**WARRANTY FOR SOFTWARE PRODUCTS**

Tektronix warrants that this software product will conform to the specifications set forth herein, when used properly in the specified operating environment, for a period of three (3) months from the date of shipment, or if the program is installed by Tektronix, for a period of three (3) months from the date of installation. If this software product does not conform as warranted, Tektronix will provide the remedial services specified below. Tektronix does not warrant that the functions contained in this software product will meet Customer's requirements or that operation of this software product will be uninterrupted or error-free or that all errors will be corrected.

In order to obtain service under this warranty, Customer must notify Tektronix of the defect before the expiration of the warranty period and make suitable arrangements for such service in accordance with the instructions received from Tektronix. If Tektronix is unable, within a reasonable time after receipt of such notice, to provide the remedial services specified below, Customer may terminate the license for the software product and return this software product and any associated materials to Tektronix for credit or refund.

This warranty shall not apply to any software product that has been modified or altered by Customer. Tektronix shall not be obligated to furnish service under this warranty with respect to any software product a) that is used in an operating environment other than that specified or in a manner inconsistent with the Users Manual and documentation or b) when the software product has been integrated with other software if the result of such integration increases the time or difficulty of analyzing or servicing the software product or the problems ascribed to the software product.

TEKTRONIX DISCLAIMS ANY IMPLIED WARRANTIES OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE. TEKTRONIX RESPONSIBILITY TO PROVIDE REMEDIAL SERVICE WHEN SPECIFIED, REPLACE DEFECTIVE MEDIA OR REFUND CUSTOMER'S PAYMENT IS THE SOLE AND EXCLUSIVE REMEDY PROVIDED TO CUSTOMER FOR BREACH OF THIS WARRANTY. TEKTRONIX WILL NOT BE LIABLE FOR ANY INDIRECT, SPECIAL, INCIDENTAL OR CONSEQUENTIAL DAMAGES IRRESPECTIVE OF WHETHER TEKTRONIX HAS ADVANCE NOTICE OF THE POSSIBILITY OF SUCH DAMAGES.

OPERATORS SAFETY SUMMARY

This general safety information is for both operating and servicing personnel. Specific warnings and cautions will be found throughout the manual where they apply, but may not appear in this summary.

TERMS

IN THIS MANUAL

CAUTION statements identify conditions or practices that can result in damage to the equipment or other property.

WARNING statements identify conditions or practices that can result in personal injury or loss of life.

AS MARKED ON EQUIPMENT

CAUTION indicates a personal injury hazard not immediately accessible as one reads the marking, or a hazard to property including the equipment itself.

DANGER indicates a personal injury hazard immediately accessible as one reads the marking.

SYMBOLS

IN THIS MANUAL

⚠️ This symbol indicates where applicable cautionary or other information is to be found.

As Marked on Equipment

⚡️ DANGER high voltage.

 AuthenticationService

⚠️ Protective ground (earth) terminal.

⚠️ ATTENTION — refer to manual.

⚠️ Refer to manual.

POWER SOURCE

This product is designed to operate from a power source that does not apply more than 250 volts rms between the supply conductors or between either supply conductor and ground. A protective ground connection by way of the grounding conductor in the power cord is essential for safe operation.

GROUNDING THE PRODUCT

This product is grounded through the grounding conductor of the power cord. To avoid electrical shock, plug the power cord into a properly wired receptacle before connecting to the power input or output terminals. A protective ground connection by way of the grounding conductor in the power cord is essential for safe operation.

DANGER ARISING FROM LOSS OF GROUND

Upon loss of the protective-ground connection, all accessible conductive parts (including knobs and controls that may appear to be insulating) can render an electric shock.

USE THE PROPER POWER CORD

Use only the power cord and connector specified for your product.

Use only a power cord that is in good condition.

Refer cord and connector changes to qualified service personnel.
OPERATORS SAFETY SUMMARY

USE THE PROPER FUSE
To avoid fire hazard, use only the fuse specified in the parts list for your product, and which is identical in type, voltage rating, and current rating.

Refer fuse replacement to qualified service personnel.

DO NOT OPERATE IN EXPLOSIVE ATMOSPHERES
To avoid explosion, do not operate this product in an atmosphere of explosive gases unless it has been specifically certified for such operation.

DO NOT REMOVE COVERS OR PANELS
To avoid personal injury, do not remove the product covers or panels. Do not operate the product without the covers and panels properly installed.
Figure 1-1. The 4404 Artificial Intelligence System
Section 1

INTRODUCTION

ABOUT THIS MANUAL

This is the introductory manual to the 4404 Artificial Intelligence System. (We call it the 4404 from here on.) You should read this manual before attempting to use your new 4404—it contains useful information that can help you get the most out of the 4404. You'll find instructions on how to unpack and connect the system, a guided tour of the first time you turn it on, a discussion on how to work with the system on a day-by-day basis, suggestions for working with more than one user on the system, and some ways to recover from the inevitable errors to which humans are prone.

YOUR QUALIFICATIONS

This manual is not a tutorial document. Although we’ve tried to keep this manual clear and simple, it assumes that you’re an experienced computer user. You need not have systems programming experience, or be a “Wizard,” but you should be past the neophyte stage on a large computer operating system. You should be comfortable with a hierarchical or tree-structured filing system, know how to issue commands and run applications, and, in general, be a “knowledgeable user.”

If you’re comfortable with an operating system such as Unix, TOPS-10/20, VMS, RSTS, or any of the other multi-user operating systems that abound, you should have little trouble adapting to the 4404 operating system. If you are not, you should take a course, read through one of the many tutorials, or find a knowledgeable person to help you adjust to the 4404. If you must search out tutorial information on your own, look for tutorials on the Unix operating system. The 4404 operating system is not Unix, but the structure and philosophy behind it is not too dissimilar, and tutorial information explaining the Unix operating system is readily available.
UNPACKING THE 4404

If you’ve just purchased your 4404—congratulations! You’ll want to get it put together and running as soon as possible. First, *don’t discard your shipping cartons*. If you ever want to move your 4404 any distance, you should use these containers. Exercise patience, follow instructions, and you should have no trouble bringing the system up for the first time.

To save time and trouble, follow this sequence:

1. Skim over this procedure to get a feel for the sequence.
2. Turn to Appendix A and follow those instructions. This appendix shows you, in detail, how to unpack and connect the pieces that form the 4404.
3. Come back to this point and read the rest of Section 1, the introduction. You need to get an overview of the 4404 before trying to use it.
4. Read Section 2, *The First Time User* next. Follow the examples on your 4404. This section takes you through an initial introduction to the 4404 operating system and shows you a few of its many features.
5. Next read through Section 3, *Using the 4404*. This section talks about normal, day-to-day use of the 4404. You’ll want to experiment with the system—you shouldn’t have any trouble at this point.
6. Read Section 4, *System Configuration and Software Maintenance*, to get an idea of the maintenance tasks you’ll have to deal with. If more than one user will be using the 4404, one person should be responsible for these tasks.
7. Section 5, *Recovery and Rebuild*, is the section we all hope to avoid. If you must, you can find system rebuilding procedures here.
OVERVIEW OF THE 4404

GENERAL INFORMATION

The 4404 is a single-user computer system that has been designed for the efficient development and use of artificial intelligence (AI) applications. *Single-user* means that, although the 4404 can have many separate user accounts, it is not a time-sharing system; only one user may be logged in at a time.) The 4404 can be used both as a stand-alone applications development system and as a terminal connected to a host computer.

As an applications development system, the 4404 provides a programming environment for the Smalltalk-80 system, LISP, and PROLOG. These languages run under the 4404’s multi-tasking operating system. The 4404 also has a hierarchical file system, complete with various graphics and mathematics libraries to assist with program development. In addition, the 4404 contains a ‘C’ programming environment that allows porting of many applications programs to it.

As a terminal, the 4404 easily interfaces, via a RS-232-C line, to various computers in use by the AI community. The 4404 functions as an ANSI X3.64 compatible terminal with some extensions to allow it to work with most popular screen-oriented editors.
4404 HARDWARE OVERVIEW

The 4404 consists of two major components, the Display/CPU module and mass storage unit (MSU). These, in addition to a keyboard and mouse, make up the basic 4404. The following discussion examines each component in detail.

THE 4404 DISPLAY/CPU

The Display/CPU is the heart of the 4404 system. Although it is no larger than the display cabinet of a conventional terminal, it contains the central processing unit, one or two megabytes of fast semiconductor memory, and the interface electronics that allow the 4404 to communicate with the outside world.

Connected to the rear of the Display/CPU unit are the power cord, mass storage unit, keyboard, and mouse. There, we also find a volume control for the internal speaker, an audio connector for an external speaker, a parallel printer port, and the RS-232 port.

The 4404 uses a monochrome 640 X 480 pixel display as a window into a 1024 X 1024 bit-map. The 4404’s electronics allow smooth panning of the 640 X 480 window over the virtual display under control of the operating system.

Figure 1-2 shows how the 640 X 480 pixel display relates to the 1024 X 1024 bit-map.
INTRODUCTION

Figure 1-2. 640 X 480 Window Into 1024 X 1024 Bit-Map.

This is the default screen position.

4404 USERS
Figure 1-3 shows the front of the Display/CPU unit. Two controls are located at the front of the unit: the brightness control and the power switch. Figure 1-4 shows the rear panel controls and connectors on the Display/CPU.

Figure 1-3. Display/CPU Front Panel Controls.
Figure 1-4. Display/CPU Rear Panel.
THE 4404 KEYBOARD

Figure 1-5 shows the 4404 keyboard. This keyboard is similar to that used by the Tektronix 4100 Series terminals. The joydisk, function keys, numeric pad, and keyboard keys are all accessible to the 4404 software. The only unfamiliar key is the up-arrow/left-arrow key used in Smalltalk programming (this key is also available to the programmer and produces the underscore character outside of Smalltalk-80).

Figure 1-5. The 4404 Keyboard.
THE 4404 MOUSE

The 4404 mouse, shown in Figure 1-6 is the primary pointing device used with Smalltalk-80. The mouse consists of an optical sensor (to detect movement over the pre-printed mouse pad) and three buttons. To use the mouse, place it on the mouse pad and guide it with one hand. Use your fingers to press the mouse buttons. The mouse connector plugs into the back of the 4404 Display/CPU unit near the keyboard connector.

Figure 1-6. The 4404 Mouse.
INTRODUCTION

THE 4404 STANDARD MASS STORAGE UNIT

Figures 1-7 and 1-8 show the front and rear of the standard 4404 mass storage unit (MSU). The front panel of the MSU contains the winchester disk activity light and flexible disk drive activity light to show when these drives are in use. The only controls used on the MSU are the power switch and the door handle of the flexible disk drive.

The rear of the MSU contains the power cord, the SCSI connector and terminator.

Figure 1-7. Front of MSU.
Figure 1-8. Rear of MSU.
4404 STANDARD AND OPTIONAL SOFTWARE

STANDARD SOFTWARE

Smalltalk-80

The standard programming language for the 4404 is Smalltalk-80, version 2, developed by Xerox corporation. Smalltalk-80 is an object-oriented, general-purpose programming language that makes extensive use of the 4404 bit-mapped screen and mouse. A full description of the Tektronix implementation of Smalltalk-80 is given in the companion manual An Introduction to the Smalltalk-80 System.

The 4404 Operating System

The 4404 contains a small, robust operating system, based on UniFLEX, by Technical Systems Consultants, Inc. The operating system gives one user at a time access to the 4404’s resources. The operating system gives you these features:

- Single-user operation
- Multiple user accounts (with password protection)
- A hierarchical, tree-structured file system
- Multi-tasking
- An interactive shell featuring command aliasing, history, shell variables, definable search path, and command line editing
- Command file (script) execution
- User and system utilities
- A relocating assembler and linking loader
- A 'C' compiler and libraries that include standard 'C' functions and access to the 4404’s hardware resources
- A symbolic debugging tool for 'C' and assembly language programs
- An ANSI X3.64 terminal emulator, available both to the 4404 operating system and to an external host via a RS-232-C connection
- A line and content oriented text editor
- Printer support
- Remote file transfer and host communications
4404 OPTIONS

In addition to the standard 4404 hardware and software, many additional options are available. Some of these are:

1 MB Physical Memory

Option 1, an additional one Megabyte of semiconductor memory gives you a total of two Megabytes of physical memory for your 4404.

40 MB Hard Disk with Streaming Tape

This hardware option (Option 20) adds an additional 40 Megabytes of disk memory and a streaming tape drive for hard disk backups.

ETHERNET Interface

This option adds the hardware and software necessary for the 4404 to function in an ETHERNET network.

LISP

An implementation of the LISP programming language that is widely available on UNIX systems.

PROLOG

An implementation of this logic programming language.

EMACS

A widely used, extensible, screen-oriented editor with mouse extensions.

Other Options

Additional 4404 options may be available in the future. Please contact your local Tektronix Sales Representative for currently available 4404 options.
INTRODUCTION

4404 DOCUMENTATION

STANDARD DOCUMENTATION

With your 4404, you received three principal manuals. This standard set of documentation includes:

The 4404 Users Manual (This Manual)

This manual should be the first manual you read. It contains the introductory material to the 4404: unpacking and connection procedures, a first-time user’s session, hints on daily use of the system, discussions on software configuration, maintenance and data security. This manual contains the general “how-to-do-it” information that you’ll need while getting acquainted with your new 4404. You’ll probably need to use this manual extensively for the first week or so, then will probably need to refer to it only in emergencies.

An Introduction to the Smalltalk-80 System

This manual is the introduction to Smalltalk-80 as implemented on the 4404. This manual is not a “stand-alone” manual, it is meant to be used in conjunction with two other texts, Smalltalk-80: the Programming Environment and Smalltalk-80: The Language and Its Implementation published by Addison-Wesley. You will need both these books in order to use Smalltalk-80. The manual An Introduction to Smalltalk-80 makes extensive references to the Addison-Wesley books and details the differences between the image in those books and the image on the 4404.

The Introduction does contain some tutorial information, and an excellent overview of the language, as well as providing the intimate details that affect the language user.

The 4404 Reference Manual

The 4404 Reference Manual contains the detailed description of the 4404 hardware and software from the programmer’s point of view. This book is the basic 4404 reference, and contains information on the details of commands, syntax, extensions, and the other operating system level concerns. It contains detailed information on system calls, hardware support, the assembler, loader, and ‘C’ compiler. Look in this manual for detailed information not covered elsewhere.
DOCUMENTATION OF OPTIONS

Each software option has its own reference manual(s) that details its operation. Refer to these manuals for details of how to use these software packages.

