill of Materials created by Create Bill of Materials.
**Chapter 27: Create Bill of Materials**

**Key fields**  
Create Bill of Materials has one key field. It is shown in the Key Fields section of the Configure Schematic Design Tools screen as follows:

Create Bill of Materials

Part Value Combine

Include File Combine

Create Bill of Materials uses the Part Value Combine key field to combine the part value and part fields together to become the value used in the summary list. For parts to have the same value in the Create Bill of Materials report, they must have the same values in the key field. If you do not specify a key field, the Create Bill of Materials value is the part's value.

The Include File Combine is used to build a lookup string to match in the Include File. As with the Part Value Combine, if this key field is not specified, the Part Value is assumed to be the match string.

For more information about key fields, see Chapter 1: Configure Schematic Tools.
Local Configuration

With the Schematic Design Tools screen displayed, select Create Bill of Materials. Select Local Configuration from the menu that displays.

Select Configure PARTLIST. A configuration screen appears (figure 27-2).

![Figure 27-2. Local configuration screen for Create Bill of Materials.](image)

File Options

File Options defines the source file and its type. It also defines the destination file and whether to merge an include file with the partlist.

Source

The Source can be the root sheet name of the design, or the filename of a single sheet. It may have any valid pathname.

△ NOTE: If you want ESP to configure the filename of the source for you, enter a question mark instead of the filename, followed by the file extension. For example, if you enter `? .SCH`, ESP changes the `?` to the name of the Startup Design configured in the Design Options section of the Configure ESP screen when you leave the local configuration screen.
After entering the source filename, select one of the following:

- **Source file is the root of the design**
  Specifies that the source file is the root sheet name of a hierarchical or flat design. If the root sheet contains sheet symbols, then the design is hierarchical. If it contains a Link, it is a flat design.

- **Source file is a single sheet**
  Specifies that the source file is a single worksheet and you want to process the single sheet only.

**Destination**

The Destination is any valid system pathname, and is where the output of the report is to be placed. If a destination is not specified, the output of Create Bill of Materials displays in the monitor box at the bottom of the screen.

**Include**

- **Merge an include file with report**
  The Include is the path and filename of a text file containing information to be merged in the Bill of Materials. The format of this file is discussed below.

  After you select this option, the Include entry box changes from dim to highlighted. Enter the name of the include file in the Include entry box.
Include file format

The include file is a text file in which you place additional part information. This part information is included in the Create Bill of Materials summary list. A sample include file is shown in figure 27-3.

The first line of the file is a header line. The line begins with a pair of single quotes with no characters or spaces between them. The rest of the line contains the header information you want to include.

The remainder of the file contains separate lines for each part needing additional information. Each line must begin with the part name as it appears in your worksheet. The name must be enclosed within single quotes (such as '74LS00'). Following the part name (on the same line), place the information that you want included for that part (for example, “TTL Quad Two Input NAND Gate 10004040000”).

For both types of lines, header and part, the line will be aligned with the first non-space character of the information portion of the line. When Create Bill of Materials has finished scanning the sheets, it then scans the include file to include the rest of the line after any part name that matches.

Figure 27-3. Include file format.
Chapter 27: Create Bill of Materials

Processing Options

You may select any combination of the following options:

- **Quiet mode**
  - Turns quiet mode on.

- **Descend into sheetpath parts**
  - Tells Create Bill of Materials to descend into any parts defined as sheetpath parts. Without this option selected, Create Bill of Materials treats the sheetpath itself as a part to be listed and does not list the parts within a sheetpath.

- **Place each part entry on a separate line**
  - Tells Create Bill of Materials to put each part entry on a separate line in the summary.

- **Verbose report**
  - Tells Create Bill of Materials to produce a more detailed report. This report includes the title block information.

Select either of the following options:

- **Insert a header for each page**
- **Do not insert a header for each page**

These options specify whether or not to insert a header on each page. The header includes information such as the title of the design, the date, the document number, the revision code, the report name, the page number (if you select **Insert a header for each page**), and the time the report is created.

Select either of the following options:

Report is

- **single-spaced**
- **double-spaced**

These options specify whether the report is single- or double-spaced.
If desired, select either of these options:

☑ Report un-used match strings in an include file

Tells Create Bill of Materials to keep track of which strings in an include file don’t have a corresponding match string in the design. This report can be used to find match strings in an include file that were accidentally entered duplicated.

☑ Ignore warnings

Causes Create Bill of Materials to continue running when it encounters warnings, instead of halting in the middle of execution.
Show Design Structure

Execution
Show Design Structure scans the schematics in a design to display the sheet names and their associated worksheet filenames.

Running Show Design Structure
With the Schematic Design Tools screen displayed, select Show Design Structure. Select Execute from the menu that displays.

While Show Design Structure runs, messages display in the monitor box at the bottom of the screen. When the report is complete, the Schematic Design Tools screen appears.

Sample output
Figure 28-1 shows a sample report created by Show Design Structure.

```
<<<root>>>
  halfadd_A
[ex6b.sch] October 11, 1990
  halfadd_B
[ex6b.sch] October 11, 1990
```

Figure 28-1. Report created by Show Design Structure.
Local Configuration

With the Schematic Design Tools screen displayed, select Show Design Structure. Select Local Configuration from the menu that displays.

Select Configure TREELIST. A configuration screen appears (figure 28-2).

![Figure 28-2. Show Design Structure's local configuration screen.](image-url)
File Options

**File Options** defines the source file and its destination file.

*Source*

The **Source** is the name of the root sheet of the design.

⚠️ **NOTE:** To have ESP configure the source filename for you, enter a question mark instead of the filename, followed by the file extension. For example, if you enter `? .SCH`, ESP changes the `?` to the name of the Startup Design (configured in the **Design Options** section of the Configure ESP screen) when you leave the local configuration screen.

*Destination*

A pathname where the output of **Show Design Structure** is to be placed. If a path is not specified, the output displays in the monitor box at the bottom of the screen.

Processing Options

You may select any combination of the following options:

- **Quiet mode**
  
  Turns quiet mode on.

- **Descend into sheetpath parts**
  
  Tells **Show Design Structure** to descend into any sheetpath parts. Without this option selected, **Show Design Structure** treats the sheetpath itself as a part and does not descend into the sheetpath.

- **Ignore warnings**
  
  Causes **Show Design Structure** to continue running when it encounters warnings, instead of halting in the middle of execution.
PART VI: TRANSFERS

Schematic Design Tools includes Transfer tools that manage the steps needed to move design information from one tool set to another. Transfers update the database then change from Schematic Design Tools to other OrCAD tool set screens.

Part VI describes Transfer tools and provides instructions for their use.

Chapter 29: To PLD describes the transfer to the Programmable Logic Design Tools screen.

Chapter 30: To Digital Simulation describes the transfer to the Digital Simulation Tools screen.

Chapter 31: To Layout describes the transfer to the PC Layout Tools screen.

Chapter 32: To Main describes the transfer to the main ESP design environment screen.
About To PLD

The To PLD transfer consists of three processes that update the database so that the design may be viewed by the Programmable Logic Design Tools. These processes are:

- **FLDSTUFF (Update Field Contents)** loads information you define into the fields of parts on a specified schematic.

  FLDSTUFF constructs a string from the key field designators for a specified field. Then, if that string equals a match field in a designated update file, it replaces the specified field with the update value.

  For more information about this process, see Chapter 13: Update Field Contents.

- **ANNOTATE (Annotate Schematic)** scans a design and automatically updates the reference designators of all parts in the worksheet.

  ANNOTATE updates reference designators in the order they were placed in the worksheet. When the worksheet is annotated, all parts may be assigned a new reference designator, including any manually edited parts. To selectively change reference designators and leave others unmodified, use Draft.

  For more information about this process, see Chapter 6: Annotate Schematic.
EXTRACT (the Extract PLD processor on the Programmable Logic Design Tools screen) extracts PLD source code from a schematic for use with Programmable Logic Design Tools. The program reads a .SCH file and produces one or more .PLD files, adding pin information and other coding in the process.

For more information about this process, see Chapter 8: Using the Extract PLD processor in the Programmable Logic Design Tools User's Guide.

Execution

To PLD reads the schematic database and updates the PLD source files for all devices found in the design. The design may be a complex or simple hierarchy, or a flat design.

NOTE: If the source code for the PLD logic is a schematic, it should be created and edited in the Programmable Logic Design Tools area with the Edit Schematic Logic button. While technically the schematic for the internals of the PLD is part of the design, it is isolated by the fact that it represents the internal logic of the device. The schematics for the board, on the other hand, represent the external view of the logic for the design.

Running To PLD

With the Schematic Design Tools screen displayed, select To PLD. Select Execute from the menu that displays.

When the transfer process is complete, the Programmable Logic Design Tools screen displays (figure 29-1).

The Edit Schematic Logic and Compile Schematic Logic buttons are preconfigured at OrCAD with the correct libraries for logic development and the correct settings for the PLD compiler.
Figure 29-1. Programmable Logic Design Tools screen.

Local Configuration of To PLD

Since FLDSTUFF, ANNOTATE, and EXTRACT are each configured individually, To PLD has three configuration screens. To configure To PLD, select To PLD. Select Local Configuration from the menu that displays.

The menu shown at right displays. Use this menu to choose which To PLD process to configure or to turn a process on or off. When you run To PLD, only the processes that are turned on run. In most cases, you will have EXTRACT turned on and the other processes turned off.

To turn a process on or off, choose the desired process from the menu. For example, to turn FLDSTUFF on, select FLDSTUFF off from the menu. Schematic Design Tools displays:

A menu with the options on and off displays. Select on to turn the process on.
With the Schematic Design Tools screen displayed, select To PLD. Select Local Configuration from the menu that displays, and then select Configure FLDSTUFF. A configuration screen displays (figure 29-2).

**Figure 29-2. FLDSTUFF's local configuration screen.**

**File Options**

File Options defines the source file and its type. It also defines the update file.

**Source**

The Source is the root sheet and filename of the design or the filename of a single sheet. It may have any valid pathname. After entering the source filename, select one of the following:

- **Source file is the root of the design**
  
  Specifies that the source file is the root sheet filename of a hierarchical or flat design.

- **Source file is a single sheet**
  
  Specifies that the source file is a single worksheet and you want to process the single sheet only.

**Update-file**

The Update-file is a text file that you create. The file format is described in Chapter 13: Update Field Contents.
Select one of the following options to define which field is to be updated:

- **Part Value**
- **Part Field 5**
- **Part Field 1**
- **Part Field 6**
- **Part Field 2**
- **Part Field 7**
- **Part Field 3**
- **Part Field 8**
- **Part Field 4**

The field parameter selected above also identifies a key field designator. There are nine key field designators, one for the part's value, and one for each of the eight part fields. They are found on the Configure Schematic Design Tools screen as shown in figure 29-3.

![Update Field Contents](image)

**Figure 29-3. Key field designators for FLDSTUFF.**

FLDSTUFF constructs a string from the key field designator set up for the field parameter selected. For example, if you select "Part Field 3" and the Update Field Contents Combine for Field 3 is V 2, then Update Field Contents constructs a string consisting of the part's value, a space, and the contents of 2nd Part Field.

FLDSTUFF then tries to match that string with the match fields listed in the update file. Each match field has a corresponding update field. If a match occurs, Update Field Contents replaces the contents of the field parameter (selected above) with the corresponding update field.

For additional information about key fields, see the Schematic Design Tools User's Guide.
The key fields shown are shared between this process and the Update Field Contents processor. For more information on the key fields and other operating characteristics, see Chapter 13: Update Field Contents.

Select any combination of the following options:

- Quiet mode
  
  Turns quiet mode on.

- Create an update report
  
  Creates a report listing all the parts on each sheet and whether a field was updated for each part. If this option is selected, the Destination entry box is used to specify where the report is written.

- Unconditionally update field (Normally stuffed only if empty)
  
  Unconditionally changes the specified field. By default a field is only updated if it is empty. That is, fields with values already in them are not updated.

Select one of the following options to indicate whether you want the updated field to be visible, invisible, or to stay in its current state:

- Leave visibility of specified field unaltered
- Set specified field to visible
- Set specified field to invisible

You may select either or both of these options:

- Convert stuff to uppercase Field
  
  Converts the match strings in the update file to uppercase as they are inserted into the fields on the schematic.

- Ignore warnings
  
  Causes FLDSTUFF to continue running when it encounters warnings, instead of halting in the middle of execution.
With the Schematic Design Tools screen displayed, select To PLD. Select Local Configuration from the menu that displays, and then select Configure ANNOTATE. A configuration screen appears (figure 29-4).

**File Options**

**File Options** defines the source file and its type.

**Source**

The **Source** is the root sheet filename of the design or the filename of a single sheet. It may have any valid pathname. After entering the source filename, select one of the following:

- **Source file is the root of the design**
  
  Specifies that the source file is the root sheet filename of a hierarchical or flat design. If the root sheet contains sheet symbols, then the design is hierarchical. If it contains a Link, it is a flat design.

- **Source file is a single sheet**
  
  Specifies that the source file is a single worksheet and you want to process the single sheet only.
Processing Options

You may select any combination of the following options:

- **Quiet mode**
  
  Turns quiet mode on.

- **Do NOT change the sheet number**
  
  Causes the sheet number set in the title block to remain unchanged. If this option is not selected, ANNOTATE renumbers all of the schematics in the design.

- **Unannotate schematic**
  
  Resets all of the reference designators in the design. When parts were first placed, the reference designator had a numeric component of "?". This option resets all numbers to "?".

- **Report the last assigned reference values**
  
  Tells ANNOTATE to report the last reference designator assigned to a design, after it is done annotating. The report is placed in a file with the same name as the source ending with the extension .END.

- **Reset reference numbers to begin with 1 on each sheet of the hierarchy**
  
  Restarts all reference designators used at 1 for each sheet of the design instead of only on the first sheet. This option is used when annotating a complex hierarchy. If you are using OrCAD's Digital Simulation Tools and your design is a complex hierarchy, this option is recommended.
Select one of the following:

- **Incremental annotation (only update reference designators shown as ?)**

  Updates only the reference designators that have a "?". When new parts are placed on a sheet, the reference is not assigned a numeric value, but rather is given the unassigned designation of "?". If you do not wish to renumber all reference designators, including all previously set references, this option should be used.

- **Unconditional annotation (update all reference designators)**

  Updates all reference designators in the order in which they are placed in the worksheet. All references are updated, even those that may have been assigned previously.

If desired, select this option:

- **Ignore warnings**

  Causes ANNOTATE to continue running when it encounters warnings, instead of halting in the middle of execution.
With the Schematic Design Tools screen displayed, select To PLD. Select Local Configuration from the menu that displays, and then select Configure EXTRACT. A configuration screen appears (figure 29-5).

![Figure 29-5. EXTRACT's local configuration screen.](image)

**File Options**

File Options defines name and type of the schematic from which to extract the PLD information.

**Source**

The source file is the root sheet filename of the design or the filename of a single sheet. It may have any valid pathname. After entering the source filename, select one of the following:

- **Source file is the root of the design**

  Specifies that the source file is the root sheet name of a hierarchical or flat design. If the root sheet contains sheet symbols, then the design is hierarchical. If it contains a \Link, it is a flat design.

- **Source file is a single sheet**

  Specifies that the source file is a single worksheet and you want to process the single sheet only.
Processing Options

You may select either or both of the following options:

- **Quiet mode**
  - Turns quiet mode on.

- **Descend into sheet path parts**
  - Tells EXTRACT to descend into parts defined as sheetpath parts. That is, it treats a sheetpath part as a sheet. This option, while designed for complex hierarchies, may be used in simple hierarchies. It is not recommended to be used except for FPGA, ASIC, or other designs that require a complex hierarchy.

- **Produce a flat-file listing of extracted files**
  - Tells EXTRACT to produce a text file listing all the PLD files in the design.

Select one of the following:

- **Extract all PLD information**
  - Causes EXTRACT to extract all PLD source code from the schematic.

- **Extract information on device**
  - Causes EXTRACT to extract the PLD source code for one specific device. Selecting this option makes the Extract part value entry box active. Specify the device to extract by entering its part value (the value that appears on the schematic for the particular device) in the entry box.

You may select this option:

- **Ignore warnings**
  - Causes EXTRACT to continue running when it encounters warnings, instead of halting in the middle of execution.
About EXTRACT

The names and number of output files EXTRACT creates depend on specially-formatted text (also called source code) that you place in your worksheet. This source code specifies information about a part in the Programmable Logic Design Tools language.

Key fields

EXTRACT uses two key fields. They are shown on the Configure Schematic Design Tools screen as:

```
Extract PLD
PLD Part Combine
PLD Type Combine
```

When EXTRACT creates a .PLD file, it uses these key fields to fill in the Part: and Type: data fields. The PLD Part Combine data is enclosed in quotation marks and placed after the word “Part:”. The PLD Type Combine data is enclosed in quotation marks and placed after the word “Type:”. Figures 29-6 and 29-7 show an example.

More information about key fields for EXTRACT is found in Chapter 1: Configure Schematic Tools.

Unified documentation

The source code for a PLD is compiled separately from the schematic. To keep all documentation about a design together, though, it is a good idea to place the code on the schematic. It is also easier to write the source code for a PLD as part of the schematic, because EXTRACT will create pin definitions and title information for you.

In a schematic, PLD source code is placed on the same sheet as the schematic symbol for the programmable device. The source code can be anywhere on the sheet.

Make a custom symbol

Unlike non-programmable devices that have the same behavior every time they are used in a design, the behavior of programmable devices varies as the internal logical configuration changes. So, to represent a PLD in a design, you first need to create an appropriate symbol for it. The schematic library MEMORY.LIB contains generalized symbols for programmable devices, with values like 16R6 and pin names like I1, I2, and O1.
To customize a part to fit your application, use Edit Library to modify the pin names and device names to be the values for this specific application. When you create a custom part, it is always best to store it in your own custom library. That way, if you receive new libraries from OrCAD, you can replace your old libraries without fear of erasing your custom parts.

Using OrCAD's Programmable Logic Design Tools, you can define logic in several different ways. You can use Boolean equations, indexed equations, numerical maps, state machine procedures, truth tables, streams, or schematics. See the Programmable Logic Design Tools Reference Guide for more information.

The logic definition for the PLD consists of a series of text objects placed on the schematic. The text may be placed line-by-line with Draft's PLACE Text command or may be created using Edit File and placed on the schematic using the BLOCK ASCII Import command.

PLD logic definitions must begin with a key statement:

```
|PLD part
```

Use Draft's PLACE Text command to add the statement to the schematic.

This is done by moving the pointer to an open area on your schematic. Select PLACE, then Text. Type the pipe or vertical bar symbol ( | ) followed by PLD and the name of the custom part:

```
|PLD name
```

If more than one PLD is defined on this schematic, create a |PLD key statement for each one. EXTRACT creates a .PLD file for each part specified in the schematic. Each .PLD file contains the source code associated with its corresponding part.
For example, suppose you have included the source code for two different PLDs (A and B) in your schematic. When you run EXTRACT, two files are created: A.PLD and B.PLD. If either file already exists, EXTRACT renames the original file with a .BAK extension before creating the new .PLD file. For example, if A.PLD already exists, it is renamed A.BAK before the new A.PLD is created.

You can add comments, too. Just enter each line individually and place it in the schematic so that the first character of the line is in the same column as the pipe symbol of the device name line (see figure 29-7). Comment lines (those lines that do not start with a pipe character) are ignored by the Programmable Logic Design Tools compiler.

Select a device

Selecting a device is a decision based primarily on two factors: design complexity and cost. You base your decision on the number of inputs and outputs needed, how complex the logic is that the device needs to handle, and how much the device costs. Just exactly when, in the design process, you have to choose a device, is a matter for you, the designer, to determine. For example, you may want to define the logic completely, test it to be sure it performs as you expect, and then pick a device that accommodates the logic. On the other hand, you may have a device in mind before you begin designing the logic—one that for cost or availability reasons is your definite choice.

Record part type and value on the schematic

After you have selected a device, record your choice on the schematic in the device symbol’s part fields. Typically, the 1st Part Field is used to specify the PLD type (22V10, for example) and the 2nd Part Field is used to specify the manufacturer’s exact part number—but you can use any pair of the eight part fields to hold this information. EXTRACT uses this information to create a PLD header file.
When you run EXTRACT on the schematic containing the part, it creates a file called HRS.PLD. The contents of HRS.PLD are shown in figure 29-7. In the HRS.PLD output, the PLD Type Combine key field (1st Part Field) is shown in \textit{bold italics}, and the PLD Part Combine key field (2nd Part Field) is shown in \textbf{bold}.

Figure 29-7. Sample EXTRACT output (continued from previous page).
The To Digital Simulation transfer consists of four processes that update the connectivity database and simulation directives for the design. These processes are:

- **ANNOTATE (Annotate Schematic)** scans a design and automatically updates the reference designators of all parts in the worksheet.

  ANNOTATE updates reference designators in the order they were placed in the worksheet. When annotating the worksheet, you may assign all parts a new reference designator, including any manually edited parts. To selectively change reference designators and leave others unmodified, use **Draft**.

  For more information about this process, see *Chapter 6: Annotate Schematic*.

- **INET (Create Netlist)** creates or updates the incremental connectivity database for the design. INET is an incremental processor. It updates the database only for those worksheets that have changed.

- **IBUILD (Build Simulation Specification File)** extracts the trace, stimulus, and test vector information from the connectivity database, creating text trace (.ATR) and stimulus (.AST) files.

- **ASCTOVST (Compile Simulation Specification File)** reads the text file IBUILD creates, converts it to binary format, and copies the results to a breakpoint, stimulus, or trace file. ASCTOVST displays twice on the configuration screen, so you can convert both the stimulus and trace files when transferring to Digital Simulation Tools.
Execution

To Digital Simulation updates the schematic database, the connectivity database, and the simulation directives. The design may be a complex or simple hierarchy, or a flat design.

Running To Digital Simulation

With the Schematic Design Tools screen displayed, select To Digital Simulation. Select Execute from the menu that displays.

During the transfer process, a monitor box displays at the bottom of the screen where messages report the progress of transfer tasks.