Hardware options come with installation instructions (if the option is customer-installed) and the necessary manuals for operation of that option.

SERVICE DOCUMENTATION

Two service manuals are available for the 4404. These are:

The 4404 Field Service Manual

The 4404 Field Service Manual contains information useful for a technician troubleshooting a 4404 in the field. It contains commonly used adjustments, checks, and information that enables a technician to repair a 4404 to the module level. (Modules are subassemblies that should be repaired at the factory or other service location that has specialized diagnostic instrumentation.)

The 4404 Component-Level Service Manual

This manual is designed for the experienced electronic technician and gives the information necessary to repair the 4404 subassemblies. It is not intended for use in the field; it requires test fixtures and specialized knowledge to use it.
INTRODUCTION

You should now have your 4404 unpacked, connected, and ready for its first use. This section is a commented transcript of a new user trying the 4404 for the first time.

Think of this section a guided tour of the 4404 operating system. Follow along on your own machine—feel free to experiment as you go along. This section won’t cover all of the features and capabilities of the operating system, but it will show you enough to get you started.

In this transcript, the actual dialog between the user and the 4404 is indented and in a different type style than the comments and explanations. The actual commands that you type are shown as they appear on the screen; enter them exactly as shown (omit the system prompt, but be sure to include the spaces). Remember, for commands to be executed, you must terminate the command line by pressing the Return key—this manual doesn’t show that as an explicit part of this dialog. Your session should look very similar when you issue the same commands in the same order.
COMMENTED TRANSCRIPT OF SESSION

CAUTION

If you must leave the session early, type "stop" and wait for the message

"... System shutdown complete ...

before turning off the power. Any other method of shutting down the 4404 can seriously damage the operating system disk software structure.

TURN ON THE 4404

First, you'll want to see what happens to each unit of the 4404 when you turn on one unit at a time. (Later on, you'll just want to turn on the power to both units and start working.) Press the power switch on the MSU (mass storage unit). Notice that the winchester disk activity light on upper right hand of the MSU front panel comes on until the disk gets up to speed, then shuts off.

Now, press the power switch on the Display/CPU unit. The LED in the key marked Caps Lock comes on, flashes for a time, then goes out. When the display screen lights up, you see in the upper left corner the display:

Tektronix 4404

If this message does not appear, try adjusting the brightness control.

The winchester disk activity light on the MSU then begins to flicker, the screen clears, and a new message appears:

Tektronix 4404 Operating System

Version X.X

Total user memory = (x)xxxK

++

It usually takes a few minutes for the prompt—the + + (double plus signs)—to appear. During this time, the 4404 has gone through a power-up self-test, loaded the operating system, automatically logged you in as a user with the user-namepublic, invoked the interactive shell (the program that talks to you), and is now waiting for you to give it a command.

The Version X.X message tells you what version of the operating system you have, and the Total user memory message tells you how much physical memory is actually available for your use. The + + is the default system prompt, and the flashing "_" (underscore) is the cursor.
FILES AND DIRECTORIES

You have been automatically logged into the system as userpublic. The command dir shows you the visible files in your directory. Type dir:

```
++ dir
++
```

As you can see, there are no visible files in your directory (unless someone else has left them there). If someone else has used the system and created files, you'll see the file names they left.

There are a number of files in your directory that are invisible. The operating system normally doesn't show files that begin with a period. To see these files, type dir with the +a option:

```
++ dir +a
  .    ..  .home?  .login  .shellbegin
  .shellhistory
++
```

Each of these invisible files has a use. We'll talk about them later. To find out more about the command dir, you can use help, the on-line help utility. In fact, you can use help to find out about itself. (We won't show the full system response here, as it is so long. Try it for yourself on your 4404.)

```
++ help help

(Here the system gives a list of commands for which help is available. If you want no help, just press Return to exit.)

Help with what command?
dir

(The system prints the help file for dir.)

++
```

We see that the command dir also can take an argument—the name of the directory we want to list. The fundamental directory of the system, the root, is named / . To see what it contains, type (be sure to leave a space between dir and /):

```
++ dir /

(Here the system lists the files in /.)
++
```
You need not be in a particular directory to give commands concerning files. You simply give the file's *path name* (the sequence of directories from /) in front of the file name. For example, the file `system.boot` in the directory / contains the operating system kernel in addition to other components. The `info` utility shows you the version number and copyright information about this fundamental file. Type:

```
++ info /system.boot
Tektronix 4404 Operating System
Version x.x  Released MMM DD, YYYY
OS Kernel:
Other components:
Copyright (C), YYYY, by Technical Systems Consultants, Inc.
Copyright (C), YYYY, by Tektronix, Inc.
All rights reserved.
All rights reserved.
++
```

When you don’t specify a path name, you implicitly give the files the path of your *current working directory*, in this case, the directory `/public`. For example, create the following files:

```
++ create aFile
++
++ cmdr aDirectory
++
++ dir
aDirectory  aFile
++
```

you've created two files, both empty in the directory `/public`. One, aFile, is just that—a file. The other, aDirectory, is a directory, a special file that contains other files. Let’s use the `+l` (lower case L) option to `dir` to find out more about them. Type:

```
++ dir +1
aDirectory  1 d rwxrwx 2 public 12:00 Nov 29,1984
aFile  0  rw-rw- 1 public 12:01 Nov 29,1984
++
```
The fields in the directory listing (from left to right) are:

1. The name of the file.
2. The size of the file in 512 byte blocks (1 for aDirectory and 0 for aFile).
3. The file type (d for aDirectory and blank for aFile). The special file, aDirectory, has a d for directory; aFile is a normal file (blank).
4. The permissions for the file (rwxrwx for aDirectory, rw-rw- for aFile). The first three characters are the read, write, and execute permissions for the file’s owner, the next three the permissions for all others. See perms in the 4404 Reference Manual for a complete explanation of permissions.
5. A count of how many other files are linked to that file (2 for aDirectory and 1 for aFile).
6. The file’s owner (user public).
7. The time and date the file was created (or last modified).
THE FIRST TIME

MOVING AROUND IN THE DIRECTORY

Use the command `chd <directory-name>` to change your location in the directory structure (your current working directory). `chd` with no argument returns you to your home directory. The command `path` tells you the name of your current working directory:

```
++ path
/public
++
```

```
++ chd aDirectory
++
```

```
++ path
/public/aDirectory
++
```

If you now create a file, `newFile`, it will have a path name `/public/aDirectory/newFile`. To access this file from outside the directory `/public/aDirectory`, you must give the path name of the directory `/public/aDirectory`, then a `"/"`, and as the last element, the name of the file, `newFile`. Let's try it and see.

```
++ create newFile
++
```

```
++ dir newFile
newFile 0 rw-rw- 1 public 12:05 Nov 29,1984
++
```

Notice that when you give a file as an argument to `dir`, it returns the same information the `-l` option does.
Now, to change directories try `chd` without an argument. It will get you back to your home directory from wherever you might be. You can also combine more than one command on a single command line by separating them with a semicolon. Try that also:

```sh
++ chd;path
/public
++
```

Where's the file `newFile` we created a moment ago? Let's see:

```sh
++ dir newFile
*** Error: File doesn't exist. While Getting file status on file "newFile"
++
```

It's obviously not in the directory `/public`. Let's try the file's path name:

```sh
++ dir /public/aDirectory/newFile
/public/aDirectory/newFile 0 rw-rw- 1 public 12:05 Nov 29,1984
++
```

The shell also contains a directory stack, a list of directories that you can move among. To move to the directory `/bin` and save your present directory, use the `pushd` command:

```sh
++ pushd /bin;path
/bin /public
/bin
```

You are now in the directory `/bin` with the directory `/public` stored on the directory stack. To get back to the last stored directory, use the command `popd`:

```sh
++ popd
/test
++ path
/test
```
SOME SHELL FEATURES

The interactive shell contains many capabilities to help you in your work. Let's look at a few of them.

history

The shell keeps an ongoing record of the commands you've given it. This command file (.shellhistory) gets updated when you log out of the system. You can recall and edit these commands to save yourself typing.

To recall your previous commands, Type history and, if you typed exactly the commands that were given earlier in this session, you see:

```plaintext
++ history
1:  dir
2:  dir +a
3:  help help
4:  dir /
5:  info /system.boot
6:  create aFile
7:  crdir aDirectory
8:  dir
9:  dir +l
10: path
11: chd aDirectory
12: path
13: create newFile
14: dir newFile
15: chd;path
16: dir newFile
17: dir /public/aDirectory/newFile
18: pushd /bin;path
19: popd
20: path
++
```
Obviously, if you typed something else, your history will differ. To recall the last command you entered, press <Ctrl-P> (hold down the key marked Ctrl and press the key marked P). The last command reappears with the cursor under the first character of the command. Each time you press <Ctrl-P>, the command line becomes the previous history entry. To move the command line forward in your history, press <Ctrl-N>. Move up and down in your history until the command line reads path. Press Return, and the 4404 executes this command again:

```
++ path
/public
++
```

Try history again. You’ll see an additional line:

```
++ history
...
18: pushd /bin;path
19: popd
20: path
21: path
```

Notice that history doesn’t get stored.
Command Line Editing

You can edit commands, whether you are in the process of entering new ones or have retrieved old ones. Let's edit an old command.

1. Press the top of the joydisk (we'll call that action joyup—it has the same effect as <Ctrl-P>) several times. Notice how you step back through the commands.

2. Hold the top of the joydisk down until you get to the first command. (The beeping of the bell tells you that you've exhausted your stored history.)

3. Step down through the commands with either <Ctrl-N> or the bottom of the joydisk (joydown).

4. Move down until the command line is blank (at the bottom of your history). Let's take a slight detour and look at some interesting features about recalling history:
   a. Type the letters cr on the command line, then stop. Do not press Return.
   b. Move up and down through your recalled history with joyup and joydown. Notice that you can only recall three commands: create newFile, cdir aDirectory, and create aFile in addition to the cr you entered.

You can recall only those commands that match the characters to the left of the cursor on your present line—those that begin with cr.

   c. Move the cursor one character to the left on the command line (press <Ctrl-B>) so it is just under ther in cr.
   d. Try moving through your history again. Now you can retrieve any command that begins with c.

5. Use joyup and joydown until the command line becomes:

   ++ cdir aDirectory

6. Move the cursor around on the command line by using using <Ctrl-F> or Joyright and Joyleft or <Ctrl-B>.

7. Put the cursor on the character D in aDirectory and press <Ctrl-D> to delete the D.

8. Press the Back Space key to delete the a and replace it with a lower case d by pressing the d key.
At this point, you've nearly finished editing the command line. Notice that we have two types of single character deletion: Back Space and <Ctrl-D>. In addition, you have several more ways to move the cursor on the command line. Press and release the Esc key then press F to move the cursor right one word. Esc-B (the same sequence with the B key) moves the cursor left a word. <Ctrl-E> moves the cursor to the end and <Ctrl-A> moves the cursor to the beginning of the command line.

9. Press <Ctrl-E>. The cursor moves to the end of the word directory in the command line.

10. Type in B and press Return. It looks like this:

    ++ crdir directory
    ++

You've successfully retrieved a command, edited it to make a new command, and then executed the new command. You'll find that, in many cases, it's much faster to retrieve an old command and edit it than to type in a new command. To see the results of the command you just issued, type:

    ++ dir
    aDirectory aFile directory
    ++

    ++ history
    1. dir
    ...
    20: crdir directory
    21: dir

When you are editing a command line, should you want to enter a control character such as <Ctrl-P> rather than executing it, enter the quote character, <Ctrl-Q>, followed by the control character you want to insert. (We'll use this later with environment variables and alias.) Tables 2-1 and 2-2 summarize the moving and deleting commands you can use on the command line.
### Table 2-1

**MOVING COMMANDS**

<table>
<thead>
<tr>
<th>Function</th>
<th>Control and Escape keys</th>
<th>Joydisk equivalents</th>
</tr>
</thead>
<tbody>
<tr>
<td>Move up one line</td>
<td>Ctrl-P</td>
<td>joyup</td>
</tr>
<tr>
<td>Move down one line</td>
<td>Ctrl-N</td>
<td>joydown</td>
</tr>
<tr>
<td>Move right one character</td>
<td>Ctrl-F</td>
<td>joyright</td>
</tr>
<tr>
<td>Move left one character</td>
<td>Ctrl-B</td>
<td>joyleft</td>
</tr>
<tr>
<td>Move to end of line</td>
<td>Ctrl-E</td>
<td></td>
</tr>
<tr>
<td>Move to beginning of line</td>
<td>Ctrl-A</td>
<td></td>
</tr>
<tr>
<td>Move right one word</td>
<td>Esc-F</td>
<td></td>
</tr>
<tr>
<td>Move left one word</td>
<td>Esc-B</td>
<td></td>
</tr>
</tbody>
</table>

### Table 2-2

**DELETING COMMANDS**

<table>
<thead>
<tr>
<th>Function</th>
<th>Control and Escape keys</th>
</tr>
</thead>
<tbody>
<tr>
<td>Delete character left</td>
<td>Back Space (Ctrl-H)</td>
</tr>
<tr>
<td>Delete character right</td>
<td>Ctrl-D</td>
</tr>
<tr>
<td>Delete word left</td>
<td>Esc-H</td>
</tr>
<tr>
<td>Delete word right</td>
<td>Esc-D</td>
</tr>
<tr>
<td>Delete line to right of cursor</td>
<td>Ctrl-K</td>
</tr>
<tr>
<td>Delete entire line (Restore it if deleted)</td>
<td>Ctrl-U</td>
</tr>
</tbody>
</table>
This discussion has covered a lot of territory so far. You should probably clean up your directory and remove the files and directories we've left there. To test your own understanding, remove the files and directories you created in /public. At this point, you should test your understanding (and get some command line editing practice) by doing so while observing the following restrictions:

- Remove all files and directories in /public one by one.
- Type the word `remove` on the command line, then press `Return`. You will see a prompt for the syntax of the `remove` command.
- Form the other commands by recalling `remove` from your history and edit the command line. Don’t just type in your commands.

Hint: Don’t forget `help` and the options to `remove`. 
The Shell Environment

Your shell environment is the way in which the shell responds to your commands. You can change the environment in two ways: by setting environment variables and by aliasing commands.

Setting Environment Variables

The shell maintains a list of environment variables, (these are not the same as Unix environment variables) some of which are bound to special keys or functions and others that simply store values. To see what these bindings are, type set.

In response to set with no arguments, the 4404 displays a list of environment variables that are already set. You've met some of these earlier.

Control characters are shown in snoopy form; i.e. $C_R$ stands for the carriage return and $B_S$ for backspace. You've seen the joydisk variables before. It should be obvious that the lower case versions are unshifted, while the upper case versions are shifted. Joydisk variables that begin with C are the control versions of the variables. The ARROW and BREAK key variables are obvious. The function keys are represented by f1 through f12, while the shifted function keys are F1 through F8. Defining these variables effectively programs these keys for you while you are executing the shell.

PATH is the set of directories that the shell searches before deciding that it cannot recognize a command, and PROMPT is the string that it displays for the system prompt. (To put spaces in a string, you have to enclose the string in single or double quotes—otherwise the shell just takes the first word of the string.) Let's change a few variables and see what happens.

```bash
++ PROMPT="public++ 
public++

public++ f5=dir
public++

public++ F5=`dir +al`
public++
```
Notice that we didn’t have to put quotes around `dir`, the defining string for f5, but did around the string for F5 as it contained a space. Now press function key f5. (Follow with `Return` if you want to do the function, `<Ctrl-C>` or `<Ctrl-U>` if you don’t.) Now try pressing function key F5 (hold the shift key down and press f5).

Notice that pressing the keys f5 and F5 have the same effect as typing in the commands you bound to them, and that you have to press `Return` to execute the commands.

It is also possible to put a `Return` in the definition of key F5. Since we want the `Return` in the string, we can’t just press `Return` (that executes the command line). We use a pair of characters, the quote character (`<Ctrl-Q>`) followed by a lower-case n, to embed the character `Return` (shown as `CR`) in the defining string. It looks like this:

```
   public++ F5= `dir +al\n
   public++
```

Type `set` to see the definition, then press F5 to try the programmed function.

To remove a shell environment variable definition, you can define it to something else (it will overwrite the old definition) or you can use `unset`:

```
   public++ unset f5
   public++
```

If you want to remove all environment variable definitions, you can use `unset` with the `+a` option.
**Aliases**

In addition to environment variables, the shell maintains a list of aliases. When you enter a command line, the shell checks the first command against its alias list, and if the command is aliased, executes the underlying command. To see your list of aliases, type `alias` followed by `Return`.

Let's alias a command, then remove the alias.

```
    public++ alias showMe 'dir +as'
    public++
    public++ showMe
    .
    ..
    .home?
    .login
    .shellbegin
    .shellhistory
    public++
    public++ unalias showMe
    public++
    public++ showMe
    showMe: command not found
    public++
```

Like `unset`, you can use `unalias` with the `+a` option to remove all aliases from your shell.

You can use argument designators to extract arguments from commands. With environment commands, the designators apply to the last command executed, while with aliases, they apply to the current command line. To pass all the arguments to the basic command, let's alias `ll` and accept all arguments to it.

```
    public++ alias ll 'dir +a $*'
    public++
```

Now, to see the contents of three directories in long form, type:

```
    public++ ll /etc /bin .
```

Watch carefully as the system displays the directories of `/etc`, `/bin`, and `.`, your current directory. (Yes, that's what the special file `.`` is.)
Saving Definitions

You can define environment variables and aliases in a text file, then use the `set` command to pass them to the shell. To set your environment back to what you started with, type:

```
public++ set .shellbegin
++
```

If you look at your environment with `set`, you’ll find that PROMPT has been reset. If you haven’t used `unalias + a`, any aliases you made still exist since they aren’t mentioned in `.shellbegin`. The shell sets the environment automatically from `.shellbegin` when the shell starts up. You can edit `.shellbegin` to define any environment variables and aliases you want to have whenever you work on the 4404.

The file `.shellhistory` also saves your history, aliases and variables from one login to the next.

In addition, if you have any other tasks you want to do every time you login, create a script (basically, just a list of commands in a text file—see the reference manual under `script`) and leave that script in the file `.login`. The 4404 will execute that script every time you log into an account that has `.login` in its home directory.

**ENDING THE SESSION**

Experiment with the operating system commands. Read the reference manual to get an idea of the commands that are available and how they work, then try them. When you are finished, type `stop`.

```
++ stop
...
... System shutdown complete ...
```

Don’t forget to shut the power off on both the MSU and the Display/CPU units.
INTRODUCTION

At this point, you should have gone through the first-time user’s exercise in Section 2. If you have not done so yet, you should do so before proceeding.

This section covers normal day-to-day use of the 4404 from a normal user’s standpoint. This discussion takes a broader look at the operating system and how it operates than was covered in Section 2. This discussion assumes that you have not logged in as user system, are logged in under public, and are performing routine tasks.
POWER ON AND SYSTEM BOOT

To start using your 4404, turn on the power switches on both the Display/CPU unit and the Mass Storage Unit. The system then goes through a power-up self-test and initialization procedure, then logs in user public if its password has not been set.

Although this procedure is painless, quite a lot happens during this short time. If you want to reconfigure the system, or customize your environment, you can do so by altering files used in this procedure. Let's follow the boot process and see what happens.

POWER-UP SELF-TEST AND BOOT

When you first turn the power on to the Display/CPU unit, control goes to a program located in ROM (read-only memory) located on the processor board. This program executes the power-up self test. It checks and initializes the main memory (RAM), the various interfaces, and then attempts to boot the system.

The boot ROM code looks for a file named system.boot on the winchester disk. If the file system.boot is present on the winchester, the boot ROM attempts to load and execute it. (The system also checks in various other places for boot files, as explained in Section 5's discussion of self-test.) If system.boot is not present, the 4404 asks you to enter the name of the boot file.

You can also put the 4404 into an interactive boot from self-test. This option is also explained in Section 5 in the discussion of self-test.

BOOTING THE SYSTEM

When system.boot executes, it loads the operating system kernel and performs some diagnostics on the file structure. It looks for telltale signs that the system had not been shut down cleanly, and if it finds them, it executes a system utility called diskrepair. Diskrepair makes a thorough analysis of the disk file structure and repairs any defects it finds. It also (since it executes in the verbose mode) prints messages on the screen to let you know what it is doing. Diskrepair may shut down the system and ask you to reboot (press the Reset button) if it makes substantial repairs.

If the system had been shut down cleanly (or if diskrepair was able to repair the disk without needing to shut the system down) the 4404 then begins the login process for user public.
THE LOGIN PROCESS

CHECKING THE PASSWORD FILE

The 4404 begins the login process by first checking in the file /etc/log/password to see if the user-name (public on power-up/reset or the user-name from a login prompt) is valid. If the user name is valid and the name has no password associated with it, the system logs the user in.

If the user-name is not valid, or if the user has set a password, the 4404 then prompts the user for a password. (No password will be acceptable for an invalid user-name.) If the user-name and password are valid, the 4404 then logs in the user.

To login from another user name, issue the command login followed by the user name to login under:

```
login <user_name>
```

USER INITIALIZATION

On bootup, or if you login with the user-name public, the 4404 runs the shell script /public/.login. The default version of this script is empty—you can enter whatever commands you want script to execute every time you login.

Next, the interactive shell reads its own initialization files, .shel/begin and .shel/history, to define your shell environment. This file sets up environment variables, aliases, and restores your history. Finally, the shell issues you a prompt and you are ready to begin.

If you login under another user-name, the 4404 looks for the .login, and the shell looks for .shel/begin and .shel/history in your home directory.

SETTING PASSWORDS

You can set the password of your home directory with the password command. Simply type the command followed by a <Return>, and the system will prompt you for a password. After you type it, the system prompts you to type it again, then sets the password for your user-name. Only the user logged in as system can set passwords for others. If you forget your password as a user, a person logged in as system can change your password. If you forget the password for system, the forgotten password can be removed with a utility on the disk repair diskette (see Section 5, Recovery and Rebuild for information on this utility.)
STOPPING THE SYSTEM

STOP

Whenever possible, you should back up your files before stopping the system. For a discussion of backup strategy, see Section 3, System Configuration and Software Maintenance.

The command to issue when you want to shut down the 4404 is `stop`. This command terminates the system gracefully, closes open files, flushes the contents of buffers to disks, terminates background processes, and completes the other housekeeping that is necessary to gracefully shut the system down. The syntax of this command is simply:

```
stop
```

The 4404 maintains several files and buffers while it is running. If the system is not shut down gracefully, some of these files may exist after shut-down, and some of the files it maintains may not contain correct information.

**WARNING**

In extreme cases, simply turning off the power or pressing the reset button may damage the file structure to the point that the system is no longer usable. To prevent this, it is essential to stop the system gracefully before turning off the power.

POWER OFF

After you issue the command `stop`, the system begins the shutdown process. This procedure may take a few moments.

Wait. After a few more moments (the time depends on the number of background processes to shut down, and other housekeeping jobs) the system gives you the message:

```
... System shutdown complete ...
```

At this point, it is safe to turn off the power to both the MSU and the Display/CPU.
THE OPERATING SYSTEM AND UTILITIES

OVERVIEW

The 4404 operating system consists of a small kernel and a number of commands or utilities stored on disk. The kernel has the ability to execute the commands it recognizes, or to execute a disk-based utility in the file system. As a point of fact, the kernel does not deal directly with the user—the user interface is via a utility called shell. If the user input matches a file found in the search path, the kernel loads and executes that file if it is an executable file, or executes it via another utility called script if it is a text file with the proper permissions.

The two utilities, shell and script, do not follow the same search path. The path in shell is set by the string argument to the environment variable PATH, and that in script is set via a built-in command. See the documentation on script to learn more about its search path.

COMMANDS AND COMMAND SYNTAX

The general form of a 4404 operating system command or utility is the name of the file containing the command followed by a carriage return. In addition, most commands take options or switches that modify the action of the command, and some may require arguments or parameters to the command. The 4404 Reference Manual gives a full listing of the options, parameters, and arguments to the 4404 commands and utilities.

Options

Most options are introduced by the plus (+) character immediately before the option character. When a command has more than one single-character option, you can put multiple option characters together on one line following the " + ".

For example (ignoring arguments for now), the command dir takes several extensions—a, b, d, f, i, r, s, t, and S. These commands alter the format in which dir displays the directory. If you want to see a directory of normally invisible files (those that begin with "."), you add the extension + a. If you want the directory to print the files one per line, add the extension + s.

If you want to do both (show all the files, including the invisible files, one per line), the command is:

    dir +as
    (or alternatively)
    dir +a +s
Arguments and Parameters

Although there is a subtle difference between the terms "arguments" and "parameters," they are often used interchangeably to refer to the additional information needed by a command. Arguments usually take on a default value if you omit them, but the system will require you to supply parameters.

For example, the command chd (the command to change directories) takes a directory name as its argument, and defaults to your home directory if you do not supply the argument. The command perms, on the other hand, prompts you with an abbreviated syntax line if you omit the parameters.

Options That Take Arguments

Some options take arguments, such as the w option (wait) for the status command. When an option takes argument (other than its default), the option that takes the argument must be the last option in the option string (the sequence of characters following the "+"), it must have a "=" immediately behind it, and must have the argument as the last portion of the option string. Some commands can contain only one option string, while others may have multiple strings.

For example, to display the system status you can use the status command. To display the system status every 30 seconds, you can use the command:

```
status +w=30
```

To display more information, you could use:

```
status +alsx+w=30
(or one of the equivalents)
status +w=30 +alsx
status +al +sx +w=30
status +a +l +sxw=30
... etc.
```
MANUAL SYNTAX CONVENTIONS

Throughout this manual, the 4404 Reference Manual, and in the on-line Help files, the following syntax conventions apply:

1. Words standing alone on the command line are *keywords*. They are the words recognized by the system and should be typed exactly as shown.

2. Words enclosed by angle brackets ("<" and ">") enclose descriptions that you must replace with a specific argument. If an expression is enclosed *only* in angle brackets, it is an essential part of the command line. For example, in the line:

   adduser <user_name>

   you must specify the name of the user in place of the expression <user_name>.

3. Words or expressions surrounded by square brackets ("[" and "]") are optional. You may omit these words or expressions if you wish.

4. If the word "list" appears as part of a term, that term consists of one or more elements of the type described in the term, separated by spaces. For example:

   <file_name_list>

   consists of a series (one or more) of file names separated by spaces.
FILE STRUCTURE

The 4404 directory is a tree-structured hierarchy. Entries are files, some of which are themselves directories. File identifiers consist of a path name, the sequence of files beginning at the root, or fundamental directory of the hierarchy, continuing through each subdirectory to the actual file name.

The file name is the identifier for a file in a particular directory. The path name is the chain of directories that enables you to find a particular file in the entire directory structure. The full name of a file is the path name of its directory with the file name after a separating “/” character.

Directory Contents

The dir command lists the contents of a directory. Without an argument, it lists the contents of the directory it takes as a default, or your current working directory; with one or more arguments, it lists the contents of the directories you give as the arguments. To identify directory entries within a directory, use the dir command with the option +I.

For example, let’s look at the directory of “/”, the root directory. Give the command:

    dir / +l

The system shows the directory entries, one per line. Following the name field is a number (the file size in 512 byte blocks), then in some files a single character. When this character is ad, the file is a subdirectory.

Each directory contains two “relative” subdirectories. The first (.) refers to the directory itself. The second (..) refers to the parent of that directory. (Files beginning with a period are normally invisible; to see these files, use the +a option.)

You can use the “.” and “..” designations from any working directory. For example, if you were down a directory tree, you could see the contents of the grandparent of your directory with the command:

    dir ../..
Moving Around The Directory Tree

When you login to the system, the 4404 makes your home directory (this directory is defined in your entry in the password file /etc/log/password) your current working directory. You can think of your current working directory as your location in the directory tree and changing the default directory as moving to different locations in that tree.

Your current location is always available with the command path. For example if you are in the directory /neat/stuff, and type path, the system responds with /neat/stuff.

To change your position, type the command chd, with or without an argument. Without an argument, chd returns you to your home directory; with an argument, it moves you to the specified directory.

In addition, shell maintains a directory stack. You can move about the directory stack by pushing the current directory onto the stack and moving to a new directory with the command pushd. You can view the contents of the directory stack with the command dirs, and change back to the directory on the top of the stack with the command popd.