When the transfer process is complete, the Digital Simulation Tools screen displays (figure 30-1).

Figure 30-1. Digital Simulation Tools screen.
Local Configuration of To Digital Simulation

Since you can configure ANNOTATE, INET, IBUILD and each ASCTOVST individually, To Digital Simulation has five configuration screens. To configure To Digital Simulation, select To Digital Simulation. Select Local Configuration from the menu that displays.

The menu shown at right displays. Use this menu to choose which To Digital Simulation process to configure or to turn a process on or off. When you select To Digital Simulation, only the processes that are turned on will run.

For most cases, you will have INET turned on and the other processes turned off. If you are making extensive changes to trace, stimulus, or vector objects in the schematic, turn the IBUILD and ASCTOVST processes on.

To turn a process on or off, choose the desired process from the menu. For example, to turn ANNOTATE on, select ANNOTATE off from the menu. Schematic Design Tools displays:

| Configure ANNOTATE       |
| Configure INET           |
| Configure IBUILD         |
| Configure ASCTOVST       |
| ANNOTATE off             |
| INET on                  |
| IBUILD off               |
| ASCTOVST off             |

Select the new status of the executable item

A menu with the options on and off displays. Select on to turn the process on.

451
With the Schematic Design Tools screen displayed, select To Digital Simulation. Select Local Configuration from the menu that displays, and then select Configure ANNOTATE. A configuration screen appears (figure 30-2).

![Configure Annotate Schematic](image)

**Figure 30-2. ANNOTATE's local configuration screen.**

**File Options**

File Options defines the source file and its type.

**Source**

The Source is the root of the design of the filename of a single sheet. It may have any valid pathname.

After entering the source filename, select one of the following:

- **Source file is the root of the design**
  
  Specifies that the source file is the root sheet filename of a hierarchical or flat design. If the root sheet contains sheet symbols, then the design is hierarchical. If it contains a Link, it is a flat design.

- **Source file is a single sheet**
  
  Specifies that the source file is a single worksheet and you want to process the single sheet only.
Processing Options

You may select any combination of the following options:

- **Quiet mode**
  Turns quiet mode on.

- **Do NOT change the sheet number**
  Causes the sheet number set in the title block to remain unchanged. If this option is not selected, ANNOTATE rennumbers all of the schematics in the design.

- **Unannotate schematic**
  Resets all of the reference designators in the design. When parts were first placed, the reference designator had a numeric component of "?". This option resets all numbers to "?".

- **Report the last assigned reference values**
  Tells ANNOTATE to report the last reference designator assigned to a design, after it is done annotating. The report is placed in a file with the same name as the source ending with the extension .END.

- **Reset reference numbers to begin with 1 on each sheet of the hierarchy**
  Restarts all reference designators used at 1 for each sheet of the design instead of only on the first sheet. This option is used when annotating a complex hierarchy. If you are using OrCAD's Digital Simulation Tools and your design is a complex hierarchy, this option is recommended.
Select one of the following:

- **Incremental annotation (only update reference designators shown as ?)**
  Updates only the reference designators that have a "?". When new parts are placed on a sheet, the reference is not assigned a numeric value, but rather is given the unassigned designation of "?". If you do not wish to renumber all reference designators, including all previously set references, this option should be used.

- **Unconditional annotation (update all reference designators)**
  Updates all reference designators in the order in which they are placed in the worksheet. All references are updated, even those that may have been assigned previously.

You may select this option:

- **Ignore warnings**
  Causes ANNOTATE to continue running when it encounters warnings, instead of halting in the middle of execution.
Local Configuration of INET

With the Schematic Design Tools screen displayed, select **To Digital Simulation**. Select **Local Configuration** from the menu that displays, and then select **Configure INET**. A configuration screen displays (figure 30-3).

![Configure Incremental Netlist](image)

File Options  File Options defines the source file from which the incremental database files are created. It also defines the name of a file to contain data created by INET.

Source  The **Source** is the root of the design or the filename of a single sheet. It may have any valid pathname. One .INF file is created for each sheet referenced by the root sheet.

Reports Destination  The **Reports Destination** is the name of a file where the report is to be placed. This specification is optional. If a **Reports Destination** is not specified, the report is sent to the screen and the file #ESP_OUT.TXT.
Processing Options

You may elect any combination of the following options:

- Quiet mode
  
  Turns quiet mode on.

- Descend into sheet path parts
  
  Tells INET to descend into parts defined as sheetpath parts. That is, it treats a sheetpath part as a sheet. This option, while designed for complex hierarchies, may be used in simple hierarchies. It is not recommended to be used except for FPGA, ASIC, or other designs that require a complex hierarchy.

- Assign a net name to all pins
  
  Tells INET to assign a net name to all pins, including unconnected ones.

- Report off-grid parts
  
  Tells INET to check the worksheet for parts, sheets, labels, module ports, and power objects that are off-grid.

- Report all connected labels and parts
  
  Tells INET to report all connected labels and module ports.

- Report unconnected wires, pins, module ports
  
  Tells INET to report all unconnected wires, pins, and module ports.

- Run ERC on all sheets processed
  
  Runs an electrical rules check on all sheets that INET processes. This is the same process provided by Check Electrical Rules.
Do not report warnings

This option is available if you select the Run ERC on all sheets processed option. It tells INET to not test some of the conditions for which it normally issues warnings. The conditions are:

- Two power objects connected
- Single node nets
- Input signals without a driving source

These conditions are always checked—unless you select the Do not report warnings option—and cannot be changed with the Check Electrical Rules Matrix.

Use this option with caution. You may end up with a netlist containing conditions that are not acceptable.

Check module port connections

Tells INET to check all module ports for correctness after tests and processing are completed.

Rebuild file stack

Tells INET to rebuild the file stack that is used to determine the sheets that are in the incremental connectivity database. This file stack speeds the processing of the database when incremental updates occur. It may be viewed, but should not be modified. The file stack is given a .INX extension.

Unconditionally process all sheets in design

Tells INET to ignore the incremental aspect of normal connectivity database processing. All sheets in the design are recompiled, even if the current database is up to date.
☐ Do NOT create .INF files (report only)

When processing the design, you may wish to leave the incremental connectivity database unchanged and only review the reports. This option causes all checks to be run and reports to be created, but does not update the incremental connectivity database.

☐ Process one sheet only (This forces Rebuild file stack on the next run)

Tells INET to produce an incremental connectivity database for a single sheet in a design. This option is useful for troubleshooting netlist problems. The next time INET runs, it will also rebuild the file stack used to determine the sheets that are in an incremental connectivity database.

☐ Ignore warnings

Causes INET to continue running when it encounters warnings, instead of halting in the middle of execution.
With the Schematic Design Tools screen displayed, select To Digital Simulation. Select Local Configuration from the menu that displays, and then select Configure IBUILD. A configuration screen displays (figure 30-4).

![Figure 30-4. IBUILD's local configuration screen.](image)

**File Options**

File Options defines the source file from which the simulation directives are to be obtained. This source file is the incremented connectivity database.

**Source**

The Source is the connectivity database. It has an extension of .INF and a base name that is the same as the project. It may have any valid pathname.

**Processing Options**

Select any combination of the following:

- **Build trace specification file**
  
  Causes the trace objects in the schematic database to be updated as a new trace specification file for the simulation.

- **Build stimulus specification file**
  
  Causes the stimulus and vector (a vector is a form of a stimulus specification) objects in the schematic database to be updated as a new stimulus specification file for the simulator.
With the Schematic Design Tools screen displayed, select To Digital Simulation. Select Local Configuration from the menu that displays, and then select the one of the two instances of ASCTOVST. A configuration screen displays.

![Configuration Options](image)

*Figure 30-5. ASCTOVST’s local configuration screen.*

ASCTOVST displays twice so you can convert both the stimulus and trace files when transferring to Digital Simulation Tools. Usually, you configure the first instance to select Source is a stimulus file and the second instance to select Source is a trace file.

**File Options**

*File Options* specifies the source and destination filenames.

- **Source**
  - Source is a stimulus file
    - The source is a stimulus file. Enter the destination path and filename. The default is your design directory name followed by an .AST extension. Select this default file option for the first instance.
  - Source is a trace file
    - The source is a trace file. Enter the destination path and filename. The default is your design directory name followed by an .ATR extension. Select this file option for the second instance.
Source is a breakpoint file

The source is a breakpoint file. Enter the destination path and filename. The default is your design directory name followed by an .ABR extension.

Destination

The directory path and filename for the output file.
The To Layout transfer consists of four processes that are used to update the connectivity database and the layout directives given in the schematics. These processes are:

- **FLDSTUFF** loads user-defined information into part fields on a specified schematic. FLDSTUFF constructs a string from the key field designators for a specified field. Then, if that string equals a match field in a designated update file, it replaces the specified field with the update value.

  For more information about this process, see *Chapter 13: Update Field Contents*.

- **ANNOTATE** scans a design and updates the reference designators of all parts in the worksheet. ANNOTATE updates reference designators in the order they were placed in the worksheet. When the worksheet is annotated, all parts may be assigned a new reference designator, including any manually edited parts. To selectively change reference designators and leave others unmodified, use Draft.

  For more information about this process, see *Chapter 6: Annotate Schematic*.

- **INET** updates the connectivity database for the design. INET updates the database only for those worksheets that have been changed.

- **ILINK** links the incremental database into a flattened database. This flattened database contains information on the connectivity, parts, fields, pin typing information, and the layout directives.
To Layout updates the schematic database, the connectivity database, and the layout directives used in PC Board Layout Tools. The design may be a simple hierarchy or a flat design. If the design is a complex hierarchy, the Complex to Simple processor in Design Management Tools must be used to simplify the design hierarchy before you select To Layout.

Running To Layout

With the Schematic Design Tools screen displayed, select To Layout. Select Execute from the menu that displays.

When the transfer process is complete, the PC Board Layout Tools screen displays.

Local Configuration of To Layout

Since FLDSTUFF, ANNOTATE, INET, and ILINK are each configured individually, To Layout has four configuration screens. To configure To Layout, select To Layout. Select Local Configuration from the menu that displays.

The menu shown at right displays. Use this menu to choose which To Layout process to configure and to turn a process on or off. When you select To Layout, only the processes that are turned on run. In most cases, you will have INET and ILINK turned on and the other processes turned off.

To turn a process on or off, choose the desired process from the menu. For example, to turn FLDSTUFF on, select FLDSTUFF on from the menu. Schematic Design Tools displays:

A menu with the options on and off displays. Select on to turn the process on.
Local Configuration of FLDSTUFF

With the Schematic Design Tools screen displayed, select To Layout. Select Local Configuration from the menu that displays, and then select Configure FLDSTUFF. A configuration screen displays (figure 31-1).

![Configure Field Contents](image)

**Figure 31-1. FLDSTUFF's local configuration screen.**

File Options

File Options defines the source file and its type. It also defines the update file.

**Source**

The **Source** is the filename of the design's root sheet or the filename of a single sheet. It may have any valid pathname. After entering the source filename, select one of the following:

- Source file is the root of the design
  - Specifies that the source file is the root sheet filename of a hierarchical or flat design.

- Source file is a single sheet
  - Specifies that the source file is a single worksheet and you want to process the single sheet only.

**Update-file**

The **Update-file** is a text file that you create. The file format is described in *Chapter 13: Update Field Contents*. 
Processing Options  Select one of the following options to define which field is to be updated:

- Part Value
- Part Field 1
- Part Field 2
- Part Field 3
- Part Field 4
- Part Field 5
- Part Field 6
- Part Field 7
- Part Field 8

The field parameter selected above also identifies a key field designator. There are nine key field designators, one for the part’s value, and one for each of the eight part fields. They are found on the Configure Schematic Design Tools screen as shown in figure 31-2.

**Figure 31-2. Key field designators for FLDSTUFF.**

FLDSTUFF constructs a string from the key field designator set up for the field parameter selected. For example, if you select “Part Field 3” and the Update Field Contents Combine for Field 3 is V 2, then Update Field Contents constructs a string consisting of the part’s value, a space, and Part Field 2.
FLDSTUFF then tries to match that string with the match fields listed in the update file. Each match field has a corresponding update field. If a match occurs, **Update Field Contents** replaces the contents of the field parameter (selected above) with the corresponding update field.

For additional information on key fields, see the *Schematic Design Tools User's Guide*.

The key fields shown are shared between this process and the **Update Field Contents** processor. For more information on the key fields and other operating characteristics, see *Chapter 13: Update Field Contents*.

Select any combination of the following options:

- Quiet mode
  - Turns quiet mode on.

- Create an update report
  - Creates a report listing all the parts on each sheet and whether a field is updated for each part. If this option is selected, the **Destination** entry box is used to specify where the report is written.

- Unconditionally update field (Normally stuffed only if empty)
  - Unconditionally changes the specified field. By default a field is only updated if it is empty. That is, fields with values already in them are not updated.
Select one of the following options to indicate whether you want the updated field to be visible, invisible, or to stay in its current state:

- Leave visibility of specified field unaltered
- Set specified field to visible
- Set specified field to invisible

You may select either or both of these options:

- Convert match string to uppercase
- Ignore warnings

Causes FLDSTUFF to continue running when it encounters warnings, instead of halting in the middle of execution.
With the Schematic Design Tools screen displayed, select To Layout. Select Local Configuration from the menu that displays, and then select Configure ANNOTATE. A configuration screen appears (figure 31-3).

![Figure 31-3. ANNOTATE's local configuration screen.](image)

### File Options

File Options defines the source file and its type.

**Source**

The Source is the root sheet filename of the design or the filename of a single sheet. It may have any valid pathname. After entering the source filename, select one of the following:

- **Source file is the root of the design**
  
  Specifies that the source file is the root sheet filename of a hierarchical or flat design. If the root sheet contains sheet symbols, then the design is hierarchical. If it contains a Link, it is a flat design.

- **Source file is a single sheet**
  
  Specifies that the source file is a single worksheet and you want to process the single sheet only.
Processing Options

You may select any combination of the following options:

- Quiet mode
  
  Turns quiet mode on.

- Do NOT change the sheet number
  
  Causes the sheet number set in the title block to remain unchanged. If this option is not selected, ANNOTATE renumbers all of the schematics in the design.

- Unannotate schematic
  
  Resets all of the reference designators in the design. When parts were first placed, the reference designator had a numeric component of "?". This option resets all number to "?".

- Report the last assigned reference values
  
  Tells ANNOTATE to report the last reference designator assigned to a design, after it is done annotating. The report is placed in a file with the same name as the source ending with the extension .END.

- Reset reference numbers to begin with 1 on each sheet of the hierarchy
  
  Restarts all reference designators used at 1 for each sheet of the design instead of only on the first sheet. This option is used when annotating a complex hierarchy. If you are using OrCAD's Digital Simulation Tools and your design is a complex hierarchy, this option is recommended.
Select one of the following options:

- Incremental annotation (only update reference designators shown as ?)
  Updates only the reference designators that have a "?". When new parts are placed on a sheet, the reference is not assigned a numeric value, but rather is given the unassigned designation of "?". If you do not wish to renumber all reference designators, including all previously set references, use this option.

- Unconditional annotation (update all reference designators)
  Updates all reference designators in the order in which they are placed in the worksheet. All references are updated, even those that may have been assigned previously.

You may select this option:

- Ignore warnings
  Causes ANNOTATE to continue running when it encounters warnings, instead of halting in the middle of execution.
With the Schematic Design Tools screen displayed, select To Layout. Select Local Configuration from the menu that displays, and then select Configure INET. A configuration screen displays (figure 31-4).

![Figure 31-4. INET's local configuration screen.]

**File Options**

File Options defines both the source file from which the incremental connectivity database files are created and the name of a file to contain data created by INET.

**Source**

The Source is the root of the design or the filename of a single sheet. It may have any valid pathname. One .INF file is created for each sheet referenced by the source.

**Reports Destination**

The Reports Destination is the name of a file where the report is to be placed. This specification is optional. If a Reports Destination is not specified, the report is sent to the screen and the file #ESP_OUT.TXT.
You may select any combination of the following options:

- **Quiet mode**
  
  Turns quiet mode on.

- **Descend into sheet path parts**
  
  Tells INET to descend into parts defined as sheetpath parts. That is, it treats a sheetpath part as a sheet. This option, while designed for complex hierarchies, may be used in simple hierarchies. It is not recommended to be used except for FPGA, ASIC, or other designs that require a complex hierarchy.

- **Assign a net name to all pins**
  
  Tells INET to assign a net name to all pins, including unconnected ones.

- **Report off-grid parts**
  
  Tells INET to check the worksheet for parts, sheets, labels, module ports, and power objects that are off-grid.

- **Report all connected labels and parts**
  
  Tells INET to report all connected labels and module ports.

- **Report all unconnected wires, pins, module ports**
  
  Tells INET to report all unconnected wires, pins, and module ports.
- Run ERC on all sheets processed
  Runs an electrical rules check on all sheets that INET processes. This is the same process provided by Check Electrical Rules.

- Do not report warnings
  This option is available if you select the Run ERC on all sheets processed option. It tells INET to not test some of the conditions for which it normally issues warnings. The conditions are:
  - Two power objects connected
  - Single node nets
  - Input signals without a driving source
  These conditions are always checked—unless you select the Do not report warnings option—and cannot be changed with the Check Electrical Rules Matrix.

  Use this option with caution. You may end up with a netlist containing conditions that are not acceptable.

- Check all module port connections
  Tells INET to check all module ports for correctness after tests and processing are completed.

- Rebuild file stack
  Tells INET to rebuild the file stack that is used to determine the sheets that are in the incremental connectivity database. This file stack speeds the processing of the database when incremental updates occur. It may be viewed, but should not be modified. The file stack is given a .INX extension.

- Unconditionally process all sheets in design
  Tells INET to ignore the incremental aspect of normal connectivity database processing. All sheets in the design are recompiled, even if the current database is up to date.
- Do NOT create .INF files (report only)

  When processing the design, you may wish to leave the incremental connectivity database unchanged and only review the reports. This option causes all checks to be run and reports to be created, but does not update the incremental connectivity database.

- Process one sheet only (This forces Rebuild file stack on the next run)

  Tells INET to produce an incremental connectivity database for a single sheet in a design. This option is useful for troubleshooting netlist problems. The next time INET runs, it will also rebuild the file stack used to determine the sheets that are in an incremental connectivity database.

- Ignore warnings

  Causes INET to continue running when it encounters warnings, instead of halting in the middle of execution.
With the Schematic Design Tools screen displayed, select To Layout. Select Local Configuration from the menu that displays. Select Configure ILINK. A configuration screen displays (figure 31-5).

File Options
File Options defines the source file.

Source
The Source is the incremental connectivity database root file. There must be an extension on the filename. The source file is the output from INET (discussed previously) and should have the recommended extension of .INF. It may have any valid pathname.

Processing Options
You may select any combination of the following options:

- Quiet mode
  Turns quiet mode on.
Produce a linked connectivity database

Tells ILINK to produce a linked connectivity database (.LNF). This text file is read by PC Board Layout Tools. If a destination file is not supplied, the output is placed in a file with the same name as the source, except with a .LNF extension.

A Destination may be supplied to override the default output file. This file may have any valid pathname.

If this option is not selected, ILINK produces the intermediate netlist structure files (.INS, .RES, and .PIP). These binary files are used by the formatter, IFORM.

Force ILINK to always link the database

Tells ILINK to force a link of the database to occur, even if the database is up to date.

Report single net nodes

Reports all nodes that have only a single pin. This report is used to identify nodes that still need to be connected in the design.

Ignore warnings

Causes ILINK to continue running when it encounters warnings, instead of halting in the middle of execution.
The To Main tool transfers from the Schematic Design Tools screen to the design environment’s main screen. This tool does not process or create any files and has nothing for you to configure.

With the Schematic Design Tools screen displayed, select To Main. Select Execute from the menu that displays. The design environment’s main screen (figure 32-1) displays.

Figure 32-1. ESP ‘s main screen.
Command line controls

This appendix cross references command line commands and their switches with their corresponding ESP tool and local configuration buttons. This appendix is organized in alphabetical order by command.

△ NOTE: Schematic Design Tools Release IV does not support the /F switch. Many version 3 utilities used the /F switch to indicate that the source file was a text file containing a list of files to be processed in a flat file structure. Release IV uses the \LINK command to list the files. For more information, see The \LINK command in Chapter 9: Creating a netlist.
ANNOTATE source [switches]

HFORM source format destination [destination 2] [switches]

Corresponding ESP tool name: Create Hierarchical Netlist

HFORM is Create Hierarchical Netlist’s incremental hierarchical netlist formatter. An extension of .INF is assumed for the source. The format file is the path and filename of the netlist format file. OrCAD hierarchical netlist format files have an extension of .CH. A destination must be specified. If the netlist format requires two output files, destination 2 must be present on the command line.

<table>

ILINK source [switches]

Corresponding ESP tool name: Create Netlist

ILINK is the incremental netlist linker. The source is the .INF file of the incremental netlist files to be linked. The linker creates two files with the name of the source and extensions of .INS (instance file) and .RES (joined resolved file). These files are used by IFORM to produce the final version of the netlist.

PARTLIST source [destination] [include] [switches]

PARTLIST performs the functions for either Cross Reference Parts (if the /X switch is present) or Create Bill of Materials (absence of the /X switch). Some of the switches described in the table below apply only when running a cross reference report, only when running a part list report, or when running either report. The columns at the right of the table (labeled XRF for Cross Reference Part and BOM for Create Bill of Materials) indicate when each switch applies.

This chapter discusses the various netlist formatters that OrCAD provides. These formatters may be selected via the local configuration of the Create Netlist and Create Hierarchical Netlist tools. See Chapter 10: Create Netlist and Chapter 11: Create Hierarchical Netlist for information on creating netlists in these formats.

To use these netlist formats (and get predictable results), you must follow certain rules when creating your schematics. Chapter 3: Guidelines for creating designs explains these rules clearly.

The following sections contain examples of each flat and hierarchical netlist format supplied with Schematic Design Tools. Each example explains the formatting options, if any, that are available for each netlist format.