Adding and Removing Files

You can create empty files with the utility create, and directory files with the utility crdir. In addition, many applications programs (such as the text editor) will automatically create files for you. To remove files or directories, you should use the utility remove. To remove an empty directory you can use the +d option; to remove a directory and all the files in it, you can use the +k option.
**WILD CARD EXPANSION**

Both shell and script perform *wild card expansion*—they will match a series of characters against *wild cards* on the command line. The most commonly used wild card is "*", which stands for any sequence of any characters. For example, the pattern `a*x` matches `ax`, `a_fox`, `amazing_cloxe`, or any other letter combination that begins with a and ends with x. You can match single characters with "?" as a wild card. (The operating system, and most utilities, treat upper and lower case letters as distinct. A is not the same as a.)

See the 4404 Reference Manual entries under both shell and script for a more thorough discussion of wild card expansion.

**MULTI-TASKING**

The 4404 operating system is capable of *multi-tasking*, or seeming to do more than one job at a time. In reality, of course, it does one job, switches to another, then back—usually quickly enough to give the illusion that it is performing the tasks simultaneously.

The interactive shell and script control multi-tasking. To run a job in the background, you can start or end a shell command line with the character "&", while for script to do background processing, the "&" must be the last character on the command line.
USER COMMANDS BY FUNCTION

The following list summarizes the user commands by function. For details on the actual command syntax, use the help utility or see the 4404 Reference Manual, which contains an entry for each command.

FILE MANIPULATION

The following user commands and utilities are primarily used with individual files.

copy
Make copies of directories or individual files.

create
Create new empty files.

edit
Line-oriented text editor.

link
Create a link to an existing file.

list
List the contents of text files.

move
Move files to another location or rename them.

remove
Remove files or directories.

rename
Rename a file.
FILE PROCESSING

The following commands are used for file processing.

**compare**

Compare and list the differences between two files.

**dump**

Formatted file dump in hexadecimal and ASCII.

**filetype**

Print out message about the type of a file.

**find**

Search for a pattern within a file.

**info**

List information about a binary file. This command usually lists copyright information and revision numbers of the file given as an argument.

**touch**

Update the last-modified time on a file.

**tail**

Display the last 250 (or specified number of) characters of a file.
DIRECTORY MANIPULATION

The following commands and utilities are primarily used when working with directories.

**chd**
Change the current working directory.

**crdir**
Create new directories.

**dir**
List the names of files in a directory.

**path**
Display the path name of the current working directory.
SYSTEM ACCESS AND STATUS

date
Display date and time. User logged in as system may modify date and time.

dperm
Adjust the default permissions for newly created files.

exit
Terminate a subshell and return to the calling shell.

help
Obtain information about commands.

login
Access the file system as a user.

owner
Change the owner of a file.

password
Set the password of a user for login.

perms
Set the permissions for files.

status
List the status of current tasks or processes. Useful to find background jobs that may be running.

stop
Gracefully shut down the system.
DISK MANAGEMENT

backup
Create archival backups of files and directories. Also useful for interchanging programs between 4404s.

diskrepair
Check and optionally repair the logical structure of a disk system. (See Section 5, Recovery and Rebuild for hints on using diskrepair.)

format
Format and write a file system on a floppy disk.

free
List the amount of free space on a disk.

restore
Restore files from a backup format floppy disk.
COMMAND EXECUTION

echo
Display arguments to this command.

int
Send an interrupt to a task. (Used to kill background jobs.)

jobs
List information about the user’s background tasks.

script
Command language used to execute commands from a text file.

shell
Interactive system command language.

wait
Wait for background jobs to complete.
COMMUNICATIONS

commset
Examine or modify parameters for the communications port.

conset
Examine or modify parameters for the console (display and keyboard).

remote
Connect through the communications port to a host computer.
PROGRAM DEVELOPMENT

asm
The relocating assembler.

cc
The 'C' compiler.

debug
General purpose debugger.

headset
Modify task parameters in an executable file.

libgen
Generate a library file.

libinfo
List information about a library file.

load
Linking loader to produce object files.
smalltalk
Run the Smalltalk-80 interpreter and environment.

strip
Remove symbols from an executable file.

relinfo
List relocation information in an object file.

update
Execute commands based on dependencies in a makefile.
INTRODUCTION

As in any other complex software system, the 4404 requires software maintenance. If you are the sole user of your system, you must perform these tasks, which on a larger system are done for you by a system manager. We prefer not to use the term system manager with the 4404 (although the term might slip in here and there), but to think of the person or persons who perform these duties as simply the user system. The person who is logged in under system has more power and much greater responsibility for keeping the system running than someone logged in under public.

This section discusses the responsibilities and privileges that the user logged in under system must be aware of.

Many utilities will allow only the system user to invoke them. These utilities, kept in directory /etc, are the maintenance tools that user system uses to repair the disk structure, add and delete user accounts, and other system housekeeping chores. Most of these utilities are either dangerous or inappropriate for indiscriminate use.

You should be confident of your command of the operating system as a user under public before you log in under system. Many utilities and procedures require knowledge and skill to use them safely.

---

**CAUTION**

User "system" has very few safeguards against accidents. As "system", in directory "/", you can destroy the operating system by simply typing "remove *"
THE FACTORY CONFIGURATION

As supplied from the factory, the 4404 is ready to plug in and run. Two user accounts, the general user *public* and the housekeeping user *system* are predefined. Neither account has a password. Either user can set its own password, and *system* can set a password for *public*. You need not set passwords for either account unless you feel that protection is necessary.

The general user utilities are contained in directory */bin* and the *system* utilities are contained in directory */etc*. User *public* and any other general user accounts will search only their home accounts and */bin* for command names. User *system* will also search */etc* for command names. You can change the search path by changing the shell environment variable PATH.

USER

If you are the only person using the 4404, you should do most of your work logged into user *public*. This is the normal user mode of operation—you are protected against causing system-wide devastation with a few accidental keystrokes. You have the full resources of the system available, and are protected only against destroying *system* files. If several persons are using the system, each with an individual user name, or if you are using different user names to organize your work, each of these general users will have privileges similar to those of user *public*.

File Protection and Ownership

You are the owner of all files that you create. You can change the permissions on these files (and no others) with the *perms* command. If there are more than one *public* level user name is defined on the system, each user can allow or deny access to his or her owned files via *perms*. You can allow or deny access to your directories by allowing or denying *x* (execute) permission to a directory.

Passwords

You can specify or change a password for your user name by using the *password* command. This prevents anyone except user *system* from logging into your account. You can leave the password off your account if your situation does not warrant using passwords.

If you forget your password, it can be changed by user *system* using the *password* command.
Backing up User Files

You should (depending upon your system organization) back up your own files frequently. By doing so, you reduce the possibility of losing large amounts of work. You need not back up your entire file structure each time; by using the +A option you can simply backup the files that are new or changed (incremental backup).

To perform an incremental backup:

1. Move to your home directory. Type:
   
   chd
   
   (The backup process is relative. If you are not in your home directory, it will backup files under the directory in which you are currently working.)

2. Backup your files. Type:
   
   backup +dtA
   
   (See the backup command in the 4404 Reference Manual for an explanation of the options.)

3. Insert formatted diskettes as prompted by the system. If you have not formatted your diskettes, you can type JCR instead of Return, and the system will format the diskette before using it. You may format subsequent diskettes in the same way.

backup will use all the storage space on a diskette, breaking long files across diskettes. When you restore files from a backup set, they will be in the same relative position they were in when they were saved. You should maintain at least two sets of backup diskettes, using them alternately. In this way, if you damage one set, you can restore some of your files from the older backup set.

You should label your backup diskettes in sequential order. If you get them out of order, you could lose some data.

It is your responsibility to back up your files. You have the safekeeping of your work in your own hands. Should the system disk be destroyed, a current set of backup diskettes will let you recover your files up to the point of backup. You can also exchange files with other 4404 systems by backing up only the files you want to exchange, then restore the backups onto the other 4404.
A Suggestion

To prevent errors and reduce typing you might find it useful to put your backup procedure into a script file and keep it in a personal command directory. As an example, let's see how a user called sams (who changed his prompt to Sams ++ in his .shellbegin file) would do so. (The comments in parenthesis aren’t to be typed in, they just explain what the commands do.)

First, user sams creates his personal command directory /sams/bin to contain this and any other personal utilities.

```
++login sams
Password: (Sam types his password here)
Sams++ crdir bin (This will be his command directory)
```

Now he creates an empty file and gives himself execute (u+x) permission.

```
Sams++ create bin/save (The name of the command file)
Sams++ perms bin/save u+x (Make "save" executable)
Sams++ dir +dl (Let's see what we've done)
```

```
directory ".":

bin 1 d rwxrwx 2 sams 14:27 Dec 19, 1984

directory "./bin":

save 0 rwxrw- 0 sams 14:29 Dec 19, 1984
```

User sams now has two tasks left: editing his file /sams/bin/save to put in the commands he will use, and editing the /sams/.shellbegin file to put the directory /sams/bin in the search path. He can use the line editor edit, a Smalltalk-80 file list, or the optional editor, EMACS, to do so.

In /sams/.shellbegin the default line for his search path is:

```
PATH=.:/bin
```

He edits this line to read:

```
PATH="./sams/bin:/bin"
```
Now to test if PATH is right, he types:

```
sams++ set .shellbegin
sams++ save
sams++
```

When the prompt comes back after `save` it shows that the system recognized the command (which did nothing). In the file `/sams/bin/save` he puts the two lines of his command:

```
chd /sams
backup +dltAB
```

When the file is saved, the command is ready for use. Sam put in two more options: `i` to list what it is doing and `B` to not save files that end in `.bak`. You can include these if you wish, or leave them out if you prefer.

To perform his personal backups, Sam now types `save` and follows the prompts to save his new files on today’s backup disk set. The next time he backs up his files, he performs the same task using his alternate set of personal backup diskettes.
RESPONSIBILITIES OF USER “SYSTEM”

When more than one person uses a 4404, one person should be responsible for the system maintenance tasks. This person should not use the system account for his or her normal work, (use apublic level account whenever possible) but use the system account only when necessary to perform system level tasks. These accounts include the following:

BACKING UP THE SYSTEM

One of the most important tasks for system is backing up the files on the winchester disk. If users are responsible for their own files, you should do a complete system backup whenever you change any of the system files. In addition to the system backup diskettes you received with your 4404 and archived in a safe place, you should maintain at least two more system backup disk sets, alternating between them as you perform backups. If users do not maintain their own file backups, you should also do a frequent incremental backup similar to that recommended for the users earlier in this section.

Performing a System Backup

A system-level backup can take over an hour, depending on the number of files that exist on the system. To save time, you should have enough formatted diskettes, labeled in sequential order, to contain the full system backup. (16-20 diskettes will hold the system as delivered; you’ll have to add diskettes as you add files.) As mentioned, you should have at least two sets of backup diskettes. Each time, use the oldest set of diskettes for the newest backup, moving the last backup to a safe place in case anything should happen to this backup set. The backup procedure is:

1. Login as user system.
2. Type chd. If you had logged in as system previously, this gets you back to "/".
3. Type:
   
   backup +dl

4. Insert the backup diskettes in sequential order and press <Return> when prompted to do so by the system.
5. Store the latest set of backup diskettes in a safe place in case they may be needed for a system rebuild.
6. Logout from the system account. Don’t use the system account for normal work—use a public level account for that.
ADDING AND DELETING USERS

Adding and deleting users on the 4404 is a simple matter. To add a user, simply type:

```
adduser <user_name>
```

The user name should be 13 characters or less. This command creates a directory under "!/" with the same name as the user name, and puts a default copy of the .login .shellbegin, and .shellhistory files in that account. If you want to set a password for the new user, use the password command.

Deleting a user is nearly as simple. You need to decide whether to delete the user’s files and directories when you delete the user. If you want to delete the user’s files, type:

```
deluser <user_name>
```

Or, if you want to retain the user’s files, type:

```
deluser +x <user_name>
```

**CAUTION**

*Never delete users "system" or "public". If you do so, you will have to do a complete system rebuild as described in Section 5.*
INSTALLING SOFTWARE ON THE 4404

The user system is also responsible for installing software on the 4404. Exactly how you organize your system is up to you. You can put files wherever you want, but you should keep the following points in mind.

The User’s Search Path

The user’s default search path covers only two directories, his current working directory (.) and the /bin directory. If you are installing software for general use, install it (or a link to it) in /bin. If the software is for system use, the directory /etc is in the search path for system.

Keep Related Programs Together

You may wish to install a set of related programs, or programs that call each other, in a directory apart from /bin or /etc. To call these programs from /bin or /etc, you can create a link within either /bin or /etc. See link in the 4404 Reference Manual for an explanation of link.

Search Time

If you have a very large number of files that are accessible by the public level users, the search time for each command might get quite long. If you have this type of situation, you might wish to start a new command directory (for example /publicbin for less common shared commands). If you do this, the .shellbegin file for each user must be edited to add that directory to his or her search path. Change the line that assigns the environment variable “PATH” to include your new command directory in the order you want to search and separate the directories by colons.
SOFTWARE MAINTENANCE

Software Requirements

Some software requires that it be placed in a specific position on the directory structure. This limits your freedom where to place the software. If you want the command which invokes the software to reside elsewhere, use link to allow it to be addressed by both names.

Permissions and The User Bit

For a file to be executable by another user, you should set the permissions with the o+x option. In the discussion on perms in the 4404 Reference Manual, mention is made of the user bit. This is a device which temporarily grants the user of the file the permissions that the file's owner has. This allows you to grant temporary and limited system privileges to a user running a particular utility. You can set this bit on or off with the s+ and s- options to perms.

Error Recovery and System Rebuilding

You should be very knowledgeable about the 4404 operating system before attempting to recover lost files or rebuild the system. If you are unsure as to your abilities, make a separate backup of the system and run diskrepair before you attempt to recover data.

If diskrepair found any unreferenced files, they are left in the directory /lost+found. You should examine these files to see if they contain the missing data.

For other error recovery and instructions how to rebuild the system, see Section 5 of this manual.
INTRODUCTION

PROBLEMS

If you experience problems with your 4404, the trouble can arise from either the hardware or the software. Luckily, the 4404 is an extremely reliable machine and rarely experiences any hardware problems, as users can do little to solve hardware problems beyond diagnosing them. The final discussion in this section goes through how you can use your 4404's self-test facilities to determine whether your 4404 has hardware problems.