Many of these formats impose restrictions on the length of various names (reference designator and label/module port names for instance). Some formats also restrict the set of legal characters that may be used. Where appropriate, the formats check the names for validity. When illegal names are encountered, the formats attempt to recover without losing information. Where this is possible, a warning is issued; where it is not, an error is issued.

Each formatter file includes a comment section at the top that explains the restrictions imposed by that particular netlist format. Refer to this header for the exact limitations imposed by your desired format.
These examples assume the Create Netlist key fields on the Key Fields area of the Configure Schematic Design Tools screen were configured this way:

Create Netlist
Part Value Combine
Module Value Combine

In each of the example netlists that follow, the Part Value Combine key field (part value, represented by "V" in the example above) is shown in **bold** and the Module Value Combine key field (1st part field, represented by "1" in the example above) is shown in **bold italics**.

Creating your own netlist format

The formatter files are written in a small, interpreted language whose syntax is similar to the programming language "C." Appendix C explains the syntax of the language, and all of the built-in functions and symbols.

Flat netlists

To create a netlist in one of these flat formats, it is assumed that your schematic has already been simplified (if necessary), netlisted, and linked. These steps are fully explained in Chapter 10: Create Netlist.

Flat netlist formatter files are distinguished by a .CF file extension. They cannot be used by the Create Hierarchical Netlist processor (the two interpreter formats are similar, but process incompatible data structures).

Example schematics

Five sample schematics are used to create the flat netlists in this section. The first schematic, figure B-1, is a general example suitable for digital-oriented designs. The schematic in figure B-2 is used by the two ADF netlists. Figure B-3 shows how to create a model for a part for OrCAD’s Digital Simulation Tools using a schematic as the source. Figure B-4 is an analog design that demonstrates the SPICE netlist. Figure B-5 shows how to define the programming for a PLD for OrCAD’s Programmable Logic Design Tools using a schematic as the source.
Figure B.1. Used by most of the flat netlist formats.

Title: SPICE Example
Size/Document Number: A
OrCAD-04
Date: October 30, 1990 (Sheet 1 of 1)
Figure B.5: Used by the OrCAD/PLD netlist format.
The only option available for the Algorex format is:

- Do not append sheet number to labels

If this option is not selected, the Algorex formatter appends a dash (-) and the sheet number to any labels.

▲ CAUTION: If you select this option, labels with the same name on different sheets are merged into one net. This option is typically selected only when the design consists of a single schematic sheet.

The netlist in figure B-6 was created from the schematic in figure B-1 with no options selected.

Figure B-6. Example netlist in the Algorex format.
The only option available for the Allegro format is:

- Do not append sheet number to labels

If this option is not selected, the Allegro formatter appends a slash (/) and the sheet number to any labels.

⚠️ **CAUTION:** If you select this option, labels with the same name on different sheets are merged into one net. This option is typically selected only when the design consists of a single schematic sheet.

The netlist in figure B-7 was created from the schematic in figure B-1 with no options selected.

```

Figure B-7. Example netlist in the Allegro format.
AlteraADF
(ALTERAAD.CF)

Three formatting options are available for AlteraADF format.

- Suppress comments in the netlist file
  If this option is selected, the formatter won't put comments in the resulting netlist file. Comments in the AlteraADF format are delimited by the percent (%) character.

- Include unconnected pins
  If this option is selected, the AlteraADF formatter assigns all unconnected pins a unique net. If this option is not selected, the AlteraADF formatter assigns an unique net and reports an error.

- Do not append sheet number to labels
  If this option is not selected, the AlteraADF formatter appends a period (.) and the sheet number to any labels.

◇ CAUTION: If you select this option, labels with the same name on different sheets are merged into one net. This option is typically selected only when the design consists of a single schematic sheet.

Title block

Title block information is placed in the first 10 lines of the netlist. Table B-1 shows an example netlist header and the title block information from which the header was extracted. Header information in bold is text entered in the schematic's title block.

Table B-1. Title block information in AlteraADF netlists.
Pipe commands

You can place equations in your schematic to be included in the netlist. To place these equations in your worksheet, use the Draft's PLACE Text command. You can also use a text editor to put the equations in an ASCII file, then use Draft's BLOCK ASCII Import command to import the contents of the file and place it on the worksheet.

Each equation must start with the pipe character (\|). (On many PC keyboards, the pipe character appears as a broken vertical bar). The first line must be:

| EQUATIONS

This tells the formatter that some AlteraADF equations need to be included in the netlist. The equations can contain any information you want to include in the netlist.

Caveats

When you create an AlteraADF netlist, you must configure Schematic Design Tools to use the OrCAD-supplied ADF.LIB library. You can only use the parts provided in the ADF library to create the schematic.

Inputs and outputs are handled differently in Schematic Design Tools and the Altera software. Schematic Design Tools defines inputs and outputs with module ports and an input/output library object. Altera defines inputs and outputs with a library object which is then tagged with the appropriate pin number. In figure B-2, the CLOCK signal is an input and the STROBE signal is an output.

Additionally, library objects with unused pins default to pre-defined levels in the Altera software. Because Schematic Design Tools does not default unconnected pins to any particular level, you must tie all unused pins to the appropriate level.

The netlist in figure B-8 was created from the schematic in figure B-2 with no options selected.

Figure B-11. Example netlist in the Cadnetix format.
Calay (CALAY.CF) Only one option is available for the Calay format:

- Do not append sheet number to labels

If this option is not selected, the Calay formatter appends a dash (-) and the sheet number to any labels.

⚠️ CAUTION: If you select this option, labels with the same name on different sheets are merged into one net. This option is typically selected only when the design consists of a single schematic sheet.

The Calay formatter creates two files. In addition to the netlist file, it also creates a component file. A second filename must be entered in the "Destination 2" entry box for the formatter.

The netlist in figure B-12 and its corresponding component file in figure B-13 were created from the schematic in figure B-1 with no options selected.

```

74LS32  U2  14DIP300  000  000  0
```

Figure B-13. Example component file in the Calay format.
Case (CASE.CF) Two options are available for the Case format. The first is:

- Do not append sheet number to labels

If this option is not selected, the Case formatter appends an underscore (\_) and the sheet number to any labels.

▲ CAUTION: If you select this option, labels with the same name on different sheets are merged into one net. This option is typically selected only when the design consists of a single schematic sheet.

The second option is:

- Include unconnected pins

If this option is selected, the Case formatter assigns all unconnected pins a unique net. If it is not selected, the Case formatter assigns an unique net and reports an error.

The netlist in figure B-14 was created from the schematic in figure B-1 with no options selected.
Figure B-14. Example netlist in the Case format.
CBDS (CBDS.CF)  The only option available for the CBDS format is:

☐ Do not append sheet number to labels

If this option is not selected, the CBDS formatter appends a dash (-) and the sheet number to any labels.

▲ CAUTION: If you select this option, labels with the same name on different sheets are merged into one net. This option is typically selected only when the design consists of a single schematic sheet.

The netlist in figure B-15 was created from the schematic in figure B-1 with no options selected.

```

```

Figure B-15. Example netlist in the CBDS format.
ComputerVision (COMPVISN.CF)

The only option available for the ComputerVision format is:

- Do not append sheet number to labels

If this option is not selected, the ComputerVision formatter appends a slash (/) and the sheet number to any labels.

⚠️ CAUTION: If you select this option, labels with the same name on different sheets are merged into one net. This option is typically selected only when the design consists of a single schematic sheet.

The netlist in figure B-16 was created from the schematic in figure B-1 with no options selected.

Figure B-16. Example netlist in the ComputerVision format.
EDIF (EDIF.CF)  This is one of two EDIF (Version 2 0 0) formatters supplied with Schematic Design Tools. This formatter can only be used to create flat EDIF netlists. The hierarchical EDIF formatter is discussed in the following section.

The first option available for the EDIF format is:

- Do not append sheet number to labels

If this option is not selected, the EDIF formatter appends an underscore (_) and the sheet number to any labels.

\[\text{\textbf{CAUTION: If you select this option, labels with the same name on different sheets are merged into one net. This option is typically selected only when the design consists of a single schematic sheet.}}\]

The EDIF formatter can also output pin numbers to the netlist instead of pin names.

- Output pin numbers (instead of pin names)

Not all parts have both pin names and pin numbers defined. If the option is selected, and a pin is encountered with no number, then the pin name is still used. If a netlist consisting entirely of pin numbers is required, you may need to modify the library part.

The netlist in figure B-17 was created from the schematic in figure B-1 with no options selected.

Figure B-18. Example netlist in the EEDesigner format.
The FutureNet system has two connectivity output formats: a netlist, and a pinlist. The netlist format lists each net in the schematic and the part pins that belong in that net. The pinlist format is a list of each pin on a part, and the net in which that pin belongs.

The FutureNet format can create both netlists and pinlists. By selecting the option:

- Create a netlist (instead of a pinlist)

a netlist is created instead of a pinlist. The two formats contain the same information, hence, neither has any inherent advantages over the other. You need to decide which format is best suited to your needs.

Another option available for the FutureNet format is:

- Do not append sheet number to label names

If this option is not selected, the FutureNet formatter adds an underscore (_.) and the sheet number to any labels.

⚠️ **CAUTION:** If you select this option, labels with the same name on different sheets are merged into one net. This option is typically selected only when the design consists of a single schematic sheet.
The FutureNet formatter can also output pin numbers to the netlist or pinlist instead of pin names.

- **Output pin numbers (instead of pin names)**

Not all parts have both pin numbers and pin names defined. If the option is selected, and a pin without a number is found, then the pin name is used. If a netlist consisting entirely of pin numbers is desired, you may need to modify the OrCAD-supplied libraries, which is explained in the SPICE netlist section.

The FutureNet format also has several options for setting the attributes of parts in the netlist or pinlist. Normally, all module ports (input, output, and bidirectional) are assigned the attribute of 5 (signal name). The option:

- **Create SIG* attributes to module ports**

substitutes the more precise attributes 10, 11, and 12 (input signal, output signal, and bidirectional signal, respectively) for the generic signal attribute 5.

Additionally, module ports can also have CON* symbols created for them using the option:

- **Create CON* symbols for module ports**

This option creates FutureNet SYMbol objects for the module ports. The new SYMbol objects (input, output, and bidirectional) are assigned the attributes 24, 25, and 26, respectively; and have the names CONI, CONO, and CONB, respectively, assigned in their data fields.
This option assigns FutureNet power attributes to Schematic Design Tools power objects:

- Assign FutureNet power attributes to power objects

When this option is selected, the pins on the following Schematic Design Tools power objects (which are matched by name) are assigned FutureNet power attributes.

Figure B-20. Example netlist in the FutureNet netlist format.
HiLo (HILO.CF) The first option available for the HiLo format is:

- Do not append sheet number to labels

If this option is not selected, the HiLo formatter appends a dollar sign ($) and the sheet number to any labels.

⚠️ CAUTION: If you select this option, labels with the same name on different sheets are merged into one net. This option is typically selected only when the design consists of a single schematic sheet.

The second option available for the HiLo format is:

- Include unconnected pins

If this option is selected, the HiLo formatter assigns all unconnected pins a unique net. If this option is not selected, the HiLo formatter assigns an unique net and reports an error.

The netlist in figure B-21 was created from the schematic in figure B-1 with no options selected.

Figure B-21. Example netlist in the HiLo format.
Three formatting options are available for the IntelADF format.

- **Suppress comments**
  If this option is selected, the formatter won't put comments in the resulting netlist file. Comments in the IntelADF format are delimited by the percent (%) character.

- **Do not append sheet number to labels**
  If this option is not selected, the IntelADF formatter appends a period (.) and the sheet number to any labels.

  **CAUTION:** If you select this option, labels with the same name on different sheets are merged into one net. This option is typically selected only when the design consists of a single schematic sheet.

- **Include unconnected pins**
  If this option is selected, the IntelADF formatter assigns all unconnected pins a unique net. If this option is not selected, the IntelADF formatter assigns an unique net and reports an error.

**Title block**
Title block information is placed in the first 10 lines of the netlist. Table B-2 shows an example netlist header and the title block information from which the header was extracted. Header information in bold is text you enter in the schematic's title block.
### Table B-2. Title block information in IntelADF netlists.

Pipe commands

You can place equations in your schematic to be included in the netlist. To place these equations in your worksheet, use the Draft's PLACE Text command. You can also use a text editor to put the equations in an ASCII file, then use Draft's BLOCK ASCII Import command to import the contents of the file and place it on the worksheet.

Each equation must start with the pipe character (|). (On many PC keyboards, the pipe character appears as a broken vertical bar). The first line must be:

```
|EQUATIONS
```

This tells the formatter that some IntelADF equations need to be included in the netlist. The equations can contain any information you want to include in the netlist.

Caveats

When you create an IntelADF netlist, you must configure Schematic Design Tools to use the OrCAD-supplied ADF.LIB library. You can only use the parts provided in the ADF library to create the schematic.

Inputs and outputs are handled differently in OrCAD's Schematic Design Tools and the Intel software. Schematic Design Tools defines inputs and outputs with module ports and an input/output library object. Intel defines inputs and outputs with a library object which is then tagged with the appropriate pin number. In figure B-2, the CLOCK signal is an input and the STROBE signal is an output.

Additionally, library objects with unused pins default to pre-defined levels in the Intel software. Because Schematic Design Tools does not default unconnected pins to any particular level, you must tie all unused pins to the appropriate level.

The netlist in figure B-22 was created from the schematic in figure B-2 with no options selected.

Figure B-26. Example netlist in the MultiWire format.
Appendix B: Netlist formats

**OrCAD/PCB II (PCBII.CF)**

This netlist formatter provides backward compatibility to OrCAD/PCB II. **PC Board Layout Tools, Release IV, uses the connectivity database directly, so no formatting is required.** For more information on transferring to **PC Board Layout Tools**, see Chapter 31: To Layout, and the **PC Board Layout Tools User’s Guide**.

The only option available for the OrCAD/PCB II format is:

- Do not append sheet number to labels

If this option is not selected, the OrCAD/PCB II formatter appends an underscore (_) and the sheet number to any labels.

▲ **CAUTION:** If you select this option, labels with the same name on different sheets are merged into one net. This option is typically selected only when the design consists of a single schematic sheet.

The netlist in figure B-27 was created from the schematic in figure B-1 with no options selected.

Figure B-27. Example netlist in the OrCAD/PCB II format.
OrCAD Programmable Logic Design Tools (PLDNET.CF)

This netlist format is used only when defining Programmable Logic Design Tools logic graphically. See the Programmable Logic Design Tools User’s Guide and the Programmable Logic Design Tools Reference Guide for details.

One option is available for the PLD Netlist format:

☐ Do not append sheet number to labels

If this option is not selected, the PLD Netlist formatter adds an underscore (_) and the sheet number to any labels.

⚠️ **CAUTION:** If you select this option, labels with the same name on different sheets are merged into one net. This option is typically selected only when the design consists of a single schematic sheet.

**Caveats**

When you create a PLD netlist, you must configure Schematic Design Tools to use the OrCAD-supplied PLDGATES.LIB part library. You can only use the parts provided in PLDGATES.LIB to create the schematic.

The netlist in figure B-28 was created from the schematic in figure B-5.
Figure B-28. Example netlist in the PLD Netlist format.
This netlist format is used only when compiling Digital Simulation Tools simulation models. See the Digital Simulation Tools User's Guide for details.

One option is available for the VSTModel netlist.

☐ Suppress comments in the netlist file

If this option is selected, the formatter won’t put comments in the resulting netlist file. Comments in the VSTModel format begin with a semicolon (;

Pipe commands

Lines of text may be placed in your schematic, to be included in the VSTModel netlist. Use Draft’s PLACE Text command to place the text in your schematic, or use an editor to put the text in a text file, then use Draft’s BLOCK ASCII Import command to import the contents of the file and place it on the worksheet.

Each line of text must start with the pipe character (|). (On many PC keyboards, the pipe character displays as a broken vertical bar.) The first line must be:

|VST_MODEL

This tells the formatter to extract the information in the following lines of text when generating a VSTModel netlist. The remaining lines can contain a header, comments, and directives compatible with OrCAD’s Digital Simulation Tools Add Device Model device modeling language. For details on the Add Device Model Language, see the Digital Simulation Tools User’s Guide.

Caveats

When you create a VSTModel netlist, you must have Schematic Design Tools configured to use the OrCAD-supplied VSTGATES.LIB, VSTRAM.LIB, VSTROM.LIB, and VSTOTHER.LIB part libraries. You can only use the parts provided in these libraries to create the schematic.
The netlist in figure B-29 was created from the schematic in figure B-3 with no options selected.

%
```

Figure B-29. Example netlist in the VSTModel format.
Appendix B: Netlist formats

**PADS ASCII (PADSASC.CF)**

The only option available for the PADS ASCII format is:

- Do not append sheet number to labels

If this option is not selected, the PADS ASCII formatter appends a dash (-) and the sheet number to any labels.

▲ **CAUTION:** If you select this option, labels with the same name on different sheets are merged into one net. This option is typically selected only when the design consists of a single schematic sheet.

In addition to the connection list file, the PADS ASCII formatter also creates a part list file. A second filename must be entered in the Destination 2 entry box for the formatter.

The netlist in figure B-30 and the corresponding component file in figure B-31 were created from the schematic in figure B-1 with no options selected.

Figure B-31. Example part list in the PADS ASCII format.
PCAD (PCAD.CF) The first option available for the PCAD format is:

- Do not append sheet number to labels

If this option is not selected, the PCAD formatter appends an underscore (_) and the sheet number to any labels.

⚠️ CAUTION: If you select this option, labels with the same name on different sheets are merged into one net. This option is typically selected only when the design consists of a single schematic sheet.

The second option available for the PCAD format is:

- Include unconnected pins

If this option is selected, the PCAD formatter assigns all unconnected pins a unique net. If this option is not selected, the PCAD formatter assigns an unique net and reports an error.

The netlist in figure B-32 was created from the schematic in figure B-1 with no options selected.
Figure B-32. Example netlist in the PCAD format (continued).
Figure B-32. Example netlist in the PCAD format.
The only option available for the PCADnlt format is:

- Do not append sheet number to labels

If this option is not selected, the PCADnlt formatter adds an underscore (_) and the sheet number to any labels.

⚠️ CAUTION: If you select this option, labels with the same name on different sheets are merged into one net. This option is typically selected only when the design consists of a single schematic sheet.

The netlist in figure B-33 was created from the schematic in figure B-1 with no options selected.

Figure B-33. Example netlist in the PCADnlt format.
The only option available for the RacalRedac format is:

- Do not append sheet number to labels

If this option is not selected, the RacalRedac formatter adds an underscore (_) and the sheet number to any labels.

⚠️ **CAUTION:** If you select this option, labels with the same name on different sheets are merged into one net. This option is typically selected only when the design consists of a single schematic sheet.

The RacalRedac formatter creates two files. In addition to the netlist file, it also creates a component file. A second filename must be entered in the Destination 2 entry box for the formatter.

The netlist in figure B-34 and the corresponding component file in figure B-35 were created from the schematic in figure B-1 with no options selected.

*Figure B-36. Example netlist in the Scicards format.*
SPICE (SPICE.CF)  This is one of two SPICE formatters supplied with OrCAD's Schematic Design Tools. This formatter can only be used to create flat SPICE netlists. The hierarchical SPICE formatter is discussed in the next section.

The first option available for the SPICE format is:

- Do not append sheet number to labels

If this option is not selected, the SPICE formatter appends an underscore (_) and the sheet number to any labels.

▲ CAUTION: If you select this option, labels with the same name on different sheets are merged into one net. This option is typically selected only when the design consists of a single schematic sheet.

The second available option is:

- Include unconnected pins

If this option is selected, the SPICE formatter assigns all unconnected pins a unique net. If this option is not selected, the SPICE formatter assigns an unique net and reports an error.

The third available option is:

- Use node names

If this option is selected, the SPICE formatter uses the node names you have placed on the schematic (via labels and module ports) where available. Not all versions of SPICE support alphanumeric node names, check your SPICE manual. If your version of SPICE does not allow alphanumeric node names, you can still give them numeric names (such as '17'). These numeric names will not interfere with the ones generated by the SPICE formatter, since formatter generated node numbers begin at 10000 (except GND, which is always 0).
Pipe commands

You can place lines of text in your schematic, to be included in the SPICE netlist. Use Draft's PLACE Text command to place the text in your schematic, or use an editor to put the text in an ASCII file, then use Draft's BLOCK ASCII Import command to import the contents of the file and place it on the worksheet.

Each line of text must start with the pipe character (|). (On many PC keyboards, the pipe character appears as a broken vertical bar.) The first line must be:

|SPICE

This tells the formatter to extract the information in the following lines of text when generating a SPICE netlist. The remaining lines can contain any information you want to include in the netlist. The lines following |SPICE are placed at the top of the netlist.

Caveats

Schematic Design Tools can create netlists larger than most PC-based SPICE programs accept. Consult your SPICE manual for the limits. If your PC meets SPICE's memory requirements, you can generate the largest netlist allowed.

The part value is used to pass modeling information to the netlist. For instance, resistor RS1 in figure B-4 has a value of 1K Ohms.

Use the special PSPICE.LIB or SPICE.LIB libraries supplied by OrCAD when generating a SPICE netlist. These libraries already have pin numbers on the parts and are compatible with most versions of SPICE. The PSPICE.LIB contains many specific part types, such as a 2N2222 NPN transistor, that are not provided in the generic SPICE.LIB.

To modify or create your own SPICE library, you must support the proper model pin numbers. To implement this, use the Decompile Library or Edit Library librarians and convert the desired OrCAD-supplied libraries into a library source file. Make the appropriate changes to the source file and recompile the modified library back to an object file using the Edit Library button.
All library part pin names should be changed to reflect the model node index. To find out the proper node ordering, see your SPICE manual.

As an example of what to change, the OrCAD-supplied NPN transistor has the pin names defined as base, emitter, and collector in the DEVICE.LIB library. For SPICE to understand the nodal information, the pin names must be changed from base, emitter, and collector to 2, 3, and 1 (as defined in the SPICE manual). Therefore, the library source file for an NPN transistor that is compatible with the SPICE pin numbering convention is as follows:

```
'NPN'
REFERENCE 'Q'
{X Size =} 2 {Y Size =} 2 {Parts per Package =} 0
L1  SHORT  IN  '2'
B2  SHORT  IN  '3'
T2  SHORT  IN  '1'
{ 0}........##............#
{ 1}        ##         #
   .
   .
```

Figure B-37. Library source file for the NPN transistor.

The SPICE formatter creates two files. In addition to the netlist file, it also creates a map file. The node numbers created by the formatter are placed in the .MAP file so you may cross reference the SPICE node numbers with the node names that you have specified in your schematic. The filename for this map file must be entered in the Destination 2 entry box for the formatter.

The netlist in figure B-38 and the corresponding map file in figure B-39 were created from the schematic in figure B-4 with no options selected.
Figure B-38. Example netlist in the SPICE format.

Tango (TANGO.CF)  The only option available for the Tango format is:

- Do not append sheet number to labels

If this option is not selected, the Tango formatter appends a dash (-) and the sheet number to any labels.

⚠️ **CAUTION:** If you select this option, labels with the same name on different sheets are merged into one net. This option is typically selected only when the design consists of a single schematic sheet.

The netlist in figure B-40 was created from the schematic in figure B-1 with no options selected.
Figure B-40. Example netlist in the Tango format (continued).
Figure B-40. Example netlist in the Tango format.
The only option available for the Telesis format is:

- Do not append sheet number to labels

If this option is not selected, the Telesis formatter appends a slash (/) and the sheet number to any labels.

▲ CAUTION: If you select this option, labels with the same name on different sheets are merged into one net. This option is typically selected only when the design consists of a single schematic sheet.

The netlist in figure B-41 was created from the schematic in figure B-1 with no options selected.

Appendix B: Netlist formats

WireList  Three options are available for the WireList format is:

- Do not append sheet number to labels

  If this option is not selected, the WireList formatter appends an underscore (_) and the sheet number to any labels.

▲ CAUTION: If you select this option, labels with the same name on different sheets are merged into one net. This option is typically selected only when the design consists of a single schematic sheet.

- Do not output pin numbers for Grid Array parts

  When this option is not selected, the WireList format does not output pin numbers for grid array parts.

- Abbreviate label descriptions

  If this option is selected, the WireList format shortens label descriptions.

The netlist in figure B-44 was created from the schematic in figure B-1 with no options selected.

Hierarchical netlists

In order to create a netlist in one of the hierarchical formats, your schematic must have been processed by INET (linking is not necessary). The necessary steps are explained in Chapter 11: Create Hierarchical Netlist.

Hierarchical netlist formatter files are distinguished by a .CH file extension. They cannot be used within the Create Netlist processor (the two interpreter formats are similar; but process incompatible data structures).

Each of the formatters can create formatted netlists that contain either simple or complex hierarchies.

Example Schematics

The two schematics shown in figures B-45 and B-46 are used by the hierarchical EDIF and SPICE netlists.
Figure B-45: Root sheet used by the hierarchical EDIF format.
Figure B.46. Leaf sheet used by the hierarchical EDIF format.
Figure B.47. Root sheet used by the hierarchical SPICE format (continued).

Date: October 30, 1990
Sheet 3 of 3
EDIF (EDIF.CH)  This is one of two EDIF (Version 2 0 0) formatters supplied with OrCAD's Schematic Design Tools. This formatter can only be used to create hierarchical EDIF netlists. The flat EDIF formatter was discussed in the previous section. All of the options that apply to the flat EDIF format apply to the hierarchical version as well.

The first option available for the EDIF format is:

- Do not append sheet number to labels

If this option is not selected, the EDIF formatter appends an underscore (_) and the sheet number to any labels.

▲ CAUTION: If you select this option, labels with the same name on different sheets are merged into one net. This option is typically selected only when the design consists of a single schematic sheet.

The EDIF formatter can also output pin numbers to the netlist instead of pin names.

- Output pin numbers (instead of pin names)

Not all parts have both pin names and pin numbers defined. If this option is selected, and a pin without a number is found, the pin name is used. If a netlist consisting entirely of pin numbers is required, you may need to modify the library part.

The hierarchical EDIF formatter manages the hierarchy by turning sheets in the schematic into CELLS in the main LIBRARY. These cells can then be referred to by INSTANCE where needed. Because EDIF requires a define-before-use philosophy, the hierarchy appears to be inverted in the netlist (the root sheet is the last CELL in the main LIBRARY).

The netlist in figure B-49 was created from the schematic in figure B-44 with no options selected.
Figure B-49. Example netlist in the hierarchical EDIF format (continued).
Figure B-49. Example netlist in the hierarchical EDIF format (continued).

Figure B-49. Example netlist in the hierarchical EDIF format.
SPICE (SPICE.CH) This is one of two SPICE formatters supplied with OrCAD's Schematic Design Tools. This formatter can only be used to create hierarchical SPICE netlists. The flat SPICE formatter was discussed in the previous section. The formatting options and caveats explained in the flat SPICE netlist section apply to the hierarchical netlist as well.

The first option available for the SPICE format is:

- Do not append sheet number to labels

If this option is not selected, the SPICE formatter appends an underscore (_) and the sheet number to any labels.

▲ CAUTION: If you select this option, labels with the same name on different sheets are merged into one net. This option is typically selected only when the design consists of a single schematic sheet.

The second option available is:

- Include unconnected pins

If this option is selected, the SPICE formatter assigns all unconnected pins a unique net. If this option is not selected, the SPICE formatter assigns an unique net and reports an error.

The third available option is:

- Use node names

If this option is selected, the SPICE formatter uses the node names you have placed on the schematic (via labels and module ports) where available. Not all versions of SPICE support alphanumeric node names, so check your SPICE manual. If your version of SPICE does not allow alphanumeric node names, you can still give them numeric names (for example '17'). These numeric names will not interfere with the ones generated by the SPICE formatter, since formatter-generated node numbers begin at 10000 (except GND, which is always 0).
Pipe commands

You can place lines of text in your schematic to be included in the SPICE netlist. Use Draft's PLACE Text command to place the text in your schematic, or use an editor to put the text in an ASCII file, then use Draft's BLOCK ASCII Import command to import the contents of the file and place it on the worksheet.

Each line of text must start with the pipe character (|). (On many PC keyboards, the pipe character appears as a broken vertical bar.) The first line must be:

```
|SPICE
```

This tells the formatter to extract the information in the following lines of text when generating a SPICE netlist. The remaining lines can contain any information you want to include in the netlist. The lines following |SPICE are placed at the top of the netlist.

Caveats

Schematic Design Tools can create netlists larger than most PC-based SPICE programs accept. Consult your SPICE manual for the limits. If your PC meets SPICE's memory requirements, you can generate the largest netlist allowed.

The part value is used to pass modeling information to the netlist. For instance, resistor RS1 in figure B-4 has a value of 1K Ohms.

Use the special PSPICE.LIB or SPICE.LIB libraries supplied by OrCAD when generating a SPICE netlist. These libraries already have pin numbers on the parts and are compatible with most versions of SPICE. The PSPICE.LIB contains many specific part types, such as a 2N2222 NPN transistor, that are not provided in the generic SPICE.LIB.

To modify or create your own SPICE library, you must support the proper model pin numbers. To implement this, use the Decompile Library or Edit Library librarians and convert the desired OrCAD-supplied libraries into a library source file. Make the appropriate changes to the source file and recompile the modified library back to an object file using Edit Library.
All library part pin names should be changed to reflect the model node index. To find out the proper node ordering, see your SPICE manual.

As an example of what to change, the OrCAD-supplied NPN transistor has the pin names defined as base, emitter, and collector in the DEVICE.LIB library. For SPICE to understand the nodal information, the pin names must be changed from base, emitter, and collector to 2, 3, and 1 (as defined in the SPICE manual). Therefore, the library source file for an NPN transistor that is compatible with the SPICE pin numbering convention is as follows:

```
'NPN'
REFERENCE 'Q'
{X Size =} 2 {Y Size =} 2 {Parts per Package =} 0
L1  SHORT  IN  '2'
B2  SHORT  IN  '3'
T2  SHORT  IN  '1'
{  0}.........#...............#
{  1}       #
  

Figure B-50. Library source file for the NPN transistor.
```

The hierarchical version of the SPICE netlist creates subcircuit (.SUBCKT) definitions for sheets in the hierarchy. These subcircuits are “called” via the X command. Since SPICE does not require the subcircuits to be defined before use, the hierarchy appears in normal form in the netlist (the root sheet at the top of the netlist file).

The SPICE formatter creates two files. In addition to the netlist file, it also creates a map file. The node numbers created by the formatter are placed in the .MAP file so you may cross reference the SPICE node numbers with the node names that you have specified in your schematic. The filename for this map file must be entered in the Destination 2 entry box for the formatter.

The netlist in figure B-51 and the corresponding map file in figure B-52 were created from the schematic in figure B-45 with no options selected.
Figure B-51. Example netlist in the hierarchical SPICE format.
Figure B-52. Example map file in the hierarchical SPICE format.

Interpreting connectivity databases

This appendix covers the following topics:

- Introduces connectivity databases
- Describes in detail the format of incremental and linked connectivity databases that are new with OrCAD's Release IV tools
- Includes a sample .INF file with comments

OrCAD's Schematic Design Tools, Digital Simulation Tools, and PC Board Layout Tools use a series of databases to organize design information.

Two of the databases, the *incremental connectivity database* and the *linked connectivity database*, organize information about a design's connectivity. Basic information about these databases is contained in Chapter 9: *Creating a netlist*.

The information in these two databases is stored in .INF format, which is described in this appendix. With an understanding of this file format, you can develop programs that use connectivity databases as source files or that convert files in other formats to connectivity databases.

**Overview of connectivity databases**

A connectivity database is a group of one or more files that contain data extracted from schematic worksheets. The figure on the next page shows the relationship of INET, ILINK, IFORM, and HFORM, their source and destination files, and the name of each database.
About the incremental connectivity database

INET gathers data from title blocks, parts, and connections between parts on schematics. INET can also gather specially-marked text and stimulus, trace, and vector data placed on schematics. INET creates one .INF file for each sheet in the design and one .INX file for the entire design.

This appendix describes the format of .INF files; the .INX file is a text file containing a list of the sheets in the design. INET uses the list to track which sheets need updated .INF files. Together, the .INF files and .INX file are called the *incremental connectivity database*.

This database is the source for both HFORM and ILINK. OrCAD’s Digital Simulation Tools uses the incremental connectivity database for simulation.
About the linked connectivity database

Using the incremental connectivity database as input, ILINK, depending on the local configuration options selected, creates one or two databases: an intermediate netlist structure or an intermediate netlist structure and a linked connectivity database.

The linked connectivity database is in the same format as the .INF files, but is a single ASCII file with the .LNF extension. OrCAD's PC Board Layout Tools Release IV uses the linked connectivity database.

Typographical conventions

This appendix contains several typographical, or notational, conventions that are in addition to or used differently than the rest of this reference guide. The conventions are:

*Italic text*

This italic font shows a parameter representing specific data.

... Ellipses shows the continuation of a series.

"parameter"

Double quotes surrounding a parameter indicate the parameter is a quoted token. The double quotes are part of the syntax.

?parameter?

Question marks surrounding a parameter indicate the parameter can be either a number or a quoted token. The question marks are *not* part of the syntax.

Parameter

Parameters without double quotes or questions marks are either numbers or strings. Parameter definitions specify the type of token.

Terminology

This section includes definitions for the various parts of .INF and .LNF files. You need to know these terms to correctly interpret the syntax of the statements defined in this appendix. See the Glossary for other terms.
Token
A token is a group of characters preceded and followed by white space. Files in the .INF format contain six kinds of tokens: quoted tokens, strings, delimiters, commands, numbers, and sub-part codes.

White space
Files in the .INF format may contain white space between tokens. White space can be a space, a horizontal tab, a carriage return, a line feed, or any combination of these characters. Spaces are also allowed within quoted tokens.

Quoted token
A quoted token is a token that begins and ends with double quotes. Quoted tokens may contain any ASCII character except the back quote (`) and may be empty. Two double quotes in a quoted token represent one double quote. This table shows some examples:

<table>
<thead>
<tr>
<th>Quoted token</th>
<th>Corresponds to</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;OUTPUT2&quot;</td>
<td>OUTPUT2</td>
</tr>
</tbody>
</table>
| ""SEC""
    Carry" | "SEC" Carry    |
| " "         | (empty field)  |

Examples of quoted tokens.

String
A string is an unquoted token that may contain only these characters:

```
abcdefghijklmnopqrstuvwxyz
ABCDEFGHIJKLMNOPQRSTUVWXYZ
1234567890
= -= ! # $ % , . : ; = ? @ \ ^ _ * ( ) | ~ / 
```

Strings may not contain spaces. For example:

Clock
42.22V10
@17#sec?

Delimiter
A delimiter is an unquoted token comprised of a right or left parentheses. Delimiters occur in pairs to enclose groups of parameters. For example:

( R U1 11 ) ( R U2 9 )
Appendix C: Interpreting connectivity databases

**Command**
A command is an unquoted token comprised of a back quote immediately followed by a single character from this list:

BEFHJIPLSTVW`

The characters must be uppercase. For example:

`H`

**Character**
A character is an unquoted token comprised of a single character. For example:

C

**Number**
A number is an unquoted token comprised of characters from this list:

0123456789
ABCDEFabcdef

The format supports decimal, hexadecimal, and binary numbers and requires numbers to be in specific formats. For example, the parameter `absolute_identifier` must be an eight-digit hexadecimal number that does not include a suffix. For example:

023FB897

**Sub-part code**
A sub-part code is an unquoted token that begins and ends with square brackets. The square brackets may enclose only zeros (0) and ones (1). The binary digit 1 indicates a sub-part is used; 0 indicates a sub-part is unused. The number of digits indicates the number of sub-parts. For example:

[1010] Means four sub-parts, first and third used
[1] Means a one-part package
[0] Invalid sub-part code
[ ] Means a zero-part package
Statement  A statement is a group of tokens that begins with a command and ends with either the blank space before the next command or with the end-of-file character. The tokens following the command are parameters. Statements may extend over multiple lines in a file. For example:

'W S "INPUT_PORT" 1 (0:0)

Parameter  A parameter is a single token or a group of tokens delimited by parentheses. The .INF format requires a specific type of token, such as a number or quoted token, for each parameter. For example:

absolute_identifier
( S "signal_name" sheet_number )

.INF format specification  The following sections list the types of statements that appear in incremental and linked connectivity databases in the order they appear in the .INF and .LNF files. Each discussion includes syntax and an example; notes contain software-related information.

For ILINK to read .INF files, the statements must appear in the order and frequency shown in the table below. The port and signal statements can be intermingled, as can the trace, vector, and stimulus statements.

<table>
<thead>
<tr>
<th>Command</th>
<th>Name</th>
<th>Frequency in .INF files</th>
<th>Frequency in .LNF files</th>
</tr>
</thead>
<tbody>
<tr>

<td>Zero or more</td>
<td>Zero or more</td>
</tr>
</tbody>
</table>

Order and frequency of statements in .INF and .LNF files.
**H or F Header**

The header specifies information about the .INF file and must be the first line in the file. The syntax is:

```
'file_type format_version file_name
```

- **file_type**
  - Tells whether the design is flat or hierarchical. *file_type* is one of two characters: F for flat or H for hierarchical.

  △ **NOTE:** ILINK accepts references to children in instance commands only from hierarchical .INF files.

- **format_version**
  - Tells the version of the format. A string.

- **file_name**
  - Tells the name of the .INF or .LNF file. A string.

**Example**

```
'F 1.00 NEWALARM
```

---

**B Title block**

The title block statement contains information from the title block. Each .INF file contains only one title block command. The title block statement immediately follows the header. The syntax is:

```
'B "sheet_number" "total_sheet_number" "sheet_size"
"date" "document_number" "revision_code" "title"
"organization_name" "address_line_1" "address_line_2"
"address_line_3" "address_line_4"
```

- **B**
  - Begins parameters describing title block information.

- **"sheet_number"**
  - Tells the sheet number field on the title block.

- **"total_sheet_number"**
  - Tells the total sheets field on the title block.

- **"sheet_size"**
  - Tells the sheet size field on the title block.
"date"  Tells the date field on the title block.

"document_number"  Tells the document number field on the title block.

"revision_code"  Tells the revision code field on the title block.

"title"  Tells the title field on the title block.

"organization_name"  Tells the organization field on the title block.

"address_line"  Tells one of four address line field on the title block.

Example

'B "1" "7" "A" "January 27, 1991" "1860107-001" "A"
"Demonstration Schematic" "OrCAD LP"
"3175 NW Alopec Drive" "Hillsboro, Oregon 97124"
"(503) 690-9881" " "

**L Link**

Link statements specify the files to include in an intermediate netlist structure or a linked connectivity database. The syntax is:

```
'L netlist_filename

'L  Begins the link statement.
```

`netlist_filename`  Tells the name of a file, with the extension omitted, to be linked. An .INF file contains one link statement for each linked file; .LNF files contain no link statements. A string.

\_ NOTED: ILINK assumes the extensions are .INF.

INET and ILINK accept link commands only from a root schematic in a flat design. In addition, every schematic in a linked design must be a single sheet.
Module port statements define module port types and names. The syntax is:

\begin{verbatim}
`P module_port_type "module_port_name"
\end{verbatim}

`P 

Begins a module port definition.

\textit{module_port_type} 

Tells a module port type from this table:

\begin{center}
\begin{tabular}{|c|c|}
\hline
Character & Module port type \\
\hline
I & Input \\
O & Output \\
B & Bidirectional, IO \\
U & Unspecified \\
S & Supply \\
\hline
\end{tabular}
\end{center}

\textit{Module port characters and types.}

\textit{"module_port_name"} 

Tells the name of the module port.

\textbf{△ NOTE: The supply port type is global, crossing all hierarchical boundaries.}

\textbf{Example}

\begin{verbatim}
`P I "OPEN CARRY"
\end{verbatim}
S  Signal

Signal statements define signal names and the worksheets containing them. The syntax is:

`S "signal_name" sheet_number

`S  Begins a signal definition.

"signal_name"  Tells the name of the signal.

sheet_number  Equals the number of the worksheet containing the signal. A whole decimal number.

Example

`S "TRYIN1" 2

E  External

External statements specify configured libraries. The .INF file must contain an external statement for every library referenced on the schematic. The syntax is:

`E library_name

`E  Begins the external statement.

library_name  Tells the name of a library. A string.

Example

`E TTL.LIB

I  Instance

Instance statements declare the instance of objects on a schematic. The part instance syntax is for parts and sheetpath parts; the child instance syntax is for sheets and sheet parts. This discussion has two sections; the first describes the part instance syntax, and the second describes the child instance syntax.

•  Part instance

The part instance syntax is:
Appendix C: Interpreting connectivity databases

`I R "part_value" library "library_part_name"
absolute_identifier part_reference [sub_part_code]
"part_field_1" . . . "part_field_8" "module_field"
( "pin_name_1" ?pin_number_1? pin_type_1 )
( "pin_name_2" ?pin_number_2? pin_type_2 ) . . .
( "pin_name_n" ?pin_number_n? pin_type_n )

`I Begins a declaration of an instance of a part or child.

R Means the following parameters describe a part or a sheetpath part.

△ NOTE: Sheetpath parts may appear in .INF files as either parts or children, depending on the local configuration settings for INET. If the option Descend into sheetpath parts is selected, INET classifies sheetpath parts as children; otherwise, INET classifies sheetpath parts as parts.

"part_value" Tells the part value field from the schematic.

library Tells the name, excluding extension, of the library containing the part. A string.

"library_part_name" Tells the name of the part in the library specified by the library parameter.

absolute_identifier Tells the eight-digit hexadecimal number based on the date and time the part was first placed on the schematic. The number remains unchanged and is unique.

△ NOTE: When a part is one of several in a package, every part in the package has a unique absolute identifier. The absolute identifier in the .INF file is the latest one of all the parts in the package.
Schematic Design Tools Reference Guide

\[ \text{part_reference} \]  Tells a unique reference designator for the part containing the pin. A string.

\[ \text{[sub_part_code]} \]  Tells the number of sub-parts in a part and which of those sub-parts is used. A sub-part code. See the section Terminology for examples.

\"part_field\"  Tells user-supplied information from a part field. All eight part fields must be included, even if they are empty.

\(\Delta\)  **NOTE:** Parts that are packages may have only one set of part_field parameters. In cases where the sub-parts placed on a schematic have different information in the part fields, INET selects information for each field from the first sub-part it sees containing information in that field. INET looks at the sub-parts in absolute identifiers order, starting with the smallest absolute identifier.

\"module_field\"  Tells package description information consolidated from one or more of the part fields. The configuration of the Module Value Combine key field in Schematic Design Tools determines the combination.

\(\Delta\)  **NOTE:** When sub-parts have different information in part fields used to create the module-field parameter, INET uses the information from the first sub-part in the package even if the part fields are empty.

(  Begins a pin description. The instance command must contain one delimited set of pin parameters for each pin.

\"pin_name\"  Tells the name of the pin.
Appendix C: Interpreting connectivity databases

?pin_number? Tells the number of a pin on a part or a sheet net on a sheetpath part. ?pin_number? is either a whole decimal number or a quoted token, depending on whether the characters are numeric or alphanumeric.

pin_type Tells one of the pin types listed in the table below.

<table>
<thead>
<tr>
<th>Character</th>
<th>Pin type</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>Input</td>
</tr>
<tr>
<td>O</td>
<td>Output</td>
</tr>
<tr>
<td>B</td>
<td>Bidirectional, IO</td>
</tr>
<tr>
<td>S</td>
<td>Supply, power</td>
</tr>
<tr>
<td>P</td>
<td>Passive</td>
</tr>
<tr>
<td>T</td>
<td>Three-state</td>
</tr>
<tr>
<td>C</td>
<td>Open collector</td>
</tr>
<tr>
<td>E</td>
<td>Open emitter</td>
</tr>
</tbody>
</table>

Characters for pin types.