Software, on the other hand, can be damaged by many things—from a runaway program to the problem of hyperactive fingers. Since software is more prone to damage than hardware, the first discussion in this section is on recovering from software errors.

YOUR BACKUP DISKETTES

Your 4404 was delivered with the software installed on the hard disk and ready to run. In addition, you received a number of diskettes that contain copies of the system software, and three additional diskettes that contain utilities that can be used to rebuild a damaged system.

The three additional disks are especially formatted and contain a special version of the operating system that will boot from the floppy disk drive. They provide you a minimal set of tools to build up a complete hard disk version of the operating system. Since these diskettes are logically formatted differently than normal 4404 file diskettes, you must back them up with the utility jdup. (To do so, format three blank diskettes with format, then use jdup for each of your three special diskettes.)

Let's look at each of the special diskettes.
The SYSREFORMAT Disk

This disk contains the system reformatting utilities. It contains a special (bootable from floppy) version of the operating system and three formatting utilities. They are:

1. **crdisk**—This utility physically reformats the winchester disk. It uses formatting information unique to that specific winchester disk.

   **CAUTION**
   "crdisk" uses information specific to the winchester disk assigned to it at the factory. Do not attempt to use this with any other winchester disk—it could result in an extremely unreliable or even unusable system. "crdisk" destroys all data on the winchester disk.

2. **qfmt**—This utility performs a "logical reformat" of the winchester disk. It does not physically reformat the disk, but it destroys all information on the disk.

3. **rpdisk**—A service formatting utility. Do not attempt to use this utility, it is for the use of a competent technician only.

   **CAUTION**
   Using "rpdisk" requires hard disk information that is not available to the user. If you use "rpdisk" without this information, it can cause unreliable system operation.
The SYSINSTALL Disk

This disk is another bootable floppy that contains the information necessary to restore the hard disk to a bootable state from the system backup diskettes.

The DISKREPAIR Disk

This disk contains two useful utilites that may let you recover information without reformatting the winchester. It is a bootable system that can run diskrepair on the winchester and often recover the system without a complete rebuild. In addition, it contains a utility called rmpass that removes the password from the user system; it supplies a non-destructive means to recover the system if the system password is forgotten.

Your System Backup Disks

This sequentially numbered set of disks contains your system software, as delivered from the factory. You will normally use your own set of backups to rebuild your system, but this set gives you an immediate set of backups and a reference set should your working backup diskettes become damaged.
SOFTWARE FIRST AID

PREVENTIVE MEDICINE

The most effective insurance against software disasters is a carefully followed plan of backing up your software. Without recent back ups, recovery of lost files is nearly impossible. With a systematic and regular backup procedure, you can minimize data loss from even the most severe system crash. Read the discussion on *Backing Up the System* in section 4 of this manual and follow either the schedule presented there, or a more rigorous backup schedule.

AUTOMATIC SYSTEM REPAIRS

Each time the 4404 boots, either from power-on or from a reset, it checks to see that it was shut down gracefully. If there is a possibility that the system was crashed or shut down in any other manner (someone pressed the reset button, or simply turned the power off), it runs the utility *diskrepair* to diagnose and repair potential or actual problems.

If you suspect that something has happened during normal operation that could damage the system structure, log in as *usersystem* and run *diskrepair*. If you use the +v option, it will report any potential problems it finds. You can also run the disk diagnostic utilities without attempting to repair the disk structure by using the n, b, and f options. In some cases, this may help you to recover damaged files without doing a complete system rebuild. If your system cannot be booted, you can try booting the *DISKREPAIR* disk and run *diskrepair* from it. If *diskrepair* cannot repair your system, you will need to do a complete system rebuild.

REMOVING A FORGOTTEN "SYSTEM" PASSWORD

If you lose or forget the *system* password, you can recover use of the system by using the *rmpass* utility on the *DISKREPAIR* disk. This utility removes the password from the user *system*. 
RESTORING A USER'S FILES

If the system-wide structure seems intact, and damage is confined to one or two user accounts, you should restore only that portion of the system from the user’s incremental backups. If you have followed the recommended procedure in section 4, you (or the user) can do so by following this procedure:

1. Login under the user’s name.
2. Have the latest set of incremental backup disks available.
3. Be sure you are in the user’s home directory.
4. Give the command:
   
   restore +dl

5. Insert the incremental backup disks in order as the system prompts for them.
RESTORING FILES ON A BOOTABLE SYSTEM

If the system is damaged but still bootable (some files deleted, but you are still running), you can often restore it by:

1. Login as user system.
2. Have the most recent set of system backup disks at hand.
3. Give the command:
   
   restore +dl

4. Insert the disks as the program prompts you for them.

If the lost files were not due to operator error, you should rundiskrepair before restoring the system files.
WHEN THE SYSTEM WILL NOT BOOT

When the system boots, it tries to locate a file in the root of the winchester disk called system.boot. If this file is lost, when you turn on the 4404 it displays the message:

        Cannot Locate Boot File
        Enter <filename>: _

If you have merely renamed the file system.boot, you can type in the new boot file name and the system will boot normally. If the system tries to boot, but fails (you get another error message) the file system.boot is there, but too damaged to function; you will need to work from a floppy-based system to try to recover.

RECOVERING AN UNBOOTABLE SYSTEM

At times, a system can become unbootable but otherwise sound (at least sound enough to recover some data). Before completely rebuilding your system, try booting your DISKREPAIR diskette. You can then run diskrepair on the winchester (typediskrepair /dev/disk after the boot) and perhaps be able to repair the system to the point you can recover otherwise lost data. When this procedure does not work, you must totally rebuild the system.
OVERVIEW

Rebuilding a complex software system from scratch is not a trivial task. However, the procedure has been simplified as much as possible. You first boot a simplified system from a flexible disk—a system that performs a single task, it formats the winchester disk. Next, you boot another simplified system that restores the entire system from the system backups. The final rebuild step is to restore any user's files that were made after the last full system backup. These steps are treated in detail for the remainder of this discussion.

STEP 1—FORMAT THE WINCHESTER WITH "SYSREFORMAT"

The "SYSREFORMAT" disk contains formatting information unique to the winchester disk for which it was constructed. Do not attempt to format any other winchester disks with this disk—an unreliable or unusable system may result.

To format the winchester, you must boot the minimal system contained on the disk marked "SYSREFORMAT". This disk contains enough of a system to format the winchester in one of three ways:

- Logical format— a procedure that erases all the data and file structure information on the disk, but does not physically reformat the disk. This format is performed by the utility qfmt.
- Physical format from file—a procedure that physically erases and reformats the disk. Formatting information is taken from a file on the floppy disk that is specific to the winchester it was made for. This format is performed by the utility crdisk.
- Physical format from keyboard—a physical format that requires the user to manually enter the formatting information. This information is marked on the body of the winchester disk and is not normally available to the user. This procedure is used by a service person after replacing a winchester disk. The utility to perform this format is called rpdisk.

When you must rebuild your system, first try qfmt, the logical format, then crdisk, the physical format from file. If the physical format does not work, the winchester disk may be defective. If this should happen, contact your local Tektronix Field Service office for servicing.
A—Boot the "SYSREFORMAT" Diskette

1. Insert the "SYSREFORMAT" diskette into the floppy disk drive and power on the system.

2. Press and release the Reset Button twice. Hold the Reset Button down briefly each time. The Reset Button is located on the rear panel of the Display/CPU unit.

3. When the Interactive Boot/Self Test Menu appears, press function key f1 (Interactive Menu).

4. When the Interactive Boot Menu appears, press function key f3 (Boot Floppy System).

5. Wait for the system to successfully boot from the floppy disk. (This takes about a minute.)

B—Format the Winchester

Logical Format. If this is your first attempt, logically format the winchester. Type qfmt then press CR.

Physical Format. If you have previously attempted an unsuccessful logical format, physically format the disk.

CAUTION

Be sure that your "SYSREFORMAT" diskette is the correct one for your winchester drive. Remove the diskette and check the serial number against the serial number on the MSU. If they do not match, do NOT proceed.

Type crdisk and press return. The physical format will take five to ten minutes to complete. Do not disturb the system while it is formatting.

C—Stop the System

You have now formatted the winchester disk (either logically or physically). When the prompt returns to the screen, type stop followed by a carriage return. Remove the "SYSREFORMAT" disk when the message "... System shutdown complete ..." appears.
STEP 2—RESTORE THE SYSTEM WITH THE "SYSINSTALL" DISK

A—Boot the "SYSINSTALL" Disk

The "SYSINSTALL" disk contains a minimal bootable operating system that can restore your system software. To boot the install disk, simply:

1. Insert the "SYSINSTALL" diskette into the floppy disk drive and power on the system.

2. Press and release the Reset Button twice. Hold the Reset Button down briefly each time. The Reset Button is located on the rear panel of the Display/CPU unit.

3. When the Interactive Boot/Self Test Menu appears, press function key f1 (Interactive Menu).

4. When the Interactive Boot Menu appears, press function key f3 (Boot Floppy System). If you get the message: "Cannot Locate Boot File" "Enter <filename>:" enter system.boot and press <Return>.

5. Wait for the system to successfully boot from the floppy. (This takes about a minute.)
B—Restore Files from Your System Backups

You now have a minimal system running from the floppy disk. This system is capable of reading the system software, either from a complete system backup you made (as advised in Section 4) or from the set of backup diskettes you received with your system. To restore your system, type fileRestore.

When the system prompts you with the message “Insert next volume—Hit C/R to continue:”, remove the “SYSINSTALL” disk and insert disk #1 of your backup diskettes. Press the <Return> key, and if everything is correct, the system will restore the files from that diskette.

As each diskette is restored to the system, the system will prompt you to insert the next disk with the “Insert next volume—Hit C/R to continue:” message. When the system restoration is complete, the system will return a message to that effect. The “SYSINSTALL” system now performs a verification of your system and will tell you if the system has been restored correctly or not. In case of errors, you should reformat and try to restore the system again.

C—Stop the System and Reboot

You should now type stop to stop the “SYSINSTALL” system. When the command “... System shutdown complete ...” appears, you can reboot by simply pressing the Reset Button. The system should go through a normal boot-up sequence and log you in as user public.

STEP 3—RESTORE USER’S FILES

The last task of the system rebuild is to restore any user files that were not copied during the last system backup. You can do this, or, if other users keep their own backups, they can restore their own files.
FINDING HARDWARE PROBLEMS—4404 SELF-TEST

OVERVIEW

Self-test is used primarily during manufacturing and servicing of the 4404. It contains many functions that are not of great interest to the user. A complete discussion of self-test may be found in the 4404 AIS Field Service Manual.

If you have any question whether a problem is caused by a fault in the 4404's hardware, you can run self-test to either confirm or deny that suspicion. Each time you turn on the 4404 (or press the Reset button) it executes a power-up self-test that is invisible to the user unless it detects an error. If you saw no error messages the probably of a hardware problem is low.
RUNNING SELF TEST

If you still suspect that you may have a hardware problem, you can invoke a more extended self-test by the following procedure:

1. If the system is on, stop it gracefully by typing `stop` and waiting until the system shut-down message appears. The shut-down message is:

   "...System Shutdown complete..."

   (If the system is already shut off, turn on the power to both the Display/CPU unit and the MSU and perform step 2 before the system begins to boot.)

2. Locate the Reset button (on the left rear of the Display/CPU unit as you face it) and press it twice. Hold it in briefly for each press and wait a moment between pushes.

3. The LED in the Caps Lock key will flash off and on until the keyboard test is done.

4. The 4404 initializes its display. Errors found at this point will be shown on the display. Upon completion of the Display initialization routine, the word "Tektronix" is printed on the screen.

5. The 4404 initializes the keyboard. If the keyboard is good, the LED will be left off, otherwise it will turn on. Errors are shown on the display. Upon completion, it prints "4404" on the display.

6. The 4404 now prints the "Interactive Boot/Self Test Menu." This menu shows the function key selections available at this point. These are:
   - f1—Interactive menu (discussed under System Rebuild Procedure)
   - f2—Adjustment procedures of little value to a user
   - f10—Continuous self-test
   - f11—Continue self-test
   - f12—Exit self-test

   If you make no selection, in approximately 20 seconds the 4404 goes into "Continue Self Test".

5-13
RECOVERY AND REBUILD

Key f1

Key f1 takes you into the interactive menu. This is the boot procedure discussed under System Rebuild Procedure.

Key f2

Key f2 invokes a set of adjustment procedures used during manufacturing and repair. These are of little use to most users.

Key f10

If you select key f10, or do nothing, the 4404 goes into "Continue Self Test". The display flashes as the display memory is tested, then the 4404 begins printing messages on the screen as it tests its functions. When the self-test is complete, the 4404 will again display the "Interactive Boot/Self Test Menu."

Key f11

Key f12 invokes continuous self-test. In this mode, the 4404 repeatedly goes through its self-test, halting only if it encounters an error.

Key f12

If you press key f12, the 4404 exits from self-test. It goes through its power-up initialization and attempts to boot from the hard disk.
FINDING INTERMITTENT ERRORS

Perhaps the most annoying problem in any mechanism, from a computer to a fishing pole, is an intermittent problem—a problem that disappears whenever a service person comes within a mile of the afflicted machine. If you suspect that you have one of these pernicious bugs living in your 4404 hardware, put the machine into continuous self-test and leave it overnight. The machine will run through its repertoire of tests until it encounters an error, when it will halt. If an error occurs, make a record of it and contact your local Tektronix service center for repairs.
Appendix A

UNPACKING AND INSTALLATION

INSTALLATION

Before unpacking your 4404, you should select a site that will be suitable for comfortable operation of the 4404. You will also need a carton opener (a small stout-bladed knife will do) and a small, flat-bladed screwdriver.

Installing your 4404 consists of these basic steps:

1. Select an installation site.

2. Unpack the Display/CPU unit and the MSU (mass storage unit). Keep all your packing materials in case you later need to transport the 4404.

3. Connect the keyboard, mouse, and SCSI cable to both units.

4. Connect a power cord to both units.

5. Connect both units to a suitable power source.

6. Turn to Section 2 The First Time and go through the transcript there to verify that the 4404 is working properly.
SELECTING A SITE

You should choose a site for your 4404 that meets the following requirements:

- **Enough room for ventilation and cable routing.** You should allow at least three inches (75 mm) behind both the MSU and the Display/CPU for cable routing. You must also allow at least two inches between the ventilation openings and anything that might obstruct air flow.

  **CAUTION**

  Do not block the airflow or cover the 4404’s air vents in any way. This could cause overheating and result in circuit damage.

- **Properly grounded power source.** Be sure that a properly grounded source of power is available for your 4404.

- **A stable environment.** Ambient temperature while the 4404 is operating should stay within 50 to 104 degrees Fahrenheit (10 to 40 degrees Centigrade). Relative humidity should stay between 0 and 80%.
UNPACKING

NOTE

If your 4404 has been unpacked, move ahead to the appropriate step.

Before unpacking check both shipping cartons for signs of damage. Report any damage to the carrier and your Tektronix sales representative immediately.

Retain all packing materials in case the 4404 must be transported in the future.

UNPACK THE MSU

1. Open the MSU carton from the top using the carton opener.
2. Remove the box containing the software and instruction manuals.
3. Cautiously remove the MSU unit and place it where it will be installed.

UNPACK THE DISPLAY/CPU

1. Open the carton from the top using the carton opener.
2. Remove the keyboard and set it aside.
3. Remove the top packing pad.
4. Remove the package containing the accessories and set them aside.
5. Lift the Display/CPU unit from the packing and set it in the installation site.
6. Remove the keypad, mouse, and SCSI cable from the accessory packages and set them next to the 4404.
CHECK THE ACCESSORIES

In addition to the keyboard, mouse, SCSI cable, and the MSU and Display/CPU units, you should have the following accessories:

- 4404 Reference Manual.
- An Introduction to the Smalltalk-80 System.
- A package of printed pads for the optical mouse.
- RS-232 communications port cable.
- Two power cords; 1 for MSU, 1 for Display/CPU.
- Several blank keyboard overlays (for the function keys).
CONNECT THE CABLES

CAUTION

Check that both voltage indicators on the rear of the Display/CPU and the voltage indicator on the MSU indicate the proper voltage selection for your power source.

1. Plug the keyboard cable into the rear of the Display/CPU unit in the connector marked “KEYBOARD.”

2. Plug the mouse cable into the rear of the Display/CPU unit in the connector marked “MOUSE.”

3. If you will be using the 4404 as a terminal, plug one end of the RS-232 cable into the connector marked “COMPUTER.” Secure the cable with the two small screws in the connector.

4. Plug the small end of the SCSI cable into the connector marked “MASS STORAGE INTERFACE.” Match the keyway on the two connectors and press the male connector into the female connector without forcing it.

5. Plug the large end of the SCSI cable into the connector on the MSU. Match the keyway on the two connectors and press the male connector into the female connector without forcing it. Secure the connector with the two small screws on the connector.

6. Attach the female ends of the power cords to the MSU unit and the Display/CPU unit.

7. Inspect the power switches on the MSU and Display/CPU units. Turn them OFF if they are not already. (A green flag shows if the power switch is ON.)

8. Insert the male end of the power cords into a properly grounded outlet that supplies the correct power for the 4404.

CAUTION

Attempting to operate the 4404 from an incorrect or improperly grounded voltage source can seriously damage the 4404’s circuitry.
READ SECTION 1

Your 4404 is now ready for operation. Read through Section 1, *Introduction*, to become familiar with the controls and terminology of the 4404, then go through Section 2, *The First Time*, to verify that your system is working correctly. You should also read the rest of this manual for general information pertaining to the operation of the 4404.
Appendix B

CLEANING AND PREVENTIVE MAINTENANCE

GENERAL CLEANING

Your 4404 is a delicate instrument and has no user serviceable parts. You can clean the CRT screen and the external surface of the Display/CPU unit, the MSU unit, the mouse, and the keyboard with a soft cloth dampened with a solution of mild detergent and water. Use a soft brush with natural (not synthetic) fibers to clean dust from crevices. Refer all other cleaning and routine maintenance to a qualified technician. A yearly maintenance program is recommended in the 4404 Field Service Guide.

CAUTION

To avoid damage to the plastics used in the Display Module, the Mass Storage Unit and Keyboard, do NOT use cleaning agents that contain benzene, acetone, toluene, xylene, or similar chemicals.

CAUTION

Never use a dripping wet cloth that could allow liquid to penetrate the case of the 4404. This could cause severe circuit damage, and in some cases expose you to hazardous voltages.

CLEANING SPILLS ON THE KEYBOARD

If a container of liquid such as coffee, tea, or a soft drink should spill on the keyboard:

1. Immediately turn the keyboard upside down to keep the liquid from penetrating and causing further damage.

2. Call in a qualified service person to disassemble and clean the keyboard.
Appendix C

OPTIONS

Each option you purchase for your 4404 comes with its own installation and programming information. Insert this information in this section.
Appendix D

CONNECTING PERIPHERALS TO THE 4404

INTRODUCTION

The 4404 has several external connectors which can be used to connect peripherals. These are:

• The SCSI bus.
• The RS-232 Communications Port
• The parallel printer port.
• The speaker output.
• The (Optional) Ethernet interface.
THE SCSI BUS

LOCATION

The SCSI bus connection is located on the rear of the Display/MSU unit labeled "MASS STORAGE INTERFACE."

SOFTWARE ACCESS

SCSI bus devices, addressed through drivers built into the operating system, each have two /dev files associated with them. Each has a descriptive name as the normally used block device, and the same name with c appended as a raw or character-oriented device. The standard SCSI devices recognized by the system are:

- /dev/disk The standard winchester disk.
- /dev/diskc The raw (character-oriented) standard winchester disk.
- /dev/disk1 ... diskn Optional winchester disks.
- /dev/disk1c ... disknc Raw optional winchester disks.
- /dev/floppy The standard flexible disk.
- /dev/floppyc The raw (character-oriented) flexible disk.

In order to read or write to any SCSI device during normal operation, you must mount the device. (See the 4404 Reference Manual command entry for mount for more information.) During backup and restore the flexible disk drive should not be mounted. These commands take care of the I/O in a different manner.
THE RS-232 COMMUNICATIONS PORT

LOCATION

The RS-232 Communications Port is located on the rear of the Display/CPU unit marked "computer."

SOFTWARE CONTROL

The communications port is addressed as /dev/comm. It is a character-oriented device.

You can examine or set the communications port parameters via the commset utility.

'C' programmers should check the files in /lib/include/sys (particularly sgtty.h) if they will be working with the communications port.
THE PARALLEL PRINTER PORT

LOCATION

The Parallel Printer Port is located on the rear of the Display/CPU unit marked "copier."

SOFTWARE ACCESS

The printer port is identified by the special file /dev/printer. It is a character-oriented device.

THE EXTERNAL SPEAKER JACK

LOCATION

The external speaker jack is located on the rear panel of the Display/CPU unit, marked "SPEAKER."

SPECIFICATIONS

The 4404 has a low power audio output jack capable of driving a small external speaker. The audio output is optimized for an eight-ohm speaker, but other common speakers can be driven (at reduced volume) without damage to the audio circuitry.

The external speaker jack is a small, two-conductor, switching phone jack. (When you insert a external speaker plug, the internal speaker is disabled.)

The output from either an internal or external speaker can be varied with the volume control located directly above the external speaker jack.

SOFTWARE ACCESS

You can drive the speaker via the device /dev/sound. Section 8, Hardware Support, of the 4404 Reference Manual contains a discussion under THE SOUND GENERATOR that discusses driving/dev/sound.
THE ETHERNET INTERFACE

The ethernet interface is a separate option. It is fully described in its own manual, which you can include in this manual in Appendix C, OPTIONS.

OPERATORS SAFETY SUMMARY

This general safety information is for both operating and servicing personnel. Specific warnings and cautions will be found throughout the manual where they apply, but may not appear in this summary.

TERMS

IN THIS MANUAL
CAUTION statements identify conditions or practices that can result in damage to the equipment or other property.

WARNING statements identify conditions or practices that can result in personal injury or loss of life.

AS MARKED ON EQUIPMENT
CAUTION indicates a personal injury hazard not immediately accessible as one reads the marking, or a hazard to property including the equipment itself.

DANGER indicates a personal injury hazard immediately accessible as one reads the marking.

SYMBOLS

IN THIS MANUAL
⚠️ This symbol indicates where applicable cautionary or other information is to be found.

As Marked on Equipment
⚡ DANGER high voltage.
➕ Protective ground (earth) terminal.
⚠️ ATTENTION — refer to manual.
⚠️ Refer to manual.

POWER SOURCE

This product is designed to operate from a power source that does not apply more than 250 volts rms between the supply conductors or between either supply conductor and ground. A protective ground connection by way of the grounding conductor in the power cord is essential for safe operation.

GROUNDING THE PRODUCT

This product is grounded through the grounding conductor of the power cord. To avoid electrical shock, plug the power cord into a properly wired receptacle before connecting to the power input or output terminals. A protective ground connection by way of the grounding conductor in the power cord is essential for safe operation.

DANGER ARISING FROM LOSS OF GROUND

Upon loss of the protective-ground connection, all accessible conductive parts (including knobs and controls that may appear to be insulating) can render an electric shock.

USE THE PROPER POWER CORD

Use only the power cord and connector specified for your product.

Use only a power cord that is in good condition.

Refer cord and connector changes to qualified service personnel.
USE THE PROPER FUSE

To avoid fire hazard, use only the fuse specified in the parts list for your product, and which is identical in type, voltage rating, and current rating.

Refer fuse replacement to qualified service personnel.

DO NOT OPERATE IN EXPLOSIVE ATMOSPHERES

To avoid explosion, do not operate this product in an atmosphere of explosive gases unless it has been specifically certified for such operation.

DO NOT REMOVE COVERS OR PANELS

To avoid personal injury, do not remove the product covers or panels. Do not operate the product without the covers and panels properly installed.

Figure 1-9. The SCSI Terminator.
4404 STANDARD AND OPTIONAL SOFTWARE

STANDARD SOFTWARE

Smalltalk-80

The standard programming language for the 4404 is Smalltalk-80, version 2, developed by Xerox corporation. Smalltalk-80 is an object-oriented, general-purpose programming language that makes extensive use of the 4404 bit-mapped screen and mouse. A full description of the Tektronix implementation of Smalltalk-80 is given in the companion manual *An Introduction to the Smalltalk-80 System.*

The 4404 Operating System

The 4404 contains a small, robust operating system, based on UniFLEX, by Technical Systems Consultants, Inc. The operating system gives one user at a time access to the 4404's resources. The operating system gives you these features:

- Single-user operation
- Multiple user accounts (with password protection)
- A hierarchical, tree-structured file system
- Multi-tasking
- An interactive shell featuring command aliasing, history, shell variables, definable search path, and command line editing
- Command file (script) execution
- User and *system* utilities
- A relocating assembler and linking loader
- A 'C' compiler and libraries that include standard 'C' functions and access to the 4404's hardware resources
- A symbolic debugging tool for 'C' and assembly language programs
- An ANSI X3.64 terminal emulator, available both to the 4404 operating system and to an external host via a RS-232-C connection
- A line and content oriented text editor
- Printer support
- Remote file transfer and host communications
CONNECT THE CABLES

CAUTION

Check that both voltage indicators on the rear of the Display/CPU and the voltage indicator on the MSU indicate the proper voltage selection for your power source.

1. Plug the keyboard cable into the rear of the Display/CPU unit in the connector marked "KEYBOARD."

2. Plug the mouse cable into the rear of the Display/CPU unit in the connector marked "MOUSE."

3. If you will be using the 4404 as a terminal, plug one end of the RS-232 cable into the connector marked "COMPUTER." Secure the cable with the two small screws in the connector.

4. Plug the small end of the SCSI cable into the connector marked "MASS STORAGE INTERFACE." Match the keyway on the two connectors and press the male connector into the female connector without forcing it.

5. Install the SCSI (Small Computer System Interface) terminator and plug the large end of the SCSI cable into the two large connectors on the back of the MSU.
   a. Plug the SCSI terminator into the lower connector (J1001) and secure it with two small mounting screws.
   b. Plug the large end of the SCSI cable into the upper connector (J1000) and secure it with two mounting screws.

CAUTION

Match the keyway on the connectors and the SCSI terminator and SCSI cable plug before seating the plugs. Tighten the mounting screws firmly (do not force). The terminator must be installed and the cable and terminator must be secured with the mounting screws to prevent noise and errors on the SCSI bus.
6. Attach the female ends of the power cords to the MSU unit and the Display/CPU unit.

7. Inspect the power switches on the MSU and Display/CPU units. Turn them OFF if they are not already. (A green flag shows if the power switch is ON.)

8. Insert the male end of the power cords into a properly grounded outlet that supplies the correct power for the 4404.

**CAUTION**

Attempting to operate the 4404 from an incorrect or improperly grounded voltage source can seriously damage the 4404's circuitry.

**READ SECTION 1**

Your 4404 is now ready for operation. Read through Section 1, *Introduction*, to become familiar with the controls and terminology of the 4404, then go through Section 2, *The First Time*, to verify that your system is working correctly. You should also read the rest of this manual for general information pertaining to the operation of the 4404.

**NOTE**

The 4404 time and date have been set to factory time. To set the date to your local time, login as “system” and give the command:

```
date <mm>-<dd>-<yy> <hr>:<min><sec>]
```

(see the “4404 Reference Manual” for details of the “date” command.)
INTRODUCTION

PROBLEMS

If you experience problems with your 4404, the trouble can arise from either the hardware or the software. Luckily, the 4404 is an extremely reliable machine and rarely experiences any hardware problems, as users can do little to solve hardware problems beyond diagnosing them. The final discussion in this section goes through how you can use your 4404's self-test facilities to determine whether your 4404 has hardware problems.

Software, on the other hand, can be damaged by many things—from a runaway program to the problem of hyperactive fingers. Since software is more prone to damage than hardware, the first discussion in this section is on recovering from software errors.

YOUR BACKUP DISKETTES

Your 4404 was delivered with the software installed on the hard disk and ready to run. In addition, you received a number of diskettes that contain copies of the system software, and three additional diskettes that contain utilities that can be used to rebuild a damaged system.