Example

```
'I R "74LS00" TTL "74LS00" 74A3F631 U1 [1000] "" ""
"14PDIP" "" "" "" "" "" "" "" "" "" "" "" "" "" "" "" "" "" "" "" "" "" "" "" "" "" "" "" "" "" ""
( "I0_B" 4 I ) ( "I0_C" 9 I ) ( "I0_D" 12 I )
( "I1_A" 2 I ) ( "I1_B" 5 I ) ( "I1_C" 10 I )
( "I1_D" 13 I ) ( "O_A" 3 O ) ( "O_B" 6 O )
( "O_C" 8 O ) ( "O_D" 11 O ) ( "GND" 7 S )
( "VCC" 14 S )
```

Child instance

The child instance syntax is:

```
'I C "sheet_file_name" absolute_identifier "sheet_name"
( "sheet_net_name_1" sheet_net_type_1 ) . . .
( "sheet_net_name_n" sheet_net_type_n )
```

'1 Begins a declaration of an instance of a part or child.
Means the next parameters describe a sheet or a sheet part.

△ NOTE: Sheetpath parts may appear in .INF files as either parts or children, depending on the configuration settings for INET. If the option Descend into sheetpath parts is selected, INET classifies sheet-path parts as children; otherwise, INET classifies sheetpath parts as parts.

"sheet_file_name" Tells the complete filename of the worksheet containing the child’s logic.

absolute_identifier Tells the absolute identifier, a unique eight-digit hexadecimal number based on the date and time the part was first placed on the schematic. This number remains unchanged.

"sheet_name" Tells the schematic name of a child. This name is unique for each instance of a child on a worksheet; if several children reference the same schematic, each instance has the same sheet_file_name but a unique sheet_name.

"sheet_net_name" Tells the name of the sheet net.

sheet_net_type Tells one of the sheet net types listed in this table:

<table>
<thead>
<tr>
<th>Character</th>
<th>Sheet net type</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>Input</td>
</tr>
<tr>
<td>O</td>
<td>Output</td>
</tr>
<tr>
<td>B</td>
<td>Bidirectional, IO</td>
</tr>
<tr>
<td>S</td>
<td>Supply, power</td>
</tr>
<tr>
<td>P</td>
<td>Passive</td>
</tr>
<tr>
<td>T</td>
<td>Three-state</td>
</tr>
<tr>
<td>C</td>
<td>Open collector</td>
</tr>
<tr>
<td>E</td>
<td>Open emitter</td>
</tr>
<tr>
<td>U</td>
<td>Unspecified</td>
</tr>
</tbody>
</table>

Characters for sheet net types.
Appendix C: Interpreting connectivity databases

\[ \text{J \ Joined} \]

Join statements specify entities made electrically common in a net. An entity is a signal, module port, pin, or sheet net. Join statements can contain any combination of one or more entities. Join statements containing only one entity indicate single-node nets. The syntax is:

`J ( entity_1 ) ( entity_2 ) . . . ( entity_n )`

`J` Begins a list of electrically common entities.

\[ \text{entity} \]

Represents one of four types of parameters describing a signal, module port, pin, or sheet net. Each type has its own syntax as described on the next several pages.

\[ \text{Example} \]

`J ( R U3 14 I ) ( R U2 "CENTER 1" P ) ( P S "VCC" ) ( S "X0" 3 ) ( C "TRYAGAIN" "X" U )`

\[ \text{Signal} \]

The syntax of a signal entity is:

\[ ( S \ "signal\_name" \ sheet\_number ) \]

`S` Begins a signal description.

"signal\_name" Tells the name of a signal.

sheet\_number Tells the number of the worksheet containing a signal. A whole decimal number.

\[ ) \]

Ends a set of parameters describing a signal.

Example

( S "TRYIN1" 2 )

Module port

The syntax of a module port entity is:

( P module_port_type "module_port_name" )

( P Begins a module port description.

module_port_type Tells the type of module port as listed in this table:

\begin{tabular}{|c|c|}
\hline
Character & Module port types \\
\hline
I & Input \\
O & Output \\
B & Bidirectional \\
U & Unspecified \\
S & Supply, power \\
\hline
\end{tabular}

Characters for module port types.

"module_port_name" Tells the name of the module port.

) Ends a module port description.

Example

( P S "VCC" )

Pin

The syntax of a pin entity is:

( R part_reference ?pin_number? pin_type )

( R Begins a pin description.

part_reference Tells the unique reference designator for the part containing the pin. A string.
Appendix C: Interpreting connectivity databases

\( ?\text{pin\_number}\) Tells the pin number. \( ?\text{pin\_number}\) is either a whole decimal number or a quoted token. When the pin is a zero-part-per-package pin, \text{pin\_number} is the pin name.

\text{pin\_type} Tells one of the pin types listed in this table:

<table>
<thead>
<tr>
<th>Character</th>
<th>Pin type</th>
</tr>
</thead>
<tbody>
<tr>

\) Ends a pin description.

Example

\((\text{R COAX1 "CENTER 1" O })(\text{R U2 9 B })\)

\(\checkmark\text{ Sheet\ net}\) The syntax of a sheet net entity is:

\((\text{C "sheet\_name" "sheet\_net\_name" sheet\_net\_type })\)

\((\text{C})\) Begins a sheet net description.

"sheet\_name" Tells the part value of a sheet part or sheetpath part, or the name of a sheet.

"sheet\_net\_name" Tells the name of the sheet net.

sheet\_net\_type Tells one of the sheet net types listed in the table at the top of the next page.

) Ends a sheet net description.

Example

( C "TRY" "A0" I )

Trace statements specify trace information for OrCAD’s Digital Simulation Tools. Four types of trace statements are possible: signal, pin, sheet net, and bus. Each is described separately.

Signal

The syntax of a signal trace is:

```
`T S "signal_name" sheet_number "signal_display_name"
```

`T Begins trace information.

S Begins a signal definition.

"signal_name" Tells the name of the signal.

sheet_number Tells the number of the worksheet containing the signal.

A whole decimal number.
"signal_display_name" Tells the trace name to be displayed during simulation.

Example
\`T S "OUTPUT" 4 "Y Output"

Pin

The syntax of a pin trace is:
\`T R part_reference ?pin_number? "part_display_name"

\`T Begins parameters describing trace information.

R Means the following three parameters describe a pin or a sheet net. The next section describes the parameters for sheet nets.

part_reference Tells the unique reference designator for the part containing the pin or sheet net. A string.

?pin_number? Tells the pin number. Either a whole decimal number or quoted token.

"part_display_name" Tells the trace name to be displayed during simulation.

Example
\`T R U1 11 "ALTERNATE"

Sheet net

The syntax of a sheet net trace is:
\`T R sheet_name "sheet_net_name" "sheet_display_name"

\`T Begins trace information.

R Means the following parameters describe a sheet net or pin. The previous section describes the parameters for pins.

sheet_name Tells the name of the sheet. A string.
"sheet_net_name"  Tells the sheet net name.

"sheet_display_name"  Tells the trace name to be displayed during simulation.

Example

\`T R U1 "ALTERNATE" "ALTERNATE"

\* Bus

The syntax of a bus trace is:

\`T B "bus_name\[range\]" sheet_number display_type
"bus_display_name"

\`T  Begins trace information.

B  Means the following three parameters describe a bus.

"bus_name\[range\]"  Tells the name of the bus immediately followed by a range index. If the range is a single value, the index is a decimal number. If the range is more than one value, square brackets enclose the index that is comprised of two whole decimal numbers separated by two periods. The smallest value must be listed first. For example:

"COUNTER2"
"COUNTER\[0..1\]"

sheet_number  Tells the number of the worksheet containing the bus. A whole decimal number.

display_type  Tells one of the display types listed in the table below.

<table>
<thead>
<tr>
<th>Character</th>
<th>Display type</th>
</tr>
</thead>
<tbody>
<tr>
<td>B</td>
<td>Binary bus</td>
</tr>
<tr>
<td>D</td>
<td>Decimal bus</td>
</tr>
<tr>
<td>H</td>
<td>Hexadecimal bus</td>
</tr>
<tr>
<td>O</td>
<td>Octal bus</td>
</tr>
</tbody>
</table>

Characters for bus types.

"bus_display_name"  Tells the name of the bus to display during simulation.
Appendix C: Interpreting connectivity databases

\[ \text{NOTE: If no value for display_type is provided, INET assigns hexadecimal.}\]

\textit{Example}

`T B "AD[0..7]" 4 H "ADDRESS"

\underline{V Vector}

Vector statements specify vector information for OrCAD's Digital Simulation Tools. Three types of vector specifications are possible: signal, pin, and bus.

\begin{itemize}
  \item \textbf{Signal}
    \begin{itemize}
      \item The syntax of a signal vector is:
        \begin{verbatim}
        \`V S "signal_name" sheet_number column_number
        \end{verbatim}
      \end{itemize}
    \end{itemize}

  \begin{itemize}
    \item `V Begins parameters describing vector information.
    \item S Means the following three parameters describe signals.
    \item "signal_name" Tells the name of the signal.
    \item sheet_number Tells the number of the worksheet containing the signal. A whole decimal number.
    \item column_number Tells the column number in the test vector. A whole decimal number.
    \textit{Example}
    \begin{verbatim}
    `V S "OUTPUT" 4 13
    \end{verbatim}
  \end{itemize}

  \begin{itemize}
    \item \textbf{Pin}
      \begin{itemize}
        \item The syntax of a pin vector is:
          \begin{verbatim}
          `V R part_reference ?pin_number? column_number
          \end{verbatim}
        \end{itemize}
      \end{itemize}

    \begin{itemize}
      \item `V Begins parameters describing vector information.
    \end{itemize}

601
R Means the following three parameters describe a pin.

part_reference Tells the unique reference designator for the part containing the pin. A string.

?pin_number? Tells the pin number. Either a quoted token or a whole decimal number.

column_number Tells the column number in the text vector. A whole decimal number.

Example

`V R U1 3 8`

❖ Bus

The syntax of a bus vector is:

`V B "bus_name[range]" sheet_number first_column_number`

`V` Begins vector information.

B Means the following three parameters describe a bus.

"bus_name[range]" Tells the name of the bus immediately followed by a range index. If the range is a single value, the index is a decimal number. If the range is more than one value, square brackets enclose the index that is comprised of two whole decimal numbers separated by two periods. The smallest value must be listed first.

sheet_number Tells the number of the worksheet containing the bus. A whole decimal number.

first_column_number Tells the starting column number in the test vector. A whole decimal number.

Example

`V B "AD[0..7]" 4 14`
W Stimulus

Stimulus statements specify stimulus information for OrCAD’s Digital Simulation Tools. Three types of stimulus specifications are possible: signal, pin, and bus. Stimulus statements for signals and pins can contain set and branch parameters, which are described first.

◊ Set parameter

The syntax of a set parameter is:

\[ \text{time: function} \]

- **time**: Tells the time at which a state function will occur. An unsigned whole number.
- **function**: Tells a state function as shown in the table below.

<table>
<thead>
<tr>
<th>Character</th>
<th>State function</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Set to value 0</td>
</tr>
<tr>
<td>1</td>
<td>Set to value 1</td>
</tr>
<tr>
<td>U</td>
<td>Set to undefined state</td>
</tr>
<tr>
<td>Z</td>
<td>Set to high impedance state</td>
</tr>
<tr>
<td>T</td>
<td>Toggle the signal state</td>
</tr>
</tbody>
</table>

Characters for state functions.

**Example**

100:Z

◊ Branch parameter

The syntax of a branch parameter is:

\[ \text{time1: G: time2} \]

- **time1**: Tells the start time. An unsigned whole number.
- **G**: Represents the GOTO function.
- **time2**: Tells the target time. An unsigned whole number.
△ NOTE: Only one branch statement per stimulus is allowed.

Example
0:G:200

❖ Signal

The syntax of a signal stimulus is:

`\W S "signal_name" sheet_number ( stimuli )

`\W Begins parameters describing stimulus information.

S Means the following parameters are for signals.

"signal_name" Tells the name of the signal.

△ NOTE: Digital Simulation Tools does not recognize signal names containing periods (.) anywhere in the signal name or colons (:) at the end of the signal name.

sheet_number Tells the number of the worksheet containing the signal. A whole decimal number.

( Begins a list of stimuli.

stimuli Lists one or more set or branch parameters.

) Ends a list of stimuli.

Example
`\W S "INPUT" 3 ( 0:0 50:1 100:T 200:G:50 )

❖ Pin

The syntax of a pin stimulus is:

`\W R part_reference ?pin_number? ( stimuli )
Appendix C: Interpreting connectivity databases

`W` Begins a stimulus description.

R Means the following parameters describe a pin.

part_reference Tells the unique reference designator for the part containing the pin. A string.

?pin_number? Tells the pin number. Either a whole decimal number or quoted token.

( Begins a list of stimuli.

stimuli Lists one or more set or branch parameters.

) Ends a list of stimuli.

Example

`W R U1 3 ( 0:1 50:T )`

◊ Bus

The syntax of a bus stimulus is:

`W B "bus_name[range]" sheet_number ( stimuli )`

`W` Begins parameters describing stimulus information.

B Means the following three parameters describe a bus.

"bus_name[range]" Tells the name of the bus immediately followed by a range index. If the range is a single value, the index is a decimal number. If the range is more than one value, square brackets enclose the index that is comprised of two whole decimal numbers separated by two periods. The smallest value must be listed first.
NOTE: Digital Simulation Tools does not recognize bus names containing periods (.) anywhere in the bus name or colons (:) at the end of the bus name. You can include periods in the range index.

\( \text{sheet\_number} \) Tells the number of the worksheet containing the bus. A whole decimal number.

( Begins a list of stimuli.

\( \text{stimuli} \) Lists stimuli information. Version 1.00 of the .INF format does not define a syntax for bus stimuli, so the stimuli can be any valid string.

NOTE: Digital Simulation Tools simulates only signals and parts.

) Ends a list of stimuli.

Example

`W B INPUTBUS[1..4] 3 ( 0:1 50:T )`

Pipe commands contain text extracted from the schematic. For the text to be extracted, each line must begin with a pipe (|) symbol. Pipe text may contain any type of information; each program that uses the .INF file scans the pipe commands for keywords and uses those it recognizes. OrCAD tools recognize the keywords PLD, VSTModel, SPICE, and others. An .INF or .LNF file may contain more than one section of pipe commands. Pipe commands appear at the end of the file. The syntax is:

```
| keyword
"information_line_1"
"information_line_2"
```
\`
| \n| "| keyword" | Lists a command word or string for a specific program or any text.
| "| information_line" | Lists text.

\> \> NOTE: Each section of pipe commands on a schematic created with OrCAD's Schematic Design Tools should begin in a different column.

Example

\`
| "| IPDX1 in: (A1, A2, B1, B2),"
| "| io: (Y1, Y2)"
| "| Y1 = A1 & B1"
| "| Y2 = A2 # B2"
\`

Sample .INF file

The sample .INF file in this section was created from the schematic drawing below. The schematic shows a variety of objects and how they appear in an .INF file, but is not a working circuit.
The schematic TEST_INF.SCH.
Appendix C: Interpreting connectivity databases

Sample .INF file.

Sample .INF file.
Both .INF and .LNF files are in the .INF format described in this appendix. However, when ILINK links a series of .INF files to create a .LNF file, it uses the following guidelines during the process.

Sub-parts in .LNF files

It is possible that sub-parts from a single package reside on separate schematics and have conflicting information in the part fields. When this happens, ILINK merges the instance commands for the sub-parts, using the first parameter containing information. ILINK combines the pin number parameters, discarding duplicates such as power and ground pins.

For example, if the following two instance commands are in separate .INF files processed by ILINK, the .LNF file contains the third instance command.

The instance command below is from the first .INF file.

```
'I R 74LS21 TTL.LIB "74LS21" 34D55A33 U1 [10] "" ""
"14PDIP" "" "" "" "" "" ""14PDIP" ("IOA" 1 I)
("I1A" 2 I) ("I2A" 4 I) ("I3A" 5 I)
("OA" 6 0) ("GND" 7 S) ("VCC" 14 S)
```

This instance command is from the second .INF file:

```
'I R 74LS21 TTL.LIB "74LS21" 34D55A16 U1 [01] "" ""
"16PDIP" "" "" "" "" "" ""16PDIP" ("IOB" 9 I)
("I1B" 10 I) ("I2B" 12 I) ("I3B" 13 I)
("OB" 8 0) ("GND" 7 S) ("VCC" 14 S)
```

This is the resulting instance command in the .LNF file:

```
"14PDIP" "" "" "" "" "" ""14PDIP" ("IOA" 1 I)
("I1A" 2 I) ("I2A" 4 I) ("I3A" 5 I) ("OA" 6 0)
("GND" 7 S) ("VCC" 14 S) ("IOB" 9 I)
("I1B" 10 I) ("I2B" 12 I) ("I3B" 13 I)
("OB" 8 0)
```

Notice that ILINK used the latest absolute identifier, 34D55A33, and the first occurrences of the part fields and module field.
Creating a custom netlist format

This appendix describes the process of creating a custom netlist format to use with OrCAD's Schematic Design Tools. You specify a netlist format for flat netlists in a netlist format file or for hierarchical netlists in a hierarchical netlist format file.

IFORM uses the netlist format file and an intermediate netlist structure created by ILINK to create a flat netlist in the format you defined.

HFORM uses the hierarchical netlist format file and an incremental connectivity database created by INET to create a hierarchical netlist in the format you defined. The figure below shows both processes.

```
Netlist format file that you can create
Intermediate netlist structure created by ILINK
Hierarchical netlist file that you can create
Incremental connectivity database created by INET
```

Figure D-1. Source and destination files for IFORM and HFORM.

To create a custom netlist format file, you should be familiar with programming, preferably in the C language.
At the end of OrCAD's netlist process, IFORM and HFORM use netlist format files and OrCAD databases to create flat and hierarchical netlists in formats you select from Local Configuration screens. OrCAD supplies over thirty format files for the most common file formats; you can create your own format files for uncommon or situation-specific formats.

For more information about the netlist process, see chapters 9, 10, and 11 in this reference guide.

The two types of netlist formats are:

- A flat format where all ports and signals are resolved across the entire design.
- A hierarchical format where all instances of sheets and subsheets, called children, remain intact and are used to reference subnets.

Either type of netlist format can be part-oriented or net-oriented.

**Flat formats**

The flat format gives all parts unique references and all nodes unique names. Although this view accurately reflects the design, it removes evidence of the structure of the design.

**Hierarchical formats**

The hierarchical format retains the hierarchical format of the original design, complete with all subsheets and non-unique references and nodes.

**Part and net orientations**

Both flat and hierarchical netlist formats can focus on parts or on nets. IFORM and HFORM manage separate data structures for parts, nets, and children; you use different functions to access the data structures. A subset of the pre-defined functions work only when creating part-oriented netlists; the remaining functions work for both net- and part-oriented netlists. For specifics, see the section *Data structures*. 
Appendix D: Creating custom netlist formats

**OrCAD-supplied formats**
OrCAD supplies format files for over thirty formats with Schematic Design Tools. The formats and sample netlists are in Appendix B: Netlist formats.

**Customer-contributed formats**
In addition to OrCAD-supplied netlist formats, customers who create netlist format files can post them on OrCAD's bulletin board so other customers can use them.

---

**How to create a new format**
This section describes the process of creating a new netlist format; the following sections contain suggestions and syntax information.

1. **Know what you want the destination file to look like.**
   You should have sample netlists in the desired format, and, if possible, a specification for the format.

2. **Check for one or more formats that are similar to what you want.**
   Look through Appendix B: Netlist formats in the Schematic Design Tools Reference Guide and find one or two netlist formats that are similar to the one you want. If your netlist format is in two parts like the Spice or Vectron formats, find the one that is closest to your format. In the following steps, you will use the corresponding format files as templates for the new format.

3. **Examine the .CF or .CH files and compare them to the netlists they create.**
   Examine the .CF or .CH files for the formats you identified as being similar to yours. Determine how IFORM or HFORM creates the netlist, looking at how nets and pins are written.

4. **Identify what changes you need to make.**
   Identify the changes you need to make in the .CF or .CH file. When necessary, refer to the syntax and reference information later in this appendix.
5. **Make the changes.**

Edit a copy of the .CF or .CH file that is nearest to what you want using a text editor or Edit File. Be sure to name it something different.

6. **Test the format file.**

Create a netlist for a sample schematic using the Create Netlist or Create Hierarchical Netlist tool on the Schematic Design Tools work screen.

Chances are, IFORM or HFORM will report error messages. A list of the messages and explanations is at the end of this appendix.

7. **Fine tune the format file.**

Go back to step 3 and identify what worked and what didn’t, then redo steps 4 through 7 until IFORM or HFORM creates a netlist that matches your specification.

---

**About format files**

Netlist format files must contain specific constructs that IFORM and HFORM can use. This section describes language guidelines, functions, and symbols. Following sections, including the reference portion of this appendix, describe individual elements of format files.

**File names**

Netlist format files must have the extension .CF for flat netlists IFORM creates and .CH for hierarchical netlists HFORM creates.

**Language**

The language used in format files is a subset of the C language. Local and global variables are supported, as well as function calls and recursion. The following list contains exceptions, restrictions, and conventions:

- **Int** and **char** are the only data types supported.
- All functions are assumed to return **int**.
- Argument passing to user-defined functions is not supported.
Appendix D: Creating custom netlist formats

- If, if/else, while, do-while, and for statements are supported.
- All blocks must begin with an opening curly brace ( { ) and end with a closing curly brace ( } ).
- Nesting statements surrounded by curly braces is supported.
- The ASCII character set is supported except that symbol names may not contain double quotes.
- These operations are supported:
  +  -  /  *
  =  ==  !=  %
  >  <  >=  <=
  unary +  unary -
- Bit and logical operations are not supported.
- Arrays and pointers are not supported.
- Quoted strings are supported.
- Quoted strings can contain these escapes:
  \n  new line  \b  backspace
  \t  tab  \f  form feed
  \r  return
- Quoted strings can contain backslashes ( \ ) to indicate the next character is to appear within the string. For example, this represents a double quote ( " ) in a string:

  \"

  This represents a backslash in a string:

  \\n
Functions

IFORM and HF ORM recognize both a subset of C-language functions and OrCAD-defined functions; you can define others. The reference part of this appendix describes both types of functions. For information about defining your own functions or symbols, see a C-language reference manual such as *The C Programming Language* by Brian W. Kernighan and Dennis M. Ritchie.
Standard symbols  IFORM and HFORM recognize a number of pre-defined standard symbols. For a list of the standard symbols, see the section Symbol reference.

User-defined symbols  IFORM and HFORM recognize up to thirty-six user-defined symbols. You refer to each symbol by the name you specify in its definition. Symbol names may be up to thirty-two characters long and may contain any ASCII character except the double quote. User-defined symbols can be set, reset, deleted, and printed.

Two user symbols are already be defined for you. See the discussions for ExitType and LocalSignal for more information about these symbols.
Flat format

This section includes pseudocode of the loop that IFORM executes to perform netlist formatting. Pseudocode is an English-like description of what happens in a program. For information about required functions in .CF files, see the section Required functions.

Following the pseudocode is a "Hello World" example that, like many first examples of computer languages, simply writes the words "Hello World" to a file.

```c
FormatNetlist() /* Pseudocode for creating a flat netlist */
{
    InitializeFormatModule();

    /* either output a header directly for a net based netlist
    * or create the part data base for a part based netlist */
    WriteHeader();

    NetNumber = 0;
    read the TypeCode from the Resolved File

    while not at the end of the Resolved File
    {
        increment NetNumber
        NotConnected = FALSE;

        switch (TypeCode)
        {
            'L' : read the SignalType
                  read the SignalNameString from resolved file
            | 'P' : SignalType = Byte('u');
                  read the SignalNameString from resolved file
            | 'U' : NotConnected = TRUE;
            | 'N' : /* do nothing * /
        }

        HandleNodeName(); /* part- or net-oriented */

        FirstTime = TRUE;
        NetCount = 0;
    }
```

Pseudocode of the format loop IFORM executes (continued).
read the ReferenceString
while ReferenceString is not empty
{
    read PinNumberString from resolved file
    read PinNameString from resolved file
    read PinIndex from resolved file
    read PartName from resolved file
    read ModuleName from resolved file
    read PinType from resolved file

    /* Either output to a file directly for net-oriented netlists
    or add the net to an internal data structure for part-oriented
    netlists */
    WriteNet();
    FirstTime = FALSE;
    read the ReferenceString
}
WriteNetEnding(); /* can be empty if part-oriented */
read the TypeCode from the Resolved File

ProcessFieldStrings();

/* output the trailer for net-oriented netlists or output the netlist
itself for a part-oriented netlist */
WriteNetListEnd();

} /* end of FormatNetlist */

Pseudocode of the format look IFORM executes (continued from previous page).
/* Hello World example for a flat netlist */

Initialize()
{
 /* add a symbol called Formatter */
 AddSymbol( "Formatter" );

 /* set formatter to a value */
 SetSymbol( Formatter, "Hello World" );
}

WriteHeader()
{
 /* now output the symbol to the first file */
 WriteSymbol( 1, Formatter );

 /* write a newline to the first file */
 WriteCrLf( 1 );
}

/* the following required functions are not used but are still required in the file, so leave them empty */
WriteNet()
{
}

HandleNodeName()
{
}

WriteNetEnding()
{
}

ProcessFieldStrings()
{
}

WriteNetListEnd()
{
}

"Hello World" example for a flat netlist.
Hierarchical format

This section includes pseudocode of the loop that HFORM executes to perform netlist formatting. For information about required functions in .CH files, see the section Required functions.

Following the pseudocode is a “Hello World” example.

FormatNetList() /* Pseudocode for creating a hierarchical netlist */
{
  InitializeFormatModule();
  InitializeParser();

  /* call the user initialization function */
  Initialize();

  NetNumber := 0;
  depth := 0;

  scan for all parts in the design and build a small version
  of the libraries containing only the parts used in the design

  add all files found in the design to the file stack

  set the worksheet number to zero
  WHILE not empty file stack
  {
    increment the worksheet number

    open the top file on the stack
    pop the file stack

    PreFile;

    parse the current .inf file
    PostFile();
  }

  /* initialize the pipe file and call the user post processing function,
  finally, cleanup and leave */
  InitializePipeFile();
  PostProcess();
  CleanupFormatModule;

  exit with the indicated code
}
/* end of FormatNetlist */

Pseudocode of the format loop HFORM executes.
/* Hello World example for a hierarchical netlist */

Initialize()
{
    /* add a symbol called Formatter */
    AddSymbol( "Formatter" );

    /* set formatter to a value */
    SetSymbol( Formatter, "Hello World" );

    /* now output the symbol to the first file */
    WriteSymbol( 1, Formatter );

    /* write a newline to the first file */
    WriteCrLf( 1 );
}

/* the following required functions are not used but are still required */
/* in the file, so leave them empty */

PreFile()
{
}
PostFile()
{
}
PostProcess()
{
}

"Hello World" example for a hierarchical netlist.

**Required functions**

IFORM and HFORM require netlist format files to include the following functions in any order:

<table>
<thead>
<tr>
<th>Required functions for IFORM</th>
<th>Required functions for HFORM</th>
</tr>
</thead>
<tbody>
<tr>
<td>HandleNodeName();</td>
<td>Initialize();</td>
</tr>
<tr>
<td>Initialize();</td>
<td>PreFile();</td>
</tr>
<tr>
<td>ProcessFieldStrings();</td>
<td>PostFile();</td>
</tr>
<tr>
<td>WriteHeader();</td>
<td>PostProcess();</td>
</tr>
<tr>
<td>WriteNet();</td>
<td></td>
</tr>
<tr>
<td>WriteNetEnding();</td>
<td></td>
</tr>
<tr>
<td>WriteNetListEnd();</td>
<td></td>
</tr>
</tbody>
</table>
Schematic Design Tools Reference Guide

Data functions

IFORM and HFORM access data from data structures and from instance files. This section describes data structures and instance files.

Data structures

IFORM and HFORM use four data structures to manage data extracted from the intermediate netlist structure and the incremental connectivity database, respectively. The data structures contain net, part, and child data.

IFORM accesses the part, part-oriented, and net-oriented data structures. HFORM accesses the part, child, and net-oriented data structures for each file on the file stack.

The following sections describe four types of data structures: part, child, net-oriented, and part-oriented, and lists the functions you use with each type.

Part data structure

The part data structure contains information about all parts; it contains the symbols ReferenceString, PartName, ModuleName, TimeStamp, PinNameString, PinNumberString, and PinType.

HFORM accesses and traverses the part data structure when you use these functions in .CH files:

FirstPin();
int AccessPart( user_symbol );
int FirstPart();
int NextPart();
int NextPin();
int PinCount();
int SetPartIndex( integer_constant );
int SetPartIndex( variable );
int SetSignal();

IFORM, however, accesses part data information from part-oriented data structures as described on the next page.
Appendix D: Creating custom netlist formats

Child data structure

The child data structure, accessed only by HFORM, contains information about the children for the current worksheet in a hierarchical design. The child data structure is comprised of children and the sheet nets on each child; each child and sheet net is represented by standard symbols. The standard symbols are PinNameString, PinNumberString, PinType, ModuleName, PartName, ReferenceString, and TimeStamp.

The functions that access child data structures are:

FirstChildPin();
int AccessChild( user_symbol );
int ChildPinCount();
int FirstChild();
int NextChild();
int NextChildPin();

Net-oriented data structure

Net-oriented databases contain all the net information in flat designs and all the net information for the current worksheet in hierarchical designs. The data is arranged by nets, with information about nodes and parts subordinate to the net information. Both IFORM and HFORM can access the net-oriented database.

HFORM can also access data in a net-oriented data structure from a part perspective.

The net-oriented data structure is the default data structure. Until you load another data structure, a net from the net-oriented data structure is current. Net-oriented data structures are comprised of nets and nodes comprised of standard symbols.

IFORM and HFORM access net-oriented data structures differently. IFORM scrolls through data structure automatically and you have no control over what is current unless you traverse the part-oriented data structure and use the function SetSignal() to synchronize the two data structures.

HFORM, however, accesses information from net data structures in a variety of ways depending on which functions you use to traverse the data structure. When you use such a function to change the current net, the first node on that net also becomes current.
The functions for net-oriented data structures you use in .CH format files for HFORM are:

FirstNet();
FirstNode();
int NextNet();
int NextNode();
int PreviousNode();

Part-oriented data structures contain net information about flat designs organized so IFORM can access data from a part perspective.

You can include functions that direct IFORM to create and use a part-oriented data structure. When creating a part-oriented data structure, include these functions in the format file:

- Include the function RecordNode() in the WriteNet() function.
- Include the function AddSignalName() in the HandleNodeName() function.
- Include the function CreatePartDatabase() in the WriteHeader() function.

These functions access part-oriented data structures:

int EndNode();
int GetIndex( part_symbol );
SetFirst( part_symbol );
int SetIndexByRef( user_symbol );
int SetNext( part_symbol );
int SetPrevious( part_symbol );
int SetToIndex( part_symbol, variable );

With one exception, you can use all other functions with part-oriented netlists: using SortByNumber scrambles the data, making the part-oriented data structure invalid.

Instance files The instance file (*.INS), part of the intermediate netlist structure, contains a list of all parts and instances in a design. Each instance file is comprised of instances that, in turn, are comprised of standard symbols. At any given time, one instance is current.
Appendix D: Creating custom netlist formats

IFORM accesses the instance file automatically; HFORM can create an instance file and access it if you use the function MakeInstanceFile(). Once HFORM creates an instance file, it can use all the instance file functions.

These functions access instance files:

- `LoadFieldString(string_symbol);`
- `int LoadFirstPin();`
- `int LoadInstance();`
- `int LoadPin();`
- `MakeInstanceFile();`
- `int NextAccessType();`
- `int NextInstance();`
- `RewindInstanceFile();`
- `SetAccessType(string_symbol);`
- `SortByNumber();`

**Traversal functions**

Traversal functions allow you to control how HFORM traverses a design. HFORM recognizes two variations of a traversal function: `SetTraversal(string_constant)` and `SetTraversal(user_symbol)`.

**Pipe file functions**

IFORM can access the pipe file (*.PIP) of the intermediate netlist structure for pipe information, and HFORM can access the incremental connectivity database for pipe information.

When using HFORM, the .PIP file can only be accessed during the `PostProcess()` function.

The pipe file functions are:

- `int AccessKeyWord(string_constant);`
- `int AccessKeyWord(standard_symbol);`
- `int AccessKeyWord(user_symbol);`
- `int FirstPipe();`
- `int IsKeyWord();`
- `int NextKeyWord();`
- `int NextPipe();`

For more about these functions, see the section *Function reference*. See also the function `PostProcess()`.
General functions are OrCAD-defined functions. Some access data structures and some do not. The general functions are:

```c
AddSymbol( string_constant );
ClearSymbolicStrings();
int CompareSymbol( symbol, symbol );
ConcatFile( file_index, file_index );
CopySymbol( symbol, user_symbol );
ExceptionsFor( string_constant, user_symbol );
int FindSymbolChar( variable, user_symbol );
int GetStandardSymbol( standard_symbol );
int GetSymbolChar( variable, user_symbol );
MakeLocalSignal( string_constant );
int PackString( integer_constant, integer_constant, user_symbol, user_symbol );
int PackString( variable, variable, user_symbol, user_symbol );
PadSpaces( user_symbol, integer_constant );
PadSpaces( user_symbol, variable );
PutSymbolChar( variable, integer_constant, user_symbol );
PutSymbolChar( variable, variable, user_symbol );
SetAccessType( user_symbol );
SetCharSet( string_constant );
SetNumberWidth( integer_constant );
SetNumberWidth( variable );
SetPinMap( integer_constant, string_constant );
SetPinMap( variable, string_constant );
SetSymbol( user_symbol, string_constant );
int SwitchIsSet( string_constant );
int SymbolIn CharSet( user_symbol );
int SymbolLength( symbol );
ToUpper( user_symbol );
WriteCrLf( file_index );
WriteMap( file_index, integer_constant );
WriteMap( file_index, variable );
WriteString( file_index, string_constant );
WriteSymbol( file_index, user_symbol );
WriteStdSymbol( file_index, standard_symbol );
```

For more about these functions and symbols, see the reference portion of this appendix.
You can use these C-language functions in netlist format files:

```c
int getche();
int getnum();
int print( variable );
int print( string_constant );
int putch( variable )
int puts ( string_constant );
```

You can define switches, called “options” in the ESP design environment, that provide options for creating custom netlists. Then when you configure IFORM and HFORM, you select a file format and select options for that format. The first comment in the .CF or .CH file names switches and defines descriptions that display on the configuration screen. Then you use SwitchIsSet() to find out if IFORM or HFORM was called with the switch set.

The switch names can be uppercase or lowercase. However, IFORM and HFORM convert all lowercase switch names to uppercase.

\[ \text{△ NOTE: Do not use these switches that IFORM or HFORM already use: /B, /Q, and /Z.} \]
Symbols are names associated with an array of characters that is accessed via the symbol name. Functions use symbolic information as the main method for accessing data. Standard symbols may be accessed and printed but may not be changed.

This section lists standard symbols of four classifications:

- **Symbols for HFORM** that you use only for hierarchical format files.
- **Title block symbols** that contain information from worksheet title blocks.
- **User symbols** that act as standard symbols.
- **Standard symbols** that contain information about parts, pins, nets, and children, text from the pipe file, and indexes.

<table>
<thead>
<tr>
<th>AddressLine1-AddressLine4</th>
<th>title block symbol</th>
<th>String. The address lines from the worksheet.</th>
</tr>
</thead>
<tbody>
<tr>
<td>DateString</td>
<td>title block symbol</td>
<td>String. The date string from the worksheet.</td>
</tr>
<tr>
<td>DocumentNumber</td>
<td>title block symbol</td>
<td>String. The document number from the worksheet.</td>
</tr>
<tr>
<td>ExitType</td>
<td>user symbol</td>
<td>String. This is a reserved symbol in the user symbol space since this symbol may be set. The symbol is read after the formatting loop is complete.</td>
</tr>
</tbody>
</table>

- If the symbol contains “W,” then there were warnings found during the format process.
- If the symbol contains “E,” then errors were found during the format process.
Appendix D: Creating custom netlist formats

IFORM and HFORM each have the Ignore warnings option on the Local Configuration screen. This table shows the results of combinations of ExitType values and option settings:

<table>
<thead>
<tr>
<th>ExitType contains</th>
<th>Ignore warnings option</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>W</td>
<td>ON</td>
<td>Exits</td>
</tr>
<tr>
<td>W</td>
<td>OFF</td>
<td>Exits reporting a warning</td>
</tr>
<tr>
<td>E</td>
<td>ON or OFF</td>
<td>Exits reporting an error</td>
</tr>
<tr>
<td>nothing</td>
<td>ON or OFF</td>
<td>Exits</td>
</tr>
</tbody>
</table>

Results of combinations of ExitType and Ignore warnings options.

You use this symbol when you define error or warning messages for a format file. You do not need to use the AddSymbol() function for ExitType; it is already defined.

The function ClearSymbolicStrings() does not clear ExitType.

FieldString1—FieldString8 standard symbol String. Field strings for an instance of a part. A LoadInstance() call must precede use of this symbol.

FileName standard symbol String. The file that is being processed.

KeyWord standard symbol String. Contains the current keyword from the pipe file.

LastFile symbol for HFORM String. Returns 1 if the current file is the last file in the file stack, otherwise returns 0.
### Schematic Design Tools Reference Guide

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LibraryNameString</td>
<td>standard symbol</td>
<td>String. Contains the library name for the current part.</td>
</tr>
<tr>
<td>LocalSignal</td>
<td>user symbol</td>
<td>A user symbol containing a local signal name constructed from a specified string_constant and the standard symbols SignalNameString and SheetNumber. The function that creates this user symbol is MakeLocalSignal(). You do not need to use AddSymbol() to define this symbol.</td>
</tr>
<tr>
<td>LookupNameString</td>
<td>standard symbol</td>
<td>String. Contains the name used to look up the current part in the part library indicated by LibraryNameString.</td>
</tr>
<tr>
<td>ModuleName</td>
<td>standard symbol</td>
<td>String. This is the module name obtained from the module value field.</td>
</tr>
<tr>
<td>NetCode</td>
<td>symbol for HFORM</td>
<td>Character. Contains the current net node type. It may be one of: L Label node—a node labeled on a worksheet, P Port node—a node connected to a module port on a worksheet, S Power node—a node connected to power or ground, N Node—an unlabeled node connected to something other than a module port, power, or ground, U Unconnected node—a node unconnected to anything on a worksheet.</td>
</tr>
</tbody>
</table>

This is only loaded when a net is made current in HFORM. It is the NetType obtained from scanning the nodes on the net as though a “link” had been run for the net.
Appendix D: Creating custom netlist formats

<table>
<thead>
<tr>
<th>Variable</th>
<th>Symbol for</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NetNameString</td>
<td>symbol for HFORM</td>
<td>String. The name of the current net. Since a net for HFORM is composed of all the nodes, including multiple ports or labels if present, the NetNameString is built as it would have been if the net had been &quot;linked&quot;. This is a unique name and is loaded if the NetType is &quot;L,&quot; &quot;P,&quot; or &quot;S.&quot;</td>
</tr>
<tr>
<td>NetNumber</td>
<td>standard symbol</td>
<td>Unsigned integer. The current net number. IFORM and HFORM assign unique net numbers to all nodes in a net.</td>
</tr>
<tr>
<td>NetType</td>
<td>symbol for HFORM</td>
<td>Character. Contains the signal type. This may be one of:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0  Unspecified</td>
</tr>
<tr>
<td></td>

</tr>
<tr>
<td></td>
<td></td>
<td>3  Bidirectional</td>
</tr>
<tr>
<td></td>
<td></td>
<td>255  Not Used (0FFH)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>HFORM loads NetType only when a net is made current.</td>
</tr>
<tr>
<td>Organization</td>
<td>title block symbol</td>
<td>String. The organization name string from the worksheet.</td>
</tr>
<tr>
<td>PartIndex</td>
<td>standard symbol</td>
<td>Unsigned integer. The index corresponds to the parts-per-package number of the current part. This value represents the annotated suffix, with 0 = &quot;A&quot;, 1 = &quot;B&quot;, and so on. The value is loaded when a signal is made current. For a part-oriented netlist, PartIndex is loaded with the index into the part list when a part is made current. Since parts are assumed to have unique references, the PartIndex is unique for each part in the package.</td>
</tr>
</tbody>
</table>
PartName  standard symbol  String. This is the part name obtained from the part value field.

PinIndex  standard symbol  Unsigned integer. If PinNameString is "OUT" or "FBK", then the index is set to 0xFFFFH to accommodate Altera's ADF netlist format. Otherwise, the integer is encoded with the most significant four bits containing which device in the package this pin belongs to and the lower twelve bits containing the pin definition offset. The value of interest is 0xFFFFH or not 0xFFFFH.

PinNameString  standard symbol  String. Contains the pin name string for the current instance of a node.

PinNumberString  standard symbol  String. Contains the string representation of the pin number for the current instance of a node.

PinType  standard symbol  Character. Contains one of these types for pins, ports and signals, or sheets:

Pin
0  Input
1  BiDirectional
2  Output
3  Open Collector
4  Passive
5  Hi-Z
6  Open Emitter
7  Power

Port & signal
0  Unspecified
1  Output
2  Input
3  BiDirectional
### Appendix D: Creating custom netlist formats

</tbody>
</table>

**PipeLine** standard symbol
String. This contains the current line in the pipe file.

**ReferenceString** standard symbol
String. Contains the reference designator for either the instance of a part or of a node.

**Revision** title block symbol
String. The revision number from the worksheet.

**SheetNumber** title block symbol
Unsigned integer. Contains the current worksheet number. In IFORM, if the current TypeCode is “L”, SheetNumber reflects the number of the sheet containing the signal. If TypeCode is any other value, SheetNumber may not be accurate because it is updated only if the current signal net has a label.

In HFORM, SheetNumber is always correct.

**SheetSize** title block symbol
Character. Contains the size of the worksheet.

**SignalNameString** standard symbol
String. May contain a signal name. If TypeCode is “L”, “P”, or “S”, then SignalNameString contains the signal name. The SignalNameString is empty otherwise.
<table>
<thead>
<tr>
<th><strong>SignalType</strong></th>

</tr>
<tr>
<td></td>
<td></td>
<td>&quot;LIBRARY&quot;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;LOOKUP&quot;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;REFERENCE&quot;</td>
</tr>
</tbody>
</table>

See SetAccessType() in the section Function reference.
### File Index

**Type**: For General Functions

An integer constant that indicates to which output file IFORM or HFORM writes. Index 0 is reserved for output to the screen while index 1 and index 2 refer to the files specified on the Local Configuration screen. Index 3 refers to a scratch file that is deleted after IFORM or HFORM are finished. The default is 0. A file index may also be a variable.

### Format Constant

**Type**: Definition

One of these three values:

- **ADF**: A standard known as both the Altera Design Format and Intel's Advanced Design File.
- **MOD**: OrCAD's Programmable Logic Device Modeling Tools.
- **EDIF**: Electronic Design Interchange Format

See ExceptionsForO in the section Function reference.

### Integer Constant

**Type**: Definition

A whole number in the range -32,678 to 32,767.

### Part Symbol

**Type**: Definition

A subset of user_symbol for use with functions for part-oriented netlists. The following tables are the source of all the standard symbols when writing format files for creating part-oriented netlists.

**Signals**
The table of all signal names and types. The net contains one signal name and type for each connected node.
Schematic Design Tools Reference Guide

PARTS The table of all parts found in the instance file. Each part entry is comprised of the standard symbols ReferenceString, PartName, and ModuleName. A one-to-one correspondence exists between entries in the PARTS and NETS tables.

NETS The table of all nets. The table entry points to all the pins, or nodes, on a part that are electrically connected to another node.

NODES The list of all nodes on a given net. Each pin on a part may occur in a net. The electrical node is identified by the SIGNAL name.

ALL The list of all signals, parts, nets, and nodes.