The three additional disks are especially formatted and contain a special version of the operating system that will boot from the floppy disk drive. They provide you a minimal set of tools to build up a complete hard disk version of the operating system. Since these diskettes are logically formatted differently than normal 4404 file diskettes, you must back them up with the utility \texttt{fdup}. (To do so, format three blank diskettes with \texttt{format}, then use \texttt{fdup} for each of your three special diskettes.)

Let's look at each of the special diskettes.
The SYSREFORMAT Disk

This disk contains the system reformatting utilities. It contains a special (bootable from floppy) version of the operating system and three formatting utilities. They are:

1. **crdisk**—This utility physically reformats the winchester disk. It uses formatting information unique to that specific winchester disk.

   **CAUTION**

   Before using “crdisk”, verify that the serial number on your SYSREFORMAT disk matches the serial number of your MSU (located under the front cover). “crdisk” uses information specific to the winchester disk assigned to it at the factory. Do not attempt to use this with any other winchester disk—it could result in an extremely unreliable or even unusable system. “crdisk” destroys all data on the winchester disk.

2. **qfmt**—This utility performs a “logical reformat” of the winchester disk. It does not physically reformat the disk, but it destroys all information on the disk.

3. **rpdisk**—A service formatting utility. Do not attempt to use this utility, it is for the use of a competent technician only.

   **CAUTION**

   Using “rpdisk” requires hard disk information that is not available to the user. If you use “rpdisk” without this information, it can cause unreliable system operation.

4. Five special utilities used to rebuild portions of a damaged system. These are:
   - **restoreOS**—a utility to recover the operating system files from the standard system diskettes supplied with your system.
   - **restoreK**—a utility to recover the operating system kernel from the standard system diskettes supplied with your system.
   - **restoreC**—a utility to recover the ‘C’ environment files from your standard system diskettes.
   - **restoreSTI**—a utility to recover the Smalltalk-80 interpreter from your standard system diskettes.
   - **restoreSTS**—a utility to recover the Smalltalk-80 image, sources, changes, and other system files from your standard system diskettes.

Details of how to use these utilities are given in the *Non-destructive System Rebuild Procedure*. 

REV, FEB 1985
4404 USERS
Updating Your SYSREFORMAT Disk

If your SYSREFORMAT disk must be replaced or updated, use the following procedure. This procedure assumes that you have received a new (no MSU serial number on the label) SYSREFORMAT diskette as part of a software update.

1. Verify that the serial number on your old SYSREFORMAT disk matches the serial number of your MSU.
   a. Grasp the front bezel of the MSU in both hands, and with a gentle rocking motion pull it straight forward approximately one inch.

   **CAUTION**

   *Do not twist or jerk the bezel. It could damage the shaft of the power switch.*

   b. The MSU serial number is located on the right side of the cabinet under the bezel. Verify that this serial number matches that on your old SYSREFORMAT diskette.

   c. Be sure that the wire to the hard disk activity light has not been disconnected. (If you reconnect it wrong, it will cause no damage—it just won't light up. Turn over the plug on the activity light and try again.)

   d. Carefully replace the bezel on the MSU. Press gently until all four detents grasp the bezel.

2. If your system is not turned on, turn on and boot the system.

3. Copy your new SYSREFORMAT diskette with the *dup* utility.

4. Login as *system* and copy the hard-disk specific format information file (named *badblks*) from your original SYSREFORMAT diskette.

   Insert your original SYSREFORMAT diskette in the floppy drive and give the following sequence of commands:

   ```
crdir /floppy
mount /dev/floppy /floppy
     copy +IP /floppy/badblks /
    unmount /dev/floppy
```

   This procedure creates a new directory in which to mount the floppy, mounts it, and copies the format information file to the hard disk while preserving the original date stamp of the hard disk format information.
5. Copy the hard disk formatting information to your new SYSREFORMAT diskette.

Insert your new SYSREFORMAT diskette in the floppy drive and give the following sequence of commands:

```
mount /dev/floppy /floppy
copy +1P / /floppy/badblks
unmount /dev/floppy
```

6. Using a felt-tip pen (pencil or ball-point pen can damage a diskette), enter the serial number of your MSU on the new SYSREFORMAT diskette label.

7. Destroy all copies of the old SYSREFORMAT diskette.

8. Remove the file /badblks (and optionally, the directory/floppy) on your hard disk.

The SYSINSTALL Disk

This disk is another bootable floppy that contains the information necessary to restore the hard disk to a bootable state from the system backup diskettes.

Your DISKREPAIR Disk

This disk is a bootable minimum system that contains two useful utilities:

- `diskrepair`—a copy of the system `diskrepair` utility that can run from a floppy-based system. This utility can sometimes repair a system that will not boot.

- `rmpass`—this utility removes the system password, should it be forgotten.

The Non-destructive System Rebuild Procedure tells how to use these utilities.
Your Standard System Diskettes

Your standard system diskettes contain archival copies of the system software as delivered from the factory. You should copy these diskettes using `fdup` and store the originals in a safe place. Use the copies to rebuild your system should that become necessary.

Your standard system diskettes contain five groups of files:

1. The operating system files
2. The operating system kernel
3. The ‘C’ compiler and environment
4. The Smalltalk-80 interpreter
5. The Smalltalk-80 standard image and system files

These diskettes are in absolute, rather than relative backup format. They cannot be restored to other than their correct places in the system. If you must restore files from these diskettes, the directories which will contain the restored files must be present on the hard disk; `restore` will not create directories in absolute format. If you get errors during an attempt to restore files from these diskettes, follow the procedure under “Non-destructive System Rebuild.”
SOFTWARE FIRST AID

PREVENTIVE MEDICINE

The most effective insurance against software disasters is a carefully followed plan of backing up your software. Without recent back ups, recovery of lost files is nearly impossible. With a systematic and regular backup procedure, you can minimize data loss from even the most severe system crash. Read the discussion on Backing Up the System in section 4 of this manual and follow either the schedule presented there, or a more rigorous backup schedule.

AUTOMATIC SYSTEM REPAIRS

Each time the 4404 boots, either from power-on or from a reset, it checks to see that it was shut down gracefully. If there is a possibility that the system was crashed or shut down in any other manner (someone pressed the reset button, or simply turned the power off), it runs the utility diskrepair to diagnose and repair potential or actual problems.

If you suspect that something has happened during normal operation that could damage the system structure, log in as usersystem and run diskrepair. If you use the +v option, it will report any potential problems it finds. You can also run the disk diagnostic utilities without attempting to repair the disk structure by using the n, b, and f options. In some cases, this may help you to recover damaged files without doing a complete system rebuild. If your system cannot be booted, you can try booting the DISKREPAIR disk and run diskrepair from it. If diskrepair cannot repair your system, you will need to do a complete system rebuild.

REMOVING A FORGOTTEN "SYSTEM" PASSWORD

If you lose or forget the system password, you can recover use of the system by using the rmpass utility on the DISKREPAIR disk. This utility removes the password from the user system.

To use the rmpass utility, boot the DISKREPAIR diskette (see the booting instructions under Non-Destructive System Rebuild) and type:

   rmpass

This utility is an executable script that mounts the hard disk, edits the password file, then unmounts the hard disk. If this script runs into trouble (for example if the hard disk does not mount) you may need to run diskrepair as in the Non-Destructive System Rebuild Procedure.
RESTORING A USER’S FILES

If the system-wide structure seems intact, and damage is confined to one or two user accounts, you should restore only that portion of the system from the user’s incremental backups. If you have followed the recommended procedure in section 4, you (or the user) can do so by following this procedure:

1. Login under the user’s name.
2. Have the latest set of incremental backup disks available.
3. Be sure you are in the user’s home directory.
4. Give the command:
   
   restore +dl

5. Insert the incremental backup disks in order as the system prompts for them.
RESTORING FILES ON A BOOTABLE SYSTEM

If the system is damaged but still bootable (some files deleted, but you are still running), you can often restore it by:

1. Login as user system.
2. Have the most recent set of system backup disks at hand.
3. Give the command:

   restore +dl

4. Insert the disks as the program prompts you for them.

If the lost files were not due to operator error, you should rundiskrepair before restoring the system files.
WHEN THE SYSTEM WILL NOT BOOT

When the system boots, it tries to locate a file in the root of the winchester disk called "system.boot." If this file is lost or renamed, when you turn on the 4404 it displays the message:

   Cannot Locate Boot File
   Enter <Return> to continue:

When you press return, the system will find and display a menu of files ending in "boot" that it finds on the hard disk. Press the function key associated with the "boot" file you wish to try. If you cannot boot the system from this menu, you should try the Non-destructive System Rebuild Procedure.

RECOVERING AN UNBOOTABLE SYSTEM

If your system will not boot, you will see an error message indicating either a hardware or software error. Hardware errors will be such things as "Device not ready" or "10 error." Software errors will be of the type "Cannot locate boot file" or "Wrong file type."

If you have a hardware error, first check the following:

- Does the disk drive indicate activity? If not, check that the power cord is connected, that the power switch is on, and that the fuse in the back panel of the MSU is intact.
- If the MSU is running, check that the SCSI terminator is installed and secured with two screws and that the SCSI cable is securely seated and that the two mounting screws are snug.
- If you receive a "Device not ready" error, try turning the power to the MSU off, then on. Try booting again by pressing the Display/CPU reset button.

If you have software errors, or suspect that the errors could be caused by software, you should perform the following Non-destructive System Rebuild Procedure.
NON-DESTRUCTIVE SYSTEM REBUILD PROCEDURE

OVERVIEW

If you have important files on a non-bootable system, it is sometimes possible to rebuild all or portions of the system and recover the lost data. Before attempting this task, you should verify that the system hardware is running correctly, that the SCSI cable and terminator are completely seated, and that the mounting screws are snugged down. If you doubt the system’s hardware integrity, run it in Continuous Self-Test overnight, as described in the final discussion in this section.

Figure 5-1 shows the 4 steps involved in the Non-destructive System Rebuild Procedure. They are:

1. Boot the "DISKREPAIR" diskette, a minimal floppy-based system and repair the directory structure of the hard disk if necessary.

2. Boot the "SYSREFORMAT" diskette with another minimal floppy-based system and construct the proper operating system file structure. This step also installs the files necessary for the hard disk based system to run.

3. Boot the "SYSINSTALL" diskette. This runs a minimal hard disk system with which you can restore the remaining operating system and other files.

4. Boot the repaired system from the hard disk. The operating system files and any other files you needed to restore are now in place, along with undamaged files from the previous operating system. The password file has been completely replaced. You can replace it from your incremental backup disks or rebuild it with the adduser utility.

The remainder of this discussion deals with the details of each of these steps.
Figure 5-1. Non-Destructive System Rebuild Procedure.
STEP 1 "DISKREPAIR"

The first step in rebuilding a non-bootable system is to determine how badly it is damaged, and to repair the directory structure if it has become corrupted. Your DISKREPAIR diskette is a bootable diskette that contains utilities that will allow you to inspect the hard disk system and a copy of the diskrepair utility to rebuild a damaged directory structure. Figure 5-2 shows some of the possible choices available when you have successfully booted a DISKREPAIR system.

To boot your DISKREPAIR system:

A—Boot the "DISKREPAIR" Diskette

1. Insert the "DISKREPAIR" diskette into the floppy disk drive and power on the system.

2. Press and release the Reset Button twice. Hold the Reset Button down briefly each time. The Reset Button is located on the rear panel of the Display/CPU unit.

3. When the Interactive Boot/Self Test Menu appears, press function key f1 (Interactive Menu).

4. When the Interactive Boot Menu appears, press function key f2 (Boot system.boot from Floppy).

5. Wait for the system to successfully boot from the floppy disk. (This takes about a minute.)

If the DISKREPAIR diskette will not boot, it indicates that either the DISKREPAIR diskette is damaged, or that you have hardware problems with your system.

To isolate the problem further, attempt to boot your SYSREFORMAT diskette. If this diskette will not boot, you have hardware problems. Recheck your cables and terminator, and attempt to boot again. If the problem persists, contact your local Tektronix service representative.

If your SYSREFORMAT diskette boots, this indicates that your DISKREPAIR diskette is damaged. Contact your local Tektronix sales representative for assistance in replacing it.
RECOVERY AND REBUILD

Figure 5-2. Step 1. Using "DISKREPAIR".

1. Using "DISKREPAIR" diskette

   Boot OK?
   YES
   - type: mount /dev/disk /usr1
   - possible hardware or diskette problem

   Mount OK?
   YES
   - Inspect Hard Disk files
   - type: diskrepair /dev/disk +V
   - type: unmount /dev/disk
   - type: stop
   go to step 2.

   NO
   - Normal Exit?
   YES
   NO
   - if this loop does not terminate, perform complete system rebuild

REV, FEB 1985
5-13
B—Mount the Hard Disk
When the DISKREPAIR system returns with the ++ prompt, type:

```
mount /dev/disk /usr1
```

If the hard disk mounts successfully, this indicates that the directory structure on the hard disk is intact. You can inspect files on the hard disk without attempting to repair it. Go to the step marked D—Inspect Your Hard Disk Files.

C—Run "diskrepair"
If the hard disk does not mount, the directory structure on the hard disk has been damaged. To repair it, type:

```
diskrepair /dev/disk +v
```

The +v option to diskrepair causes the program to inform you of its progress (see the 4404 Reference Manual for details).

If diskrepair terminates normally (it returns you to the ++ prompt with no warning messages), go on to the next step. If diskrepair exits with warning messages, or shuts the system down, then you should boot the system if necessary and run diskrepair again. If, after several tries, diskrepair cannot repair the hard disk, your data is most likely lost. You must do a complete system rebuild.

D—Inspect Your Hard Disk Files
When you have successfully mounted the hard disk, you are running as system and have full access to any undamaged files and utilities that reside on the hard disk as well as the utilities on the DISKREPAIR diskette. You can use some of the hard disk utilities (but not those dependent on absolute path names such as backup) to inspect the hard disk directories and files. You need not inspect the hard disk files if you already know what file sets you will be restoring.

When you are running from your DISKREPAIR system, the root of the directory tree is on the floppy drive, while the root of the hard disk is at /usr1. To access hard disk files, you must type the full path name (starting from /usr1) of the utility you want to use or file you want to reference. For example, if you want to use a utility found in /bin on the standard system, you must type /usr1/bin/<utility>. Alternatively, you could change your working directory to /usr1/bin (to put the utility in your search path), but must still remember to type the full name of the files you reference.
The following examples show two ways to move files from one user on the hard disk to another.

```
/usr1/bin/copy /user1/firstuser/filea /user1/seconduser/filea
```

```
chd /usr1/bin
copy /user1/firstuser/filea /user1/seconduser/filea
```

You can sometimes diagnose the hard disk booting problem by inspecting the hard disk file structure. The following files with the correct permissions must be present for a disk system to boot. (Use `dir +al` from `/` to find them).