This symbol is one of the thirty-six you can define. However, to access a part-oriented database, part_symbol must contain one of the five table names listed above.

standard_symbol type definition for general functions One of the standard symbols listed in the section Symbol reference.

string_constant type definition for general functions A string enclosed in quotation marks.

symbol type definition for general functions Either a standard_symbol or a user_symbol.
Appendix D: Creating custom netlist formats

traversal_constant  
| type  | A subset of string_constant, this must be either "ROOT" or "LEAF". See SetTraversal() in the section Function reference.  
| definition  |  

user_symbol  
| type  | A user-defined symbol.  
| definition  |  

variable  
| type  | An integer defined with an int statement in the range -32,768 to 32,767.  
| definition  |  

Function reference  
This portion of the appendix lists all the standard functions that IFORM and HFORM recognize in format files. The functions appear in alphabetical order, disregarding any int prefixes. The descriptions include a function classification and definition.

int AccessChild( user_symbol );  
child data function  
Uses the input user_symbol containing a valid PartName to access the child that matches the name. The function returns 1 on success or 0 otherwise.

int AccessKeyWord( string_constant );  
pipe file functions  
Uses the input string_constant or symbol containing a pipe symbol keyword to make the next line in the file containing that keyword current. KeyWord and PipeLine are both loaded. The function returns 1 on success or 0 otherwise. If the function returns 0, then no action has been taken—the position in the file is the same as before the call and KeyWord and PipeLine are the same as before the call.
int AccessPart (user_symbol);

( part data structure function )

Makes the part that matches the input user symbol—assumed to contain a valid ReferenceString—current. The function loads the associated standard symbols and returns 1 on success or 0 if the input reference was not found. Use this function only when creating format files for hierarchical netlists.

AddSignalName();

( part-oriented netlist function )

Adds the current SignalNameString and SignalType to the signal table. If the SignalNameString is empty, the NetNumber is used instead. This function is required in formats for part-oriented netlists and should be used within the HandleNodeName() required function.

AddSymbol (string_constant);

( general function )

Adds the symbol name indicated by string_constant to the list of available symbols. You must use this function to create new user symbols before you use the symbols.

int ChildPinCount();

( child data structure function )

Returns the total number of sheet pins on the current child.

ClearSymbolicStrings();

( general function )

Clears the list of available user symbols. All user symbols and their contents are erased. See also AddSymbol() in the section Function reference.

int CompareSymbol (symbol, symbol);

( general function )

Returns 0 if the values represented by the two input symbols are the same and 1 if they either are not the same or are not both strings or both numbers.

ConcatFile (file_index_1, file_index_2);

( general function )

Places the contents of the file specified by file_index_2 at the end of the file specified by file_index_1. The type definitions file_index_1 and file_index_2 must be either 1, 2, or 3. See file_index.
Appendix D: Creating custom netlist formats

<table>
<thead>
<tr>
<th>Function</th>
<th>Category</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CopySymbol</td>
<td>General function</td>
<td>Copies the contents of the symbolic string indicated by symbol into the indicated user_symbol.</td>
</tr>
<tr>
<td>CreatePart Database()</td>
<td>Part-oriented  netlist function</td>
<td>Uses the instance file to create a part-oriented database IFORM can use. You call this function within the required function WriteHeader().</td>
</tr>
<tr>
<td>int EndNode();</td>
<td>Part-oriented netlist function</td>
<td>Returns 1 if the current node in the NETS table is EndNode and 0 otherwise. For information about the NETS table, see part_symbol in the section Type definition reference.</td>
</tr>
<tr>
<td>ExceptionsFor</td>
<td>General function</td>
<td>Modifies user_symbol according to the format specified in format_constant. IFORM sets user_symbol to the appropriate characters for three different standards: ADF, MOD, and EDIF. For example, to have IFORM parse symbols and convert them to symbols that meet EDIF standards, write this: ExceptionsFor(&quot;EDIF&quot;, TempStr )</td>
</tr>
<tr>
<td>int FindSymbolChar</td>
<td>General function</td>
<td>Finds the indicated variable in the string represented by user_symbol. The index into the string of the first occurrence of the character is returned if the character was found, otherwise 0FFFFH (65535) is returned. For these and other functions that access specified locations in a string, the first character in the string is at location zero.</td>
</tr>
</tbody>
</table>
### Schematic Design Tools Reference Guide

#### int FirstChild();

**child data structure function**

Makes the first child in a child data structure current. The first sheet net, `ReferenceString`, `TimeStamp`, `PartName`, `PinNameString`, and `PinType` are also made current. The function returns 1 on success or 0 if the first child is empty. An empty first child means that the incremental netlist file is a leaf node containing no children.

#### FirstChildPin();

**child data structure function**

Makes the first sheet net current and loads the associated standard symbols.

#### FirstNet();

**net-oriented data structure function**

Makes the first net the current net. The first node on the net is made current and the associated standard symbols are loaded. Use this function only when creating format files for hierarchical netlists.

#### FirstNode();

**net-oriented data structure function**

Makes the first node on the current net current and loads the associated standard symbols. Use this function only when creating format files for hierarchical netlists.

#### int FirstPart();

**part data structure function**

Makes the first part current and loads the associated standard symbols. The first pin of the part also becomes current. The function returns 1 on success or 0 if there are no parts in this incremental netlist file. A file containing no parts occurs when the schematic is composed only of children or when the schematic is empty. In both cases, `FirstPart()` and `FirstChild()` return 0. Use this function only when creating format files for hierarchical netlists.

#### FirstPin();

**part data structure function**

Makes the first pin of the current part current. The associated standard symbols are loaded. Use this function only when creating format files for hierarchical netlists.
### Appendix D: Creating custom netlist formats

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>int FirstPipe();</code></td>
<td>Sets the seek pointer to either zero or the start of the pipe file. This function returns 1 on success or 0 otherwise. On success, the <code>KeyWord</code> and <code>PipeLine</code> are loaded.</td>
</tr>
<tr>
<td><code>int getche();</code></td>
<td>Returns a character from the keyboard.</td>
</tr>
<tr>
<td><code>int GetIndex(part_symbol);</code></td>
<td>Returns the current index for the table indicated by <code>part_symbol</code>. For example: <code>GetIndex(SIGNALS);</code> For a discussion of the tables, see the type definition <code>part_symbol</code>.</td>
</tr>
<tr>
<td><code>int getnum();</code></td>
<td>Returns an integer that is input from the keyboard. This function does not check the input to make sure it is valid.</td>
</tr>
<tr>
<td><code>int GetStandardSymbol(standard_symbol);</code></td>
<td>Returns the value associated with <code>standard_symbol</code>. If <code>standard_symbol</code> is a string, then 0 is returned. Otherwise the integer or the char value cast as an integer is returned.</td>
</tr>
<tr>
<td><code>int GetSymbolChar(variable, user_symbol);</code></td>
<td>Returns the character at the location <code>variable</code> in the string associated with <code>user_symbol</code>. For example, if <code>user_symbol</code> is <code>Part</code> and contains <code>PLD22V10</code>, this function returns <code>v</code>: <code>GetSymbolChar(5, Part);</code> For this and other functions that access specified locations in a string, the first character in the string is at location zero.</td>
</tr>
</tbody>
</table>
HandleNodeName ()

required function for IFORM

Allows access to several symbols, depending on which type of net it encounters. When IFORM reads the *.RES file and encounters a net, it calls this function. This table lists node types and the symbols HandleNodeName() can access:

<table>
<thead>
<tr>
<th>Net type</th>
<th>Symbols accessed by HandleNodeName()</th>
</tr>
</thead>
<tbody>
<tr>
<td>Label (L)</td>
<td>TypeCode, NetNumber, SignalType, SignalNameString</td>
</tr>
<tr>
<td>Port (P)</td>
<td>TypeCode, NetNumber, SignalType, SignalNameString</td>
</tr>
<tr>
<td>Power (S)</td>
<td>TypeCode, NetNumber, SignalType, SignalNameString</td>
</tr>
<tr>
<td>Node (N)</td>
<td>TypeCode, NetNumber</td>
</tr>
<tr>
<td>Unconnected (U)</td>
<td>TypeCode, NetNumber</td>
</tr>
</tbody>
</table>

Initialize();

required function for IFORM and HFORM

Here you can initialize symbols and variables, define character sets, write headers, and set number widths.

int IsKeyWord();

pipe file function

Returns 1 if the current standard symbol Pipeline contains a keyword and 0 if it does not.

LoadFieldString ( user_symbol );

instance file function

Uses the input user_symbol that represents a part reference and loads associated standard symbols from the instance file. The function returns 1 on success or 0 on end of file.

int LoadFirstPin();

instance file function

Loads the first pin in the current instance. This function must follow a LoadInstance() call. The function loads PinNameString, PinNumberString, and PinType. The function returns 1 on success or 0 otherwise.
int LoadInstance();  

instance file function  

Loads the standard symbols from the current entry in the instance file. This function returns 1 if the values were loaded correctly and 0 on end of file. This function may be called in a conditional statement.

int LoadPin();  

instance file function  

Loads the next pin in the current instance. A LoadInstance() call must precede this function. The function loads PinNameString, PinNumberString, PinType, LibraryNameString, and LookupNameString. The function returns 1 on success or 0 otherwise.

MakeInstanceFile();  

instance file function  

Creates an instance file for HFORM. This function must be called in the Initialize() loop. This function is valid only in *.CH format files.

MakeLocalSignal(string_constant);  

general function  

Uses the current standard symbols to construct a local signal name and places it in the user symbol LocalSignal. LocalSignal is built by concatenating SignalNameString, the input string_constant, and the SheetNumber. The current number width—set with SetNumberWidth()—determines the width of LocalSignal. LocalSignal is one of the thirty-six user symbols.

int NextAccessType();  

instance file function  

Makes the next instance that contains an access field different than the current access field current. The function returns 1 on success or 0 otherwise. When you use this function with SetAccessType(), SetAccessType() should occur first. For a list of the access fields, see access_constant in the section Type definition reference.
int NextChild();  child data structure function  Makes the next child current and loads the associated standard symbols. This function returns 1 on success or 0 at end of list. This function must follow the FirstChild() function.

int NextChildPin();  child data structure function  Makes the next sheet net current. This function returns 1 on success or 0 at end of list. This function must follow the FirstChildPin() function.

int NextInstance();  instance file function  Makes the next instance that contains an access field matching the current access field current. If the current access field is not set, the next instance becomes current. When you use this function with the SetAccessType() function, SetAccessType() should precede NextInstance(). For a list of the access fields, see access_constant in the section Type definition reference.

int NextKeyword();  pipe file function  Accesses the next keyword in the pipe file. This function returns 1 on success or 0 otherwise. If the function returns 0, then no action is taken. If the function returns 1, then Keyword contains the next keyword and Pipeline contains the line in which the keyword appears.

int NextNet();  net-oriented data structure function  Makes the next net current and makes the associated standard symbols current. This function returns 1 on success or 0 at end of list. The FirstNet() function must precede NextNet(). Use this function only when creating format files for hierarchical netlists.
Appendix D: Creating custom netlist formats

```c
int NextNode();
```

*net-oriented data structure function*

Makes the next node current and loads the associated standard symbols. This function returns 1 on success or 0 at end of list. The `FirstNode()` function must precede `NextNode()`. Use this function only when creating format files for hierarchical netlists.

```c
int NextPart();
```

*part data structure function*

Makes the next part current and loads the associated standard symbols. This function returns 1 on success or 0 at end of list. The `FirstPart()` function must precede `NextPart()`. Use this function only when creating format files for hierarchical netlists.

```c
int NextPin();
```

*part data structure function*

Makes the next pin on the current part current and loads the associated standard symbols. This function returns 1 on success or 0 on end of list. The `FirstPin()` function must precede `NextPin()`. Use this function only when creating format files for hierarchical netlists.

```c
int NextPipe();
```

*pipe file function*

Makes the next pipe line current and loads `PipeLine` and `KeyWord`. This function returns 1 on success or 0 otherwise. The `FirstPipe()` function must precede `NextPipe()`.
<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
</table>
| `int PackString(integer_constant, integer_constant, user_symbol, user_symbol)` | Deletes a substring of the first `user_symbol`, starting with the character in the space specified by the first `integer_constant` and ending with the second `integer_constant`. Then it places the deleted substring into the second `user_symbol`. This function returns 1 on success or 0 otherwise. For example:  
\[
\text{PackString(6, 4, SigNameStr, Str)};
\]
| `int PackString(variable, variable, user_symbol, user_symbol)` | The second variation of the function behaves the same except the spaces are defined by variables. For example:  
\[
\text{PackString(pos, len, SigNameStr, Str)};
\]
| `PadSpaces(user_symbol, integer_constant)` | Sets the length of `user_symbol` to the length specified by `integer_constant` or `variable`. The function either pads the string with spaces or truncates it.  
\[
\text{PadSpaces(user_symbol, variable)};
\]
| `int PinCount();` | Returns the number of pins on the current part. Use this function only when creating format files for hierarchical netlists.  
\[
\text{PinCount();}
\]
| `PostFile();` | HFORM calls this function after parsing the current worksheet. All the data structures are loaded and available for use.  
\[
\text{PostFile();}
\]
| `PostProcess();` | HFORM calls this function after reading all the worksheets in the design. The pipe file functions are valid during this function call. Pipes are considered a post processing function.  
\[
\text{PostProcess();}
\]
PreFile(); \hspace{1cm} \textit{required function for HFORM}

HFORM calls this function before processing the next worksheet in the design. HFORM has not parsed the worksheet yet, but the filename and worksheet number are set. The function is called once for every file in the design.

```c
\begin{align*}
\text{int } & \text{PreviousNode(); } \hspace{1cm} \text{net-oriented data structure function} \\
\text{int print } & \hspace{1cm} \text{C-language functions} \\
( \text{string_constant } ) ; \\
( \text{standard_symbol } ) ; \\
( \text{user_symbol } ) ; \\
\text{int print( variable ); } \\
\text{ProcessFieldStrings } & \hspace{1cm} \text{required function for IFORM} \\
\end{align*}
```

Makes the previous node current and loads the associated standard symbols. This function returns 1 on success or 0 on start of list. Used with NextNode(), this function allows bi-directional movement through net-oriented data structures. Use this function only when creating format files for hierarchical netlists.

```c
\begin{align*}
\text{int putch( variable ) } & \hspace{1cm} \text{C-language function} \\
\text{int puts } & \hspace{1cm} \text{C-language functions} \\
( \text{string_constant } ) ; \\
( \text{user_symbol } ) ; \\
( \text{standard_symbol } ) \\
\end{align*}
```

Writes the contents of \textit{string_constant}, \textit{standard_symbol}, \textit{user_symbol}, or \textit{variable} to the screen. The function returns 0.

IFORM calls this function.

Writes \textit{variable} to the screen. This function returns the value of \textit{variable}.

Prints a string or symbol and a newline to the screen. As listed at the beginning of this appendix, arrays are not supported, so the argument is either \textit{string_constant}, \textit{user_symbol}, or \textit{standard_symbol}. This function returns 0.
PutSymbolChar
( variable,
  integer_constant,
  user_symbol );

Inserts the character in integer_constant into the string specified by user_symbol at the location specified by variable.

The second form inserts the binary value contained in the second variable into the string specified by user_symbol at the location specified by the first variable.

For these and other functions that access specified locations in a string, the first character in the string is at location zero.

PutSymbolChar
( variable,
  variable,
  variable,
  user_symbol );

RecordNode();

Adds the current net node to the node table. If PinNumberString is not a number, this function sets the pin number in the table to zero. On access, PinNumberString is set to PinNameString. The function is only valid within the WriteNet() required function.

RewindInstanceFile
();

Makes the first instance in the instance file current and loads the associated standard symbols. A MakeInstanceFile() call must occur before this function is called.

SetAccessType
( access_constant );

Sets the access type to the value specified by access_constant or user_symbol, where the value of user_symbol must evaluate to one of four access fields.

You use this function with the function int NextAccessType(). This table shows the symbols accessed for each value:

<table>
<thead>
<tr>
<th>Value of access_constant or user_symbol</th>
<th>Symbol accessed</th>
</tr>
</thead>
<tbody>
<tr>
<td>PARTVALUE</td>
<td>PartName</td>
</tr>
<tr>
<td>LIBRARY</td>
<td>LibraryNameString</td>
</tr>
<tr>
<td>LOOKUP</td>
<td>LookupNameString</td>
</tr>
<tr>
<td>REFERENCE</td>
<td>ReferenceString</td>
</tr>
</tbody>
</table>

Symbols accessed.
Appendix D: Creating custom netlist formats

For example:

SetAccessType("LIBRARY");

For information about the symbols listed in the table, see the section Symbol reference.

SetCharSet (string_constant); general function
Sets the valid character set to be the input string. Using SymbolInCharSet(), you can check symbols against the list of valid characters.

SetFirst (part_symbol); part-oriented netlist function
Makes the first entry in the table indicated by part_symbol current. For example:

SetFirst(SIGNALS);

int SetIndexByRef (user_symbol); part-oriented netlist function
Accesses the PARTS table, making the part with the reference specified by user_symbol current. This function returns 1 on success or 0 otherwise.

int SetNext (part_symbol); part-oriented netlist function
Makes the next index in the table indicated by part_symbol current. This function returns 1 on success or 0 otherwise. This function appears in loop constructs. For example:

SetNext(ALL);

SetNumberWidth (integer_constant); general functions
Sets the width of fields containing output number to the value specified by integer_constant or variable. Numbers are padded with zeros on the left up to this width when IFORM or HFORM write them to a file or to the screen. Except for the symbol LocalSignal, this function has no effect on how numbers are stored. Values of zero or one result in no padding. The default value is one. Wider numbers are not truncated.
<table>

### Appendix D: Creating custom netlist formats

**SetToIndex**  
```c
int SetToIndex(part_symbol, variable);
```

Sets the index of the table specified by `part_symbol` to the input `variable`. Returns 1 on success or 0 otherwise. For example:

```
SetToIndex(NETS, 5);
```

**SetTraversal**  
```c
SetTraversal(traversal_constant);
```

Sets the way HFORM traverses a design. A top down traversal is a depth first traversal that starts at the root. A bottom up traversal is a breadth first traversal that starts at the leaf nodes. The input value `traversal_constant` is either "ROOT" or "LEAF", and `user_symbol` should evaluate to either `ROOT` or `LEAF`. For example:

```
SetTraversal("ROOT");
```

**SortByNumber()**  
```c
SortByNumber();
```

Sorts only the instance file by reference number. As a side effect, the seek pointer is set to start of file, so if you have made a pass through the instance file using `Loadlnstance`, a `SortByNumber()` call allows you to make another pass through the file using `Loadlnstance`. Using this function on a part-oriented data structure causes the data structure to become invalid. See `CreatePartDatabase()`.

**SwitchIsSet**  
```c
int SwitchIsSet(string_constant);
```

Checks to see if the switch specified by `string_constant` is set. This function returns 1 if the switch is set or 0 if not. The first character in the input `string_constant` is the only relevant character. The character must be an alphabetic character. Include this function during initialization.

**SymbolInCharSet**  
```c
int SymbolInCharSet(user_symbol);
```

Checks the contents of the string associated with `user_symbol` against the current character set. The function returns 1 if all characters in the symbol are in the character set or 0 otherwise. The function `SetCharSet()` defines the character set.
int SymbolLength
  ( symbol );

    Returns the length of the string represented by symbol.

ToUpper
  ( user_symbol );

    Changes any lowercase alphabetic characters in user_symbol to uppercase.

WriteCrLf
  ( file_index );

    Writes a newline to the file specified by file_index.

WriteHeader();

    IFORM calls this function. It can do two things, depending on the functions you include: output a header or build a part database using the function CreatePartDatabase().

WriteMap
  ( file_index, integer_constant );

    Writes the pin map string at integer_constant or variable to the file given by file_index. See also the SetPinMap() functions.

WriteMap
  ( file_index, variable );

WriteNet();

    IFORM calls this function, setting PinIndex, ReferenceString, PinNumberString, PartName, ModuleName, and PinType. Then, depending on the functions you include, this function should either write the current net for net-oriented netlists or add the net to a part-oriented netlist by calling the function RecordNet().

WriteNetEnding();

    IFORM calls this function when it reaches the end of a net. Then this function outputs whatever you specified to terminate nets.
<table>
<thead>
<tr>
<th>Function</th>
<th>Category</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>WriteNetListEnd()</td>

<td>general</td>
<td>Writes <code>user_symbol</code> to the file specified by <code>file_index</code>.</td>
</tr>
</tbody>
</table>
### Error and warning messages

When you run IFORM or HFORM with a netlist format that contains one or more errors, the process stops at the first error and an error message and line number display. When you run IFORM and HFORM under ESP, the file #ESP_OUT.TXT contains the error messages.

For information about warnings, errors, and the Ignore warnings option, see the entry ExitType in the reference portion of this appendix.

The errors messages include:

- **Cannot SortByNumber after CreatePartDatabase.** Calling the function SortByNumber() scrambles the data in the part-oriented data structure.

- **Closing comment, no opening comment.** A closing comment (/\*) was found but no opening comment (/\*) was found.

- **Closing quote expected.** A string constant was found but not correctly terminated.

- **Equal sign expected.** An assignment was attempted without the equal sign (\=\).

- **Function expected.** A function definition or call was expected.

- **Index out of range.** The index is out of range. Either a file index or a pin map index is not valid.

- **Nested comments.** Two opening comments (/\*) were found before a closing comment (/\*) was found.

- **No expression present.** An expression was expected but none was found.

- **Not a string.** The value required should be a string constant.

- **Not a variable.** An attempt to set or read a value that is not a variable.

- **Opening comment, no closing comment.** An opening comment (/\*) and end of file were found before a closing comment (/\*) was encountered.
Parameter error. A general error for internal functions when a parameter type did not match.

Parentheses expected. A parentheses—either "(" or ")"—was expected but not found.

RETURN without call. A return statement was found before a function call was made.

Semicolon expected. The start of another statement was found before a terminating semicolon (;) was found.

Symbol not found. The intended symbol was not found in either the standard symbol table or the user symbol table.

Symbol table overflow. An attempt to add too many user defined symbols. Use fewer symbols.

Syntax error. General syntax error.

Too many local variables. The local variable table has overflowed. Try using fewer variables or try to make some of them global.

Too many nested function calls. The internal function call stack was exceeded. Reduce the call nesting depth.

Type specifier expected. A variable declaration needs to have a type (int or char) supplied.

Unbalanced braces. Found a statement requiring a matched set of curly braces ({ and }) before encountering a closing curly brace (}) such as in a function definition.

Unbalanced parentheses. An end of a statement was found before the final closing parentheses (""") was found.

While expected. Do-while statement ended the block, but a while was not found.
This appendix contains additional information you may need to setup, configure, and use your plotter with Schematic Design Tools. The sections in this appendix discuss:

- Plotter cable wiring
- Plotter problems
- Plotter hints
- Plotting to a printer
- HP plotters
- HI plotters
- Calcomp plotters
- Plotter driver considerations
- Postscript plotter drivers
The Plot Schematic tool uses DOS BIOS calls to communicate with the serial port. It does not talk to the hardware directly. This is to ensure compatibility with all PC's and compatibles.

For this reason, additional wires other than TXD and RXD must be connected to implement hardware handshake.

Figure D-1 is a wiring diagram showing the connections necessary to connect a 25-pin connector to a plotter. Figure D-2 is a wiring diagram showing the connections necessary to connect a 9-pin connector to a plotter. Figure D-3 is a wiring diagram showing the connections necessary for a 25-pin connector to an IOline plotter.

Since this cable connects the TXD and RXD lines, it also works with software that communicates to the hardware directly.

Figure D-1. 25-pin cable wiring diagram.
Appendix E: Plotter information

Figure D-2. 9-pin cable wiring diagram.

Figure D-3. 25-pin cable to I0line plotter.
Most plotter problems are caused by incorrectly wired plotter cables. If you have difficulty with your plotter, check the following items before proceeding or calling OrCAD:

1. Wire the cable as shown in Figures D-1, D-2, and D-3. If your plotter works with another software package, and does not work with OrCAD, the first item to check is the wiring of your cable. Chances are the other CAD packages only require the TXD and RXD signal lines. OrCAD requires additional connections.

   The cable must be wired as recommended.

2. Check for an open in the cable by performing a continuity check.

3. Read your plotter manual to be sure you understand how the plotter operates. Know how it is programmed for baud rate, parity, word length, and find out what these settings are.

4. Ensure that the plotter baud rate, parity, and word length settings correspond to the plotter configuration information.

5. Select the View Reference Material button on the Schematic Design Tools screen to see other reference material about plotting.

6. Use DOS to send a plot file to the plotter. This is useful for isolating whether the problem is in the serial port hardware or the plotter hardware. To do this, first send the worksheet to a plot file as outlined below:

   Use the Plot Schematic tool to plot to a file.
Then, use the DOS MODE command to configure the serial channel as follows:

```
MODE COM1:2400,N,8,1,P
```

This assumes that you are using serial channel 1 (COM1) and have your plotter set for 2400 baud, no parity, 8 data bits, and 1 stop bit. For more information on the MODE command, see your DOS user’s guide for Asynchronous Communications.

After the serial channel has been configured, send the plot file to the plotter using the DOS COPY command as follows:

```
COPY whatfile COM1:
```

Where `whatfile` is the name of the plot file.

If the plotter works, this indicates the problem may be in the plotter cable (incorrectly wired), or the hardware handshaking is incorrectly set (check the Printer/Plotter Output Options section of the Configure Schematic Design Tools screen).

If the plotter does not work, this indicates that there is a hardware problem. Check the following: serial card, incorrect serial channel configuration, plotter hardware, or a cable problem.

7. If you’re using an IOLine plotter, be sure you have PROM version 114 or greater.
When plotting to a printer, make the pen width for buses small enough to make the lines thin. This will make the print neater and more readable. For example, if you have a printer with a resolution of 180 dots per inch (dpi) you would set the pen width to be:

\[
\frac{1}{180} = \frac{0.00277 \text{ inches}}{2}
\]

for the best results. The same value is also used for the part body pen width. This pen width value is used during FILL commands in the vector stream of the part definition.
When making a plot, use the proper pens and paper designed for the plotter. Plotter paper has a "memory" to it. If it hangs on the plotter bed for a period of time, it will stretch. This effects the registration of the plot. Plotter paper is also temperature sensitive. Be sure that the paper is at room temperature before plotting. The longer the drawing takes to plot, the more care must be exercised with the paper.

The configuration of the plotter includes the ability to change the velocity of the pens. When the pen cannot draw at the speed the plotter is capable of moving, reduce the velocity. You will need to consult your plotter manual for the range to set the velocity. The velocity can be set only in whole number values.

When you make a plot with different pens, the plotter has a registration inaccuracy that must be considered. If you wish to have the highest quality plot, always use only one pen.

When you are directed by the program to change paper or pens, always wait until the plotter has finished the present plotting activity. Before sending a plot directly to the plotter, be sure that the plotter is on line, the pen(s) are properly set up, and the paper size is correct. When you have a pen that must be manually changed, the Plot Schematic program will pause and inform you of the objects to be plotted with the new pen.

Make sure that the template Horizontal and Vertical dimensions are correct for your plotter. Some plotters have a larger margin requirement and, therefore, less usable plotting area. Check your plotters user's manual to get the actual plot area dimensions and change the values in the Template Table area of the Configure Schematic Design Tools screen accordingly. You have this problem if the top or right edge of your plot is clipped. In addition, you may use more plot area if your plotter has a usable plot area greater than that set in the Template Table section of the Configure Schematic Design Tools screen. If this is true, change the Template Table.
The HP plotter family has a facility to set the corner points of the plot and automatically scale the plot to be within these points. These points are called P1 and P2. Plot Schematic ignores the preset P1 and P2 values and draws in 0.001 inch resolution.

Plot Schematic assumes the origin of the plot is the lower left corner of the page (when the finished plot is viewed). Rotation and paper size must be set before you run a plot.

If the plotter's origin (0,0) is not the lower left corner, it may be moved via the Template Table section of the Configure Schematic Design Tools screen. To move the origin, configure the Plot X Offset and Plot Y Offset (value 32.76 inches to +32.76 inches) in the Template Table. Note that this origin offset can be used on any plotter to adjust where the plot is made on the page.

For large HP plotters (HP 7580, 7585, 7586), the origin is the center of the page and the template offset values must be set. For these HP plotters, the offset values are negative. The offset values are added to the location values and then sent to the plotter.

For example, suppose you set the Plot X Offset to -10 and the Plot Y Offset to -5. If your plot contains the logical point X=1 and Y=2, that point is actually sent to the plotter as X=-9 and Y=-3 (-9 = 1 + -10; -3 = 2 + -5).
HI plotters

The HI 40 Series defaults to 2400 baud, and the 50 Series defaults to 9600. Always check to make sure that the plotter baud rate, and data bit settings correspond to the Printer/Plotter Output Options section of the Configure Schematic Design Tools screen.

Be sure that the plotter is on line before beginning a plot. The HI plotters do not have a means to set the velocity to the power-up default. If you change any of the velocity settings of the pens in the configuration, you will need to change them all. The velocity ranges can be found in the plotter operation manual for your specific plotter.

On HI plotters that print on D and E size paper, you may need to change the horizontal dimension in the Template Table section of the Configure Schematic Design Tools screen. For example, you may need to change the D-size horizontal dimension from 32.2 inches to 32.0 inches.

Calcomp plotters

This section lists supported Calcomp plotters and provides setup information for the Calcomp 1043 plotter. You must have one of the listed controllers (supplied by Calcomp) for the plotter to work. See your Calcomp plotter documentation for configuration information.

OrCAD has followed Calcomp’s recommended procedure for connecting a Calcomp plotter to the IBM PC. Thus, any cabling changes that Calcomp recommends should be followed instead of the cabling information in this manual.
### Tables of supported Calcomp plotters

This section contains two tables listing intelligent and non-intelligent Calcomp plotters supported by Schematic Design Tools. The following characters are used in the tables to provide support information about the plotters:

1. Use CALCOMP1.DRV for Schematic Design Tools.
2. Use CALCOMP2.DRV for Schematic Design Tools.
   - Configuration not supported by Calcomp Company.
   - Plotter and controller configuration supported by Calcomp Company. There is no driver for Schematic Design Tools.
   - The 906 controller and 960 format lack of built-in commands to draw circles, arcs, and dashed lines.
   - The extended 960 format is not supported because of a different command code structure.
   - The remaining unsupported configurations are due to differences in plotter step size. The two CALCOMP drivers use a step size of 2032. Schematic Design Tools does not support this step size.

Table D-5. Switch settings.
Appendix E: Plotter information

**Notes on plotter and printer drivers**

This section contains notes on the following plotter and printer drivers:

- HP.DRV
- HPLASERx.DRV
- DXF.DRV
- Postscript drivers

**HP.DRV**

This driver may report a divide error on D or E-size sheet if you did not set the **Plot X Offset** and **Plot Y Offset** on the Configure Schematic Design Tools screen. This is because the values that the HP plotter uses are plotter units, not inches. A plotter unit is 0.00098 inch. The plotter units must be a 16-bit integer value (-32768 to +32767). Plot Schematic computes all dimensions with much greater range.

The plotter driver is passed word values (0.000 to +65.535) and these are converted into plotter units after adding the offset. For example, the D-size horizontal dimension of 32.2 inches with an offset of 0.000 inches would be converted by the driver to:

\[
\frac{32.200}{0.00098} = 32857 \text{ units}
\]

This value exceeds the integer limit. To be able to plot D and E-size drawings, the full integer range must be used. Therefore, the large paper plotters have the origin (0,0) in the center of the paper. The drawing coordinate system is adjusted by the **Plot X Offset** and **Plot Y Offset** on the Configure Schematic Design Tools screen to move the origin to the correct position. Typically, the offset is \( \frac{1}{2} \) of the paper dimension.

Another consequence of not setting the **Plot X Offset** and **Plot Y Offset** on the Configure Schematic Design Tools screen is that plotters having the origin in the center will draw only on the upper right quadrant of the paper. If your drawing appears this way, set the **Plot X Offset** and **Plot Y Offset** on the Configure Schematic Design Tools screen to move the origin to the lower left corner of the paper.
Some laser printers have a graphics printing limit. The Schematic Design Tools drivers place page breaks after a given number of graphics lines. To change the number of graphics lines between page breaks, change the word value in the driver at the offset specified below. The driver values were chosen to be a 10 inch graphics printing area.

</tbody>
</table>
DXF.DRV  This driver puts a drawing into a format usable by AutoCAD and some desktop publishing programs. Use Plot Schematic to plot to a file with this driver. In AutoCAD, use the dxfin command to read the file written by Plot Schematic. You will have to rename the file to have a .DXF extension. If you want colors (layers), enter the pen number in the Pen entry box in the Color and Pen Plotter Table section of the Configure Schematic Design Tools screen to put the different objects onto different layers.

△  NOTE: Dashed lines will always be layer 0 due to line definition restrictions.
PostScript

To create a PostScript file that can be printed by any PostScript compatible device on either paper or film, use the PSCRIPT.DRV plotter driver. To create ledger-size PostScript images, use the PSCRIPT2.DRV. For more information about PostScript, see the PostScript Language Reference manual and the PostScript Language Tutorial and Cookbook, both published by Addison-Wesley in 1985.

Encapsulated PostScript

To produce Encapsulated PostScript (EPS) files to import into other application programs (such as word processing and page layout programs) as illustrations, use one of these four plotter drivers:

- EPS1.DRV  Letter size, landscape
- EPS2.DRV  Letter size, portrait
- EPS3.DRV  Legal size, landscape
- EPS4.DRV  Legal size, portrait

Files produced by these drivers can be used by any application that accepts EPS V2.0.

Like other “standards,” some applications interpret EPS a little differently than others. Usually the problem can be corrected with a minor adjustment to the plot file. If you have trouble importing EPS into an application, contact technical support at the developer of your application to determine its exact requirements for EPS. For more information about EPS, contact Adobe Systems Incorporated, 1585 Charleston Road, Mountain View, CA 94039.

Other PostScript

To produce a PostScript file for the special PostScript “environment” within the Macintosh version of Microsoft Word, use the PWORD.DRV plotter driver. PWORD files can be placed into Word documents or can be incorporated by reference using Word’s include and Print Merge features. PWORD files start with Word’s special .para. operator.

For more information about Word’s PostScript environment, see Microsoft’s Reference to Microsoft Word manual.
A

analogue ■ Circuitry where both voltage and frequency output vary continuously as a function of the input.

annotation ■ Assigning reference designators to components in a schematic.

ASCII ■ An acronym for American Standard Code for Information Interchange; a seven-bit code used to represent letters of the alphabet, the ten decimal digits, and other instructions used to edit text on a computer, such as Backspace, Carriage Return, Line Feed, etc.

B

bitmap ■ An image made up of dots (bits).

bulletin board system ■ A computer dedicated to maintaining messages and software and making them available over telephone lines. People upload (contribute) and download (gather) messages by calling the bulletin board from their own computers. Abbreviated BBS.

button ■ A pushbutton-like image that you click to initiate an action.

byte ■ A piece of computer data composed of 8 contiguous bits that are grouped together as a single unit.

c

CAE ■ An acronym for computer aided engineering.

c

c

c

c

check box ■ A small square button: □. Check boxes are used in lists of options when more than one option can be active at a time.

child ■ A worksheet containing circuitry referred to by a sheet, sheet part, or sheethpath part. The child may contain module ports that connect signals from this worksheet to signals on the parent. A child can also be a parent, if it contains a child.

complex hierarchy ■ A design in which two or more sheet symbols reference a single worksheet. Compare with simple hierarchy.

configuration ■ The information a program uses to operate. The configuration can be tailored to your needs.

connectivity database ■ The connectivity database consists of the incremental connectivity database (created by INET) and the linked connectivity database (created by ILINK). It describes the connectivity of a design, and is used to transfer a design to Digital Simulation Tools or PC Board Layout Tools. See incremental connectivity database and linked connectivity database.

cursor ■ A square marker inside a text field showing where characters typed on the keyboard will appear: ■ See pointer.
**D**

**default** — A value or setting provided by the software that is assumed to be correct in most cases and is used if no other value is entered.

**design cycle** — The process of conceiving, developing, testing, and producing a circuit.

**digital** — Circuitry where data in the form of digits are produced by binary on and off or positive and negative electronic signals.

**dpi** — An abbreviation for *dots per inch*.

---

**E**

**EDA** — An acronym for *electronic design automation*.

**editor** — A tool used to create or modify a design file.

**EMS** — An acronym for Extended Memory Standard.

**entry box** — A box indicating that something (text or numbers) should be entered using the keyboard:  

---

**F**

**flat design** — A schematic structure in which output lines of one sheet connect laterally to input lines of another sheet through graphical objects called *module ports*. Flat designs are practical for small designs of three or fewer sheets. See *module port*, schematic, hierarchical structure.

---

**H**

**hierarchical design** — A schematic structure in which sheets are interconnected in a tree-like pattern vertically and laterally. At least one sheet, the root sheet, contains symbols representing other sheets, called subsheets.

---

**I**

**incremental connectivity database** — INET produces the *incremental connectivity database*. It consists of an incremental connectivity database file (.INF) for each sheet in the design and an .INX file. The .INF file is a description of connectivity on each sheet. The .INX file lists each sheet referenced in the design. The *incremental connectivity database* is used by ILINK to create an incremental netlist. See connectivity database and incremental netlisting.

**incremental netlisting** — A method of creating a netlist in which only changed worksheets are processed each time Create Netlist or Create Hierarchical Netlist runs.

**initial macro** — A macro that runs automatically when you run Draft or Edit Library. For the initial macro to work, you must configure Schematic Design Tools to load a macro file containing the desired macro definition.
intermediate netlist structure  ILINK produces the incremental netlist structure. This consists of the .INS (instance) file, the .RES (resolved) file, and the .PIP file (contains pipe link commands). These files are used by IFORM to create a netlist in one of over 30 formats.

different configuration in different places in the same design. For example, Netlist is configured differently under the To Layout button and under the To Simulate button.

K

K  A unit of measurement. 1K byte is equal to 1024 bytes. The “K” is taken from the metric system, where it stands for “kilo,” or 1000. 1024 is $2^{10}$ and is close to 1000.

key field  To tell Draft and other tools which fields you want to combine and compare, key fields are used. A key field lists the part fields to combine and compare. Key fields are defined on the Configure Schematic Design Tools screen.

M

MB  An abbreviation for megabyte. See megabyte.

macro  Series of commands you can execute automatically at the touch of a single key or key combination. Macros dramatically reduce the number of keystrokes required to perform complex or repetitive actions.

megabyte  Slightly more than one million bytes; 10 megabytes equals 10 million bytes. A megabyte is equal to $2^{20}$ bytes (1,048,576). “Mega” is taken from the metric system, where it is a prefix meaning one million.

module port  Graphical objects that conduct signals between schematic worksheets. See flat file.

N

net  Just as signals are conducted between schematic worksheets through module ports, they are conducted into and out of sheet symbols through graphical objects called nets.

netlist  An ASCII file that lists the interconnections of a schematic diagram by the names of the signals, modules, and pins connected together on a PCB. The nodes in a circuit. See incremental netlisting.
PCB • An acronym for printed circuit board.

package • A physical component. A package may contain one or more subparts. For example, a 2N3905 transistor, a fuse, and a 74LS00 are packages.

pan • To change the portion of the worksheet being viewed by dragging the pointer from one location on the worksheet to another location. As you drag the pointer, the worksheet pans across the screen.

parent • A worksheet that contains hierarchical references to other worksheets. These references are either sheets, sheet parts, or sheetpath parts, which are, from the viewpoint of the parent worksheet, children.

part • A schematic symbol that represents an object. The object can be either a package or another worksheet. OrCAD schematics can have four kinds of parts: packages, sheets, sheet parts, and sheetpath parts.

part field • A slot for holding text or data to be associated with a part. Each part has two part fields reserved for part value and part reference. It has eight other part fields that can be used to store other useful information. See key fields.

pixel • Any of the little dots of light that make up the picture on a computer or television screen. The name is short for picture element. There more pixels there are in an area—the smaller and closer together they are—the higher the resolution. Sometimes pixels are just called dots.

pointer • An arrow on the screen that moves as you move the mouse: See cursor.

processor • A tool that subjects a design file to a specific process.

programmable logic device • A type of integrated circuit that contains fuses that can be blown, eliminating certain logical operations in the device and leaving others intact, giving the device one of many possible logical architectures or logical configurations.

prompt • A query from a program asking you to enter specific information.

quiet mode • An option on the local configuration screen for many tools. When quiet mode is selected, tracking information does not echo on the screen. Only execution messages and error messages (if any) display. If quiet mode is turned off (not selected), the tool displays intermediate tracking information in the monitor box at the bottom of the screen. For most applications you do not need to turn quiet mode on.
R

radio button A small round button: Ø. Radio buttons are used in lists of mutually exclusive options: only one button can be active at a time.

raster An array of dots.

reporter A tool that creates a report, but does not modify design data.

root directory The main directory on your computer; the directory that the computer boots from.

root sheet The worksheet at the top of a flat or hierarchical design. A design has only one root worksheet. A root worksheet may also be a parent in hierarchical designs.

S

schematic A graphical representation of a circuit using a standard set of electronics symbols. See flat design, hierarchical design, and root sheet.

scroll buttons Buttons used to move a directory in its window so that a different part is visible. The four scroll buttons are:
- Page Up
- Line Up
- Page Down
- Line Down

sheet A schematic symbol referring to a worksheet located in the design area and containing circuitry. The connection points on sheets are called sheet nets. See nets and sheet net.

sheet net The point at which a signal from a parent connects to a module port on a child. Sheets, sheetpath parts, and sheet parts each have sheet nets.

sheet part A library part modified from a sheetpath part to represent a unique instance of a library circuit. Sheet parts refer to worksheets located in the design area as opposed to worksheets located in the library directory. The symbol resembles package symbols, but the pins are called sheet nets.

sheetpath part A part representing a library circuit. The worksheet referenced by the sheetpath part is stored in the library directory. The pins on a sheetpath part are called sheet nets to distinguish them from pins on a package.

simple hierarchy A one-to-one correspondence between sheet symbols and the schematic diagrams they reference. Each sheet symbol represents a unique subsheet. See hierarchical design.

sub-part A gate or some other subdivision of a package. Each sub-part in a package has a unique reference designator comprised of a prefix common to all the parts in the package and a letter unique to each part. For example, an instance of a 74LS00 in a design with a package reference designator of U15 would have reference designators for each of the four sub-parts as U15A, U15B, U15C, and U15D.

syntax The formal structure of a language. Syntax includes the rules for making statements in the language, but excludes the meanings of the statements.
tag - A marked or saved location on a schematic or layout. You can use the JUMP command to go to a tag.

text export - The process of copying text from a schematic worksheet to an ASCII file.

text import - The process of copying text from an ASCII file to a schematic worksheet.

TTL - An acronym for transistor transistor logic.

tool - A tool is a computer program you can use to do some useful task. Tools are grouped into five categories: editors, processors, reporters, librarians, transfers.

tool set - A collection of tools designed to perform a suite of electronic design automation tasks. OrCAD tool sets include: Schematic Design Tools, Programmable Logic Design Tools, Digital Simulation Tools, and PC Board Layout Tools.

transfer - A tool that transfers design information from one tool set to another tool set. Also runs whatever processes are necessary to go from one tool set to another.

user button - A button that you can set up to perform whatever combination of functions you find useful (such as run programs or batch files). User button definitions are saved with the design files, so you can create design-specific buttons and not worry about overwriting user button definitions for other designs.

vector - A series of points with a specific function defined. For example, a vector for a line specifies a line function, a beginning point, and an ending point.

wildcard - A symbol that means any character or any sequence of characters (just as a wild card in poker can stand for any card). Wildcards are useful in searches.

worksheet - Draft calls the sheets of drafting paper on which the schematics are drawn worksheets. Worksheets appear on the computer screen as a rectangular area in which you can place parts and draw wires.

zoom - The ability to change the view on the screen by making the objects appear larger or smaller.