Directory `"/"`:

```
<table>
<thead>
<tr>

E—Unmount the Hard Disk and Stop the System

To unmount the hard disk and stop the system, type:

    unmount /dev/disk
    stop

STEP 2. COPY THE OPERATING SYSTEM FILE STRUCTURE

Boot your "SYSREFORMAT" diskette with the same procedure you used with your "DISKREPAIR" diskette.

When you get the ++ system prompt, type:

    copyOS

The executable script file copyOS creates the necessary skeletal directory structure needed on the hard disk, then copies vital system files to the hard disk. These files can later be used with the "SYSINSTALL" diskette to create a hybrid system that frees the floppy drive and allows you to restore the bootable hard disk system.

When copyOS is finished, the script shuts the system down and prompts you to perform the next step.
STEP 3. RESTORE THE SYSTEM FILES

Following the same boot procedure, boot your "SYSINSTALL" diskette. The operating system that this boot procedure brings up allows the use of /dev/floppy—thus you can restore the standard files to bring the system up to full function. Figure 5-3 shows the choices available when restoring files.

NOTE

To use the "SYSINSTALL" scripts, you should be logged in as user "system". Booting from "SYSINSTALL" makes you "system". If you want to try these scripts from a damaged, but bootable hard disk system, login as "system", mount the "SYSREFORMAT" diskette, copy the files to the root directory and work from there.

When you get the system prompt, you have five choices:

1. If you want to restore the complete set of system files, type:

   fileRestore

   The script, fileRestore, prompts you to insert each diskette of the four sets of standard system files. Follow the prompts, and when the script is complete your system will be bootable from the hard disk.

2. If you want to restore only the operating system files, type:

   restoreOS

   This script prompts you to insert the diskettes from the set of standard operating system diskettes. When this script completes, you can either copy another group of files or stop the system.

3. If you want to restore only the operating system kernel, type:

   restoreK

   This script prompts you to insert the diskette containing the operating system kernel. When this script completes, you can either copy another group of files or stop the system.
Figure 5-3. Step 3. Restore Files.
4. If you want to restore only the ‘C’ environment, type:

   `restoreC`

   This script prompts you to insert the diskettes from the set of standard ‘C’ environment diskettes. When this script completes, you can either copy another group of files or stop the system.

5. If you want to restore only the Smalltalk-80 interpreter, type:

   `restoreSTI`

   This script prompts you to insert the standard Smalltalk-80 interpreter diskette. When this script completes, you can either copy another group of files or stop the system.

6. If you want to restore only the Smalltalk-80 files, type:

   `restoreSTS`

   This script prompts you to insert the diskettes from the set of standard Smalltalk-80 file diskettes. When this script completes, you can either copy another group of files or stop the system.

   The four partial file restore scripts leave copies of the scripts on the hard disk. To remove them, type:

   ```
   remove /restore* /fileRestore
   stop
   ```

   (If you use the `fileRestore` script, it removes these files and stops the system for you.)
RECOVERY AND REBUILD

STEP 4. RESTORE THE PASSWORD FILE

Your hard disk should now have a bootable system on it. Boot the system from the hard disk by pressing the reset switch once. When the prompt appears, you are in a standard system logged in as user "public".

Login as "system" and inspect the files remaining from the last system. If you use the +1 option to the dir command, you will notice that the retained files do not have an owner associated with them. (The operating system obtains the owner name for files from the password file, and this file has been replaced.) You should have a copy of the current password file in your incremental system backup diskettes. To find the diskette containing this file, type:

```
restore +C
```

The screen will display the files on each of the diskettes as you insert them. The password file will appear as:

"Directory etc/log"

password ...(permissions, owner, etc)

When you locate the password file, you can abort from the restore utility by typing a <Ctrl-C>. To restore it, insert the disk and type:

```
restore +1 password /etc/log/password
```

You will get a message from restore indicating that this is the wrong volume of the backup set, asking if you want to proceed. Answer "Y" and the password file will be restored.

CAUTION

Be sure you are restoring the file from /etc/log/password and not the utility from /bin/password. If the password file is incorrect, the system will not boot.
Alternatively, if you know the order in which the users appeared in the original password file, you can use the `adduser` utility to rebuild the file by adding users in the same order in which they were assigned. The utility `adduser` checks for files under that user name and complains (but creates the user) if it finds one.

**CAUTION**

File ownership is determined by user number. If you create users in a different order than they were originally created, you will have a case of massive file ownership confusion to sort out.

A final alternative is to directly edit the password file (examine a working password file before attempting this) and manually enter the fields. Either of these options requires that you know the contents of the original password file, and that users' accounts remain unprotected by passwords unless you set them as `system`. 
COMPLETE SYSTEM REBUILD PROCEDURE

OVERVIEW

Rebuilding a complex software system from scratch is not a trivial task. However, the procedure has been simplified as much as possible. You first boot a simplified system from a flexible disk—a system that performs a single task, it formats the winchester disk. Next, you boot another simplified system that restores the entire system from the system backups. The final rebuild step is to restore any user’s files that were made after the last full system backup. These steps are treated in detail for the remainder of this discussion.

STEP 1—FORMAT THE WINCHESTER WITH "SYSREFORMAT"

![CAUTION]

Verify that the serial number on your "SYSREFORMAT" diskette matches the serial number of the MSU (located under the front cover). Each "SYSREFORMAT" disk contains formatting information for one and only one hard disk. Using the wrong "SYSREFORMAT" disk can create an unreliable or unusable system.

To format the winchester, you must boot the minimal system contained on the disk marked "SYSREFORMAT". This disk contains enough of a system to format the winchester in one of three ways:

- **Logical format**—a procedure that erases all the data and file structure information on the disk, but does not physically reformat the disk. This format is performed by the utility *qfmt*.
- **Physical format from file**—a procedure that physically erases and reformats the disk. Formatting information is taken from a file on the floppy disk that is specific to the winchester it was made for. This format is performed by the utility *crdisk*.
- **Physical format from keyboard**—a physical format that requires the user to manually enter the formatting information. This information is marked on the body of the winchester disk and is not normally available to the user. This procedure is used by a service person after replacing a winchester disk. The utility to perform this format is called *rdisk*.

When you must rebuild your system, first try *qfmt*, the logical format, then *crdisk*, the physical format from file. If the physical format does not work, the winchester disk may be defective. If this should happen, contact your local Tektronix Field Service office for servicing.
RECOVERY AND REBUILD

A—Boot the "SYSREFORMAT" Diskette

1. Insert the "SYSREFORMAT" diskette into the floppy disk drive and power on the system.

2. Press and release the Reset Button twice. Hold the Reset Button down briefly each time. The Reset Button is located on the rear panel of the Display/CPU unit.

3. When the Interactive Boot/Self Test Menu appears, press function key f1 (Interactive Menu).

4. When the Interactive Boot Menu appears, press function key f2 (Boot system.boot from Floppy).

5. Wait for the system to successfully boot from the floppy disk. (This takes about a minute.)

B—Format the Winchester

Logical Format. If this is your first attempt, logically format the winchester. Type qfmt then press CR.

Physical Format. If you have previously attempted an unsuccessful logical format, physically format the disk.

CAUTION

Be sure that your "SYSREFORMAT" diskette is the correct one for your winchester drive. Remove the diskette and check the serial number against the serial number on the MSU. If they do not match, do NOT proceed.

Type crdisk and press return. The physical format will take five to ten minutes to complete. Do not disturb the system while it is formatting.

Remove the "SYSREFORMAT" disk when the message

"... System shutdown complete ..."

appears.
STEP 2—RESTORE THE SYSTEM WITH THE "SYSINSTALL" DISK

A—Boot the "SYSINSTALL" Disk

The "SYSINSTALL" disk contains a minimal bootable operating system that can restore your system software. To boot the install disk, simply:

1. Insert the "SYSINSTALL" diskette into the floppy disk drive and power on the system.

2. Press and release the Reset Button twice. Hold the Reset Button down briefly each time. The Reset Button is located on the rear panel of the Display/CPU unit.

3. When the Interactive Boot/Self Test Menu appears, press function key f1 (Interactive Menu).

4. When the Interactive Boot Menu appears, press function key f2 (Boot system.boot from Floppy).

5. Wait for the system to successfully boot from the floppy. (This takes about a minute.)
B—Restore Files from Your System Backups

You now have a minimal system running from the floppy disk. This system is capable of reading the system software, either from a complete system backup you made (as advised in Section 4) or from the set of backup diskettes you received with your system. To restore your system, type fileRestore.

When the system prompts you with the message "Insert next volume—Hit C/R to continue:", remove the "SYSINSTALL" disk and insert disk #1 of your backup diskettes. Press the <Return> key, and if everything is correct, the system will restore the files from that diskette.

As each diskette is restored to the system, the system will prompt you to insert the next disk with the "Insert next volume—Hit C/R to continue:" message. When the system restoration is complete, the system will return a message to that effect. The “SYSINSTALL” system now performs a verification of your system and will tell you if the system has been restored correctly or not. In case of errors, you should reformat and try to restore the system again.

When the message "...System shutdown complete..." appears, you can reboot by simply pressing the Reset Button. The system should go through a normal boot-up sequence and log you in as user public.

STEP 3—RESTORE USER’S FILES

The last task of the system rebuild is to restore any user files that were not copied during the last system backup. You can do this, or, if other users keep their own backups, they can restore their own files.
FINDING HARDWARE PROBLEMS—4404 SELF-TEST

OVERVIEW

Self-test is used primarily during manufacturing and servicing of the 4404. It contains many functions that are not of great interest to the user. A complete discussion of self-test may be found in the 4404 AIS Field Service Manual.

If you have any question whether a problem is caused by a fault in the 4404’s hardware, you can run self-test to either confirm or deny that suspicion. Each time you turn on the 4404 (or press the Reset button) it executes a power-up self-test that is invisible to the user unless it detects an error. If you saw no error messages the probability of a hardware problem is low.
RUNNING SELF TEST

If you still suspect that you may have a hardware problem, you can invoke a more extended self-test by the following procedure:

1. If the system is on, stop it gracefully by typing `stop` and waiting until the system shut-down message appears. The shut-down message is:

   "...System Shutdown complete..."

   (If the system is already shut off, turn on the power to both the Display/CPU unit and the MSU and perform step 2 before the system begins to boot.)

2. Locate the Reset button (on the left rear of the Display/CPU unit as you face it) and press it twice. Hold it in briefly for each press and wait a moment between pushes.

3. The LED in the `Caps Lock` key will flash off and on until the keyboard test is done.

4. The 4404 initializes its display. Errors found at this point will be shown on the display. Upon completion of the Display initialization routine, the word "Tektronix" is printed on the screen.

5. The 4404 initializes the keyboard. If the keyboard is good, the LED will be left off, otherwise it will turn on. Errors are shown on the display. Upon completion, it prints "4404" on the display.

6. The 4404 now prints the "Interactive Boot/Self Test Menu." This menu shows the function key selections available at this point. These are:
   - f1—Interactive menu (discussed under System Rebuild Procedure)
   - f2—Adjustment procedures of little value to a user
   - f3—Disk-based adjustment procedures (includes sound generator)
   - f10—Continuous self-test
   - f11—Continue self-test
   - f12—Exit self-test

   If you make no selection, in approximately 20 seconds the 4404 goes into "Continue Self Test".
Key f1

Key f1 takes you into the interactive menu. This is the boot procedure discussed under System Rebuild Procedure.

Key f2

Key f2 invokes a set of adjustment procedures used during manufacturing and repair. These are of little use to most users.

Key f3

Key f3 invokes a set of adjustment procedures stored on the hard disk. These, like those of key f2, are of little use to most users, with the exception of the Sound Generation Menu. (This test procedure is menu-driven, so feel free to experiment.)

Key f10

If you select key f10, or do nothing, the 4404 goes into "Continue Self Test". The display flashes as the display memory is tested, then the 4404 begins printing messages on the screen as it tests its functions. When the self-test is complete, the 4404 will again display the "Interactive Boot/Self Test Menu."

Key f11

Key f12 invokes continuous self-test. In this mode, the 4404 repeatedly goes through its self-test, halting only if it encounters an error.

Key f12

If you press key f12, the 4404 exits from self-test. It goes through its power-up initialization and attempts to boot from the hard disk.
FINDING INTERMITTENT ERRORS

Perhaps the most annoying problem in any mechanism, from a computer to a fishing pole, is an intermittent problem—a problem that disappears whenever a service person comes within a mile of the afflicted machine. If you suspect that you have one of these pernicious bugs living in your 4404 hardware, put the machine into continuous self-test and leave it overnight. The machine will run through its repertoire of tests until it encounters an error, when it will halt. If an error occurs, make a record of it and contact your local Tektronix service center for repairs.

Continuous Self-Test From Disk (Preferred)

If the hard disk system is working, to invoke continuous self-test:

1. Stop the system
2. Press the reset button twice, holding it briefly each time
3. When the "Interactive Boot/Self Test Menu" appears, press function key f3 to invoke the disk-based adjustment menu.
4. When the "Full Adjustment Procedure Menu" appears, press function key f10 to invoke continuous self-test. The 4404 will test several functions, then the "Interactive Boot/Self Test Menu" will appear again. The 4404 will then cycle through its ROM-based self-test, maintaining a count of the cycles it has passed through. If self-test detects an error, it will halt and display an error message. Record any errors to aid your Tektronix service representative.
5. To exit from continuous self-test, you must wait until either the "Full Adjustment Procedure Menu" or the "Interactive Boot/Self Test Menu" appears once again, then select an option from either menu before the self-test continues.

Continuous Self-Test From ROM

If you cannot run self-test from the hard disk, you can still perform an abbreviated self-test from ROM (read-only memory). To put your 4404 in continuous self-test from ROM:

1. Stop the system
2. Press the reset button twice, holding it briefly each time
3. When the "Interactive Boot/Self Test Menu" appears, press function key f10. The 4404 will then cycle through its ROM-based self-test.
5. To exit from continuous self-test, you must wait until the menu appears once again, then select an option from the menu before the self-test continues.
